# About This Document

---

This reference document lists and describes the IBM z/VM 7.3 control program (CP) commands and utilities for users of every privilege class.

## Intended Audience

---

This document is written for any and all users of CP commands. It is intended to help CP command users operate more effectively.

The descriptions of the commands and utilities contain the following types of information:

- Command or utility name
- Format and syntax
- User privilege class
- Purpose statement
- Operand descriptions
- Usage notes
- Responses
- Messages

## Where to Find More Information

---

For information about related publications, see the [“Bibliography” on page 2287](#).

## Links to Other Documents and Websites

The PDF version of this document contains links to other documents and websites. A link from this document to another document works only when both documents are in the same directory or database, and a link to a website works only if you have access to the Internet. A document link is to a specific edition. If a new edition of a linked document has been published since the publication of this document, the linked document might not be the latest edition.

# How to provide feedback to IBM

---

We welcome any feedback that you have, including comments on the clarity, accuracy, or completeness of the information. See [How to send feedback to IBM](#) for additional information.

# Summary of Changes for z/VM: CP Commands and Utilities Reference

---

This information includes terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations for the current edition are indicated by a vertical line (|) to the left of the change.

This publication is updated and published with greater frequency than user assistance (online help) is updated and delivered. If user assistance contains information that does not match the information in this publication, the publication contains the latest information.

## SC24-6268-73, z/VM 7.3 (September 2023)

---

This edition includes changes to support product changes that are provided or announced after the general availability of z/VM 7.3.

### [VM66678, VM66709] Warning Track Interruption Facility

With the PTFs for APARs VM66678 (CP) and VM66709 (Performance Toolkit), z/VM 7.3 exploits a feature of Processor Resource/Systems Manager (PR/SM) called the *warning-track-interruption facility*. z/VM's exploitation of this facility helps improve guest response time and overall performance of workloads that are run on vertical-low or vertical-medium logical processors.

The following CP commands are updated:

- “[QUERY SRM](#)” on page 1173
- “[SET SRM](#)” on page 1704

### [VM66673] Information update about Large Guest Reset Time Mitigation

In support of APAR VM66673, the descriptions of the following commands are updated to explain how multiple instances of large-memory resets are shown in responses to each command:

- “[INDICATE PAGING](#)” on page 546
- “[LOCATE VMDBK](#)” on page 642
- “[QUERY NAMES](#)” on page 1029

### [VM66683] Channel Path Usage

In support of APAR VM66683, a clarification about channel path usage is added to the description of this CP command:

- “[DEFINE NIC](#)” on page 194

## SC24-6268-73, z/VM 7.3 (May 2023)

---

This edition includes changes to support product changes that are provided or announced after the general availability of z/VM 7.3.

### [VM66423] Crypto Stateless-Command Filtering

With the PTF for APAR VM66423, z/VM 7.3 provides support for a capability of the Crypto Express8S adapter, when configured in Common Cryptographic Architecture (CCA) coprocessor mode, to enforce restrictions on classes of requests. This support is intended to be used to limit operations on shared crypto resources, such as prohibiting secure-key functions. z/VM's exploitation of this hardware capability

will replace the crypto stateless command filtering performed by z/VM for APVIRT crypto users, thus eliminating the need for future z/VM updates to allow stateless CCA operations beyond those currently supported. The z/VM hypervisor specifies the policy, and the Crypto Express8S adapter enforces it. Crypto Stateless-Command Filtering requires an IBM z16 family server with driver D51C Bundle S19 applied.

The following CP message is updated:

- HCP1711I

### **[VM66423] Removal of obsolete IOCP Parameters DYN and NODYN**

With the PTF for APAR VM66423, the IOCP parameters DYN and NODYN, which previously allowed or prevented dynamic changes to I/O configurations, no longer have any effect.

The following topics are updated:

- [“IOCP” on page 2203](#)
- [“SET IOCD\\_ACTIVE” on page 1525](#)
- [“SET TOKEN” on page 1740](#)

### **[VM66424, VM66434, VM66650] Guest Secure IPL Support**

With the PTF for APARs VM66424, VM66434, and VM66650, z/VM V7.3 supports guest secure IPL (load and dump) for both ECKD and SCSI devices. A z/VM user can request that the machine loader validate the signed IPL code by using the security keys that were previously loaded by the customer into the HMC certificate store. The validation ensures that the IPL code is intact, unaltered, and originates from a trusted build-time source.

Support is provided for the following guest operating systems:

- This support provides the ability for a Linux guest to exploit hardware to validate the code being booted, helping to ensure it is signed by the client or its supplier.

Linux on IBM zSystems instances that previously were able to perform secure boot first level on an IBM z15 or IBM LinuxONE III prior to Driver D41C Bundle S73a, or an IBM z16 or IBM LinuxONE 4 prior to Driver D51C Bundle S18, will no longer be able to use secure boot until appropriate additional support is applied to the Linux image. See [230428 Machine Alert for 8561, 8562, 3931, 3932 \(https://www-40.ibm.com/servers/resourcelink/lib03020.nsf/pagesByDocid/272B3DD994A65B538525899F005FA0E6?OpenDocument\)](https://www-40.ibm.com/servers/resourcelink/lib03020.nsf/pagesByDocid/272B3DD994A65B538525899F005FA0E6?OpenDocument) for details about the required service level of Linux to properly IPL securely first or second level after driver D41C Bundle S73a or Driver D51C Bundle S18 has been applied.

- z/OS® is supported in audit mode only. Full exploitation requires Virtual Flash Memory support, which is not available to a guest. In audit mode, the IPL code is checked but the IPL continues even if the code is not valid.

z/VM and the z/VM stand-alone dump utility do not support performing host IPL via List-Directed IPL (LD-IPL) from ECKD. In addition, Secure IPL of the z/VM host and z/VM stand-alone dump are not supported.

The following topics are updated:

- [“DEFSYS” on page 253](#)
- [“INDICATE USER” on page 555](#)
- [“IPL” on page 566](#)
- [“LOGON” on page 662](#)
- [“QUERY DUMPDEV” on page 890](#)
- [“QUERY LOADDEV” on page 985](#)
- [“SET DUMPDEV” on page 1496](#)
- [“SET LOADDEV” on page 1544](#)

- [“VMRELOCATE” on page 2083](#)

### **[VM66654] Thin Stack Adapter Interrupt Support**

With the PTF for APAR VM66654, z/VM 7.3 enhances the Thin Stack FCP SCSI device driver and associated I/O abstraction layers to exploit adapter interruptions and to implement improved error handling and reporting.

The following utility is updated:

- [“SCSIDISC” on page 2228](#)

### **[VM66673] Large Guest Reset Time Mitigation**

With the PTF for APAR VM66673, z/VM 7.3 provides support for up to 2TB virtual memory within a single virtual machine under a set of restrictions while also providing a mitigation for long logoff times of guests with a large amount of instantiated virtual memory.

The following commands are updated:

- [“INDICATE PAGING” on page 546](#)
- [“LOCATE VMDBK” on page 642](#)
- [“LOGOFF” on page 659](#)
- [“QUERY NAMES” on page 1029](#)

### **[VM66675] Enable larger (>64GB) NVMe paging allocation extents**

With the PTF for APAR VM66675, z/VM 7.3 allows paging space to be allocated anywhere on an NVMe EDEVICE and to be of any size up to the available capacity. This PTF also adds the ability for the CPFMTXA utility to accept FBA allocations specified in factors of megabytes, gigabytes, and terabytes.

See [“CPFMTXA” on page 2124](#).

This support requires the corresponding ICKDSF PTF for APAR PH52513, which removes the 64G restriction for PAGE allocation on an FBA volume.

### **[VM66677] Increase crashkernel area size**

With the PTFs for APAR VM66677, z/VM 7.2 and 7.3 increase the size of crashkernel area allocated by stand-alone dump programs in preparation for a future enhancement.

The following CP utility is updated:

- [“SDINST” on page 2235](#)

### **Miscellaneous updates for May 2023**

The following commands are updated:

- [“QUERY MONITOR” on page 1014](#): New response for next sample date and time.
- [“LOCATE VMDBK” on page 642](#): New operand \*\* to locate all VMDBKs on the system.

## **SC24-6268-73, z/VM 7.3 (September 2022)**

---

This edition supports the general availability of z/VM 7.3. Note that the publication number suffix (-73) indicates the z/VM release to which this edition applies.

## Eight-member SSI support

This support increases the maximum size of a single system image (SSI) cluster from four members to eight, enabling clients to grow their SSI clusters to allow for increased workloads and providing more flexibility to use live guest relocation (LGR) for nondisruptive upgrades and workload balancing.

The following CP commands are updated:

- [“DEFINE RELODOMAIN” on page 203](#)
- [“QUERY SSI” on page 1177](#)
- [“SET SSI” on page 1714](#)

The following CP utility is new:

- [“SFCOUNTR” on page 2241](#)

The following CP utility is updated:

- [“DIRECTXA” on page 2168](#)

## NVMe emulated device (EDEVICE) support

NVMe devices that are connected through PCI Express (PCIe) adapters can be defined and managed as Fixed-Block Architecture (FBA) EDEVICES. As such, all host and guest FBA functions are supported except for those functions that require stand-alone support such as warm start and checkpoint. Linux guests that exploit EDEVICES that are defined on NVMe adapters are not eligible for live guest relocation. NVMe adapters are only available on LinuxONE servers. For more information, see [Defining and Managing NVMe Devices in z/VM: CP Planning and Administration](#).

Documentation is updated for the following commands:

- [“ATTACH” on page 30 \(Messages\)](#)
- [“DELETE EDEVICE” on page 268 \(Usage notes, messages\)](#)
- [“QUERY CU” on page 860 \(Purpose\)](#)
- [“QUERY EDEVICE” on page 898 \(Usage notes, responses\)](#)
- [“QUERY PCIFUNCTION” on page 1070 \(Responses\)](#)
- [“RESET” on page 1387 \(Usage note\)](#)
- [“SET CPTRACE” on page 1446 \(Codes\)](#)
- [“SET CU” on page 1478 \(Purpose, usage notes\)](#)
- [“SET DUMP” on page 1493 \(Restriction for NVMe devices\)](#)
- [“SET EDEVICE” on page 1504 \(New operands, purpose, messages\)](#)

The following command is new:

- [“SET PCIFUNCTION” on page 1600](#)

## Display mnemonics for instructions that are not supported by CP Trace

z/VM 7.3 displays mnemonics for instructions in CP TRACE output regardless of whether the instruction is fully supported by z/VM. The following topics are updated:

- [“TRACE” on page 1946](#)
- [“TRACE: Command Responses” on page 1954](#)
- [“TRSOURCE” on page 2018](#)

## Miscellaneous updates for z/VM 7.3

Documentation for the following CP commands is updated:

- [“CPXLOAD” on page 111](#)

- [“DEFINE MDISK” on page 188](#)
- [“IOEXPLOR” on page 2205](#)
- [“QUERY DUMPDEV” on page 890](#)
- [“QUERY LOADDEV” on page 985](#)
- [“QUERY VIRTUAL DASD” on page 1288](#)
- [“SET CRYPTO” on page 1476](#)
- [“SET VTOD” on page 1781](#)
- Support for 4-character time zones:
  - [“DEFINE TIMEZONE” on page 225](#)
  - [“QUERY TIME” on page 1219](#)
  - [“QUERY TIMEZONES” on page 1222](#)
  - [“SET TIMEZONE” on page 1738](#)

The following CP utilities are updated:

- [“MIGR51D” on page 2211](#)
- [“SDINST” on page 2235](#)

## SC24-6268-11, z/VM 7.2 (May 2022)

---

This edition includes changes to support product changes provided or announced after the general availability of z/VM 7.2.

### **[VM66532] z/VM Support for IBM z16**

With the PTF for APAR VM66532, z/VM 7.2 provides support to enable guests to exploit function on IBM z16. The following support is included:

- Breaking-event-address register (BEAR) enhancement facility, which facilitates the debug of wild branches.
- Reset DAT protection facility, which provides a more efficient way to disable DAT protection, such as during copy-on-write or page-change tracking operations.
- RoCE Express3 adapter, which allows guests to exploit Routable RoCE, Zero Touch RoCE, and SMC-R V2 support.
- The Crypto Express8S (CEX8S) adapter, supported as a dedicated or shared resource. Dedicated guests are able to take advantage of all functions available with the CEX8S adapters, including assorted new enhancements and use of Quantum-Safe APIs. All crypto adapters that are configured in EP11 mode are reported with the 'P' suffix instead of the 'S' suffix.

The following topics are updated:

- [“DUMP \(Registers\)” on page 439](#)
- [“QUERY CRYPTO” on page 853](#)
- [“QUERY VIRTUAL CRYPTO” on page 1284](#)
- [“STORE STATUS” on page 1908](#)
- [“TRACE mnemonic1” on page 1986](#)

### **[VM66534] Host Exploitation of Crypto Interruptions**

With the PTF for APAR VM66534, z/VM V7.2 supports host crypto-interruption exploitation for APVIRT cryptographic guests. The host is not required to poll cryptographic resources for replies that are ready to be delivered to the guest.

The following topics are updated:

- [“DETACH CRYPTO” on page 286](#)
- [“QUERY CRYPTO” on page 853](#)
- [“SET CRYPTO” on page 1476](#)

## Miscellaneous updates for May 2022

References to IBM Z® Application Assist Processor (zAAP), which is not supported on IBM z13 and later models, are removed:

- [“DEFINE CPU” on page 152](#)
- [“INDICATE LOAD” on page 535](#)
- [“INDICATE USER” on page 555](#)
- [“QUERY PROCESSORS” on page 1092](#)
- [“QUERY SHARE” on page 1161](#)
- [“QUERY SRM” on page 1173](#)
- [“QUERY VIRTUAL CPUS” on page 1282](#)
- [“SET SHARE” on page 1691](#)
- [“SET SRM” on page 1704](#)

## SC24-6268-10, z/VM 7.2 (December 2021)

---

This edition includes changes to support product changes that are provided or announced after the general availability of z/VM 7.2.

### [VM66560] Preserve Partial Dump After Initial Program Load (IPL)

z/VM APAR VM66560 preserves partial dumps that are caused when an IPL of the partition ends the dump process before the dump completes. Currently, partial dumps that are ended by an IPL of the partition are not preserved after the IPL.

The following topics are updated:

- [“DUMpload” on page 2180](#)
- [“DUMPLD2” on page 2184](#)

### [VM66557] VSwitch Bridge Port Enhancements

With the PTF for APAR VM66557, z/VM 7.2 adds a new NICDISTRIBUTION option to the VSwitch HiperSockets Bridge. When activated, the option enables the Bridge to distinguish and manage separately the traffic that is generated by various HiperSockets connections that are on the same HiperSockets CHPID. Traffic that exits the Bridge Port to an OSA link aggregation group is more evenly distributed across the entire port group. Activation of the new option also enables the VSwitch to extract IPv4 and IPv6 address assignments for display in the QUERY VSWITCH command, monitor records, and DIAGNOSE code X'26C'.

The following CP commands are updated:

- [“QUERY VSWITCH” on page 1351](#)
- [“SET VSWITCH” on page 1757](#)

## SC24-6268-09, z/VM 7.2 (August 2021)

---

This edition includes terminology, maintenance, and editorial changes.

Information about the following CP command is updated:

- [“QUERY PROCESSORS”](#) on page 1092. The explanation of the CORE element of the response is updated to indicate that the value is the ID for the logical core (not the ID of a physical core). "Real processor address" is replaced by "logical processor number".

## SC24-6268-09, z/VM 7.2 (July 2021)

---

This edition includes changes to support product changes that are provided or announced after the general availability of z/VM 7.2.

### **[VM66271] Dynamic Memory Downgrade (DMD) Enablement**

With the PTF for APAR VM66271, z/VM 7.2 provides support for the dynamic downgrading of memory. *Dynamic memory downgrade (DMD)*, also known as *memory reclamation* or *storage reclamation*, extends the real storage dynamic management characteristics of z/VM to include removing up to 50% of the real storage from a running z/VM system.

This support allows a system administrator to take real memory offline from a z/VM partition, making it available to other partitions in the central processor complex (CPC). The removal is dynamic; no re-IPLing of the z/VM image is required to accomplish the change in the memory configuration. Only memory that is configured as reconfigurable can be removed without an IPL.

Memory reclamation by a first-level z/VM system can be performed on the IBM z14 (or later) family of servers (or equivalent).

The following CP commands are updated:

- [“SET RESERVED”](#) on page 1674
- [“SET STORAGE”](#) on page 1722

### **[VM66485] IPv6 Layer 2 Query Support**

With the PTF for APAR VM66485, z/VM 7.2 provides support to collect and report IPv6 addresses for Layer 2 VSwitches. IPv6 addresses for Layer 2 VSwitches are displayed by the QUERY VSWITCH and QUERY VIRTUAL NIC commands and by DIAGNOSE code X'26C'. In addition, the VSwitch Unicast IP table structure is changed from a linked list to a hash table to allow for more efficient table searches.

The following CP commands are updated:

- [“QUERY LAN”](#) on page 966
- [“QUERY VIRTUAL NIC”](#) on page 1310
- [“QUERY VSWITCH”](#) on page 1351

### **[VM66496] Improved Live Guest Relocation among Crypto Environments with Mixed Crypto Adapter Types**

Live Guest Relocation (LGR) for APVIRT crypto users is supported even when the type of the shared crypto resource on the source system does not match the type on the target system. However, the crypto adapter mode (CCA or accelerator) on the source system must match the mode on the target system.

The QUERY VIRTUAL CRYPTO command on any system in a relocation domain reports the lowest type of crypto express adapter that is available in the shared pools of all systems in a relocation domain. Only an adapter in the user's relocation domain that is compatible with the same shared crypto mode as the current system is displayed.

APVIRT crypto users can issue the QUERY VIRTUAL CRYPTO command to determine the level of functions that can be used to enable relocation between systems in the relocation domain without using the FORCE ARCHITECTURE option.

The following CP commands are updated:

- [“QUERY VIRTUAL CRYPTO”](#) on page 1284

- [“VMRELOCATE” on page 2083](#)

## **[VM66507] EDEVICE Path Management**

With the PTF for APAR VM66507, z/VM improves the following aspects of EDEVICE path management:

- Path selection
- Path state tracking
- Path health checking

Updates to the following commands enable the user to display and clear detailed information associated with individual path activity:

- [“QUERY EDEVICE” on page 898](#)
- [“SET EDEVICE” on page 1504](#)

## **Miscellaneous updates for July 2021**

Information about the following CP command is updated:

- [“QUERY STORAGE/STORE” on page 1186](#)

The following command topics are updated to clarify the interaction of several shutdown-related commands and statements and the effects on shutdown time intervals:

- [“SET SIGNAL” on page 1701](#)
- [“SET SHUTDOWNTIME” on page 1698](#)
- [“SHUTDOWN” on page 1789](#)

## **SC24-6268-08, z/VM 7.2 (March 2021)**

---

This edition includes changes to support product changes that are provided or announced after the general availability of z/VM 7.2.

### **[VM66430] Fast Dump Distiller**

With the PTF for APAR VM66430, clients can distill a hard abend or snap dump to create an abridged dump, which can be submitted to IBM customer support for diagnosis. The abridged dump alleviates the problems and delays that can occur when you submit a large hard abend dump or snap dump to IBM. The original dump remains available as a spool file and can be loaded into a CMS file for transmission to IBM later, if necessary.

The following CP utility is updated: [“DUMpload” on page 2180](#).

### **[VM66173] 4 TB Real Memory Support**

z/VM APAR VM66173 delivers support for up to 4 TB of real memory, allowing z/VM systems to address a full 4 TB of first-level (real) memory, doubling the previous supported limit of 2 TB. With advanced memory management capabilities available in the z/VM product, clients now have the ability to run workloads that exceed 4 TB of virtual memory across all hosted guest systems, depending on workload characteristics. In conjunction with z/VM support for 80 processors, IBM Z and LinuxOne servers can now host even more work in a single z/VM partition, or across multiple z/VM partitions on one system. APAR VM66173 also delivers various system command updates, such as automatic STANDBY memory for guests and an enhancement to the CP DEFINE STORAGE command.

With automatic STANDBY memory for guests, a system administrator can code a more generic DEFINE STORAGE command that does not need to be updated every time the guest's directory entry storage size changes.

The following CP commands are updated:

- [“ATTACH” on page 30](#)
- [“DEFINE STORAGE” on page 213](#)
- [“QUERY FRAMES” on page 925](#)
- [“QUERY PAGING” on page 1060](#)
- [“QUERY STORAGE/STORE” on page 1186](#)
- [“QUERY SXSSTORAGE” on page 1199](#)
- [“SET AGELIST” on page 1418](#)
- [“SET PAGING” on page 1596](#)
- [“SET STORAGE” on page 1722](#)

The following CP utility is updated: [“CPSYNTAX” on page 2143](#)

## **[VM66201] z/Architecture Extended Configuration (z/XC) support**

With the PTFs for APARs VM66201 (CP) and VM66425 (CMS), z/Architecture® Extended Configuration (z/XC) support is provided. CMS applications that run in z/Architecture can use multiple address spaces. A z/XC guest can use VM data spaces with z/Architecture in the same way that an ESA/XC guest can use VM data spaces with Enterprise Systems Architecture. z/Architecture CMS (z/CMS) can use VM data spaces to access Shared File System (SFS) Directory Control (DIRCONTROL) directories. Programs can use z/Architecture instructions and registers (within the limits of z/CMS support) and can use VM data spaces in the same CMS session. For more information, see [z/VM: z/Architecture Extended Configuration \(z/XC\) Principles of Operation](#).

Information about the following CP commands and utilities is updated:

- [“DISPLAY” on page 331](#)
- [“DISPLAY \(Guest Storage - ESA/XC, z/XC\)” on page 337](#)
- [“DISPLAY PSW” on page 373](#)
- [“DISPLAY PSWG” on page 376](#)
- [“DISPLAY \(Registers\)” on page 378](#)
- [“DUMP” on page 395](#)
- [“DUMP \(Guest Storage - ESA/XC, z/XC\)” on page 401](#)
- [“DUMP PSW” on page 434](#)
- [“DUMP PSWG” on page 437](#)
- [“DUMP \(Registers\)” on page 439](#)
- [“DEFINE DIAGNOSE” on page 172](#)
- [“DEFSYS” on page 253](#)
- [“IPL” on page 566](#)
- [“LOGON” on page 662](#)
- [“QUERY SET” on page 1156](#)
- [“SAVESYS” on page 1397](#)
- [“SET MACHINE” on page 1555](#)
- [“SET PAGEX” on page 1594](#)
- [“SET VTOD” on page 1781](#)
- [“SET 370ACCOM” on page 1787](#)
- [“STORE” on page 1879](#)
- [“STORE \(Guest Storage - ESA/XC, z/XC\)” on page 1881](#)
- [“STORE PSW” on page 1901](#)
- [“STORE PSWA” on page 1903](#)

- [“STORE PSWG” on page 1904](#)
- [“STORE \(Registers\)” on page 1905](#)
- [“TRACE” on page 1946](#)
- [“TRACE: Options” on page 1949](#)
- [“TRACE: Command Responses” on page 1954](#)
- [“TRACE GG” on page 1978](#)
- [“TRACE STORE \(ESA/390, z/Architecture\)” on page 1991](#)
- [“TRACE STORE \(ESA/XC, z/XC\)” on page 1995](#)
- [“VMDUMP” on page 2072](#)
- [“XAUTOLOG” on page 2100](#)
- [“SDINST” on page 2235](#)

## Miscellaneous updates for March 2021

The following elements are changed or deleted in this and later versions of the publication.

### **[“CPFMTXA” on page 2124](#)**

In the usage notes, consideration is added for the Stand-Alone Program Loader (SAPL) on an FBA device.

### **[“DEFINE MDISK” on page 188](#)**

The explanation of the **start** operand adds consideration of CKD and FBA DASD extents.

### **[“LOGON” on page 662](#)**

The following note about the STORAGE operand is obsolete and is deleted:

- An XC virtual machine can address up to 2047 MB of storage in its base address space.

In table [Maximum Input Values for Storage Units](#), the value for kilobytes is changed to 99999999, and the value for terabytes is changed to 16777216. The previously published values were incorrect.

### **[“SET VTOD” on page 1781](#)**

Message HCP6152E is deleted. The following usage note is obsolete and is deleted:

- The virtual machine whose TOD clock you want to change may not be in ESA/XC mode.

### **[“VMDUMP” on page 2072](#)**

The following usage notes are obsolete and are deleted:

- Access registers are dumped only for XA, ESA, XC, and z/Architecture virtual machines.
- VMDUMP dumps of z/Architecture guests on z/VM version 5.2 are not compatible with VMDUMP dumps of z/Architecture guests of previous releases.

### **[“XAUTOLOG” on page 2100](#)**

The following note about the STORAGE operand is obsolete and is deleted:

- An XC virtual machine can address up to 2047 MB of storage in its base address space.

## SC24-6268-07, z/VM 7.2 (December 2020)

---

This edition includes changes to support product changes that are provided or announced after the general availability of z/VM 7.2.

### **[VM66469] CP QUERY DEVICES Command**

The CP QUERY DEVICES command displays device setting information. The command is an extension of the existing support that is intended to simplify configuration management and problem determination. See [“QUERY DEVICES” on page 883](#).

## **[VM66420] Optional LUN Specification on SET EDEVICE Command**

The LUN operand is required when you define the first path to an EDEVICE. After the path is established, the LUN operand is optional when you define subsequent paths. See [“SET EDEVICE” on page 1504](#).

## **[VM66421] Guest HyperPAV Support for 1-END Minidisks**

Allows clients to define and associate virtual HyperPAV alias devices with 1-END base minidisks. The DEFINE HYPERPAVALIAS command does not change, but the requirement to use real cylinder 0 is eliminated. See [“DEFINE HYPERPAVALIAS” on page 180](#).

## **[VM66433] FlashCopy PRESERVEMIRROR Support**

Provides new operands to z/VM FlashCopy® commands to allow FlashCopy relationships between PPRC primary devices without affecting the PPRC status of the target devices. The new operands avoid PPRC suspend and duplex pending conditions that are associated with the target device of the FlashCopy. See [“FLASHCOPY” on page 471](#) and [“FLASHCOPY ESTABLISH” on page 483](#).

## **[VM66439] CP New Feature Interrogation API (New function indicator)**

Provides an interface for interrogating whether a named capability is present in the running CP system. This enhancement simplifies scripting and automation written by customers and vendors sensitive to the function level of CP. It facilitates adaptation of vendor products to varying CP code levels. See [“QUERY VARIABLE” on page 1267](#).

# **SC24-6268-06, z/VM 7.2 (September 2020)**

---

This edition includes changes to support the general availability of z/VM 7.2.

## **Adjunct Virtual Machine Support**

z/VM 7.2 has been updated to support adjunct virtual machines. An adjunct is a second virtual machine configuration running under your user ID, distinct from the configuration created when your user ID is logged on or autologged (called the principal configuration). Each configuration has its own virtual CPU(s), virtual storage (memory), and virtual devices, and can IPL a different instance of an operating system. The adjunct is intended to run CMS, to give you access to CMS files and tools, for example, to aid in debugging the operating system in the principal configuration while keeping the principal's operating system intact.

The following CP commands have been added:

- [“ADJUNCT” on page 18](#)
- [“QUERY ADJUNCT” on page 756](#)
- [“SET ADJUNCTS” on page 1417](#)

The following CP commands have been updated:

- [“CPACCESS” on page 89](#)
- [“CPU” on page 107](#)
- [“DEFINE” on page 122](#)
- [“DEFINE MDISK” on page 188](#)
- [“LINK” on page 578](#)
- [“LOGON” on page 662](#)
- [“QUERY LINKS” on page 979](#)
- [“QUERY VIRTUAL CPUS” on page 1282](#)

## MSS Multi-Target PPRC Exploitation

z/VM now supports up to four subchannel sets that reflect the actual hardware configuration.

The following CP commands have been updated:

- [“DELETE EDEVICE” on page 268](#)
- [“DELETE RDEVICE” on page 274](#)
- [“HYPERSWAP” on page 525](#)
- [“LOCATE RDEV” on page 618](#)
- [“QUERY CHPID” on page 791](#)
- [“QUERY DASD” on page 867](#)
- [“QUERY EDEVICE” on page 898](#)
- [“QUERY EQID” on page 905](#)
- [“QUERY HYPERSWAP” on page 941](#)
- [“QUERY MSS” on page 1025](#)
- [“QUERY PATHS” on page 1064](#)
- [“QUERY \(Real Device\)” on page 1114](#)
- [“SET DEVICES” on page 1490](#)
- [“SET EDEVICE” on page 1504](#)
- [“SET RDEVICE DASD” on page 1641](#)
- [“VARY PATH” on page 2053](#)
- [“VARY \(Real Device\)” on page 2063](#)
- [“VARY SUBCHANNEL” on page 2067](#)

The following CP utilities have been updated:

- [“CPSYNTAX” on page 2143](#)
- [“IOEXPLOR” on page 2205](#)
- [“SALIPL” on page 2222](#)

## Removal of PAGING63 IPL Parameters

The PAGING63 IPL parameter is removed because this IPL parameter blocks use of newer paging technologies (EAV, Encrypted, HPF Paging, and HyperPAV, for example) and has not been recommended for use since z/VM 6.4.

The following CP commands have been updated:

- [“QUERY PAGING” on page 1060](#)
- [“SET ENCRYPT” on page 1513](#)
- [“SET IPLPARMS” on page 1530](#)
- [“SET PAGING” on page 1596](#)

## Miscellaneous updates for September 2020

The following CP utility has been updated:

- [“MONWRITE” on page 2212](#)

---

## Chapter 1. Introduction

In this introduction, the term *command* is used generically; it refers to both CP commands and CP utilities.

z/VM uses command languages to correspond to the two environments it creates, control program and virtual machine.

Use the control program (CP) command language when:

- You are a z/VM system operator and you want to control the resources of the real machine located in your computer room.
- You are a virtual machine user and you want to control your virtual machine's configuration and environment.

Use a virtual machine command language when:

- You are communicating with the operating system you loaded into your virtual machine.

**To perform production or test work**, load your virtual machine with one of the operating systems supported by the z/VM system. Your virtual machine command language is the command language of the operating system you load. This command language is described in the library that documents that particular operating system.

**To perform service, installation, and maintenance tasks, along with editing and text creation, communicating with others, and problem solving**, load your virtual machine with the conversational monitor system (CMS). CMS is a single user, conversational operating system.

---

## Using Commands

You can use CP commands whenever:

- Your virtual machine is in the control program (CP) command environment. Your virtual machine is in the CP environment when you log on to z/VM and CP READ is displayed in the lower right-hand corner of the screen. On a line-mode ASCII device, there is no status area to display CP READ, so CP is displayed in the output area.
- You press the break key while in full-screen mode before entering a command. (The break key may be PA1, the VM default break key, or another key that you have defined as the break key using the TERMINAL BRKKEY command. Also, the break key may be totally disabled by some application programs or when in the protected application environment.)
- You are in a virtual machine command environment, not running in full-screen mode, and enter the #CP command (and # is your logical linend character).
- You are in the CMS virtual machine environment and enter the CP command.
- You are in the CMS virtual machine environment and have the IMPCP function set ON.

To determine the current command environment on a 3270 device, look at the status area in the lower right-hand corner of the display screen. CP READ indicates the CP environment, and VM READ indicates the virtual machine environment. If you are running CMS in your virtual machine, VM READ indicates the CMS environment. When RUNNING appears in the status area, enter a null input line to determine your environment. (To enter a null line, press the ENTER key but do not enter any data.) When you enter the null line, the status area displays either CP READ or VM READ. Also, if you are in a read state, in either the CP command environment (with RUN set OFF) or the CMS command environment, and you enter a null line, the system responds with the name of your command environment: CP or CMS in the system output area.

To determine the command environment for a line-mode device, a null entry (carriage return with no data) yields CP or CMS in the system output area.

## Introduction

You enter CP commands using any combination of uppercase and lowercase letters. When you have typed the command and its operands, press the ENTER key to process the command.

You may enter commands from CMS EXEC procedures or applications. See *z/VM: System Operation* and *z/VM: REXX/VM User's Guide*, and the description of `DIAGNOSE X'08'` in *z/VM: CP Programming Services*, for information on the programming interfaces for simulating the virtual console.

When simulating a virtual console, keep the following considerations in mind:

- Textual output from commands may change from release to release. In particular, command output that affects the way you use a terminal may be rearranged. NLS support may make the output available in multiple languages. Textual output is changed only when necessary.
- Return codes remain relatively stable from release to release.

## Command Structure

A VM command line consists of a command name, usually followed by one or more positional operands. The general form for the CP command line is:

command name	operands
--------------	----------

You must use one or more blanks to separate each entry in the command line unless otherwise indicated.

### The Command Name

The command name is an alphanumeric symbol, not more than 12 characters long. For example, DISCONNECT.

In general, command names are verbs that describe the function you want the system to perform. For example, if you want to attach a real device to your virtual machine configuration, enter the ATTACH command.

### The Command Operands

Command operands are keywords and positional symbols, usually no longer than eight alphanumeric characters.

You use operands to specify the information on which the system will operate when it performs the command function. For example, you use the TERMINAL operand in conjunction with the CP QUERY command to find out what terminal options are in effect for your virtual machine.

Some commands require no operands; others require several. You can find a description of each command with all of its operand requirements in [Chapter 2, "CP Commands,"](#) on page 11 or [Chapter 3, "CP Utilities,"](#) on page 2113.

Unless otherwise indicated, you must enter the operands you select in the order in which they appear in the command format.

### How to Enter Comments in the CP Command Language

You can use the CP asterisk (\*) command to annotate your display screen and console spool file. (Within this file are your input to the system and the system's response to you.) Refer to ["ASTERISK \(\\*\)"](#) on page 12 for complete details.

### Character Sets

You can enter CP commands using a combination of characters from 6 different character sets. The contents of each of these sets is summarized in [Table 1](#) on page 3.

Character Set	Names	Symbols
Separator	Blank	
National	Dollar Sign Pound Sign At Sign	\$ # @
Alphabetic	Uppercase Lowercase	A through Z a through z
Numeric	Numeric	0 through 9
Alphanumeric	National Alphabetic  Numeric	\$, #, @ A through Z a through z 0 through 9
Special		All other characters

## Using Truncations and Abbreviations

To make entering commands on the keyboard more convenient, VM lets you enter many commands and operands in a shortened form. This shortened form can be either a truncation or an abbreviation.

You truncate a command or operand name by dropping one or more letters from the end of the name. The syntax box for each command shows the truncations you can use for each command and its operands. If a letter appears in uppercase in the syntax box, you must enter it when you enter the command from your display; if a letter is in lowercase, you may omit it when you enter the command.

For example, the syntax box for the QUERY command shows the command as:

```
Query
```

This means that you can enter the QUERY command in any of the following forms:

```
query
quer
que
qu
q
```

The minimum acceptable truncation is Q, but CP will accept any of these forms of the command.

Abbreviations are also shorter forms of commands and operands, but unlike truncations, are not formed by simply dropping letters from the end of the command name.

Command syntax boxes show acceptable abbreviations for command names. The abbreviations appear below the full name of the command. Operand abbreviations are listed in the operand descriptions following the syntax box.

For example, the syntax box for the MESSAGE command shows:

```
Message
Msg
```

This means that you can:

- Truncate the command to a minimum of “M”
- Use the abbreviation “MSG”

## Introduction

- Truncate the abbreviation to “MS” or “M”.

Thus, CP accepts all of the following forms of the MESSAGE command:

```
message
messag
messa      OR      msg
mess       ms
mes        m
me
m
```

## Syntax, Message, and Response Conventions

The following topics provide information on the conventions used in syntax diagrams and in examples of messages and responses.

### How to Read Syntax Diagrams

Special diagrams (often called *railroad tracks*) are used to show the syntax of external interfaces.

To read a syntax diagram, follow the path of the line. Read from left to right and top to bottom.

- The  $\blacktriangleright$ — symbol indicates the beginning of the syntax diagram.
- The — $\blacktriangleright$  symbol, at the end of a line, indicates that the syntax diagram is continued on the next line.
- The  $\blacktriangleright$ — symbol, at the beginning of a line, indicates that the syntax diagram is continued from the previous line.
- The — $\blacktriangleright$ ◀ symbol indicates the end of the syntax diagram.

Within the syntax diagram, items on the line are required, items below the line are optional, and items above the line are defaults. See the examples in [Table 2 on page 4](#).

Syntax Diagram Convention	Example
<b>Keywords and Constants</b> A keyword or constant appears in uppercase letters. In this example, you must specify the item KEYWORD as shown. In most cases, you can specify a keyword or constant in uppercase letters, lowercase letters, or any combination. However, some applications may have additional conventions for using all-uppercase or all-lowercase.	$\blacktriangleright$ KEYWORD $\blacktriangleleft$
<b>Abbreviations</b> Uppercase letters denote the shortest acceptable abbreviation of an item, and lowercase letters denote the part that can be omitted. If an item appears entirely in uppercase letters, it cannot be abbreviated. In this example, you can specify KEYWO, KEYWOR, or KEYWORD.	$\blacktriangleright$ KEYWOrd $\blacktriangleleft$

Table 2. Examples of Syntax Diagram Conventions (continued)

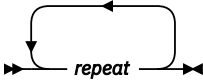

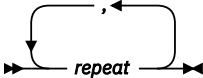

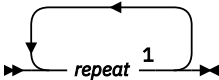

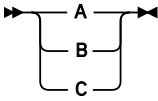

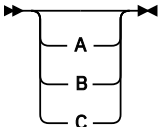

Syntax Diagram Convention	Example
<p><b>Symbols</b></p> <p>You must specify these symbols exactly as they appear in the syntax diagram.</p>	<p>* Asterisk</p> <p>:</p> <p>Colon</p> <p>,</p> <p>Comma</p> <p>=</p> <p>Equal Sign</p> <p>-</p> <p>Hyphen</p> <p>()</p> <p>Parentheses</p> <p>.</p> <p>Period</p>
<p><b>Variables</b></p> <p>A variable appears in highlighted lowercase, usually italics.</p> <p>In this example, <i>var_name</i> represents a variable that you must specify following KEYWORD.</p>	<p>▶▶ KEYWORD — <i>var_name</i> ▶▶</p>
<p><b>Repetitions</b></p> <p>An arrow returning to the left means that the item can be repeated.</p> <p>A character within the arrow means that you must separate each repetition of the item with that character.</p> <p>A number (1) by the arrow references a syntax note at the bottom of the diagram. The syntax note tells you how many times the item can be repeated.</p> <p>Syntax notes may also be used to explain other special aspects of the syntax.</p>	   <p>Notes:</p> <p><sup>1</sup> Specify <i>repeat</i> up to 5 times.</p>
<p><b>Required Item or Choice</b></p> <p>When an item is on the line, it is required. In this example, you must specify A.</p> <p>When two or more items are in a stack and one of them is on the line, you must specify one item. In this example, you must choose A, B, or C.</p>	<p>▶▶ A ▶▶</p> 
<p><b>Optional Item or Choice</b></p> <p>When an item is below the line, it is optional. In this example, you can choose A or nothing at all.</p> <p>When two or more items are in a stack below the line, all of them are optional. In this example, you can choose A, B, C, or nothing at all.</p>	 

Table 2. Examples of Syntax Diagram Conventions (continued)	
Syntax Diagram Convention	Example
<p><b>Defaults</b></p> <p>When an item is above the line, it is the default. The system will use the default unless you override it. You can override the default by specifying an option from the stack below the line.</p> <p>In this example, A is the default. You can override A by choosing B or C.</p>	
<p><b>Repeatable Choice</b></p> <p>A stack of items followed by an arrow returning to the left means that you can select more than one item or, in some cases, repeat a single item.</p> <p>In this example, you can choose any combination of A, B, or C.</p>	
<p><b>Syntax Fragment</b></p> <p>Some diagrams, because of their length, must fragment the syntax. The fragment name appears between vertical bars in the diagram. The expanded fragment appears in the diagram after a heading with the same fragment name.</p> <p>In this example, the fragment is named "A Fragment."</p>	

## Examples of Messages and Responses

Although most examples of messages and responses are shown exactly as they would appear, some content might depend on the specific situation. The following notation is used to show variable, optional, or alternative content:

**xxx**

Highlighted text (usually italics) indicates a variable that represents the data that will be displayed.

**[ ]**

Brackets enclose optional text that might be displayed.

**{ }**

Braces enclose alternative versions of text, one of which will be displayed.

**|**

The vertical bar separates items within brackets or braces.

**...**

The ellipsis indicates that the preceding item might be repeated. A vertical ellipsis indicates that the preceding line, or a variation of that line, might be repeated.

## Privilege Classes

The set of CP commands that you can use depends upon the privilege class or classes that have been assigned to you.

CP commands are divided into eight groups, each represented by a privilege class. The privilege class indicates the type of user from whom the system accepts commands.

In general, the system programmer who creates your system directory assigns you one or more privilege classes as part of your entry in the directory.

Privilege classes are denoted by the letters A through Z, the numbers 1 through 6, or the word “Any.” These classes, and the type of user who can use the commands belonging to each privilege class set, are summarized in [Table 3 on page 7](#). Classes I through Z and numbers 1 through 6 are reserved so that your installation can define them to suit its needs.

If you are authorized for some options of a command but not for others and you enter an unauthorized option, your command will be interpreted in the formats for which you are authorized. This may cause the command to either:

- execute in an unexpected fashion, or
- reflect an unexpected message.

Users whose password is NOLOG have no privilege class and can only receive spooled output as punched cards or printed forms. The NOLOG assignment is controlled by directory statements; see [IDENTITY Directory Statement in z/VM: CP Planning and Administration](#) for more information about NOLOG users.

Class	User and Function
A	<i>System Operator:</i> The class A user controls the z/VM system. The system operator is responsible for the availability of the z/VM system and its resources. In addition, the system operator controls system accounting, broadcast messages, virtual machine performance options, and other options that affect the overall performance of z/VM. <b>Note:</b> The class A user who is automatically logged on during CP initialization is designated as the primary system operator.
B	<i>System Resource Operator:</i> The class B user controls all the real resources of the z/VM system, except those controlled by the system operator and the spooling operator.
C	<i>System Programmer:</i> The class C user updates or changes system-wide parameters of the z/VM system.
D	<i>Spooling Operator:</i> The class D user controls spool files and the system's real reader, printer, and punch equipment allocated to spooling use.
E	<i>System Analyst:</i> The class E user examines and saves system operation data in specified z/VM storage areas.
F	<i>Service Representative:</i> The class F user obtains, and examines in detail, data about input and output devices connected to the z/VM system. This privilege class is reserved for IBM use only.
G	<i>General User:</i> The class G user controls functions associated with a particular virtual machine.
Any	Commands belonging to class “Any” are available to any user, regardless of the user's privilege class. These commands are primarily those used to gain access to, or relinquish access from, the z/VM system.
H	Reserved for IBM use.
I - Z 1 - 6	These classes are reserved for redefinition by each installation for its own use (using MODIFY statements or commands).

## Delayed Responses to CP Commands

Many CP commands associated with DASD subsystems result in a channel program being issued to a device or subsystem. In most cases, these operations complete in a very short time, and the command

## Introduction

response is presented to the operator immediately. However, for IBM DASD subsystems, some of these operations do not complete immediately. The command responses associated with such operations are called delayed responses.

The CP commands that may result in delayed responses are:

- COMMIT
- FLASHCOPY
- SET CACHE ON SUBSYSTEM
- SET CACHE OFF SUBSYSTEM
- SET CACHE OFF DEVICE
- SET CACHEFW OFF
- SET DASDFW OFF
- SET NVS ON
- SET NVS OFF

The responses to these commands are displayed in the following manner.

If the command completes immediately, the following response is displayed:

```
Normal command response.
```

If the command does not complete immediately, the following response is displayed:

```
Command started:  command details
```

If the command completes successfully, the following response is displayed:

```
Normal command response.
```

If errors occur during the asynchronous processing of the command that prevent the successful completion of the command, the following response is displayed:

```
Command failed:  command details
```

Under certain circumstances, it is possible that a cache storage subsystem will not notify CP when it has completed a command. When this occurs, the usual completion responses cannot be generated. Under these circumstances, command processing is ended after displaying the following response:

```
Command results lost:  command details
```

If the originator of the command is not the system operator, the following response may be issued to the system operator when the command completes.

```
Normal command response by userid.
```

The user may display the status of commands that the user has issued that have not yet completed by issuing the QUERY PENDING COMMANDS commands. QUERY PENDING COMMANDS causes the following response to be displayed for each pending CP command:

```
Command pending:  command details
```

The user may display the status of ALL commands that are pending for a device by issuing the QUERY PENDING COMMANDS ALLUSERS command. The ALLUSERS option causes one of the following responses to be displayed for each pending CP command:

```
Command pending for userid: command details  
OR  
Command pending: command details
```

**Normal command response.**

is the usual response associated with the successful completion of this command.

**userid**

is the ID of the user who issued the command if the command was not issued by the issuer of the QUERY PENDING COMMANDS ALLUSERS command.

**command details**

is the command and options with which this delayed response is associated.

**Example**

Assume that a class B user, DASDOPER, wants to deactivate the DASD fast write function for devices 190 through 194 by issuing SET DASDFW DEVICE OFF 190-194. Since SET DASDFW OFF may produce delayed responses, all of the following results are possible. Assume that the devices respond as follows:

- 190 - responds immediately as successful
- 191 - delayed response buffer indicates completed successfully
- 192 - delayed response buffer indicates completed with errors
- 193 - delayed response buffer indicates command failed
- 194 - polling detects that the response was lost.

**Note:** The operator is informed of all successful operations.

**Command Issuer's Console (DASDOPER)**

```
SET DASDFW DEVICE OFF 190-194
190 DASD fast write function has been deactivated.
Command started: SET DASDFW OFF 191.
Command started: SET DASDFW OFF 192.
Command started: SET DASDFW OFF 193.
Command started: SET DASDFW OFF 194.
:
:
QUERY PENDING COMMANDS 190-194
No pending delayed responses exist for 190.
Command pending: SET DASDFW OFF 191.
Command pending: SET DASDFW OFF 192.
Command pending: SET DASDFW OFF 193.
Command pending: SET DASDFW OFF 194.
:
:
191 DASD fast write function has been deactivated.
:
:
192 DASD fast write function has been deactivated.
:
:
Command failed: SET DASDFW OFF 193.
:
:
Command results lost: SET DASDFW OFF 194.
```

**System Operator's Console**

```
190 DASD fast write function was deactivated by DASDOPER.
:
:
QUERY PENDING COMMANDS ALLUSERS 190-194
No pending delayed responses exist for 190.
Command pending for DASDOPER: SET DASDFW OFF 191.
Command pending for DASDOPER: SET DASDFW OFF 192.
Command pending for DASDOPER: SET DASDFW OFF 193.
Command pending for DASDOPER: SET DASDFW OFF 194.
:
:
191 DASD fast write function was deactivated by DASDOPER.
:
:
192 DASD fast write function was deactivated by DASDOPER.
```

# Using the Online HELP Facility

---

You can receive online information about the commands described in this book using the z/VM\* HELP Facility. For example, to display a menu of CP commands, enter:

```
help cp menu
```

To display information about a specific CP command (BEGIN in this example), enter:

```
help cp begin
```

You can also display information about a message by entering one of the following commands:

```
help msgid or help msg msgid
```

For example, to display information about message HCP002E, you can enter one of the following commands:

```
help hcp002e or help msg hcp002e
```

For more information about [Using the HELP Facility](#), see *z/VM: CMS User's Guide*. To display the main HELP Task Menu, enter:

```
help
```

For more information about the [HELP](#) command, see *z/VM: CMS Commands and Utilities Reference* or enter:

```
help cms help
```

---

## Chapter 2. CP Commands

This section contains reference information on the CP commands. These commands are listed in alphabetical order except for the \* and #CP commands, which appear first.

Each command description is presented in the following format (some sections might not be included):

- **Name:** Identifies the name of the command.
- **Format:** Shows the syntax of the command with all the possible operands and options you can use.
- **Authorization:** Specifies the required CP privilege class, which identifies the users able to issue the command, unless user class modification is in use.
- **Purpose:** States what the command is used for.
- **Operands and Options:** Defines the function of each operand and option and any values you can include.
- **Usage Notes:** Identifies and describes special situations and other considerations that may affect your use of the command.
- **Examples:** Provides one or more examples to show how the command is commonly used.
- **Responses:** Describes the responses you might receive from the command on your display device. Responses are normal operational output; they tell you about the execution and effect of the command. Unlike system messages, command responses are not prefixed with an identifying number and are not contained in *z/VM: CP Messages and Codes*.
- **Messages:** Lists the messages issued by the command. Messages not unique to the command might also be issued. Each message is prefixed with an identifying number. For more information on the messages, including suggested actions, see *z/VM: CP Messages and Codes*.

## ASTERISK (\*)

---

### Authorization

Privilege Class: Any

### Purpose

Use ASTERISK (\*) to annotate your console sheet or display screen.

### Usage Notes

1. The control program (CP) treats any statement prefixed by an asterisk (\*) as a comment line.
2. If you start the console spooling function for your virtual machine, your commentary appears in your console spool file.

## #CP

### Authorization

Privilege Class: Any

### Purpose

Use #CP to process one or more control program (CP) commands from a guest environment.

### Operands

#### *command*

identifies the name and operands of the CP command or commands you want to enter. You must precede the first command with at least one blank. If you are specifying multiple CP commands, separate them with your logical-line-end symbol. (See Usage Note “4” on page 13.)

### Usage Notes

1. The pound sign (#) shown above represents the logical-line-end symbol in effect for your virtual machine. If you have redefined the logical-line-end symbol, you must substitute your symbol for the pound sign (#).
2. The #CP command is a handy way to reduce the number of operations required to enter a CP command from a virtual console. For example, to display the number of files you have on your virtual machine, enter **cp query files**. This command is equivalent to the following operations:
  - a. Press PA1 to enter the CP command environment.
  - b. Enter QUERY FILES to display the number of files.
  - c. Enter BEGIN to exit the CP command environment.
3. Before you enter the #CP command, be sure that:
  - Your virtual machine is operating with SET LINEDIT on. (This is the default.)
  - The first three characters you enter in the command are #CP (uppercase or lowercase); the pound sign (#) represents your currently defined logical-line-end symbol.
  - At least one blank separates the #CP from the command itself.
4. You can enter multiple commands as operands of #CP command if you separate each command from the next with the logical-line-end symbol.
5. The #CP command has no meaning if you are running in full-screen mode.
6. Table 4 on page 13 summarizes the system response to various #CP commands:

Table 4. System Responses to Various #CP Commands

Command	System Action
#CP	Your virtual machine enters the CP environment. An exception to this is when the command is issued with the AT command. See usage note “7” on page 14 for details.
#CP QUERY FILES	The QUERY FILES command is executed.

---

*Table 4. System Responses to Various #CP Commands (continued)*

---

<b>Command</b>	<b>System Action</b>
#CP QUERY FILES#QUERY USERS	Two separate QUERY commands are executed.
#CP data entered	You enter the CP environment and CP interprets the "data entered" as a CP command; the command may or may not be valid.

---

7. The #CP command is rejected with message HCP026E if it is issued with the AT command. If preceded by your terminal escape character, it is rejected with message HCP1144E.
8. The CP command, when not preceded with the logical line-end character, and when issued with the AT command, will not cause any virtual machine on the target system to enter the CP environment. However, the CP command can still be used to prefix other CP commands when issued with the AT command.

## ACNT

### Authorization

Privilege Class: A

### Purpose

Use ACNT to do the following:

- Create accounting records for active users
- Reset accumulated accounting data fields that are reset to zero after a record is created.

### Operands

#### ALL

tells the system to create accounting records for all logged-on users and for the system.

#### SYSTEM

tells the system to account for all time not charged to a specific user.

#### *userid*

identifies the list of users for whom you want the system to create accounting records. You can specify up to 10 user IDs on the command input line.

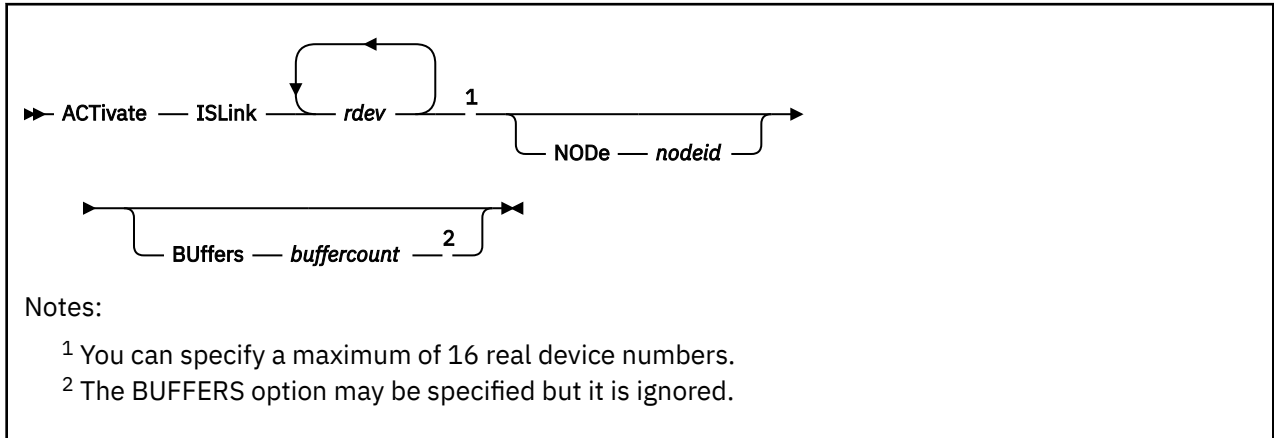

### Usage Notes

1. When you enter ACNT, all available types of accounting records are created for each user specified. For an explanation of individual accounting records, their contents, and how to set up a service virtual machine to collect them, refer to [Setting Up Service Virtual Machines in z/VM: CP Planning and Administration](#).
2. CP processes the list of user IDs in the order you enter them. If any user ID in the list is not valid, the creation of accounting records stops with the last valid user ID encountered.
3. To provide an ACNT command syntax compatible with VM/SP, z/VM accepts CLOSE as an option following ALL or ACNT (for example, ACNT ALL CLOSE or ACNT CLOSE). However, this option does not change the operation of the ACNT command.

### Messages

- HCP002E Invalid operand - *operand*
- HCP020E Userid missing or invalid
- HCP045E *userid* not logged on

## ACTIVATE ISLINK

### Authorization

Privilege Class: B

### Purpose

Use the ACTIVATE ISLINK command to identify a communication link to ISFC.

### Operands

#### **rdev**

identifies one to sixteen real device numbers you want to use as a link.

When the first device is initialized for a new link, the ISLINK for that node is created automatically.

#### **NODe nodeid**

is the optional node (gateway) identifier for the ISFC link expected for each *rdev*. If not specified, it is determined by device initialization.

If a conflicting *nodeid* is specified for an already active device, an error message is issued.

#### **BUffers buffercount**

is ignored and included for compatibility only.

### Usage Notes

1. You may also need to define the real communication link to the system; see the [RDEVICE Statement](#) in *z/VM: CP Planning and Administration* for more information.
2. The system operator receives all informational and error messages, but not immediate command responses.
3. You can improve throughput across your ISFC link by activating more than one device on the same link. Note, however, that FICON® subchannels on the same channel path share some hardware resources. In general you will observe better data transfer rates if subchannels on a given link are configured to use different channel paths.
4. Avoid using different CHPID speeds in any one logical link, as that will cause the ISFC logical link to operate less efficiently.

### Responses

Response 1:

Link *rdev* activated.

***rdev***

is the link address that has been activated.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP006E Invalid device type - *rdev*
- HCP026E Operand missing or invalid
- HCP040E Device *rdev* does not exist
- HCP046E Device *rdev* offline
- HCP049E Device *rdev* in use
- HCP2702I Link *linkname* came up
- HCP2704I Node *nodeid* added to collection
- HCP2706I Link *linkname* activated by user *userid*
- HCP2721E Link unit address *rdev* is a duplicate
- HCP2722I The BUFFERS option is ignored for ACTIVATE ISLINK.
- HCP2725E Inter-System Facility for Communication initialization failed: RC=*return-code*
- HCP2745E Link device *rdev* rejected. Defined node *nodeid1* conflicts with detected node *nodeid2*.
- HCP2750I ISFC ACTIVATE is deferred for offline device *devno*.
- HCP6005E Option BUFFERS is not supported by z/VM.

## ADJUNCT

### Authorization

Privilege Class: G

### Purpose

Use the ADJUNCT command to control the operation of an adjunct virtual machine.

An adjunct is a second virtual machine configuration running under your userid, distinct from the configuration created when your userid is logged on or autologged (called the principal configuration). Each configuration has its own virtual CPU(s), virtual storage (memory), and virtual devices, and can IPL a different instance of an operating system. The adjunct is intended to run CMS, to give you access to CMS files and tools, for example, to aid in debugging the operating system in the principal configuration while keeping the principal's operating system intact.

When both principal and adjunct configurations exist for a user, only one is runnable at a time. When the adjunct is started or resumed, the principal is suspended, and vice versa.

### Operands

#### START

The ADJUNCT START operation is analogous to LOGON for the primary configuration. It creates and IPLs an adjunct configuration, suspends execution of the principal configuration, switches the terminal session (if connected) from the virtual console of the principal to that of the adjunct, and transfers control to the adjunct configuration.

#### END

Logs off the adjunct, leaving the principal configuration active.

#### Begin

#### RESume

Suspends execution of the principal configuration, switches the virtual console to the adjunct, and transfers control to the adjunct configuration. The adjunct must already have been started. This operation is the adjunct analog to the CP BEGIN command for the principal configuration.

#### Stop

#### SUSpend

Puts the adjunct into a soft-stop state and transfers control back to the principal configuration. This operation is the adjunct analog to the CP STOP command for the principal configuration.

#### CP *command*

Permits a user or program in the principal configuration to direct commands to the adjunct configuration. Typical use includes the ability to re-IPL the adjunct when necessary (ADJUNCT CP IPL).

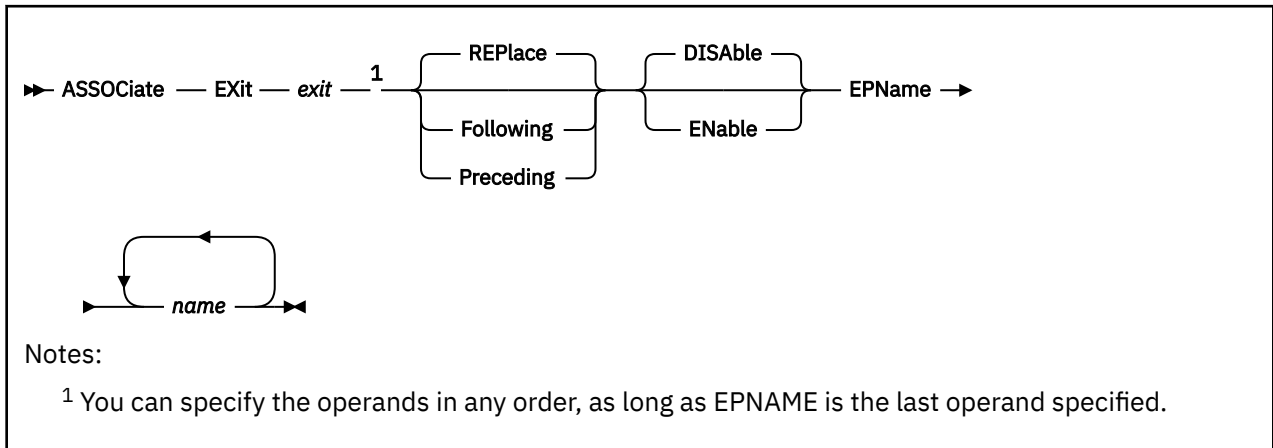

## Usage Notes

1. In order for you to create an adjunct, the feature must be enabled for the z/VM system and authorized for you by the system administrator. The administrator provides the virtual machine definition that specifies how the adjunct configuration is instantiated. Information on how to enable and set up adjuncts appears in *z/VM: CP Planning and Administration*, in the description of the FEATURE ENABLE ADJUNCTS configuration statement and the ADJUNCT directory statement.
2. To direct a command from the adjunct configuration to the principal, use the CPU prefix command, for example, CPU \* DEFINE STORAGE 4G or CPU ALL DISPLAY PSWG.
3. Use the QUERY ADJUNCT command to determine the state of your adjunct configuration.

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid
- HCP643E Adjunct feature is not enabled on this system
- HCP1461E No adjunct configuration defined
- HCP5768E *userid* Adjunct does not exist
- HCP5769E *userid* Adjunct already exists
- HCP5770E *userid* Adjunct is not exploitable

## ASSOCIATE EXIT

### Authorization

Privilege Class: A

### Purpose

Use ASSOCIATE EXIT to assign one or more entry points or external symbols to an exit point.

You can also assign entry points and external symbols to an exit point during initialization using the ASSOCIATE EXIT configuration file statement. For more information, see [ASSOCIATE EXIT Statement in z/VM: CP Planning and Administration](#).

### Operands

#### *exit*

is the number of the exit point to which you want to assign an entry point or external symbol. The variable *exit* must be a hexadecimal number between X'0000' and X'FFFF'.

#### **REPlace**

tells CP to replace the current list of entry point names and external symbols that are already associated with this exit point with the list specified after the EPNAME operand.

**Note:** The order that you specify the entry points and external symbols is the order in which CP will call them.

#### **Following**

tells CP to add the specified entry point names or external symbols to the end of the list of existing entry point names and external symbols that are already associated with the specified exit point number.

**Note:** The order that you specify the entry points and external symbols is the order in which CP will call them.

#### **Preceding**

tells CP to add the specified entry point names or external symbols to the beginning of the list of existing entry point names and external symbols that are already associated with the specified exit point number.

**Note:** The order that you specify the entry points and external symbols is the order in which CP will call them.

**DISable**

tells CP not to call the entry points and external symbols associated with this exit point until you enable it. (For more information about enabling exit points, see Usage Note “4” on page 21.) If omitted, DISABLE is the default.

**ENable**

tells CP to immediately start calling the entry points and external symbols associated with this exit point.

**EPName *name***

is the name (or names) of the entry point or external symbol that CP calls when encountering this exit point number. Each *name* must be a 1- to 8-character string. The first character must be alphabetic or one of the following special characters: dollar sign (\$), number sign (#), underscore (\_), or at sign (@). The rest of the string can be alphanumeric characters, the 4 special characters (\$, #, \_, and @), or any combination thereof.

**Note:** The order that you specify the entry points and external symbols is the order in which CP will call them.

**Usage Notes**

1. Before you use the ASSOCIATE EXIT command, you should issue the CPXLOAD command or configuration file statement to load the customer-written CP routines for the exit point into the system execution space. These CP routines should contain the entry point names and external symbols that you will specify on the ASSOCIATE EXIT command.

If you do not issue the CPXLOAD command or statement first or you issue the ASSOCIATE EXIT command with an unknown entry point or external symbol, CP just ignores any entry point name or external symbol that it does not recognize and continues normal processing. If the unknown entry point or external symbol is part of a list associated with an exit point, CP continues processing the other members of the list. CP does not ignore an exit point because it cannot find one entry point or external symbol in the list. CP only ignores an exit point if it cannot find all the entry points and external symbols in the list.

For more information about the CPXLOAD command, see “CPXLOAD” on page 111.

For more information about the [CPXLOAD Statement](#), see *z/VM: CP Planning and Administration*.

2. To display whether there are any unknown entry points or external symbols associated with an exit point, use the QUERY UNRESOLVED command (see “[QUERY UNRESOLVED](#)” on page 1250).
3. If you issue the ASSOCIATE EXIT command and do not specify the ENABLE operand, CP will redefine the exit point with the information from your ASSOCIATE EXIT command, but will not call any of the entry points or external symbols associated with that exit point until you later enable it.
4. There are 2 ways to enable an exit point:
  - Enter another ASSOCIATE EXIT command and specify the ENABLE operand, or
  - Use the ENABLE EXITS command (see “[ENABLE EXITS](#)” on page 465).

By default, exit points are disabled. Thus, in general, you should follow any ASSOCIATE EXIT commands or statements with ENABLE EXITS commands or statements.

5. CP calls the entry points and external symbols for an exit point in the order that you specify them on the ASSOCIATE EXIT command, unless an entry point overrides this action. Any entry point can tell CP to change the normal processing flow by skipping one or all subsequent entry points or external symbols.
6. To display status and usage statistics information about a specific exit point, use the QUERY EXITS command (see “[QUERY EXITS](#)” on page 907).

**Note:** While processing the ASSOCIATE EXIT command (or statement), CP creates a CP exit block for the specified exit point. For a static exit point, CP does not create CP exit control blocks until you associate one or more entry points or external symbols with that exit point. If you try to issue a QUERY EXITS command against such an exit point, CP issues message HCP2752E as the response to

your QUERY EXITS command. For a dynamic exit point, QUERY EXITS responds with the definition of the exit, even if there are no entry points associated with it.

7. To display the address of the CP exit block for a specific exit point, use the LOCATE XITBK command (see [“LOCATE XITBK”](#) on page 649). Again, if you have not associated one or more entry points or external symbols with the specified exit point, there is no CP exit block for CP to locate and display. Instead, CP issues error message HCP2752E.
8. To display the address of the CP indirect call locator block for a specific exit point, use the LOCATE ICLBK command (see [“LOCATE ICLBK”](#) on page 614).
9. To change the definition of an existing dynamic exit point, or to remove the exit point from the system, use the MODIFY EXIT command (see [“MODIFY EXIT”](#) on page 700).
10. To stop CP from calling the entry points and external symbols associated with one or more exit points after defining those exit points, use the DISABLE EXITS command (see [“DISABLE EXITS”](#) on page 319).
11. To remove the customer-written CP routines from the system execution space:
  - a. Use the DISASSOCIATE command (see [“DISASSOCIATE”](#) on page 324) to revoke all entry point and external symbol assignments made with the ASSOCIATE EXIT command or configuration file statement.
  - b. Use the CPXUNLOAD command (see [“CPXUNLOAD”](#) on page 117) to unload the customer-written CP routines.
12. Using the ASSOCIATE EXITS command or configuration file statement, you can add to the list of entry points and external symbols for an exit point, or you can replace the list. For example, if you associate entry points ZZZA1 and ZZZA2 with an exit point:

```
associate exit 1 epname zzza1 zzza2
Ready;
```

and then you associate additional entry points YYYYB1 and YYYYC2:

```
associate exit 1 preceding epname yyyb1 yyyc2
Ready;
```

the final list of entry points would be:

```
YYYYB1 YYYYC2 ZZZA1 ZZZA2
```

13. To remove one or more entry points or external symbols from the list associated with an exit point, issue the ASSOCIATE EXIT command with the REPLACE operand and specify only those entry points and external symbols that you want CP to call.
14. If the exit point is disabled when you issue the ASSOCIATE EXIT command, CP immediately updates the list of entry points and external symbols with your changes. If the exit point is enabled, CP checks to see if the specified exit point is currently processing an exit request. If the exit point is not processing any requests, CP immediately updates the list with your changes. If the exit point is processing a request, CP waits until the current request is completed and then updates the list with your changes before processing any new exit requests.
15. After creating a CP exit block, CP will not erase that CP exit block until another IPL. Disabling the exit point affects certain fields in the CP exit block, but does not erase it. Disassociating the entry point names and external symbols erases those fields in the CP exit block, but does not erase the CP exit block itself.
16. For more information about user-defined exit points, see [IBM-Defined CP Exit Points](#) in *z/VM: CP Exit Customization*.

## Responses

Response 1:

To associate entry point HCPSRC00 with exit number F and to replace any existing entry point associations, enter the following:

```
associate exit f epname hcpsrc00
Ready;
```

Response 2:

To add entry point HCPSRC04 at the end of the current list for exit point 9C, enter the following:

```
associate exit 9c following epname hcpsrc04
Ready;
```

Response 3:

Using the QUERY EXITS command and the ASSOCIATE EXIT command, you can see how you are changing the list of entry points:

```
query exit 5
Exit Status      Calls   Returns Seconds
0005 Enabled      1       1 0.000122
      EPNAME    Attempts Calls Seconds
      HCPSRC00  1       1 0.000116
Ready;
```

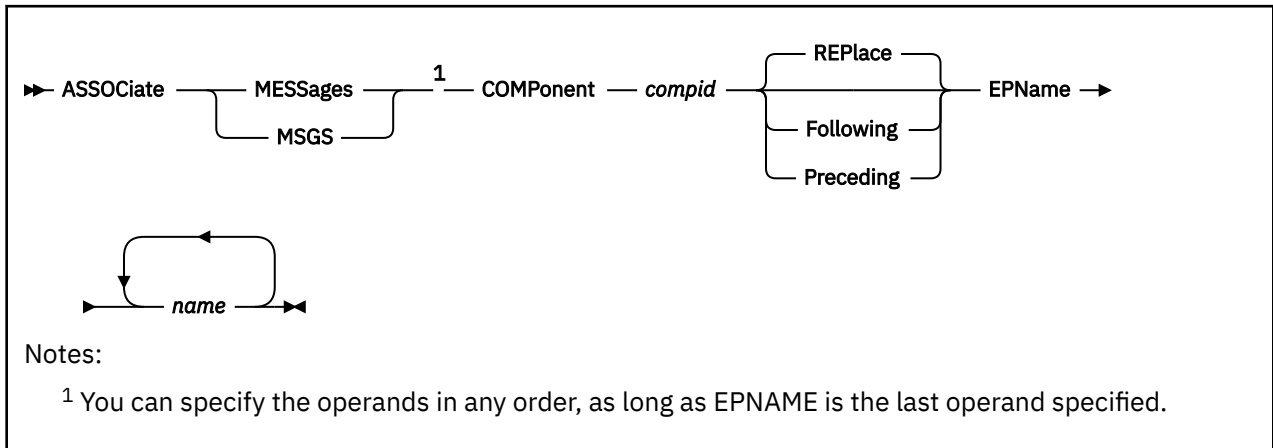

```
associate exit 5 following epname hcpsrc04
Ready;
```

```
query exit 5
Exit Status      Calls   Returns Seconds
0005 Enabled      1       1 0.000122
      EPNAME    Attempts Calls Seconds
      HCPSRC00  1       1 0.000116
      HCPSRC04  0       0 0.000000
Ready;
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP013E Unknown entry point name *entry* cannot be associated with an exit point requiring resolution
- HCP376E Unknown entry point name *entry* cannot be associated with an exit point requiring resolution
- HCP2773I Entry point name *name* is unknown at this time; processing continues
- HCP6704E Missing token at end of line
- HCP6706E {Invalid entry point name - *name* | Invalid CP Exit number - *exit*}
- HCP6709E Too many items specified - *item*

## ASSOCIATE MESSAGES / MSGS

### Authorization

Privilege Class: A

### Purpose

Use ASSOCIATE MESSAGES or MSGS to assign an external symbol to a local message repository and to give CP information about how to select the messages in that repository.

You can also assign external symbols to a local message repository and give CP information about how to select messages in that repository during initialization using the ASSOCIATE MESSAGES or MSGS configuration file statements. For more information, see [ASSOCIATE MESSAGES / MSGS Statement in z/VM: CP Planning and Administration](#).

### Operands

#### COMPONENT *compid*

tells CP the component identifier to use when issuing one of the messages in the local message repository. The variable *compid* is a 1- to 3-character alphanumeric string. For example, the component ID for the system message repository (z/VM) is HCP, which is, by default, the last message repository in the search list. For more information, see Usage Note [“1” on page 25](#).

#### REPlace

tells CP to replace the current list of entry point names and external symbols that are already associated with this local message repository with the list specified after the EPNAME operand.

**Note:** The order that you specify the entry points and external symbols is the order in which CP will search them.

#### Following

tells CP to add the specified entry point names or external symbols to the end of the list of existing entry point names and external symbols that are already associated with the specified local message repository.

**Note:** The order that you specify the entry points and external symbols is the order in which CP will call them.

#### Preceding

tells CP to add the specified entry point names or external symbols to the beginning of the list of existing entry point names and external symbols that are already associated with the specified local message repository.

**Note:** The order that you specify the entry points and external symbols is the order in which CP will call them.

### EPName *name*

is the name (or names) of the entry point or external symbol that points to the data in the system execution space where the local message repository can be found. Each *name* must be a 1- to 8-character string. The first character must be alphabetic or one of the following special characters: dollar sign (\$), number sign (#), underscore (\_), or at sign (@). The rest of the string can be alphanumeric characters, the 4 special characters (\$, #, \_, and @), or any combination thereof.

**Note:** The order that you specify the entry points and external symbols is the order in which CP will call them.

## Usage Notes

1. HCP is the standard component ID for z/VM messages. If you do not issue any ASSOCIATE MESSAGES or MSGS commands (or configuration file statements) for an entry point, HCPMES is, by default, the only message repository in the search list for that entry point.

If you do assign one or more local message repositories to an entry point, those repositories are added to the search list in the order that you specify (using the REPLACE, FOLLOWING, or PRECEDING operands) and, by default, HCPMES is the last message repository in the search list.

When the routines in that entry point issue a message, CP searches the first message repository in the search list. If CP finds the message in that repository, it issues the message and does not search any more repositories. If CP does not find the message, it continues searching through each repository until it finds the first occurrence of that message.

Using ASSOCIATE MESSAGES or MSGS commands (or configuration file statements), you can assign local message repositories which override existing z/VM messages in the HCPMES repository. Or, you can specify HCP as the component ID and move the z/VM message repository to a place in the search list other than last place.

2. Before CP can begin using your message repository, you must:
  - a. Generate your messages using the CMS GENMSG command. For more information about the [CMS GENMSG](#) command, see *z/VM: CMS Commands and Utilities Reference*.
  - b. Load the message repository file using the CPXLOAD command (see [“CPXLOAD”](#) on page 111).
3. If CP cannot find the message in the associated message repositories (or the entry point can't be found) when the message is being displayed, CP displays message substitution data, if any.
4. To display information about the local message repositories available on your system, use the QUERY CPLANGLIST command and specify the ASSOCIATED operand (see [“QUERY CPLANGLIST”](#) on page 826).
5. To remove the message repository file from the system execution space:
  - a. Use the DISASSOCIATE command (see [“DISASSOCIATE”](#) on page 324) to revoke the external symbol assignment made with the ASSOCIATE MESSAGES command or configuration file statement.
  - b. Use the CPXUNLOAD command (see [“CPXUNLOAD”](#) on page 117) to unload the repository.
6. To have CP use the message repositories associated with a specific component, you must specify that component ID on the COMPID keyword of the HCPCONSL macroinstruction. For more information about the HCPCONSL macroinstruction and about using your own message repositories, see [Creating, Controlling, and Using Local CP Message Repositories in z/VM: CP Exit Customization](#).
7. The ASSOCIATE MESSAGE configuration file statement has a DELAY/NODELAY operand so that you can delay associate processing until all CPXLOAD operations in the configuration file have been handled. For compatibility, you can specify these operands on the command line. However, CP ignores these operands, issues information message HCP2777I and continues processing the ASSOCIATE MESSAGE command immediately.

### Responses

Response 1:

To have CP assign an uppercase English message repository containing messages starting with OUR to entry point OURMESS1, enter the following:

```
associate msgs component our preceding epname ourmess1  
Ready;
```

### Messages

# AT

## Authorization

Privilege Class: A, B, C, D, E, F

There are restrictions on which CP commands can be issued with the AT command. For more information, see Usage Note “2” on page 27.

## Purpose

Use AT to issue a CP command on an active member system in an SSI cluster.

## Operands

### *sysname*

is the name of the SSI cluster member where the command is to be issued.

**\***

specifies that the command is to be issued on the SSI cluster member where the AT command is issued.

### **CMD *command\_string***

specifies the command string that will be issued on the designated member of the SSI cluster. Some commands have syntax requirements or restrictions when executed with the AT command. See the Usage Notes.

## Usage Notes

- CP commands that have an AT extension will work in an SSI cluster. However, when issued with the AT command, CP commands with an AT extension are rejected.
- Class restrictions for using the AT command include:
  - Class Any commands that are allowed: ASTERISK (\*), MESSAGE (user).
  - Class G commands that are allowed: QUERY CPLEVEL, QUERY CPOWNED, XAUTOLOG.
  - All non-class Any and non-class G commands are allowed except:
    - AT
    - AUTOLOG
    - DEFINE VFB-512
    - FLASHCOPY
    - FOR
    - GIVE
    - SAVESEG
    - SAVESYS
    - SEND
    - SET IPLPARMS
    - SET VTOD
    - SPXTAPE

- If an allowed command is authorized for multiple classes that include class Any or class G, the class Any or class G version cannot be issued with the AT command unless it is one of those specifically identified as allowed.
  - User-defined commands are processed according to the same privilege class rules.
3. Do not use an asterisk (\*) to represent a user ID in a command that is issued with the AT command. Specify the user ID. If you specify \*, it will be treated literally as a user ID, and the command will be rejected.
  4. In numerous CP commands, the command action is by default executed for the issuer of the command. When these commands are issued with the AT command to be executed on a different SSI member, it does not make sense to execute the command action for the issuer of the AT command. Because of this, some command options that are normally a default option must be specified when executed with the AT command. Commands that are affected by this have a syntax note explaining which default options must be specified when the command is issued with the AT command. Refer to the syntax for the command that you are issuing with the AT command for more details on any changes in default option handling when the command is executed with the AT command.
  5. The command text after the CMD keyword is, in most cases, passed in its entirety to the target system. An exception to this involves the LINEND setting of the CP TERMINAL command. For example, if the logical line-end symbol for the issuer's virtual machine is set to # (the default), the command at `tstmem2 cmd q cplevel # q cplevel` will display QUERY CPLEVEL results from the target system called TSTMEM2, followed by QUERY CPLEVEL results from the source system that the AT command was issued on. A logical line-end character cannot be passed as part of the command string to be executed on the target system. It will always be treated as part of the AT command.
  6. Some CP commands generate asynchronous responses. This means that the responses can be sent back to the issuer of the command after an indication has been sent back to the issuer that the command has completed initial processing.  
  
In general, if these commands are issued with the AT command, these asynchronous responses are not reflected back to the issuer of the AT command. This is consistent with how these responses are handled with commands issued with DIAGNOSE Code X'08' - Virtual Console Function. Any programs or processes that depend on these messages need to handle the fact that these asynchronous responses are not returned to the AT command issuer.
  7. The command issued with the AT command must be valid on the target system.

## Responses

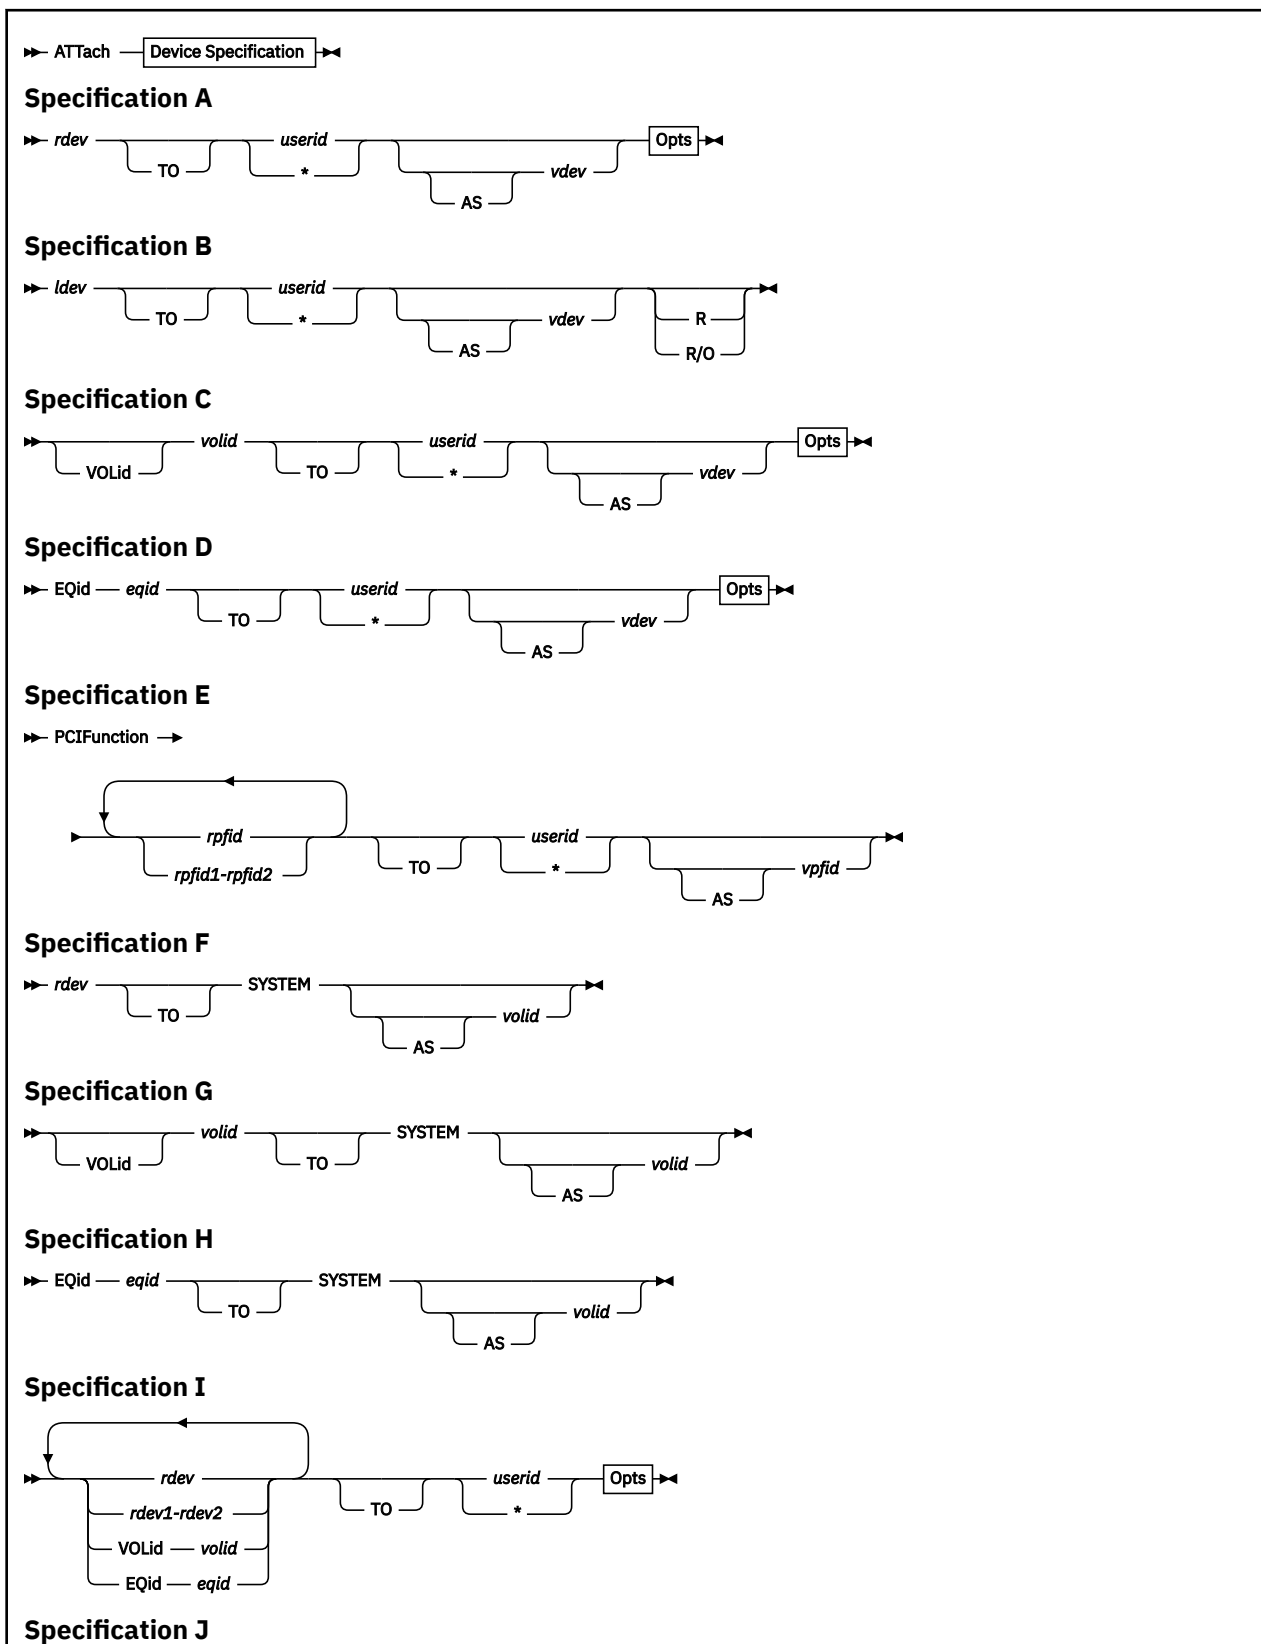

The responses received from the AT command are generated by the command that is executed on the SSI member system. Refer to the Responses section of the command that you are issuing with the AT command for response information.

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *option*
- HCP013E Conflicting option - *option*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on.
- HCP1143E Member *sysname* is not in Joined status in this SSI cluster
- HCP1144E Unknown CP command executed with the AT command: *command\_string*
- HCP1145E Unknown command option specified with the AT command: *option*
- HCP1146E Unable to open connection for \*AT to *sysname*; rc=*rc*

- HCP1149E Error communicating with another SSI member. It cannot be determined if AT executed remotely.
- HCP1927E System *sysname* is not a member of an SSI cluster
- HCP6525E The External Security Manager on *sysname* is unavailable.

# ATTACH

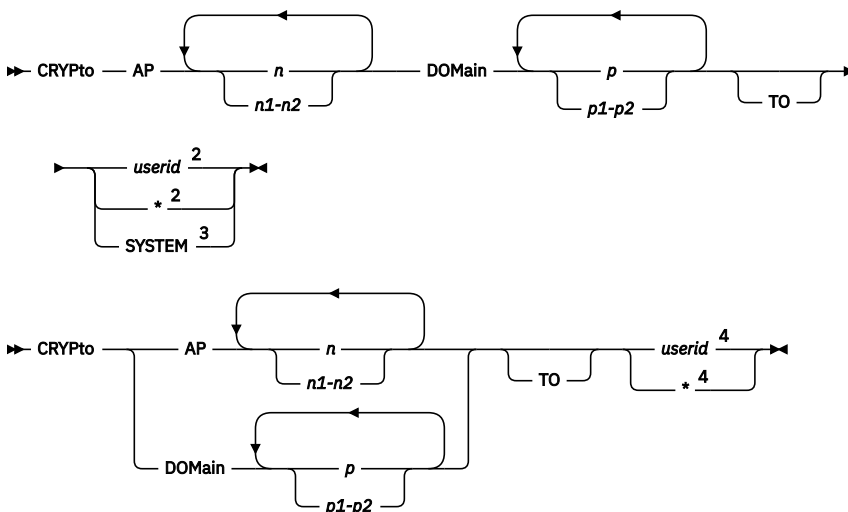

**Specification K**

**Specification L**

**Specification M**

**Notes:**

- <sup>1</sup> SYSASCII is for Linux® usage only.
- <sup>2</sup> The first ATTACH to *userid* (or ATTACH to \*) requires both crypto adapter (AP) and domain to be specified.
- <sup>3</sup> ATTACH TO SYSTEM always requires both adapter and domain to be specified.
- <sup>4</sup> After the initial set of dedicated crypto resources is attached to *userid* (or \*), you can specify only crypto adapters (AP) or domains, but not both.

**Options for Dedicated Tape Device**

## Authorization

Privilege Class: B

## Purpose

Use ATTACH to logically connect the following devices and resources:

- Connect a real or logical device to a virtual machine for exclusive use.
- Connect a real PCI function to a virtual machine for exclusive use.
- Connect a real tape device to a virtual machine for shared use.
- Connect DASD to the host system.
- Connect crypto resources to the system for shared use or to a virtual machine for dedicated use.

## Operands

**rdev**

**rdev1-rdev2**

specifies a real device number, a list of real device numbers, or a range of real device numbers to be attached to the specified user or to the CP system. Specify a real device number as 4 hexadecimal digits. You may omit leading zeros. The maximum number of devices allowed in a range is 256.

If you are not specifying a virtual device number or volume label for the real device that you are attaching, the virtual device number defaults to the real device number. You can combine device numbers, lists of device numbers, and ranges of device numbers on a single command line.

If you are specifying a virtual device number for the device, you can specify only one real device number when you enter the ATTACH command.

***ldev***

***ldev1-ldev2***

specifies a logical device number, a list of logical device numbers, or a range of logical device numbers to be attached to the specified user. Specify a logical device number as an "L" followed by up to 4 hexadecimal digits. You may omit leading zeros.

If you are not specifying a virtual device number for the logical device that you are attaching, the virtual device number defaults to the logical device number. You can combine device numbers, lists of device numbers, and ranges of device numbers on a single command line.

If you are specifying a virtual device number or volume label for the device, you can specify only one logical device number when you enter the ATTACH command.

**VOLid**

indicates that a volume serial number, which must follow this keyword, is used to identify the real device. If the volume serial number is valid as an operand of the command (e.g., is a valid device number), specify VOLID to indicate that the operand is a volume serial.

***valid***

specifies the 1- through 6-character volume serial number of a real DASD.

**EQid**

indicates that a device equivalency ID, which must follow this keyword, is used to identify the real device. If the EQID is valid and only one unattached device with this EQID exists, the device will be attached. If more than one unattached device exists with the specified EQID, the first unattached device found will be used.

***eqid***

specifies a string of 1 - 8 alphanumeric characters for a user-specified EQID or a string of 50 alphanumeric characters plus a dash ("-") for a system-generated EQID.

***userid***

**\***

is the virtual machine that is to receive the device or devices. That virtual machine must currently be logged on to the system. If you are attaching a device to your own virtual machine, you can specify your user ID as an asterisk (\*).

Use the keyword T0 when:

- You specify a user ID with three numbers or fewer in a range of addresses or multiple device addresses
- You specify a user ID that could also be a valid hexadecimal device address (for example, CE)
- You specify a user ID as "to" or "t".

***vdev***

is the virtual device number you want assigned to the device. The device number is assigned to an available virtual subchannel number, and may be as long as four digits.

**PCIFunction**

indicates that a PCI function ID, which must follow this keyword, is used to identify the real function.

***rpfid***

***rpfid1-rpfid2***

specifies a real PCI function ID or a range of PCI function IDs to be attached to the specified user. Specify a PCI function ID as 8 hexadecimal digits. You may omit leading zeros. The total number of PCI functions specified cannot exceed 256.

**TO *userid***

is the virtual machine that is to receive the function or functions. That virtual machine must currently be logged onto the system. If you are attaching a function to your own virtual machine, you can specify your user ID as an asterisk (\*).

## ATTACH

### **AS *vpfid***

specifies the virtual PCI function ID you want assigned to the function. Specify a PCI function ID as 8 hexadecimal digits. You may omit leading zeros. This option is only valid if a single *rpfid* is specified. If omitted, the virtual PCI function ID will be the same as the real PCI function ID specified.

### **SYSTEM**

makes the DASD available to CP for access to users' virtual disks, or for paging, spooling, and temporary disk functions. Indicates that crypto resources will be added to the system's shared pool.

### ***valid***

is the volume label of the volume on the device being attached. The system verifies the volume label on the device, so the label must be unique when compared with all other volumes attached to the system.

### **SYSAscii**

indicates that the real ASCII console is to be attached to the specified user.

### **SYSAscii TO *userid***

is the user ID of the virtual machine that is to receive access to the real ASCII console. The virtual machine must be currently logged on to the system. A user ID of SYSTEM is not valid.

### **SYSAscii TO \***

specifies that the virtual machine issuing the ATTACH command receives access to the real ASCII console.

### ***n***

#### ***n1-n2***

specifies a single crypto adapter number, a list of adapter numbers, a range of adapter numbers or a combination of these, to be attached. If you are specifying a list of numbers, insert at least one blank between the numbers you specify. If you are specifying a range of numbers, insert a hyphen (-) between the numbers you specify. The number is a decimal number between 0 and 255.

### ***p***

#### ***p1-p2***

specifies the crypto domain number, a list of domain numbers, a range of domain numbers or a combination of these, to be attached to the virtual machine or system. If you are specifying a list of domain numbers, insert at least one blank between the numbers you specify. If you are specifying a range of domain numbers, insert a hyphen (-) between the numbers you specify. The domain number is a decimal number between 0 and 255.

## **Options**

### **R/O**

can be used for DASD and tape devices that are attached to a user. This allows the system operator to apply read-only protection to a user's disk or tape.

CP ignores the R/O operand for any device number that does not correspond to a TAPE or DASD device.

### **SINGLEuser**

dedicates a real tape device to a single user. This is the default.

### **MULTIuser**

attaches a real tape device to be serially shared with other users. See Usage Note [“16” on page 37](#).

### **WITH ASSIGN**

specifies that the tape device you want attached to the user will be assigned to the user system. CP ignores this operand for any tape device that does not support ASSIGN and UNASSIGN CCWs.

### **WITH NOASSIGN**

specifies that the tape device you want attached to the user must not be assigned to the user system. This gives the guest the ability to control the assignment of the tape. CP ignores this operand for any tape device that does not support ASSIGN and UNASSIGN CCWs.

**Note:** When a tape attached with NOASSIGN is detached:

- The tape is *not rewound or unloaded*.
- If the tape was attached with SINGLEUSER (the default), CP does not change the ASSIGNED or UNASSIGNED status of the device. It is the responsibility of the guest to enter the ASSIGN CCW when it needs the tape and to enter the UNASSIGN CCW when it is finished using the tape.
- If the tape was attached with MULTIUSER, CP changes the status of the device to UNASSIGNED.

### **NOCPMS**

indicates that attach processing should not issue MODE SET CCWs to a tape device to initialize the Device Control Pages of the device. This option is ignored for any tape device that does not support the X'CB' MODE SET CCW. This option is not available on the DEDICATE User Directory Statement.

MODE SET CCWs are issued only if ASSIGN processing is also done. Thus, NOCPMS performs no function if NOASSIGN is specified.

The KEY option will issue MODE SET CCWs, but will respect the existing device settings if used in conjunction with the NOCPMS option.

### **CPMS**

indicates that CP will issue MODE SET CCW's with either default mode (no CPMS parameter) or with the specified mode parameter. Mode validation is done in respect of the tape hardware capabilities. CPMS and NOCPMS option cannot be issued together.

#### **EFMT1**

indicates the 512 track recording format.

#### **EFMT2**

indicates the 896 track recording format.

#### **EFMT3**

indicates the 1152 track recording format.

#### **EFMT4**

indicates the 2176 track recording format.

### **WITH DEVCTL**

means that the device accepts CCWs that have an effect on resources and functions directly related to the device. See Usage Note [“6” on page 36](#) for default values.

### **WITH NOCTL**

means that the device does not accept any CCWs that can exercise control of subsystem resources or functions, regardless of whether they directly relate to the device.

### **WITH SYSCTL**

means that the device accepts CCWs that have a direct global effect on subsystem resources and functions, not just on those related to the device. See Usage Note [“6” on page 36](#) for default values.

### **NOQIOAssist**

indicates that the devices are not eligible for Queued-I/O assist.

### **KEY keyalias**

prepares CP to enable a device's hardware encryption on behalf of a guest that is not able to manage the support itself. If a *keyalias* is specified (up to two are allowed), CP will use the encoding mechanism and key label described by the alias while setting up the encryption environment. If no aliases are supplied, the external key manager's default keys will be used.

### **USERACcesid userid**

to allow a user (guest) the ability to give FCP LUN access to the specified userid. This is a shortcut to redefining entries in the Access Control Table (ACT), and assumes the user has authority to the LUN as defined in the ACT. Please refer to Linux documentation for details on creating and maintaining the ACT for FCP configuration.

## Usage Notes

1. If you are attaching a DASD with logical addresses, the real device number you specify must be the base address for the device, and the virtual device number you specify must follow the addressing rules for base addresses.
2. The ATTACH command will not affect the various draining status indicators, so you can set the desired draining status before you attach a DASD to your system.
3. If you mount and ready a device that contains virtual minidisks after you have loaded VM onto the system, you must attach that device to the system if you want to use it. If you log on after the device has been attached, you gain access to the disk as provided by your entry in the system directory. If you were logged on before the volume was attached to the system, you must use the CP LINK command to gain access to the virtual disks.
4. CP processes all the device numbers you specify, even if it encounters errors when attempting to attach the devices. So, if you enter: `attach 108-10f user1 r` and real devices 10A and 10D were not ready and online, the following devices would be successfully attached: 108, 109, 10B, 10C, 10E, 10F. Messages tell you whether devices are successfully attached.
5. You can use the system directory DEDICATE statement to attach real devices to each virtual machine. Then, when users successfully log on, the devices (if online and available) are automatically attached to their virtual machine. This function saves Class B users the trouble of issuing multiple ATTACH commands for the devices.
6. Levels of control (SYSCTL/DEVCTL/NOCTL)
  - a. The default control level value is normally DEVCTL.
  - b. The SYSCTL, DEVCTL, and NOCTL operands apply only to DASD on a cached control unit. If one of these operands is specified for a noncached DASD, the device is attached and a response is issued stating that the operand was ignored.
  - c. Specifying a level of control (NOCTL, DEVCTL, or SYSCTL) for a DASD attached to a cache storage control unit authorizes CP to accept particular control CCWs.

Table 5 on page 36 shows the additional control CCWs CP accepts for a level of control. The DEVCTL column shows the CCWs CP accepts in addition to those it accepts for the NOCTL level of control. The SYSCTL column shows the CCWs CP accepts in addition to those it accepts for the DEVCTL and NOCTL levels of control.

Additional Control CCWs Accepted for DEVCTL	Additional Control CCWs Accepted for SYSCTL
<ul style="list-style-type: none"> <li>• Set subsystem mode               <ul style="list-style-type: none"> <li>– Activate caching for device</li> <li>– Deactivate caching for device</li> <li>– Activate DASD fast write</li> <li>– Deactivate DASD fast write</li> <li>– Force deactivate DASD fast write</li> </ul> </li> <li>• Perform Subsystem Function               <ul style="list-style-type: none"> <li>– Establish duplex pair</li> <li>– Terminate duplex pair</li> <li>– Suspend duplex pair</li> <li>– Direct I/O to one device of the duplex pair</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Set subsystem mode               <ul style="list-style-type: none"> <li>– Make cache available</li> <li>– Make cache unavailable</li> <li>– Force cache unavailable</li> <li>– Make NVS available</li> <li>– Make NVS unavailable</li> <li>– Activate cache fast write</li> <li>– Deactivate cache fast write</li> </ul> </li> <li>• Perform Subsystem Function               <ul style="list-style-type: none"> <li>– Destage Modified Tracks</li> <li>– Set Cache Allocation Parameters</li> <li>– Suspend/Resume Function</li> </ul> </li> </ul>

7. When an authorized user issues the GIVE command to transfer control of a tape drive, the ATTACH command is invoked.
8. The ATTACH command may be used to attach duplex volumes to a guest virtual machine or the system. Only the primary duplex volume may be attached to the system. Either the primary volume, the secondary volume, or both volumes may be attached to a guest virtual machine.  
When a duplexed volume is attached to a virtual machine (or to the system), the responses generated will indicate that the volume was either the primary duplex volume or the secondary duplex volume of a duplex pair.
9. For a guest virtual machine to establish a duplex pair, both of the affected volumes must be physically attached to the same 3990 storage control subsystem, and each volume must be logically attached to that guest with either DEVCTL or SYSCTL. In order for a guest virtual machine to suspend or stop a duplex pair, the guest must have DEVCTL or SYSCTL over the primary volume of the duplex pair.  
Duplexing is only allowed if both volumes are dedicated, or both are DEVNO-defined full-pack minidisks. CP does not allow a guest virtual machine to duplex a full-pack minidisk with a dedicated device.
10. The ATTACH command cannot be used to attach DEVNO-defined minidisks or secondary volumes of duplex pairs to the system.
11. The ATTACH command cannot be used to attach virtual disks in storage.
12. The ATTACH command will verify that the correct allocation map is used by the volume. Only FBA and devices with greater than 4K cylinders will use the extent-based allocation map. All other DASD will use the cylinder-based allocation map.
13. If a device is being throttled, you cannot attach it to the system as a CP-owned device. To display whether a device is being throttled, use the QUERY THROTTLE command (see [“QUERY THROTTLE” on page 1217](#)). To turn throttling off for a device, use the SET THROTTLE command (see [“SET THROTTLE” on page 1734](#)).
14. When attaching Parallel Access Volume DASDs:
  - To a guest, the base Parallel Access Volume must be attached first, before any associated alias Parallel Access Volumes. The associated alias Parallel Access Volumes can only be attached to the same guest as the base Parallel Access Volume.
  - To the system, the base Parallel Access Volume must be attached first, before any associated alias Parallel Access Volumes. Alias Parallel Access Volumes can be attached to the system, but are only exploited for VM I/O if they contain minidisk (PERM) or temporary disk (TDSK) allocations. Other CP volume allocations receive no benefit from system-attached alias Parallel Access Volumes.
15. HyperPAV aliases that are attached to the system are exploited by:
  - VM I/O, for minidisk (PERM) and temporary disk (TDSK) allocations
  - The CP paging subsystem, for directory (DRCT), page (PAGE), and spool (SPOL) allocations, when the feature has been enabled through one of the following:
    - In the system configuration file:
      - The PAGING\_ALIAS FEATURES statement (the preferred method)
      - The FEATURES ENABLE PAGING ALIAS statement
    - The SET PAGING command.
16. The MULTIUSER function is intended for guest operating systems that manage their own assignment of tape devices. It is not intended for CMS unless some external means of managing assignments or serializing access to the tape device among the sharing users is explicitly implemented. Third party assignment and multiple system assignment (Control Access CCW) are not supported.  
To share a tape device, a user must specify the MULTIUSER option when attaching the device, or the CP directory entry for that user must contain a DEDICATE statement for the device that includes the MULTIUSER operand. If the first user to log on attaches the device without specifying MULTIUSER, or has a DEDICATE statement for the device that does not include MULTIUSER, the device becomes

dedicated to that user. The device then cannot be attached as MULTIUSER by any user until it is detached by the user to whom it is dedicated.

The MULTIUSER function is valid only for 3480, 3490, and 3590 tape devices.

17. The USERACcesSid option applies only to first-level and second-level users. If it is attempted on a third-level or higher virtual machine, the request is translated into corresponding first-level and second-level information only.
18. The KEY option (and any supplied keyaliases) are valid only for 3592 tape drives that support hardware encryption. It is to be used only for those guests that do not exploit hardware encryption itself. If used with guests that do exploit hardware encryption, problems may occur such as missing interrupts or mode sense errors.
19. Encryption settings can persist on a device, via an ATTACH with encryption settings followed by a DETACH LEAVE or through an ATTACH MULTIUSER with encryption settings, as two examples. An ATTACH without encryption settings for either case will then pick up those settings on the device, while an ATTACH with encryption settings will fail if the encryption settings differ from what is currently associated with the device.
20. During an ATTACH TO SYSTEM command, a test is performed to determine if any non-PERM space is the Target of a FlashCopy relationship. If so, the command fails with message HCP2463E.
21. ATTACH fails if the device being attached has CHPID Virtualization on and the device is an unsupported DPS=NO DASD or TAPE. The following message is issued:
 

HCP6863E Device *ldev* has not been attached because it is a DPS=NO device and CHPIDVirtualization option is not specified for the user in the directory.
22. When issuing an ATTACH *rdev* to SYSTEM command for a CP owned volume, note that for SPOOL and DIRECTORY volume types extents are limited to cylinders 0-65519, and for PAGE volume types extents are limited to cylinders 0-1182005. TEMP and PARM disks can be located anywhere on the volume, but the PARM disk size is limited to 65520 cylinders. PERM space allocation is allowed anywhere on the volume.
23. When a CP-owned DASD volume with SPOOL extents is attached to a member of an SSI cluster, the volume will be automatically attached to the other active members where the device is online and not already attached. Also, if the volume is not in the CP-owned list on another active member where the device is being attached, the attach process will automatically add the volume to the CP-owned list on that member.
24. When ENFORCE\_BY\_VOLID has been enabled in the system configuration file, ATTACH commands will be rejected and message HCP6419E will be issued unless the ATTACH command specifies targets by VOLID.
25. The z/VM CP definition of a virtual function is a guest's view of a real function. This should not be confused with a virtual function associated with a PCI function where an adapter, identified by its PCHID, supports more than one PCI function.
26. The maximum value of the virtual function id number may be model dependent and limited by the machine and may also be limited by the guest operating system or application using the function. For example, z/OS 2.1 Communications Server IP Configuration allows a 2-byte hexadecimal value in the range 0-00FF.
27. When UID uniqueness enforcement is enabled by the SET IO\_OPT UID command, the attach of a PCI function will be rejected if another function with an identical UID value is already attached to the target guest.
28. The DEFINE CRYPTO APVIRTUAL command will give a virtual machine access to the system's shared crypto resources for the current logon session. The CRYPTO APVIRTUAL user directory statement will give a virtual machine access to the system's shared crypto resources at each logon.
29. The ATTACH CRYPTO TO SYSTEM command can be used to assign crypto resources to the system for shared use. This assignment can also be made during system IPL using a CRYPTO APVIRTUAL statement in the system configuration file.
30. The ATTACH CRYPTO TO userid command may be used to provide a virtual machine with dedicated access to one or more crypto resources for the duration of a logon session. This is the same authority

given to a virtual machine with a CRYPTO APDEDICATED statement in the directory entry. The CRYPTO APDEDICATED directory statement will give the virtual machine access to the specified crypto resources at each logon. The ATTACH CRYPTO command will give the virtual machine access to the specified crypto resources for the current logon session only.

31. Dedicated crypto resources must be assigned to a virtual machine as a rectangular resource set so that the resources available to a virtual machine are a cross-product of all assigned adapters and domains.

In order for a virtual machine to have dedicated access to a crypto resource, each specified domain number must be available for dedicated use by this virtual machine on all specified adapter numbers. If one or more domains on an adapter are not available for dedicated use by this virtual machine, then none of the domains on the adapter will be assigned. Any requested domains that are not assigned to the LPAR that the z/VM system is running on will be eliminated from the request and will not be reason to deny access to the remaining requested adapters or domains.

For example, assume that domain 1 on adapters 1, 2, and 3 are resources that are dedicated to virtual machine vmach1. You can then attach domain 2 to vmach1 only if domain 2 is available to vmach1 on all of adapters 1, 2, and 3. If domain 2 is not available on one or more of adapters 1, 2, or 3, then you cannot attach domain 2 to vmach1 on any of adapters 1, 2, or 3.

For more examples, see [“Examples” on page 39](#).

32. A crypto adapter must be configured in CCA coprocessor mode or accelerator mode in order to be attached to the system for shared use.
33. For information on planning and managing crypto resources on a z/VM system, see [Crypto Planning and Management in z/VM: CP Planning and Administration](#).

## Examples

Example 1:

```
ATTACH CRYPTO AP 2 3 DOMAIN 1 TO USER1
```

USER1 has:

Dom \ AP	000	001	002	003	004	005	006
000							
001			USER1	USER1			
002							
003							
004							
005							
006							
007							
008							

```
ATTACH CRYPTO AP 5 6 TO USER1
```

USER1 now has:

Dom \ AP	000	001	002	003	004	005	006
000							

*Table 7. Example 1B - Crypto Configuration (continued)*

Dom \ AP	000	001	002	003	004	005	006
001			USER1	USER1		USER1	USER1
002							
003							
004							
005							
006							
007							
008							

ATTACH CRYPTO DOMAIN 7 8 TO USER1

USER1 now has:

*Table 8. Example 1C - Crypto Configuration*

Dom \ AP	000	001	002	003	004	005	006
000							
001			USER1	USER1		USER1	USER1
002							
003							
004							
005							
006							
007			USER1	USER1		USER1	USER1
008			USER1	USER1		USER1	USER1

Example 2:

USER1 has:

AP 2 DOMAIN 1  
 AP 3 DOMAIN 1  
 and  
 AP 4 DOMAIN 2 is attached to the system.

USER1 has:

*Table 9. Example 2A - Crypto Configuration*

Dom \ AP	000	001	002	003	004
000					
001			USER1	USER1	
002					SHARED
003					

Table 9. Example 2A - Crypto Configuration (continued)

Dom \ AP	000	001	002	003	004
004					

ATTACH CRYPTO AP 4 to USER1

USER1 has:

Table 10. Example 2B - Crypto Configuration

Dom \ AP	000	001	002	003	004
000					
001			USER1	USER1	USER1
002					SHARED
003					
004					

ATTACH CRYPTO DOMAIN 2 TO USER1

This creates a conflict on adapter 4, domain 2 which is a shared crypto resource. Because domain 2 is not available on every adapter that USER1 currently has access to, the ATTACH command will fail.

## Responses

The receiver of the device attached, the user who issued the ATTACH command, and the primary system operator all receive messages indicating that the ATTACH was successful.

**Note:** The variable *type* is omitted from ATTACH responses when a range of device numbers or multiple device numbers are being reflected in the response. Control levels (for example, WITH xxxCTL) and PAV information (BASE and ALIAS) apply only to DASD; R/O applies to DASD and tapes.

In ATTACH responses, *type* is one of the following:

### Type

#### Meaning

#### DASD

Direct access storage device

#### FCP

SCSI Device Adapter

#### TAPE

Magnetic tape

#### RDR

Card reader

#### PRT

Printer

#### PUN

Card punch

#### GRAF

Display device

#### CTCA

Channel-to-channel adapter

## ATTACH

### OSA

Open Systems Adapter

### CTLR

Communications Controller

### MSC

Mass Storage Controller

### SWCH

Dynamic Switching Device

### DEV

Any other device

### LINE

Communication line

### SYSASCII

Integrated ASCII console

Response 1:

One of the following responses go to the receiver of the device:

```
{rdev... } ATTACHED TO userid
{rdev-rdev}
{ldev... }
{ldev-ldev}
```

– or –

```
{type rdev} ATTACHED TO userid vdev [R/O] [WITH SYSCTL] [PRIMARY DUPLEX ]
{type ldev} [WITH DEVCTL] [SECONDARY DUPLEX]
[WITH NOCTL ] [PAV BASE ]
[PAV ALIAS ]
[HYPERPAV BASE ]
[HYPERPAV ALIAS ]
```

informs the user that the devices have been attached to the user's virtual machine.

Response 2:

Depending on the command format the Class B user enters, this response indicates the devices attached to a specified user's virtual machine (and, if appropriate, the virtual device number, access mode, the level of control, and the duplex state, the PAV state, or the HyperPAV state for the device) or indicates that the device has been attached to the CP system.

One of the following responses go to the originator of the ATTACH command:

```
{rdev... } ATTACHED TO userid
{rdev-rdev}
{ldev... }
{ldev-ldev}
```

– or –

```
{type rdev} ATTACHED TO userid vdev [R/O] [WITH SYSCTL] [PRIMARY DUPLEX ]
{type ldev} [WITH DEVCTL] [SECONDARY DUPLEX]
[WITH NOCTL ] [PAV BASE ]
[PAV ALIAS ]
[HYPERPAV BASE ]
[HYPERPAV ALIAS ]
```

– or –

```
DASD rdev ATTACHED TO SYSTEM volid [PRIMARY DUPLEX ]
[PAV BASE ]
[PAV ALIAS ]
[HYPERPAV BASE ]
[HYPERPAV ALIAS ]
```

Response 3:

One of the following responses is sent to the primary system operator, if this operator did not issue the command. The response indicates that the device has been attached to either the specified user's machine (at virtual device number *vdev*) or to the CP system. The *originator* field designates the user ID of the user who issued the command.

One of the following responses go to the system operator:

```
{rdev... } ATTACHED TO userid BY originator
{rdev-rdev}
{ldev... }
{ldev-ldev}
```

– or –

```
{type rdev} ATTACHED TO userid vdev BY...con't
{type ldev}
```

Continued:

```
originator [R/O] [WITH SYSCTL] [PRIMARY DUPLEX ]
                  [WITH DEVCTL] [SECONDARY DUPLEX]
                  [WITH NOCTL ] [PAV BASE       ]
                              [PAV ALIAS      ]
                              [HYPERPAV BASE  ]
                              [HYPERPAV ALIAS ]
```

– or –

```
DASD rdev ATTACHED TO SYSTEM volid
BY originator [PRIMARY DUPLEX ]
                [PAV BASE       ]
                [PAV ALIAS      ]
                [HYPERPAV BASE  ]
                [HYPERPAV ALIAS ]
```

Response 4:

```
ctllevel IGNORED - INVALID FOR rdev
```

informs the originator of the command that control options have been specified for a noncached DASD.

***ctllevel***

is the level of control: SYSCTL, DEVCTL, or NOCTL.

***rdev***

is the real device number.

Response 5:

```
The directory on volume volume at address
rdev has been brought online.
```

indicates that a CP directory has been brought online during system initialization or during the process of attaching DASD to the system. The specified directory is the active system directory.

Response 6:

The following response goes to the user to whom the ASCII console is attached:

```
SYSASCII attached by originator
```

The variable *originator* designates the user ID of the person who entered the command.

The following response goes to the originator of the ATTACH command:

```
SYSASCII attached to userid
```

## ATTACH

If the primary system operator did not enter the command, the following response is sent to the primary system operator:

```
SYSASCII attached to userid by originator
```

The response indicates that the ASCII console has been attached to the specified user's virtual machine. The variable *originator* designates the user ID of the person who entered the command.

The receiver of the PCI function attached, the user who issued the ATTACH command, and the primary system operator all receive messages indicating that the ATTACH was successful.

Response 7:

The following response goes to the originator and receiver of the PCI function:

```
PCI FUNCTION rpfid ATTACHED TO userid upfid
```

Response 8:

The following response goes to the system operator:

```
PCI FUNCTION rpfid ATTACHED TO userid upfid BY originator
```

Response 9:

This response is sent to the command issuer and to the target when the target is not the command issuer or the primary system operator.

```
Crypto AP nnn Domain ppp attached to target
```

Response 10:

This response is sent to the primary system operator when the primary system operator is not command issuer.

```
Crypto AP nnn Domain ppp attached to target by originator
```

Response 11:

This response is sent to the originator of the command.

```
Crypto AP nnn Domain ppp attached to SYSTEM
```

Response 12:

This response is sent to the primary system operator when the primary system operator is not the originator of the command.

```
Crypto AP nnn Domain ppp attached to SYSTEM by originator
```

### ***nnn***

is the adapter number.

### ***ppp***

is the domain number.

- HCP122E SYSASCII already attached to *userid*
- HCP125E DASD *rdev* EQID *eqid* already attached to system
- HCP125E DASD *rdev* volid *valid* already attached to system
- HCP126E DASD *rdev* error reading volid
- HCP127E DASD *rdev* volid *valid* does not match
- HCP128E DASD *rdev* error reading allocation record
- HCP130E No devices with EQID *eqid* are available to attach with the parameters provided.
- HCP142E *type rdev* not drained
- HCP153E Device {*vdev|range*} exceeds maximum number of virtual devices
- HCP155E Device *rdev* has not been attached to the system because it is not a DASD device.
- HCP263E Too many operands were supplied for this command.
- HCP845E DASD *rdev* not attached; paging addresses offline
- HCP1014E A required option is missing
- HCP1100E A logical device number was not supplied or it is invalid.
- HCP1101E DASD *rdev* is not supported as a system-owned device.
- HCP1102E DASD *rdev* has not been attached because the paging subsystem is already owned by *userid*.
- HCP1103E DASD *rdev* has not been attached because a real DASD paging subsystem must map to only one virtual paging subsystem.
- HCP1104E DASD *rdev* has not been attached because multiple real DASD paging subsystems must not map to the same virtual DASD paging subsystem.
- HCP1105E Tape *rdev* not attached; tape assigned elsewhere.
- HCP1107E Attach failed; I/O error on tape *rdev*
- HCP1107E Attach failed; encryption requires tape *rdev* to be positioned at the beginning-of-tape
- HCP1113I DASD *rdev* was not ATTACHED to the SYSTEM because this operation would conflict with an MDISK definition for user *userid*.
- HCP1114I DASD *rdev* was not ATTACHED to the SYSTEM because it is the secondary in a duplex pair.
- HCP1116E Tape *rdev* not attached; the tape is being rewound.
- HCP1117I DASD *rdev* was not ATTACHED to the SYSTEM because it is the secondary in a PPRC pair or a cascading intermediate PPRC volume.
- HCP1124I An allocation map containing invalid data was found on DASD *rdev* volume *valid*; the device is not attached.

- HCP1125I The allocation map for DASD *rdev*, volume *valid* contains an area that is currently undefined. That area will be ignored.
- HCP1128E Device *rdev* not attached; MULTIUSER or SINGLEUSER not supported on this device.
- HCP1128E Device *rdev* not attached; hardware encryption not supported on this device.
- HCP1128E Device *rdev* not attached; a mismatch in hardware encryption settings was detected.
- HCP1128E Device *rdev* not attached; *user* is not authorized.
- HCP1128E Device *rdev* not attached; unsupported mode specified.
- HCP1129I *type rdev* has invalid volume label.
- HCP1129I *type rdev* has invalid volume prefix.
- HCP1150E DASD {*rdev|vdev*} is not a valid base exposure.
- HCP1168E PCI function *rpfid* cannot be attached to *userid* because a function with the same UID is already attached to that *guest*.
- HCP1280E Device *vdev* not usable; reserve lost [by *userid* as *vdev*]
- HCP1281I Path *channel* to device *rdev* now offline; path group ID mismatch.
- HCP1401I Expanded storage is not supported.
- HCP1561I Real device *rdev* forced R/O; unauthorized for R/W.
- HCP1728E AP Crypto resources are not installed on this system.
- HCP1728E Crypto AP *apnum* Domain *domnum* is not assigned to this system.
- HCP1728E Crypto AP *apnum* is not assigned to this system.
- HCP1728E Crypto Domain *domnum* is not assigned to this system.
- HCP1737E Crypto AP *apnum* Domain *domnum* cannot be attached to SYSTEM because it is attached to a user.
- HCP1737E Crypto Domain *domnum* cannot be attached to SYSTEM because it is not configured in coprocessor or accelerator mode.
- HCP1737E Crypto AP *apnum* Domain *domnum* cannot be attached to SYSTEM because it does not match the currently defined shared type.
- HCP1738E Only APs or Domains can be specified, not both, when attaching AP crypto resources to a user that already has dedicated AP crypto resources assigned.
- HCP1738E Both APs and Domains must be specified when attaching AP crypto resources to a user that does not have dedicated AP crypto resources already assigned.
- HCP1739E Dedicated AP crypto resources cannot be attached to an APVIRTUAL crypto user.
- HCP1747E Crypto AP *apnum* Domain *domnum* is already attached to SYSTEM.
- HCP1748E Crypto AP *apnum* cannot be attached because not all domains assigned to this user are free on this AP.
- HCP1748E Crypto Domain *domnum* cannot be attached because this domain is not free on all APs assigned to this user.
- HCP1748E Crypto AP *apnum* Domain *domnum* cannot be attached.
- HCP1749E AP crypto resources on AP *apnum* are already attached to this user.
- HCP1749E AP crypto resources on domain *domnum* are already attached to this user.
- HCP1753E There is no directory online because the directory on volume *valid* at address *rdev* is not valid.
- HCP1831E The command could not be completed because of a temporary condition. Try again later.
- HCP2462I *extenttype* extent on CP-OWNED volume *volser*, tracks *cccc/hh* to *cccc/hh*, is the Source for FlashCopy Relationship *sequence*.
- HCP2463E *extenttype* extent on CP-OWNED volume *volser*, tracks *cccc/hh* to *cccc/hh*, is the Target for FlashCopy Relationship *sequence*.

- HCP2768E Missing user ID
- HCP2768E Missing crypto domain number
- HCP2768E Missing crypto AP number
- HCP2777I Option *option* has been ignored.
- HCP2826E *operand* contains invalid UTF-8 data: *data*.
- HCP2890E CSE I/O error, code *cc*, volume *valid*; LINK commands may fail.
- HCP3173E Device *device* is reserved for system use.
- HCP5780E Adjunct does not support the *command subcommand* command
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6005E Option *option* is not supported by z/VM.
- HCP6201E Volume *volser* cannot be associated with a dump-only CP-owned list entry.
- HCP6202E The {*spool|temporary disk|directory*} cylinders were ignored on system volume *valid*.
- HCP6275E An error occurred writing to the subchannel for device *rdev*, code = *code*.
- HCP6419E DASD *rdev* has not been attached because the system requires it to be attached with the VOLID parameter.
- HCP6430E ATTACH cannot complete because the associated PAV base is quiesced for Hyperswap.
- HCP6430E ATTACH cannot complete because there is at least one base device in this HyperPAV pool that is quiesced for Hyperswap.
- HCP6643E Device *rdev* not attached to SYSTEM. Device contains spool extents and is already attached on system *system*.
- HCP6643E Device *rdev* not attached to SYSTEM. Device contains spool extents and is in slot *slot*. System *system* contains valid *valid*.
- HCP6643E Device *rdev* not attached to SYSTEM. Device contains spool extents and is in slot *slot*. This slot does not exist on system *system*.
- HCP6643E Device *rdev* not attached to SYSTEM. Device offline on system *system*.
- HCP6643E Device *rdev* not attached to SYSTEM. SSI cluster error, code *code*.
- HCP6644E Device with EQID *eqid* not attached to SYSTEM. Device contains spool extents and has been attached on other systems in the SSI cluster and could not be attached to this system.
- HCP6645E SSI cluster is in safe mode; command rejected.
- HCP6706E Invalid user ID
- HCP6706E Invalid Crypto Domain number
- HCP6706E Invalid Crypto AP number
- HCP6790I ATTACH processing halted. The next function that would have been processed is *rpfid*
- HCP6807E Device *rdev* is being throttled and cannot be attached to the system as a CP-owned device.
- HCP6860E Device *rdev* cannot be attached to the system because it is an alias Parallel Access Volume for which the base is attached to a user.
- HCP6860E Device *rdev* cannot be attached to the system because it is an alias Parallel Access Volume for which the base is free.
- HCP6863E Device *rdev* has not been attached because it is an alias Parallel Access Volume for which the base is free.
- HCP6863E Device *rdev* has not been attached because it is an alias Parallel Access Volume for which the base is in use by another user.
- HCP6863E Device *rdev* has not been attached because it is an alias Parallel Access Volume for which the base is in use by the system.
- HCP6863E *userid*: Device *rdev* has not been attached because it is a DPS=NO device and the CHPID Virtualization option is specified for the user in the directory.

## ATTACH

- HCP6863E Device *rdev* has not been attached because it is an EDEVICE alias.
- HCP9968E The key alias contains leading or trailing blanks or an empty string.

## ATTN

---

▶- ATTN -▶

### Authorization

Privilege Class: G

### Purpose

Use ATTN to interrupt the operation of your virtual machine.

### Usage Notes

1. The CP REQUEST command performs the same function as ATTN; you can use the two commands interchangeably.
2. The ATTN command performs an implied BEGIN.
3. CP ignores the ATTN and REQUEST commands if another attention interrupt is pending for your virtual machine, or if your virtual machine is not enabled for interrupts.

### Messages

- HCP002E Invalid operand - *operand*

## AUTOLOG

```

▶▶ AUTOLOG — userid — password 1
                                     └─ console_input_data ─┘
    
```

Notes:

<sup>1</sup> The *password* operand is not accepted if password suppression is active.

### Authorization

Privilege Class: A, B

### Purpose

Use AUTOLOG to log on another virtual machine automatically.

Before a virtual machine can be automatically logged on, it must be defined in the system directory, and you must know its password. After logon, it operates in disconnect mode.

**Note:** You can also use XAUTOLOG to log on another virtual machine.

XAUTOLOG has parameters for defining the virtual machine and changing command synchronization. Class A or Class B users do not need a password to use XAUTOLOG; Class G users must be authorized in the other virtual machine system directory.

Read the XAUTOLOG command description for more information about the additional functions available.

### Operands

#### *userid*

identifies the 1-character to 8-character name of the virtual machine you are logging on.

#### *password*

identifies the password of the virtual machine you are logging on.

To determine whether password suppression is active for this command, use the QUERY PASSWORD AUTOLOG command.

If password suppression is active, all data following *userid* is taken as *console\_input\_data*. Wait for the ENTER PASSWORD prompt before you type in the password. The password is automatically masked for system security.

If password suppression is not active, the first data item following *userid* is taken as the password, and any data following the password is taken as *console\_input\_data*.

#### *console\_input\_data*

identifies the data you want used as virtual console input in response to the first read issued by the user virtual machine. You may use the remainder of the command line to enter console data. The entire line, including any logical-line-end characters (#), is passed to the virtual machine.

**Note:** # refers to the logical-line-end character currently in effect for the virtual machine in which the AUTOLOG command is being used.

If you are using CMS and you specify *console\_input\_data* with the logical line-end character (#) on the command line, CMS truncates the AUTOLOG command at the first logical line-end character. To prevent this, enter a logical escape character before the logical line-end character, or enter #CP, where # is your logical line-end character, before the AUTOLOG command itself.

## Usage Notes

1. The virtual machine that you log on using AUTOLOG must have an IPL statement in its system directory unless it is a CF Service Machine (has OPTION CFVM in the directory).
2. A virtual machine is allowed to be logged on with AUTOLOG even though the number of users already logged on is equal to or greater than the maximum allowed by the MAXUSERS operand of the FEATURES system configuration statement or by the SET MAXUSERS command if the user directory for the virtual machine was created using the IGNMAXU operand of the OPTION directory statement.
3. The virtual machine you log on using AUTOLOG operates in disconnect mode. The same restraints that apply to any disconnected machine apply to virtual machines logged on with AUTOLOG.
4. The password suppression setting for the AUTOLOG command is controlled by the PASSWORDS\_ON\_CMDs operand of the FEATURES system configuration statement or by the SET PASSWORD command.
5. CP disables the AUTOLOG command for the rest of a user logon session if the user enters too many incorrect passwords while trying to logon another user ID automatically. The initial system limit depends on how the JOURNALING system configuration statement is coded. See the [JOURNALING Statement](#) in *z/VM: CP Planning and Administration* for more information. Use the QUERY CMDLIMIT command to see the system limit value set by your installation.
6. A secondary user ID may be specified on the user system directory CONSOLE statement. All console messages are routed to the secondary user ID, if it is functional, after the user is automatically logged on.
7. If you use AUTOLOG in an EXEC or module, you must put the password in the command or set the DIAGNOSE X'08' control bit to indicate that you want a prompt. See *z/VM: CP Programming Services* for details about [DIAGNOSE X'08'](#).
8. There is no password authorization for an AUTOLOG of a *userid* defined with the NOPASS operand, unless an Extended Security Manager (ESM) is installed. When an ESM is installed, password authorization may be required despite the NOPASS operand. Refer to documentation provided by your ESM for more information.
9. CP typically presents *console\_input\_data* to CMS through an interruption sequence before a CMS program has requested a console read. CMS places the *#console\_input\_data* into its terminal input queue in anticipation of some subsequent request to read from the console. This subsequent request is usually the PARSE EXTERNAL instruction in the SYSPROF EXEC, unless the SYSPROF EXEC is bypassed or the AUTOOCR parameter was used at IPL time. The EXTERNALS() VM REXX built-in function can be used to test for the existence of *console\_input\_data* before the PARSE EXTERNAL is issued.
10. Users defined with the LBYONLY operand in the password field of their USER or IDENTITY statement in the system directory may be restricted from performing functions that require password validation. When an External Security Manager (ESM) is not installed, users defined with the LBYONLY operand cannot be logged on by the AUTOLOG command. When an ESM is installed, refer to the documentation provided by your ESM for more information.

Refer to the [USER Directory Statement](#) or [IDENTITY Directory Statement](#) in *z/VM: CP Planning and Administration* for more details on the LBYONLY operand.

## Responses

Response 1:

```
ENTER PASSWORD
(IT WILL NOT APPEAR WHEN TYPED):
```

is the response when you must enter a password. Enter the password of the user ID you want to log on automatically.

Response 2:

## AUTOLOG

```
AUTO LOGON *** userid
USERS = nnnnn
```

is the response AUTOLOG sends to the issuer of the command when that person is not the system operator. This response is generated by successful command completion.

**\*\*\***

indicates no assigned line address for the virtual console.

***userid***

identifies the virtual machine initiated by AUTOLOG.

**USERS = *nnnnn***

identifies the number of logged-on users.

Response 3:

```
hh:mm:ss AUTO LOGON *** userid
USERS = nnnnn BY {SYSTEM }
                {userid2}
```

is the response AUTOLOG sends to the system operator when the command completes successfully.

**\*\*\***

indicates no assigned line address for the virtual console.

***userid***

identifies the virtual machine initiated by AUTOLOG.

**USERS = *nnnnn***

identifies the number of logged-on users.

**SYSTEM**

indicates that the AUTOLOG process has occurred as part of VM system initialization. Typically, your primary system operator's virtual machine is logged on as part of the system initialization process.

***userid2***

identifies the user issuing the AUTOLOG command. If *userid2* and *userid* are the same, then CP has autologged this virtual machine so that an APPC private server connection can be made.

**Response 4:**

```
hh:mm:ss USER DSC LOGOFF AS userid
USERS = nnnnn Forced
```

is the response to the system operator if an invalid IPL statement is processed for the user specified in the AUTOLOG command.

***userid***

identifies the virtual machine initiated by AUTOLOG.

**USERS = *nnnnn***

identifies the number of logged-on users.

- HCP6525E Authorization request failed.

## BACKSPACE/BACKWARD

### Authorization

Privilege Class: D

### Purpose

Use BACKSPACE to restart or reposition real device output (printer or punch).

### Operands

#### *rdev*

identifies the real device number of the punch or printer to be backspaced.

#### **File**

specifies that the output spool printer or punch file is to be restarted from the beginning. For punch output, FILE is the default.

#### *nnnnn*

specifies the number of pages (in decimal, to a maximum of 32,767) to be backspaced on the printer. If you do not specify a value, the printer backspaces to the beginning of the page being printed when the command is received. For printer output, the default value is 1.

#### **EOF**

specifies that backspacing is to start from the end of the spool file and then continue backward for the requested number of pages. Printing begins again from this new position.

### Usage Notes

1. BACKSPACE is identical to BACKWARD.
2. If you enter a BACKSPACE command while an intervention-required condition is pending on your printer or punch, the command does not take effect immediately. Once the intervention-required condition is cleared and the current outstanding I/O operation completes, the BACKSPACE command is executed.
3. In BACKSPACE operations, pages are counted by looking for page ejects. If a file does not contain page ejects, 66 output lines, including blank lines, are treated as a "page."
4. This command may re-print more than the specified number of pages. The number of pages re-printed depends on the data in the file and the position within the file of the print processing at the time the BACKSPACE/BACKWARD command was issued.

## Responses

Response 1:

```
{PRT} rdev BACKSPACE userid FILE spoolid RECS {nnnn} COPY {*nnn} SEQ sss CL c typ
{PUN}                                     {nnnK}   { nnn}
                                           {nnnM}
```

### PRT

### PUN

indicates device type.

### rdev

identifies the real device number.

### userid

identifies the user whose file was active and backspaced.

### FILE spoolid

identifies the system-assigned spool ID by which the system refers to the file.

### RECS nnnn

### RECS nnnK

### RECS nnnM

identifies the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines in thousands rounded to the nearest 1000 records. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines in millions rounded to the nearest million.

### COPY \*nnn

### COPY nnn

identifies the remaining number of file copies to be produced. The asterisk (\*) is for the 3800 printer and indicates that the printer copies each page *nnn* times before going on to the next page.

### SEQ sss

identifies the sequence number for the file on the printer or punch.

### CL c

is the spool file class.

### typ

shows the device that originally produced the spool file. The type can be RDR, PRT, PUN, CON, DMP, or SYS.

## Messages

- HCP003E Invalid option - *{option|command}* contains extra option(s) starting with *option*}
- HCP021E A real device number was not supplied or it is invalid.
- HCP040E Device *{rdev/vdev/ldev}* does not exist
- HCP046E *type rdev* offline
- HCP140E *type {rdev/ldev}* attached to *userid*
- HCP141E *type rdev* not active
- HCP417E *{rdev/vdev}* is not an output spooling device.
- HCP418E *{rdev/vdev}* is not a spooled device.
- HCP9999E This is a dummy message.

## BEGIN

### Authorization

Privilege Class: G

### Purpose

Use BEGIN to resume command execution in a virtual configuration.

### Operands

#### CPU ALL

specifies all virtual processors currently defined.

#### CPU *cpuaddr*

terminates a hard stop for the specified processors without affecting any others.

#### CPU *cpuaddr1-cpuaddr2*

specifies a nonwrapping pair of addresses separated by a hyphen (-) and not separated by any blanks.

#### CPU *cpuaddr cpuaddr*

identifies a list of addresses delimited by blanks, a range of addresses delimited by blanks, or both.

#### *hexloc*

identifies the hexadecimal storage location where execution is to begin for the processor on which the command is issued. Command execution terminates a hard stop. To begin multiple processors at specified hexadecimal locations, use the CPU command with the BEGIN command.

If your virtual machine is in z/Architecture mode, up to 16 hexadecimal digits are valid. An underscore is permitted to separate the hex digits into two groups for easier reading if the location is larger than 8 digits, for example:

```
39A40B_AF8216CE
```

\*

terminates hard stop for the processor on which it is issued. No other virtual processors are affected.

### Usage Notes

1. If you enter BEGIN without operands, it terminates a soft stop on all virtual processors in your configuration. If all of your processors are in hard stop, BEGIN terminates hard stop for the processor on which it is executed.
2. If you enter BEGIN without a starting storage location, command execution begins at the location the current PSW points to. Unless the PSW was altered after you entered CP command mode, the location stored in the PSW is the location where the virtual machine stopped.

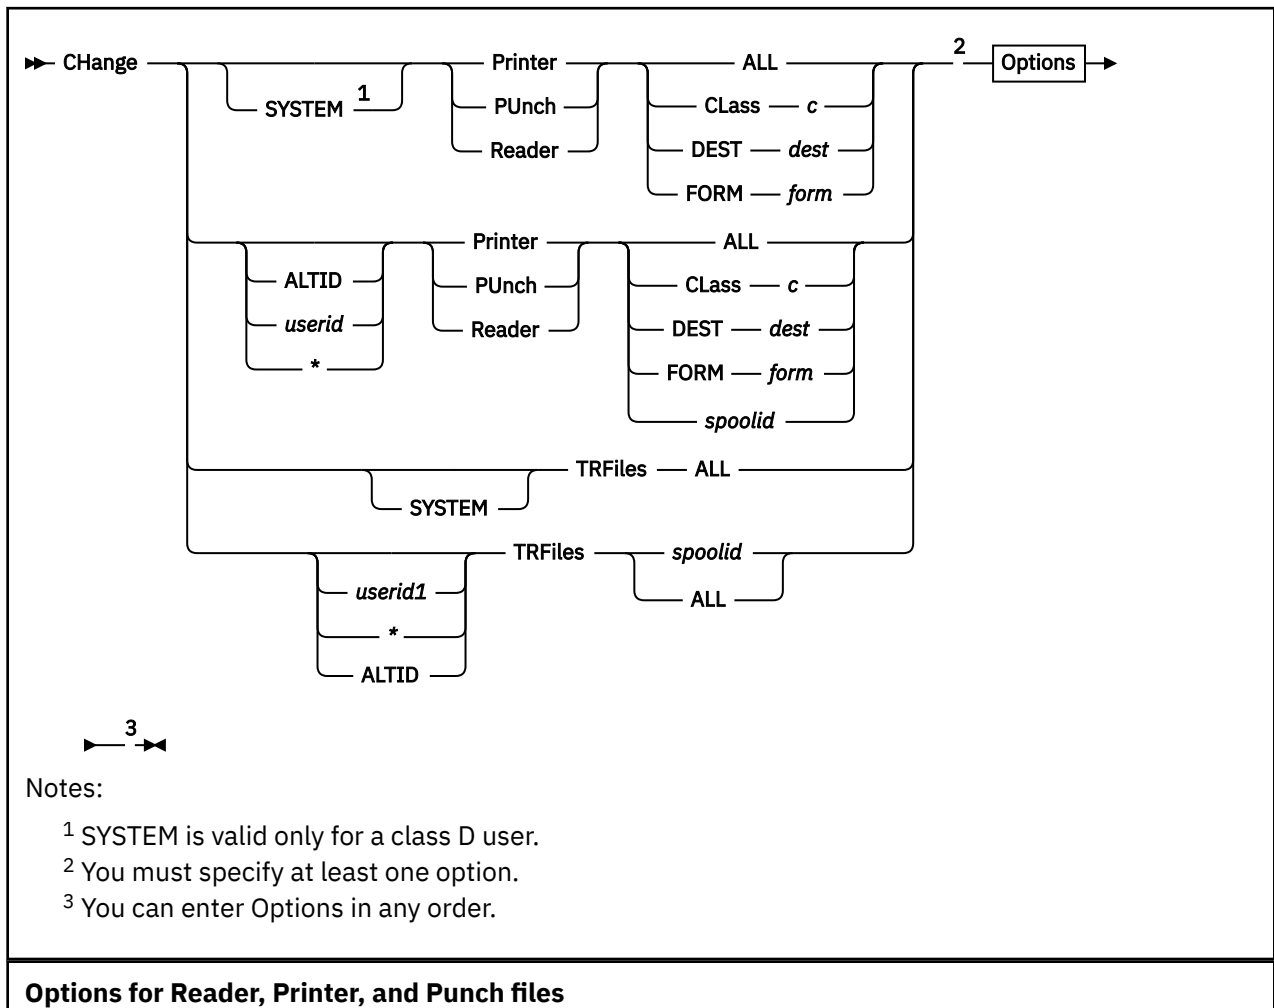

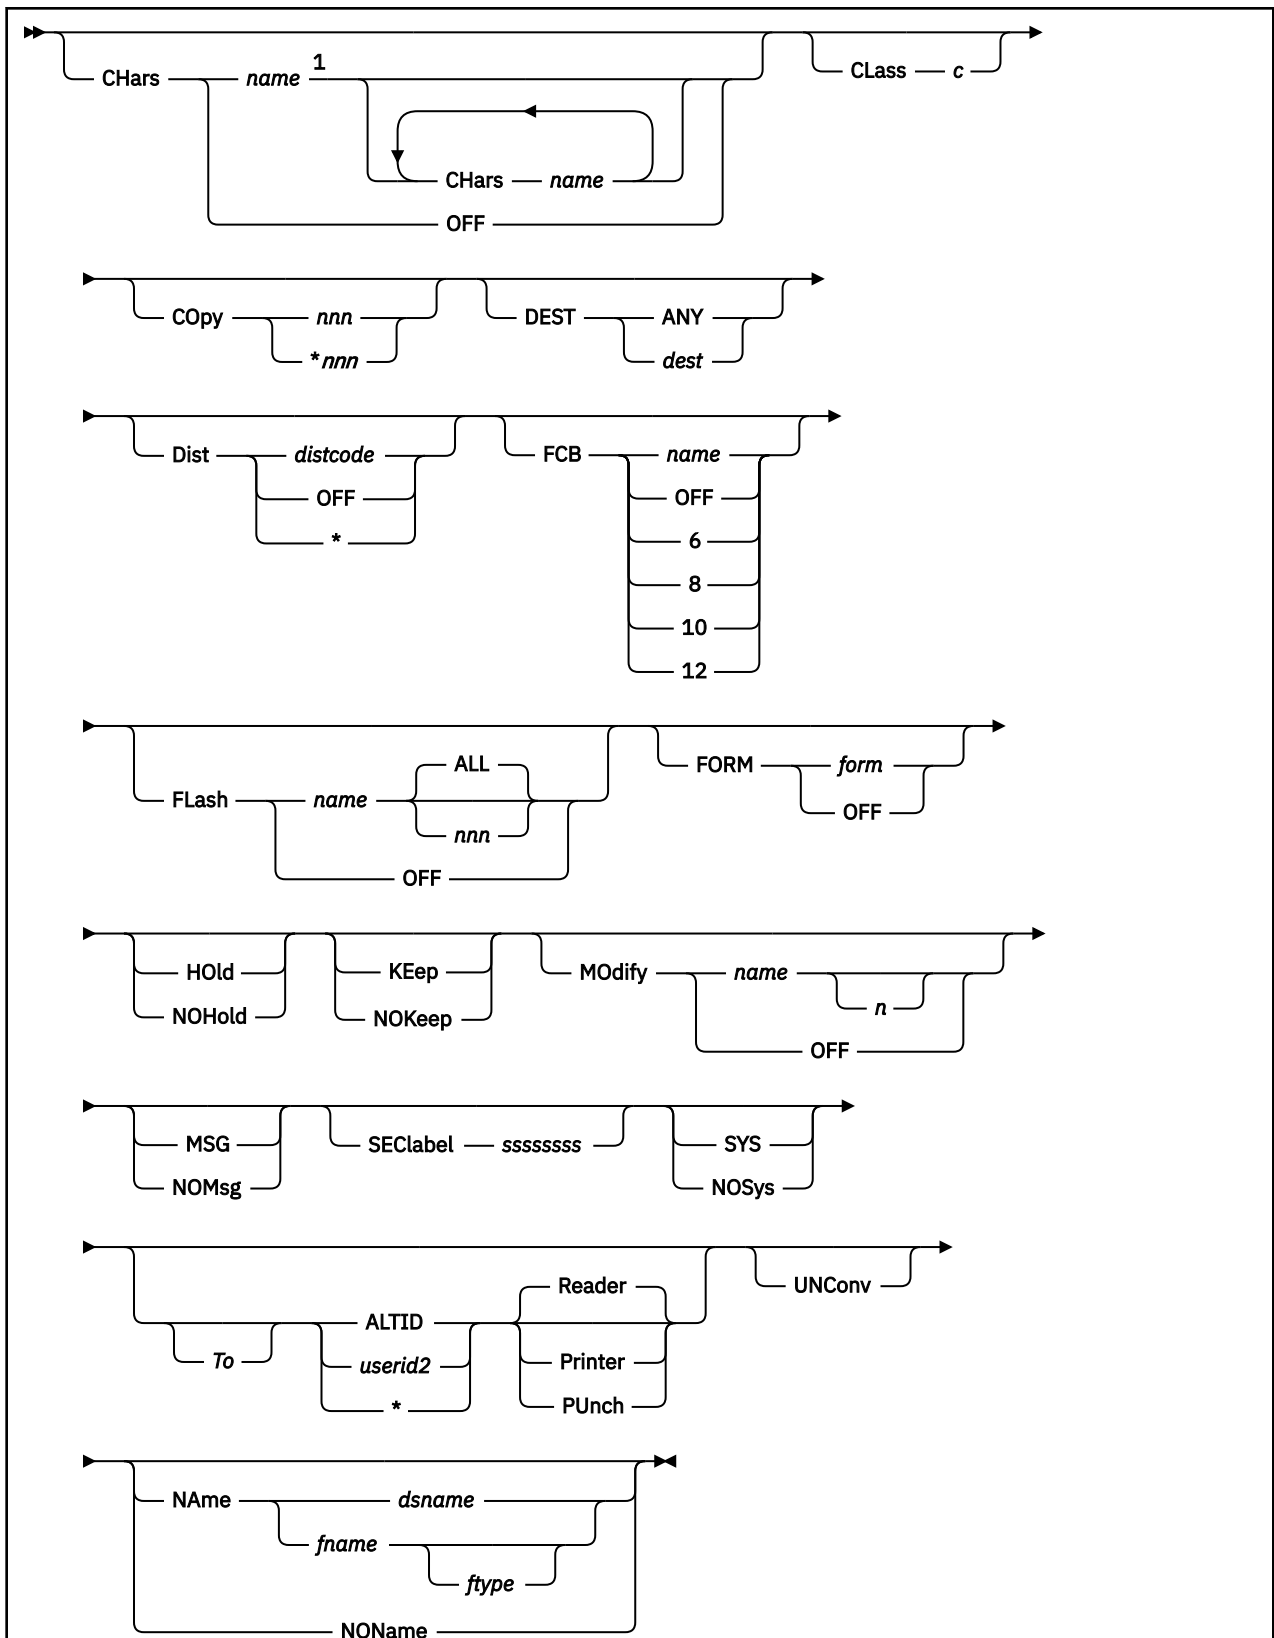

3. If you enter the BEGIN command and specify a starting storage location, execution begins at that address. The address you specify replaces the instruction address in the PSW. Then the PSW is loaded.
4. BEGIN terminates SLEEP status. For more information about SLEEP status, see the SLEEP command.
5. BEGIN cannot be used to resume execution on check-stopped processors. Refer to the SYSTEM RESET and SYSTEM CLEAR commands.
6. BEGIN cannot be used to resume execution on secondary processors that are not operational. In order for a secondary CPU to be started, the virtual machine must be in z/Architecture mode and the guest operating system must support secondary processors.

## Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid
- HCP1005E An invalid character was encountered.
- HCP1454E CPU *nn* does not exist.
- HCP1455E CPU *nn* is not started because it is a secondary processor that is not operational.
- HCP1455E CPU *nn* is not started because it is in check-stop state.

## CHANGE

## Notes:

<sup>1</sup> You can specify up to four character set names.

## Options for system trace files (TRFILES)

## CHANGE

### Authorization

Privilege Class: D, G

### Purpose

Use CHANGE to alter the following:

- One or more external attributes of a closed spool file or files.
- User hold status of an active spool file.

Class D users can change the security label (SECLABEL) associated with any spool file in the system if the following conditions are met:

- An external security manager (ESM) is installed
- Security label checking is enabled, and:
  - The user is exempt from ESM authorization checking, or
  - The system has been placed in a tranquil state by the security administrator.

For additional information, contact your security administrator.

If you are a class D user, use CHANGE SYSTEM to change any spool files on the system, regardless of origin.

If you are a class G user, use CHANGE to manipulate files you own or have created. Though you cannot use the SYSTEM option, you can use the *userid* option to manipulate your own files, files owned by your alternate user ID, or files you have created and subsequently transferred.

### Operands

#### SYSTEM

allows the class D user to manipulate any files in the system, regardless of ownership. This is not allowed with the *spoolid* option.

#### *userid*

\*

#### ALTID

identifies the user whose spool files are to be changed. If you are changing your own files, you may specify your user ID as an asterisk (\*), which is also the default. ALTID indicates that the files belonging to your alternate user ID are to be changed.

#### Printer

##### PRT

changes printer spool files.

#### Punch

##### PCH

changes punch spool files.

#### Reader

##### RDR

changes reader spool files.

#### TRFiles

specifies that the spool file is to be directed to the system trace files (TRFILES) queue.

**ALL**

specifies that all files, regardless of their class, form, or *spoolid*, are to be changed.

**Class c**

designates a spool file class, where *c* is a 1-character alphanumeric field from A to Z or 0 to 9.

**DEST *dest***

specifies a 1- to 8-character name. Use *dest* to select those files to be changed.

**FORM *form***

designates a 1- to 8-character form name. Use *form* to select those files you want to change. For the Class G user, *form* is always the user form name. For the Class D user, *form* is the user form name when the *userid* is specified as an asterisk (\*) or the default user ID. Otherwise, *form* is the operator form number.

***spoolid***

identifies the file you are selecting. Note that *spoolid* is not compatible with the keyword SYSTEM.

**Options**

**Note:** You must choose at least one option. If you specify more than one, you can combine them in any order, except for the NAME option, which you must specify last.

**HOLD****NOHOLD**

HOLD puts a file in user hold status and prevents it from being punched, printed, or read. NOHOLD releases the specified spool files that are in user hold status.

**KEep****NOKeep**

KEEP retains a processed spool file in user hold status. NOKEEP resets files that are in keep status.

**MSG****NOMsg**

MSG controls whether messages are sent to the file owner when the file begins processing, and again when the file completes processing. Although you can enter these options for any type of spool file, no message is sent when a virtual reader processes the file. NOMSG resets the MSG option.

**SYS****NOSys**

SYS puts a file in system hold status and prevents it from being punched, printed, or read. NOSYS releases the specified spool file or files in system HOLD status. (User hold status can coexist with system hold status.)

**Note:** This option is available to class D users only.

**TRFiles**

changes system trace spool files.

**UNConv**

changes the spool file to an unconverted status, thereby canceling any preprocessing that the print server may have done on the file. Options for the file can now be changed, and the file may then be selected for conversion using the new options.

**Class c**

designates the new spool class, *c*, for the files.

**COpy *nnn*****COpy \**nnn***

specifies the number of file copies you want printed or punched when the file is produced. The value of *nnn* (number of copies) must be a decimal number from 1 through 255. Leading zeros need not be specified.

When you specify the optional asterisk (\*), the 3800 printer prints each page from the spooled output files *nnn* times before going on to the next page.

## CHANGE

If a file is not spooled to the 3800 printer, the function performed by specifying the asterisk (\*) is ignored, and duplication occurs normally.

### **DIST *distcode***

specifies the new distribution code for the spool files. The *distcode* variable is a 1- to 8-character alphanumeric identifier that appears on the output separator of punch or print files.

### **DIST OFF**

#### **DIST \***

resets the distribution code of the spool files to the default specified in your system directory entry.

### ***userid2***

\*

### **ALTID**

sends the spool file to the virtual machine specified by *userid2*. If no device type is specified immediately after *userid2*, the spool file is placed on the *userid2* reader queue. Specify an \* if you want to direct the output to your own virtual machine. ALTID indicates that files are to be directed to your alternate user ID.

### **Reader**

#### **RDR**

#### **Printer**

#### **PRT**

#### **PUnch**

#### **PCH**

specify, in conjunction with the TO operand, the file queue to which the spool file or files are to be directed.

### **FORM *form***

designates the new 1- to 8-character form name for the spool file. For the Class G user, *form* is the user form name. For the Class D user, *form* is the user form name when the *userid* is specified as an asterisk (\*) or the default user ID. Otherwise, *form* is the operator form number.

**Note:** When *form* is the user form name, both the user form name and the operator form number are changed.

### **FORM OFF**

resets the form for the spool files to the system default.

### **DEST *dest***

indicates the new destination value for the files being changed. The *dest* variable is a 1- to 8-character name specifying the output device or devices eligible to process the file.

### **DEST ANY**

indicates that the file can be processed on any CP output device that meets other selection criteria, regardless of the output device DEST settings.

### **Flash *name* ALL**

#### **Flash *name* *nnn***

signifies that a form overlay contained in the 3800 printer is to be superimposed (or flashed) onto the specified number of copies of the output. The *name* variable, 1- to 4-characters in length, identifies the forms overlay to be used in the projection. The number *nnn* must be in the range of 0 to 255, and it specifies that the first *nnn* copies of output are to be flashed.

For example, if you specify COPY 4 and FLASH *name* 2, the first two copies of your file are flashed, whereas the last two copies remain unflashed. If ALL is specified, the flash count always matches the copy count. ALL is the default.

### **Flash OFF**

resets the flash parameters. Blanks are inserted into the flash *name* field of the specified spool files, and the count is set to 0.

**MOdify name *n***

assigns a copy modification module to be used when printing the spool files on the 3800. This function makes it possible to alter text by either preventing the printing of certain information or by adding labels to output. The name must be one to four characters.

The *n* variable selects one of the character sets specified by the CHARS operand to be used for the copy modification text. The values 0, 1, 2, or 3 correspond to the order in which the character sets have been specified. If no *n* is specified, the first character set (0) is assumed.

**MOdify OFF**

resets the modify parameters. Blanks are inserted into the modify name field of the spool files and, when printing takes place, no modification occurs. The modify number (*n*) is set to 0.

**FCB *name*****FCB 6****FCB 8****FCB 10****FCB 12**

specifies the forms control buffer to be used when printing the file on the 3800 printer. The *name* variable is a 1- to 4-character name of an FCB image, or the number 6, 8, 10, or 12. The number tells the 3800 to print the entire spool file at 6, 8, 10, or 12 lines to the inch, regardless of the size of the paper currently loaded. Using these unique numbers assures that printed material fits onto a specified page size. Note, however, that FCB 10 prints only on a 3800 Model 3 printer.

**FCB OFF**

resets the FCB parameter. Blanks are inserted into the FCB *name* field of the spool file or files and, when the file is printed, a default FCB controls the vertical spacing of the output text.

**CHars *name*****CHars *name* CHars *name***

specifies the name of the character set or sets used to print the spool file or files on a 3800 printer. The name or names must be from one to four characters with a maximum of four names specified. You need to use CHARS more than once only if *nameN* is the same as an option name (for example, FORM) or with a user ID. If more than one name is specified, and modification is also specified, the order in which the names appear determines the table used for copy modification text.

**CHars OFF**

resets the CHARS parameters. Blanks are inserted into the name fields of the character sets used for output generation. The spool files, therefore, use a default character set when actually printed.

**SEClabel *sssssss***

assigns a security label to the chosen files. *sssssss* is the security label to be assigned to the files, and is specified as a 1- to 8-character alphanumeric value. The SECLABEL option is valid only for class D users.

**Name *fname ftype*****Name *dsname***

NAME indicates the name is to be assigned to the spool file for identification. For output files, this name appears on the separator page or cards.

Use *fname ftype* to name files in the CMS file name and file type format. Each of these fields is a 1- to 8-character alphanumeric name. If you omit the *ftype* field, blanks are substituted.

If you want to name files in a format suitable for MVS™ use (for example, SYS1.SYSLIB.MAC1), use *dsname*. This name can be up to 24 characters long; however, if *dsname* is more than 16 characters long, it is truncated.

If specified, the NAME option must be the last operand entered.

**NOName**

resets the NAME information to blanks.

**Responses**

Response 1:

## CHANGE

```
{nnnnnn} FILE(S) CHANGED  
{ NO }
```

indicates how many files have been changed. This response is sent to the user issuing the CHANGE command.

Response 2:

If you use the TO keyword to transfer a spool file to another user, the following response is sent to you and to the user receiving the file (if that user is active on the system):

### Note:

1. In the response sent to the operator receiving the file, *spd1* and *spd2* will be in the reverse order of that shown in the following response.
2. If an external security manager is installed on your system, this command will fail if you are not authorized to CHANGE the spool file TO the specified user. For additional information, contact your security administrator.

```
{RDR} FILE spd1 SENT {TO } userid {RDR} {AS } spd2 RECS {nnnn}...con't  
{PRT} {FROM} {PRT} {WAS} {nnnK}  
{PUN} {PUN} {nnnM}
```

Continued:

```
CPY [*]nnn c {HOLD } {KEEP }  
{NOHOLD} {NOKEEP}
```

### RDR

### PRT

### PUN

indicates the spool file queue. If you are transferring a file to another virtual machine, this field indicates the queue from which the file originated. If you are receiving a file from another virtual machine, this field indicates the file queue to which the file has been added.

### spd1

is the spool ID assigned when the command is entered.

### TO *userid*

indicates the user to whom the file has been sent.

### FROM *userid*

indicates the user from whom the file came.

### RDR

### PRT

### PUN

indicates the spool file queue. If you are transferring a file to another virtual machine, this field indicates the queue to which the file has been added. If you are receiving a file from another user, this field indicates the file queue in which the file originated.

### spd2

is the spool ID of the file when the command is complete.

### RECS *nnnn*

### RECS *nnnK*

### RECS *nnnM*

is the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines rounded to the nearest 1000 records. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines rounded to the nearest million.

### CPY *nnn*

### CPY \**nnn*

specifies the number of file copies you want printed or punched when the file is produced.

When the optional asterisk (\*) is specified, the 3800 printer prints each page from the spooled output files *nnn* times before going on to the next page.

If a file is not spooled to the 3800 printer, the function performed by specifying the asterisk (\*) is ignored, and duplication occurs normally.

**c**

is the spool file class assigned to the file.

**HOLD**

**NOHOLD**

is the user HOLD status associated with the file.

**KEEP**

**NOKEEP**

is the KEEP status associated with the file.

Response 3:

```
{PRT} rdev {PRINTING} userid FILE spoolid RECS {nnnn}...con't
{PUN}      {PUNCHING}
Continued:
COPY [*]nnn SEQ sss CLc typ
```

is the message you receive when the system begins processing a spool file with the MSG attribute.

**PRT**

**PUN**

indicate the type of device on which the file is being processed.

**rdev**

is the real device number.

**userid**

is the name of the spool file owner.

**FILE spoolid**

is the spool file number.

**RECS nnnn**

**RECS nnnK**

**RECS nnnM**

is the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines rounded to the nearest 1000 records. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines rounded to the nearest million.

**COPY nnn**

**COPY \*nnn**

specifies the number of file copies you want printed or punched when the file is produced.

When the optional asterisk (\*) is specified, the 3800 printer prints each page from the spooled output files *nnn* times before going on to the next page.

If a file is not spooled to the 3800 printer, the function performed by specifying the asterisk (\*) is ignored, and duplication occurs normally.

**SEQ sss**

is the sequence number for the file on the printer or punch.

**CL c**

is the spool file class.

**typ**

shows the device type that originally produced the spool file. The type can be RDR, PRT, PUN, CON, DMP, or SYS.

## CHANGE

Response 4:

```
SPOOLID spd1 HAS BEEN CHANGED to spd2
```

is the response you receive when a converted file is changed to unconverted status, a new owner, a new queue, or an option that affects the final printing of the file. CP assigns a new spool ID to the file and marks it as unconverted.

### **spd1**

is the spool ID assigned to the file before it was changed.

### **spd2**

is the new spool ID assigned to the file after it was changed.

## Usage Notes

1. SET IMSG OFF suppresses informational messages for this command.
2. You can use QUERY RDR/PRT/PUN to determine the attributes of a spool file before and after you enter the CHANGE command.
3. You can change the status of an active file to HOLD in order to stop processing a file currently being printed or punched. No other attributes of an active file may be changed.
4. Class G users can change files they own or have created from their primary or alternate IDs.
5. If you use CHANGE to transfer a file to another user and you do not specify a distribution code, the distribution code is set to the receiving user's default distribution.
6. Although you can specify the CHANGE options of FLASH, FCB, MODIFY, CHARS, and COPY \* *nnn* for any spool file or files, they lead to system action only when a spool file with these attributes is printed on a CP-driven 3800 printer.
7. A user can cancel settings of the CHARS, MODIFY, or FCB options by specifying NULL in the name fields of these operands. In this case, NULL performs the same function as OFF.
8. The keyword OFF, which resets attributes to their default values, cannot also be used to specify a FORM, FLASH, FCB, MODIFY, DISTcode, or CHARS name. Similarly, you cannot use NULL to specify a CHARS, MODIFY, or FCB name.
9. If the NORETURN option was specified when the file was created by DIAGNOSE X'94', the originator of the file cannot retrieve that file from the current owner. If you try, the following message is issued:

```
FILE NOT CHANGED;  
FILE CREATED WITH THE NORETURN OPTION
```

10. When a file changes ownership, the spool file ID number also changes. The new number comes from the recipient's pool of available IDs. Thus, if user DORA uses the CHANGE command to send file #3 to user LILA, DORA gets the response:

```
RDR FILE 0003 SENT TO LILA  
RDR WAS 0018 RECS 1000 CPY  
001 A NOHOLD NOKEEP
```

LILA now has file #18.

11. Most of the CHANGE command options which are valid for reader, printer, or punch files are not valid for system trace files (TRFILES). Refer to the CHANGE: OPTIONS syntax diagram above for the options which are valid for system trace files.
12. System trace files (TRFILES) may only be changed from one user's TRFILES queue to another user's TRFILES queue. Only system trace files may be changed to a TRFILES queue.
13. The SYS option puts a file in system hold and NOSYS releases the file from system hold. The SYS and NOSYS can be used in addition to HOLD and NOHOLD.

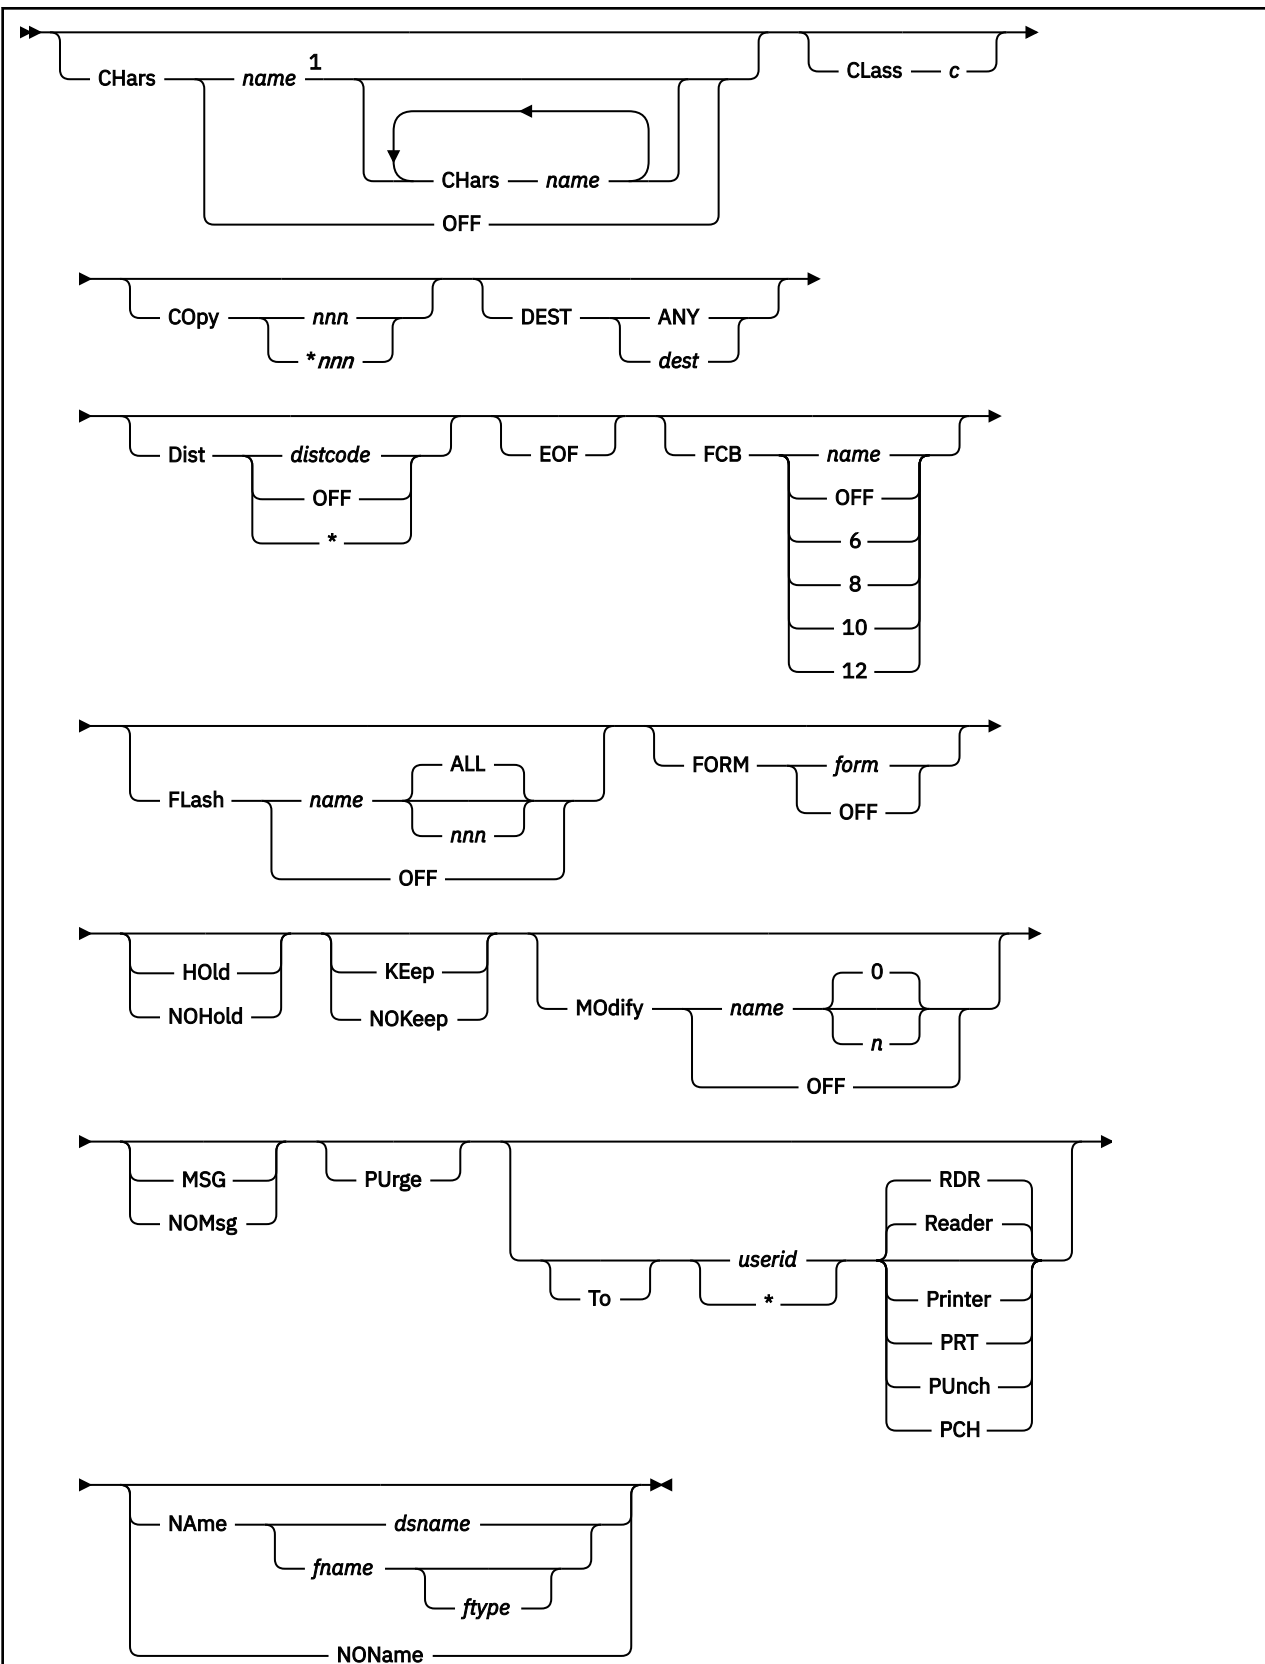

## Messages

- HCP644E Unknown/unauthorized CP command: *command*
- HCP848E SYSTEM parameter is invalid with the spoolid option
- HCP1001E An operand is missing for *option*.
- HCP1013E An invalid operand was supplied for *option* - *operand*
- HCP1551E *value* is an invalid number for MODIFY.
- HCP1552E More than {4|8} operands were specified for the {CHARS|CLASS} option.
- HCP1559E The DSNAME is truncated to 16 characters.
- HCP1560E File was not {changed|transferred} because it was created with the NORETURN option.
- HCP2505E An output device is an invalid destination for system data files.
- HCP6525E External Security Manager is unavailable.

## CLOSE

Notes:

<sup>1</sup> You can specify up to four, four-character set names.

## Authorization

Privilege Class: G

## Purpose

Use CLOSE to end spooling on a virtual spool device (reader, printer, punch, or console).

## Operands

**CONsole**

**Printer**

**PRT**

**PUnch**

**PCH**

**Reader**

**RDR**

closes all reader, printer, punch, or console devices. Once a virtual console spool file is closed, it becomes a printer spool file and can be manipulated like any printer spool file.

**vdev**

identifies the virtual device number of the device to be closed. The device number may represent a console, reader, printer, or punch. *vdev* must be a hexadecimal number between X'0000' and X'FFFF'.

## Options

**Note:** You can specify one or more of these options. If you specify more than one, you can combine them in any order, except for the NAME option, which must be specified last.

**CHars *name***

**CHars *name* CHars *name***

specifies the name of the character set or sets used to print the spool file or files on a 3800 printer. The name or names must be from one to four characters long; as many as four names may be specified. You need to use CHARS more than once only if *nameN* is the same as an option name (for example, FORM) or a user ID. If more than one name is specified, and modification is also specified, the order in which the names appear determines the table used for copy modification text.

**CHars OFF**

resets the CHARS parameters. Blanks are inserted into the name fields of the character sets used for output generation. The spool files, therefore, use a default character set when actually printed on a 3800 printer.

**Class *c***

specifies the spool class to be assigned to the file, where *c* is a 1-character alphanumeric field from A to Z or 0 to 9.

**COpy \* *nnn***

specifies the number of file copies you want printed or punched when the file is produced. The value of *nnn* (number of copies) must be a decimal number from 1 to 255. You do not need to specify leading zeros.

When the optional asterisk (\*) is specified, the 3800 printer prints each page from the spooled output files *nnn* times before going on to the next page.

If a file is not spooled to the 3800 printer, the function performed by specifying the asterisk (\*) is ignored, and duplication occurs normally.

**DEST *dest***

overrides the destination value of the spool file. The *dest* variable is a 1- to 8-character name specifying the output device or devices eligible to process the file.

**DEST ANY**

sets the destination value to ANY. This allows the file to be processed on any CP output device that meets other selection criteria, regardless of the output device DEST settings.

**Dist *distcode***

specifies the distribution code to be assigned to the resulting spool file. The *distcode* variable is a one- to eight-character alphanumeric identifier that appears on the output printer/punch separator.

**Dist OFF****Dist \***

resets the distribution code for the resulting spool file to the default specified in the system directory for your user ID.

***userid***

\*

directs the spool file from the device to the virtual machine specified by *userid*. Specify an asterisk (\*) if you want to direct the file to your own virtual machine.

**EOF**

closes the spool file on the specified device regardless of the cont setting for the device. This option is not meaningful for a reader, it will be accepted but ignored.

**FCB *name*****FCB 6****FCB 8****FCB 10****FCB 12**

specifies the forms control buffer to be used when printing the file on a 3800 printer. The *name* variable is the one- to four-character name of an FCB image, or the number 6, 8, 10, or 12. This number tells the 3800 to print the entire spool file at 6, 8, 10, or 12 lines per inch, regardless of the size of the paper that is currently loaded. Note, however, that FCB 10 prints only on a 3800 Model 3 printer.

**FCB OFF**

resets the FCB parameter. Blanks are inserted into the FCB name field of the spool file and, when the file is printed on a 3800 printer, a default FCB controls the vertical spacing of the output text.

**Flash *name* ALL****Flash *name nnn***

signifies that a form overlay contained in the 3800 printer is to be superimposed (or flashed) onto the specified number of copies of the output. The *name* variable is one to four characters long, and identifies the forms overlay to be used in the projection. The *nnn* variable must be in the range of 0 to 255, and specify that the first *nnn* copies of output are to be flashed.

For example, if you specify COPY 4 and FLASH *name*2, the first two copies of your file are flashed; the last two copies remain unflashed. If ALL is specified, the flash count always matches the copy count. ALL is the default.

**Flash OFF**

resets the flash parameters. Blanks are inserted into the flash name field of the specified spool file, and the count is set to 0.

**FORM *form***

overrides the form name of a spool file. The *form* variable is one to eight characters long. If FORM is not given for the CLOSE command, the file created has a form specified by the last SPOOL command for the device, or a default name specified during system generation.

**FORM OFF**

resets the form to the default specified during system generation.

**HOLD****NOHold**

controls the user hold status.

## CLOSE

For output devices, HOLD prevents files from being punched or printed on a real device by putting a user hold status on the file. If you specify NOHOLD, you override the spool device HOLD option and prevent the file from being placed in hold status.

For input devices, the HOLD/NOHOLD options override the setting for the virtual device or the spool file. The file is not put in hold status unless the KEEP option is also specified. If you specify HOLD, the file is not purged after processing and remains eligible for the device. If you specify NOHOLD, the file is purged unless you also specify the KEEP option.

### **KEep**

#### **NOKeep**

controls the keep status, which indicates whether the current spool file is to be placed in user HOLD after processing.

For output files, the keep status is placed on the spool file. After it is printed or punched, the file is assigned user hold status and is not purged. The file's KEEP status is retained. Specify NOKEEP to override the current keep setting for the device so that keep is not set on the spool file.

For input files, KEEP overrides the keep setting on either the virtual reader or the spool file. After processing, the file is placed in hold status, and the KEEP option on the file remains unchanged. Specify NOKEEP to override either file or device keep characteristics. The disposition of a file closed NOKEEP (whether it is purged or retained) is controlled by the hold status of the virtual reader. If it were closed KEEP, it would never be purged.

### **MODify name n**

assigns a copy modification module to be used when printing the spool file on the 3800. This function makes it possible to alter text by not printing certain information or by adding labels to output. The *name* variable must be one to four characters long.

The *n* variable selects one of the character sets specified by the CHARS operand to be used for the copy modification text. The value of 0, 1, 2, or 3 corresponds to the order in which the character sets have been specified. If *n* is not specified, the first character set (0) is assumed.

### **MODify OFF**

resets the modify parameters. Blanks are inserted into the modify-name field of the spool file and, when the file is printed, no modification occurs. The modify number (*n*) is set to 0.

### **MSG**

#### **NOMsg**

indicates whether you want to be informed about file printing and punching. If you specify MSG, you are informed of file printing and punching. The message is sent to you when the file begins either printing or punching on a real device. Specify NOMSG to reset the MSG option.

### **NAme dsname**

#### **NAme fname ftype**

enables you to assign a name to the spool file for identification.

If you want to name files in a format suitable for MVS use (for example, SYS1.SYSLIB.MAC1), use *dsname*. This name can be up to 24 characters long; however, if *dsname* is more than 16 characters long, it is truncated.

The *fname ftype* specification permits you to name a file in CMS file name and file type format. The fields *fname* and *ftype* are one- to eight-character alphanumeric names. If you omit *ftype*, blanks are substituted.

If specified, the NAME option must be the last operand entered.

### **NOName**

resets the name information to blanks.

### **PURge**

closes and purges the spool file on the specified device regardless of the cont, keep, and hold setting for the device.

**Printer**  
**PRT**  
**PUnch**  
**PCH**  
**Reader**  
**RDR**

are used with the TO operand to specify the file queue to which the spool file is to be directed. If you do not specify a queue, the file is directed to the reader.

**SYNChronous**  
**ASYNChronous**

indicates whether the command issuer wishes to wait for the CLOSE command to complete.

If you specify ASYNCHRONOUS, you are free to process other commands while the CLOSE command completes. When it does, CP will notify you with a device end (DE) interrupt on the device affected.

If you specify SYNCHRONOUS, you are prevented from executing any other commands until the CLOSE command completes. When the command completes, the file will have been closed by CP.

## Usage Notes

1. SET IMSG OFF suppresses informational messages for this command.
2. The options of the CLOSE command override the corresponding options in effect for the device you are closing. If you do not specify any optional operands, the options in effect for the device, or the status of the file you are processing, determines the file disposition.
3. Although the CLOSE options FLASH, FCB, MODIFY, and CHARS can be specified for any virtual device except a reader, they only lead to system action when a spool file with these attributes is printed on a CP-driven 3800 printer.
4. A user can cancel settings of the CHARS, MODIFY, or FCB options by specifying NULL in the name fields of these operands. In this case, NULL performs the same function as OFF.
5. The keyword OFF, which resets attributes to their default values, cannot also be used as the name specified in a FORM, FLASH, FCB, MODIFY, DISTcode, or CHARS operand. Similarly, NULL cannot be used to specify a CHARS, MODIFY, or FCB name.
6. If you close an output device (printer, punch, console) and the file you created is in hold, that file is not available for processing. If the file is not in hold, it is available for processing. You can transfer a file to another user by using the TO operand of the TRANSFER or CHANGE commands.
 

**Note:** An external security manager, if installed, may prevent you from transferring a spool file to another user unless you are specifically authorized to enter the TRANSFER and CHANGE commands. For additional information, contact your security administrator.
7. You can specify a file name and file type to help you identify a file and its contents. The file name and file type you assign have no effect on the way CMS names the file if it is read using the CMS READCARD or CMS DISK LOAD commands.
8. If you are closing a reader, the file that is being processed is purged unless HOLD or KEEP is in effect for the device or for the file. Use the appropriate CLOSE command option to override the effect of HOLD, NOHOLD, KEEP, or NOKEEP established for the reader or for the file.
9. If an input spool file has been only partially read (that is, your virtual machine did not get an end-of-file indication), you must enter a CLOSE READER command.
10. If the TO option is used to direct a file to a new user, the spool file ID number changes. The new number is obtained from the recipient's pool of available IDs. Thus, if user SAM enters CLOSE READER TO HARRY, he gets a response: RDR 0003 SENT TO HARRY RDR AS 0018. HARRY now has a file number 18.

If an external security manager is installed on your system, you may not be authorized to transfer a spool file to another user with the CLOSE TO command. For additional information, contact your security administrator.

## CLOSE

11. The disposition of a spool file that is to be processed on a real unit record device depends upon the resolution of HOLD, CONT, and KEEP status as implied by the device using the SPOOL and CLOSE commands.

For example, suppose your virtual printer is spooled CONT, and you enter `close prt class z`. Since you did not specify the CLOSE operand EOF, the file does not become available for processing on a real printer.

After completion of the CLOSE command, CP checks the hold status of the file to determine whether the files you closed can be processed. Thus, if hold is in effect for any of the closed files because you specified HOLD on the CLOSE command or because hold was set for the device using the SPOOL command, the file is not processed.

For readers only, the net effect of file status, device options, and the CLOSE command overrides is shown in [Table 11 on page 74](#).

Options in Effect for the Input File	System Action
NOKEEP/NOHOLD	The file is purged.
NOKEEP/HOLD	The file is not purged and remains available for processing in HOLD status.
KEEP/NOHOLD	The file is not purged. It is set in NOHOLD/KEEP status and is not available for processing.
KEEP/HOLD	The file is not purged. It is set in HOLD/KEEP status and is not available for processing.

In all cases, the original KEEP/NOKEEP status of the file is unchanged by the CLOSE operation.

Likewise, the disposition of a spool file that is to be processed on a real unit record device depends upon the resolution of HOLD, CONT, and KEEP status as implied by the device using the SPOOL and CLOSE commands. If an option is not specified on the CLOSE command, the option for the file is set from the corresponding option value on the virtual device.

12. If you use the ASYNCHRONOUS option when you issue the CLOSE command, CP will send a device end (DE) interrupt to the device affected when the command completes.
13. The CLOSE TO command may not be used to direct files to the RDR queue of a user with a password of NOLOG. CLOSE TO may be used to direct files to the PRT and PUN queues of a user with a password of NOLOG.

## Responses

Response 1:

```
{PRT}  rdev {PRINTING} userid
{PUN}      {PUNCHING}

FILE spoolid RECS {nnnn} COPY [*]nnn SEQ sss CL c typ
                {nnnK}
                {nnnM}
```

is the message you receive when the system begins processing a spool file with the MSG attribute.

**PRT**  
**PUN**

indicates the type of device on which the file is being processed.

**rdev**

identifies the real device number.

**userid**

identifies the user whose file was active.

**FILE spoolid**

identifies the unique, system-assigned spool ID number by which the system refers to the file.

**RECS nnnn****RECS nnnK****RECS nnnM**

identifies the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines rounded to the nearest 1000 records. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines rounded to the nearest million.

**COPY \* nnn**

identifies the remaining number of copies of the file to be created.

When the optional asterisk (\*) is specified, the 3800 printer prints each page from the spooled output files *nnn* times before going on to the next page.

If a file is not spooled to the 3800 printer, the function performed by specifying the asterisk (\*) is ignored, and duplication occurs normally.

**SEQ sss**

identifies the sequence number for the file on the printer or punch.

**CL c**

is the spool file class.

**typ**

shows the device type that originally produced the spool file. The type can be RDR, PRT, CON, DMP, or SYS.

Response 2:

If you are using the TO *userid* option with the CLOSE command, the following response is sent to you and to the operator receiving the file (if that user is active on the system):

**Note:**

1. If an external security manager is installed on your system, you may not be authorized to transfer a spool file to another user with the CLOSE TO command. For additional information, contact your security administrator.
2. In the response sent to the operator receiving the file, *spd1* and *spd2* will be in the reverse order of that shown in the following response.

```
{RDR} FILE spd1 SENT {TO } userid {RDR} {AS } spd2
{PRT}                {FROM}      {PRT} {WAS}
{PUN}                {PUN}
{CON}
```

```
RECS {nnnn} CPY [*]nnn
c{HOLD } {KEEP }
  {nnnK}
  {nnnM}
  {NOHOLD} {NOKEEP}
```

**RDR****PRT****PUN****CON**

indicates the spool file queue. If you are transferring a file to another virtual machine, this field indicates the queue on which the file originated. If you are receiving a file from another virtual machine, this field indicates the file queue to which the file has been added.

**spd1**

identifies the spool ID of the file assigned when the command is issued.

## CLOSE

### **TO *userid***

indicates the user to whom the file has been sent.

### **FROM *userid***

indicates the user sending the file. If the PURGE option is used with the CLOSE command, this field is replaced by \*\*\*\* PURGED \*\*\*\* to indicate that the file has been deleted.

### **RDR**

### **PRT**

### **PUN**

indicates the spool file queue. If you are transferring a file to another virtual machine, this field indicates the queue to which the file has been added. If you are receiving a file from another virtual machine, this field indicates the file queue on which the file originated.

### ***spd2***

identifies the spool ID of the file after the command is complete.

### **RECS *nnnn***

### **RECS *nnnK***

### **RECS *nnnM***

identifies the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines rounded to the nearest 1000 records. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines rounded to the nearest million.

### **CPY \* *nnn***

specifies the number of file copies you want printed or punched when the file is produced.

When you specify the optional asterisk (\*), the 3800 printer prints each page from the spooled output files *nnn* times before going on to the next page.

If a file is not spooled to the 3800 printer, the function performed by specifying the asterisk (\*) is ignored, and duplication occurs normally.

### **c**

identifies the spool file class assigned to the file.

### **HOLD**

### **NOHOLD**

identifies the user hold status associated with the file.

### **KEEP**

### **NOKEEP**

identifies the keep status associated with the file.

# COMMANDS

## Authorization

Privilege Class: Any

## Purpose

Use COMMANDS to display the commands and diagnose codes you are authorized to use.

## Operands

### *command*

the names of commands to be checked for authorization.

## Usage Notes

1. The same function is available through the QUERY COMMANDS.
2. Some commands have more than one version, but the user may not be authorized to use all versions of the command. If the system rejects a command, it is probably because the user is not authorized to enter the command with the operand or operands entered.
3. To see the command versions you are authorized to use, enter `COMMANDS cmd`, where *cmd* is the name of the command or commands that interests you. You are shown the default IBM privilege classes of the commands that you are authorized to enter.

You may specify any number of commands. If a command name is entered twice, it appears twice in the response. No duplicate-entry checking is done.

4. Diagnose codes cannot be queried separately from commands.
5. `IBMCLASS=ANY` will output if:
  - the command is allowed before logon and not disabled, or
  - the user privilege class is ANY, meaning the command version is not associated with any particular privilege class and the command is enabled.

## Responses

Response 1:

```
cmd1    cmd2    cmd3    cmd4    cmd5    cmd6
cmd7...
:
diag1   diag2   diag3   diag4   diag5   diag6
diag7...
```

is the response when the command COMMANDS is entered alone; all authorized commands and diagnose codes are displayed.

**cmd1,2...**

the names of authorized commands.

**diag1,2...**

the names of authorized diagnose codes.

Response 2:

```
AUTHORIZED {QUERY|SET} OPERANDS:
operand1  IBMCLASS={c1,c2,c3}      operand2  IBMCLASS={c1,c2,c3}
           {ANY}                    {ANY}
           {NONE}                    {NONE}
operand3  IBMCLASS={c1,c2,c3}      operand4  IBMCLASS={c1,c2,c3}
           {ANY}                    {ANY}
           {NONE}                    {NONE}
:
```

is the response when the command COMMANDS is entered with the QUERY or SET operand; all authorized operands of the QUERY or SET command are displayed.

**operand1,2...**

the names of authorized QUERY or SET operands.

**c1,c2,...**

the IBM-defined privilege classes of the operands that you are authorized to enter.

Response 3:

```
cmd1      IBMCLASS=c1,c2,c3
cmd2      IBMCLASS=ANY
cmd3      IBMCLASS=NONE
```

is the response you receive when you specifically enter commands to check authorization for them. The response includes one line of output for each command listed.

**cmdx**

is the name of the command you entered on the command line.

**IBMCLASS=c1,c2,c3**

the IBM-defined privilege classes of the command specified; the privilege class displayed reflects the authorization of the user making the inquiry.

**IBMCLASS=ANY**

indicates that the command is a class ANY command, and all users may enter the command.

**IBMCLASS=NONE**

indicates that you are not authorized to enter any version of the command.

**Messages**

- HCP003E Invalid option - {option|command contains extra option(s) starting with option}

## COMMIT

### Authorization

Privilege Class: B

### Purpose

Use COMMIT to cause any cache fast write data to be transferred from the cache to the addressed device. This command is valid for cache storage subsystems that support the cache fast write function.

### Operands

#### DEVICE

emphasizes that only data for the specified devices is to be committed (for example, written to DASD). This is the default value.

#### *rdev*

#### *rdev1-rdev2*

is the real device number, a list of real device numbers, or a range of real device numbers, of the devices to which the commit order is to be sent.

### Usage Notes

1. This command may produce delayed responses. For more information, see [“Delayed Responses to CP Commands”](#) on page 7.
2. The COMMIT command is only valid for cache storage subsystems that support the cache fast write function. An error message is generated if the subsystem containing the specified device does not support this function.

### Responses

Response 1:

*Immediate Response:* If the transfer of cache fast write data occurs immediately, the following response is issued to the originator of the command. This response is repeated for each device specified on the command line.

```
rdev Cache fast write data has been committed.
```

#### *rdev*

is the real device number of a device for which cache fast write data has been transferred to the backing storage device.

*Delayed Response:* If the transfer of cache fast write data does not occur immediately, the following response is issued:

```
Command started: COMMIT rdev.
```

When the transfer of cache fast write data completes, the following responses are issued:

```
rdev Cache fast write data has been committed.
```

Under certain circumstances, it is possible that a cache storage subsystem will not notify CP when it has completed the transfer of the cache fast write data. When this occurs, the appropriate command response cannot be generated. Under these circumstances, command processing is ended after generating the following response:

```
Command results lost: COMMIT rdev.
```

If errors occur during the asynchronous processing of the command that prevent the successful completion of the command, the following response is displayed:

```
Command failed: COMMIT rdev.
```

### **rdev**

is the real device number of a device for which cache fast write data has been transferred to the backing storage device.

*Response to the System Operator:* If the originator of the command is not the system operator, the following response is issued to the system operator when the transfer of cache fast write data completes. This response is also repeated for each specified device.

```
rdev Cache fast write data was committed by userid.
```

### **rdev**

is the real device number of a device for which cache fast write data has been transferred to the backing storage device.

### **userid**

is the ID of the user who issued the command.

## **Messages**

- HCP006E Invalid device type - {rdev/vdev/ldev}
- HCP009E Invalid range - range
- HCP021E A real device number was not supplied or it is invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {rdev/vdev/ldev} does not exist
- HCP046E type rdev offline
- HCP319E Error processing subsystem command - cmd for DASD rdev
- HCP332E Invalid control unit type - rdev
- HCP1109E The command command cannot be processed for device rdev because the device is the secondary in a duplex pair.

## CONCOPY TERMINATE

### Authorization

Privilege Class: B

### Purpose

Use the CONCOPY TERMINATE command to end Concurrent Copy (CONCOPY) sessions on behalf of a virtual machine that started CONCOPY but which, because of a malfunction, cannot end CONCOPY itself. This command ends all the CONCOPY sessions on all storage controls for the virtual machine.

### Operands

#### *userid*

is the virtual machine for which CONCOPY sessions are to be terminated.

\*

indicates that CONCOPY sessions are to be terminated for the virtual machine issuing the command.

### Responses

Response 1:

```
All CONCOPY sessions have been terminated for userid
userid
```

indicates that the command has successfully ended all CONCOPY sessions for virtual machine *userid*.

Response 2:

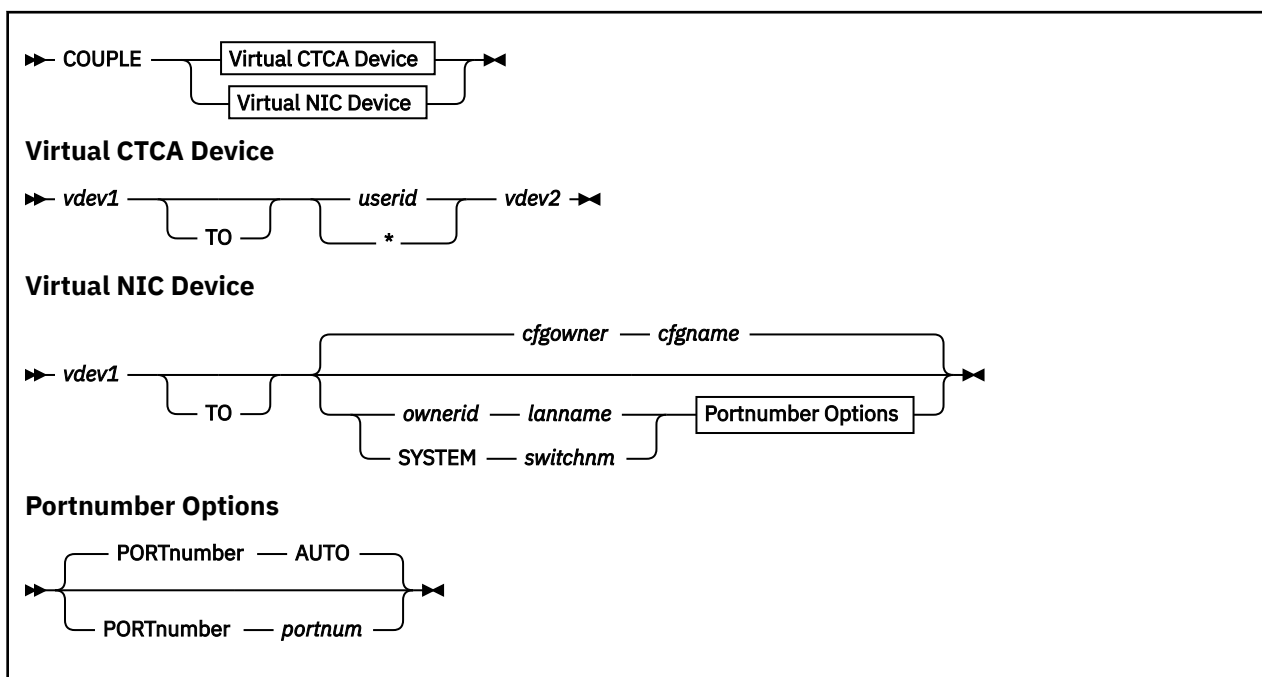

```
No CONCOPY session was found to be terminated for
userid userid
```

indicates that virtual machine *userid* does not have any CONCOPY sessions to be ended.

### Messages

- HCP026E Operand missing or invalid
- HCP319E Error processing subsystem command - *cmd* for userid *userid*

## COUPLE

### Authorization

Privilege Class: G

### Purpose

Use COUPLE to connect a virtual channel-to-channel adapter (CTCA) to a compatible virtual CTCA, or to connect a simulated network interface card (NIC) to a compatible guest LAN or virtual switch.

### Operands

#### **vdev1**

is the virtual device number (hex) of a CTCA, or network device in the invoker's virtual machine configuration. If *vdev1* is a virtual CTCA, it can be connected with a compatible virtual CTCA (designated by *userid vdev2*). If *vdev1* is a fully-simulated virtual OSA device type (created by the DEFINE NIC command), the adapter can be connected to a compatible guest LAN (designated by *ownerid* and *lanname*).

#### **userid vdev2**

is the target 'remote' virtual CTCA when *vdev1* is a virtual CTCA. If *userid* is specified as \*, it represents the user ID of the invoker. Use this form of the command to connect two virtual CTCA devices to emulate a single adapter. The invoker should be able to communicate with the 'remote' virtual machine using software appropriate for a compatible physical CTCA.

#### **cfghowner cfghname**

if a network is configured on the NICDEF user directory statement, the COUPLE command defaults to the configured network (*cfghowner cfghname*).

#### **ownerid lanname**

identifies a guest LAN as the target of the connection when *vdev1* is a virtual OSA device. The subject adapter is connected to the LAN named *lanname* owned by *ownerid*. Use this form of the command to connect a simulated network interface card (NIC) to a guest LAN. After a successful connection,

the invoker should be able to communicate with other virtual machines on the same guest LAN using software appropriate for a comparable physical network adapter.

#### **SYSTEM *switchnm***

identifies a virtual switch as the target of the connection when *vdev1* is a virtual OSA device. Use this form of the command to connect a simulated network interface card (NIC) to a virtual switch.

#### **PORTnumber *AUTO***

CP determines the virtual switch port number to be used.

Connect using an automatically assigned port number. If a NICDEF PORTNUMBER is configured for this device, the configured port and associated NICDEF attributes will be used. If a single port has been reserved for this user (using SET VSWITCH), the port and its associated port settings will be used. If more than one port has been reserved for this user, then the COUPLE command will fail because it cannot automatically resolve port number.

#### **PORTnumber *portnum***

The NIC is coupled to the specified *portnum* on the virtual switch. The specified *portnum* must be configured by SET VSWITCH, or the NICDEF must include network attributes. Otherwise the COUPLE command will fail. The *portnum* is a value from 1 to 2048.

### **Usage Notes**

1. If you do not specify TO, the *userid* you specify cannot be T or TO.
2. If *vdev1* is already connected to another virtual device, a guest LAN, or a virtual switch, that connection is broken. However, when a target virtual CTCA is already connected to another virtual device, the existing connection is **not** broken.
3. If an external security manager is installed on your system, you may not be authorized to enter this command. For additional information, contact your security administrator.
4. The connection established by the **COUPLE** command is automatically broken when the adapter, the guest LAN, or the virtual switch is detached. If you need to break this connection without detaching the adapter, the guest LAN, or the virtual switch, use the **UNCUPLE** command.
5. A simulated network interface card (NIC) can be coupled only to a compatible guest LAN or virtual switch. For example, a QDIO NIC can be coupled only to a QDIO LAN or a QDIO virtual switch. Any attempt to connect to an incompatible network will be rejected and reported by message HCP6024E.
6. To connect a NIC to a virtual switch:
  - The connection may be configured by the NICDEF user directory statement that defines this virtual NIC. This method binds the port configuration to a specific virtual NIC in the user directory. When NICDEF LAN is configured, it also authorizes the connection (without the need for a SET VSWITCH command). If the network is protected by an External Security Manager (ESM) then use the appropriate ESM interface to authorize this connection.
  - A user-defined port may be configured with the SET VSWITCH PORTNUMBER command. This method binds the network configuration to a specific port (in the range 1-2048) and allows the user to decide which virtual NIC to connect with each port. Use the appropriate External Security Manager (ESM) interface to grant authorization if the virtual switch is protected by an ESM.
  - A port may be configured with the SET VSWITCH GRANT command where the port number is assigned by z/VM. This method binds the network configuration to a user ID. Any virtual NIC belonging to this user will be connected to a port (in the range 2176-4095) and will adopt the port configuration. Use the appropriate External Security Manager (ESM) interface to grant authorization if the virtual switch is protected by an ESM.
7. After the virtual NIC is coupled to a virtual network, the port configuration can be changed dynamically:
  - Use a SET VSWITCH GRANT or PORTNUMBER command to change the configuration, including the configured Virtual Local Area Network (VLAN) ID set, dynamically. The guest does not have to uncouple and re-couple to activate this change. This method only overrides the NICDEF configuration until the next time this virtual NIC is coupled to the virtual network.

- If the NICDEF statement (in the user directory) provides network configuration, update the directory with a new configuration and refresh the configuration by having the guest uncouple and re-couple to the virtual network.
8. For a virtual CTCA the specified user must be logged on, and the virtual machine must have a virtual CTCA defined. The virtual machine may be operating in disconnect mode.
  9. If you want to connect the *vdev1* CTCA to another CTCA in your own virtual machine, specify *userid* as an asterisk (\*).
  10. The *vdev2* user must have authorized the connection using the DEFINE CTCA command or the SPECIAL directory entry.
  11. The originator of the command and the owner of the coupled CTCA (if different from the originator) receive messages indicating that the CTCAs have been coupled.
  12. It is possible to "UNCOUPLE" a virtual CTCA device by using an obscure form of the **COUPLE** command (**COUPLE vdev1 TO \* vdev1**). This method is supported for compatibility, but should be replaced by the **UNCOUPLE** command. Message HPCPCPL058E (RC58) results when using this method.
  13. The virtual ESCON® devices (defined with subclass SCTC, BCTC or CNC) cannot be coupled to virtual 3088 devices (defined with subclass CTCA or 3088), or to virtual FICON devices (defined with subclass FCTC). A virtual ESCON connection requires one controller (SCTC or BCTC) coupled with one non-control device (the CNC). The following combinations are permitted for ESCON devices:
    - COUPLE a subclass SCTC device with a subclass CNC device to get a virtual ESCON connection in Standard Mode
    - COUPLE a subclass BCTC device with a subclass CNC device to get a virtual ESCON connection in Basic Mode.

A virtual FICON device (defined with FCTC) cannot be coupled to virtual 3088 devices (defined with subclass CTCA or 3088) or to virtual ESCON devices (defined with subclass SCTC, BCTC, or CNC).

Any other combination of virtual device types will be rejected and the invoker will receive message HCP6024E.

## Responses

Response 1:

```
CTCA vdev1 COUPLED TO userid vdev2
```

is the normal response sent to the invoker of the COUPLE command when *vdev1* represents a virtual CTCA.

### **vdev1**

is the virtual device address of the invoker's CTCA.

### **userid vdev2**

is the user ID and virtual device address of the targeted CTCA.

Response 2:

```
CTCA vdev2 COUPLED BY invoker vdev1
```

is the normal response sent to the owner of the target CTCA.

### **vdev2**

is the virtual device address of the targeted CTCA.

### **invoker vdev1**

is the user ID and virtual device address of the originating CTCA.

Response 3:

```
CTCA vdev1 DROPPED FROM userid vdev2
```

## COUPLE

is the normal response sent to the invoker (and to the other userid) if the originating CTCA was already coupled to a different device.

### **vdev1**

is the virtual device address of the "local" CTCA.

### **userid vdev2**

is the user ID and virtual device address of the "remote" CTCA.

Response 4:

```
NIC vdev1 is connected to ownerid lanname
```

is the normal response sent to the invoker if *vdev1* is part of a simulated network interface card (NIC).

### **vdev1**

is the virtual device address that is part of a simulated network interface card (NIC).

### **ownerid lanname**

is the fully-qualified name of the coupled guest LAN.

Response 5:

```
NIC vdev1 is connected to SYSTEM switchnm
```

is the normal response sent to the invoker if *vdev1* is part of a simulated network interface card (NIC) connected to the virtual network via a port assigned by z/VM (2176-4095).

### **vdev1**

is the virtual device address that is part of a simulated network interface card (NIC).

### **switchnm**

is the name of the virtual switch.

Response 6:

```
NIC vdev1 is connected to SYSTEM switchnm port portnumber
```

is the normal response sent to the invoker if *vdev1* is part of a simulated network interface card (NIC) connected to the virtual network via a user-defined port (1-2048).

### **vdev1**

is the virtual device address that is part of a simulated network interface card (NIC).

### **switchnm**

is the name of the virtual switch.

### **portnumber**

is the port number assigned to the connection.

- HCP6024E Incompatible LAN - *ownerid lanname* is a *vdevtype* LAN.
- HCP6525E External Security Manager is unavailable.
- HCP6528E The ESM has more than 2000 VLAN entries so the COUPLE command cannot be completed.

## CP

---

### Authorization

Privilege Class: Any

### Purpose

Use CP as a preface to identify control program (CP) commands issued.

### Operands

#### *command*

are the name and operands of the CP command or commands you enter. You must precede the first command with at least one blank.

### Usage Notes

1. In the CP environment, you can enter multiple commands as operands of the CP command, but you must separate each command by the logical-line-end (#) symbol.

The pound sign (#) shown in the format block represents the logical-line-end symbol in effect for your virtual machine. If you have redefined the logical-line-end symbol, you must substitute your symbol for the pound sign (#).

Before you enter the CP command, be sure that your virtual machine is operating with the SET LINEDIT function set on. (This is the default.)

2. The CP command is treated as a null by the control program; for that reason it can precede any command if one or more blanks separates CP from the command.
3. If you enter CP with commands, you receive the responses appropriate to the commands entered.
4. The CP command, when not preceded with the logical line-end character, and when issued with the AT command, will not cause any virtual machine on the target system to enter the CP environment. However, the CP command can still be used to prefix other CP commands when issued with the AT command.

## CPACCESS

### Authorization

Privilege Class: A

### Purpose

Use CPACCESS to identify a CMS-formatted minidisk to CP and to make the files on that minidisk available to CP by establishing a file mode letter for the files. Before you can tell CP to link a minidisk, you must have the authority to access that minidisk. You do not have to actually link to or access the minidisk; you only need the capability to do so without specifying a password.

You can also do this by using the CP\_ACCESS statement in the system configuration file. For more information about the [CP\\_ACCESS Statement](#), see *z/VM: CP Planning and Administration*.

### Operands

#### *userid*

specifies the user ID of the owner of the minidisk that you want to make available to CP.

#### *vdev*

is the virtual device number of the specified user's minidisk, as defined in the user's entry in the system directory. The address can be any hexadecimal number between X'0000' and X'FFFF'.

#### *fm*

is the file mode letter that you want to assign to all files on the specified minidisk. You can specify any letter from A to Z.

#### *mode*

is the access mode. Valid modes are:

#### **ER**

Exclusive read-only access. CP establishes read access unless a user has an existing access to this disk. CP denies all requests for access to a disk with an existing exclusive mode.

#### **EW**

Exclusive write access. CP establishes write access unless a user has an existing access (any mode) to the disk. CP denies all requests for access to a disk with an existing exclusive mode access.

**Note:** An EXCLUSIVE access (ER, EW) is a stable access with the added restriction that no one else has, or can get access to, the specified minidisk until the access is released.

#### **M**

Multiple-write access. CP establishes write access unless a user has an existing write, stable, or exclusive mode access to the disk.

#### **MR**

Multiple-write access. CP establishes write access unless a user has an existing write, stable, or exclusive mode access to the disk. If a previous write or stable access exists, CP establishes read-only access. If an exclusive mode access exists, access is denied.

**MW**

Multiple-write access. CP establishes write access in all cases except when a user has an existing stable or exclusive mode access to the disk.

**R**

Read-only access. CP establishes read access unless a user has an existing write or exclusive mode access to the disk.

**RR**

Read-only access. CP establishes read access unless a user has an existing exclusive mode access.

**SM**

Stable multiple access. CP establishes write access unless a user holds a write, a stable, or an exclusive mode access to this disk. CP denies all requests for write access to a disk with an existing SM mode access.

**SR**

Stable read-only access. CP establishes read access unless a user has an existing write or exclusive mode access to this disk. CP denies all requests for write access to a disk with an existing SR mode access. SR is the default.

**SW**

Stable write access. CP establishes write access unless a user has an existing access (any mode) to this disk. CP denies all requests for write access to a disk with an existing SW mode access.

**Note:** A stable access means that the user holding the (SR, SW, or SM) access can be assured that the disk remains stable, unchanged by others, until the access is released.

**W**

Write access. CP establishes write access unless a user has an existing access (any mode) to the disk.

**WR**

Write access. CP establishes write access unless a user has an existing access (any mode) to the disk. If write access is denied, CP establishes read access unless another user has an existing exclusive mode access for the disk.

**ASYNChronous**

tells CP to schedule the command and lets you enter other commands before the CPACCESS command completes. When the CPACCESS command completes, CP displays a 1-line response, such as:

```
CPACCESS request for userid's vdev in mode mode completed
```

ASYNCHRONOUS is the default.

**SYNChronous**

tells CP to process the command immediately and does not allow you to enter any other commands until the CPACCESS command completes.

**Usage Notes**

1. Even though CP may establish write access to a minidisk (for example, by using the link mode MW), CP itself does not write to the minidisk.
2. When you enter the CPACCESS command and specify a file mode letter that CP is using for another minidisk, CP releases the first minidisk and accesses the minidisk you specified.
3. If the specified minidisk contains files that will be used frequently, you should either:
  - Issue the CPCACHE command to cache each file into storage.
  - Create a CPCACHE FILES file on the minidisk before you enter the CPACCESS command. The CPCACHE FILES file should contain the file names and file types of the frequently used files.

See [“CPCACHE” on page 94](#) for more information on caching files.

4. Use the CPRELEASE command to release a disk that you have accessed using the CPACCESS command. For more information, see [“CPRELEASE” on page 103](#).
5. Many users can link to a minidisk. We *strongly* recommend that you do not use the CPACCESS command to identify a minidisk to CP when some other user has write access to that minidisk. After accessing the minidisk, CP creates in storage a directory of all the files on that minidisk. If someone updates a file on that minidisk, CP is no longer maintaining a current directory and the results can be unpredictable. If you need to update a file on a disk that CP is accessing, use the CPRELEASE command to release the disk before you update the file.
6. CPACCESS accesses a minidisk for CP to read from. If you need to change a file on that disk, you must link and access the disk first. The size of the minidisk that can be accessed by the CPACCESS command is limited to 65520 cylinders.
7. If your virtual machine has privilege class A or E and can access a CP-accessed minidisk in read mode, you can use the CPTYPE command to look at the contents of a file on that disk. You do not have to link to the disk; you only need to have the capability to do so without a password. For more information, see [“CPTYPE” on page 105](#).
8. If the volume that contains the minidisk is under cross-system link protection (SSI cluster or XLINK), interpretation of the access mode takes into account all use of the minidisk by users on those systems.
9. The use of the stable and exclusive link modes (SR, SW, SM, ER, EW) is controlled by the LNKSTABL and LNKEXCLU options on the OPTION directory statement. For more information about the [OPTION Directory Statement](#), see *z/VM: CP Planning and Administration*.
10. If you have an ESM installed and the LINK command is controlled, the ESM will be queried to determine LINK authorization. For further information about linking restrictions, see [“LINK” on page 578](#).

## Responses

Response 1:

If you specify the SYNCHRONOUS operand, you see something like:

```
cpaccess oper1 06dc b sr synchronous
OPER1's 06DC accessed in mode B
Ready;
```

Response 2:

If you specify the ASYNCHRONOUS operand or you choose it as the default by specifying nothing, you see something like:

```
cpaccess oper1 06dc b sr
CPACCESS request for mode B scheduled
Ready;
CPACCESS request for OPER1's 06DC in mode B completed
```

- HCP6772E Not authorized to link disk without a password

## CPCACHE

### Authorization

Privilege Class: A

### Purpose

Use CPCACHE to cause CP to cache a file on a CP-accessed minidisk. When you cache a file, CP moves the file into storage where it can find and access the file quickly. Use the CPCACHE command after you use the CPLISTFILE command to identify any files on the minidisk that are used frequently. After caching, you have faster access to your heavily-used files. You can also use a CP\_ACCESS statement in the system configuration file to identify a minidisk to CP. For more information on the CPACCESS command, see “CPACCESS” on page 89. You can use the CPCACHE command to identify frequently used files on minidisks that have been specified with a CP\_ACCESS statement. For more information on the CP\_ACCESS Statement, see *z/VM: CP Planning and Administration*.

### Operands

**fn**  
\*

is the file name of the file that you want CP to cache. If you specify an asterisk (\*), CP caches all file names. You can use generic file names to request a specific subset of files. A generic file name is a 1- to 8-character string with asterisks (\*) in place of 1 or more arbitrary characters and percent signs (%) in place of exactly 1 arbitrary character. For example:

```
cpcache hc%p* *
```

caches all files that start with HC and have P as their fourth character.

**ft**  
\*

is the file type of the file that you want CP to cache. If you specify an asterisk (\*), CP caches all file types. You can use generic file types to request a specific subset of files. A generic file type is a 1- to 8-character string with asterisks (\*) in place of 1 or more arbitrary characters and percent signs (%) in place of exactly 1 arbitrary character. For example,

```
cpcache * con%%g *
```

caches all files whose file types start with CON and have G as their sixth (and last) character.

**fm**  
\*

is the file mode letter of the minidisk that you had CP access. If omitted, the default is A. If you specify an asterisk (\*), CP caches the specified files on all accessed disks.

### Usage Notes

1. To release a minidisk and all cached files on that minidisk, enter a CPRELEASE command and specify the access mode of the minidisk. For more information, see “CPRELEASE” on page 103.

- If you find yourself caching the same files each time, you can avoid issuing the CPCACHE command by creating a CPCACHE FILES file on the minidisk. The CPCACHE FILES file lists all the files on that minidisk that you want CP to cache. You can use generic file names and file types. When you use the CPACCESS command or the CP\_ACCESS statement to identify the minidisk to CP, CP looks for a CPCACHE FILES file on that minidisk and caches all the specified files.

Here is an example of what a CPCACHE FILES file might look like:

```
/*-----
Cache often-used logo picture files
-----*/
TCP/IP LOGO
PVM LOGO

/*-----
Cache all log message files
-----*/
* LOGMS*
```

- If you want to see which files are being used the most, enter a CPLISTFILE command with the STAT option. This gives you a list of the files and how many times they have been opened and closed. For more information on the CPLISTFILE command, see [“CPLISTFILE” on page 99](#).

## Responses

Response 1:

If you want to cache all LOGO files on your A-disk that start with the string SYS, you can enter the following:

```
cpcache sys* logo a
1 file(s) cached
Ready;
```

Response 2:

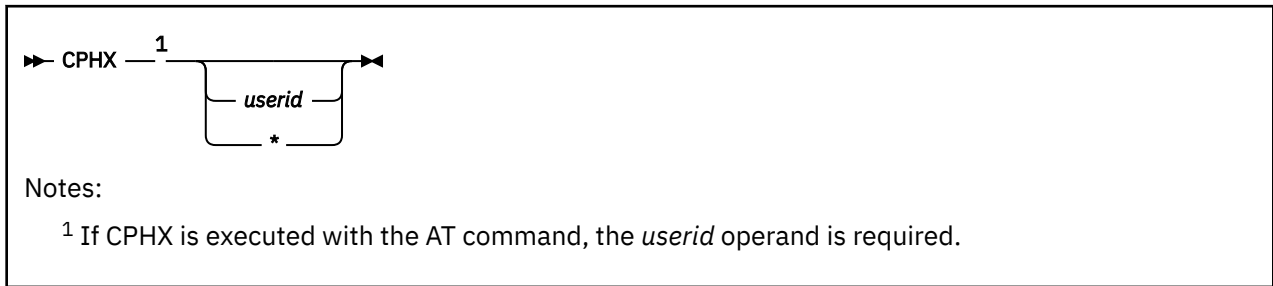

If CP cannot find any files that match the specified file name and file type, you see the following:

```
cpcache my logo a
No files cached
Ready;
```

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *operand*
- HCP6704E Missing token at end of line
- HCP6706E Invalid file {name|type|mode} - {fn|ft|fm}
- HCP6729I No files cached.
- HCP6731E Disk *fm* is being released -- command rejected

## CPHX

### Authorization

Privilege Class: A

### Purpose

Use CPHX to stop the execution of the following CP commands:

- ATTACH commands for devices
- DELETE EDEVICE command for devices
- FLASHCOPY commands for devices
- LOCATE commands searching storage
- LOCATEVM commands
- VARY ONLINE and VARY OFFLINE commands for devices
- VMDUMP command and DIAG94
- VMRELOCATE command with the SYNCHRONOUS option.

### Operands

*userid*

\*

is the user ID of the virtual machine whose command is to be canceled. An asterisk (\*) tells CP to use the issuer's user ID. You must have class A privilege to specify a user ID other than your own.

### Usage Notes

1. To cancel a command running in your own virtual machine, you must prefix the CPHX command with the string "#CP" followed by 1 blank, for example, #CP CPHX. The pound sign (#) represents the logical-line-end symbol in effect for your virtual machine. If you have redefined the logical-line-end symbol, you must substitute your symbol for the pound sign (#).
2. The ATTACH, DELETE EDEVICE, and VARY command processors check to see if a CPHX command has been issued before they process another device number specified on the ATTACH, DELETE EDEVICE, or VARY command.
3. The LOCATE and LOCATEVM command processors check to see if a CPHX command has been issued before they search another page of storage for data specified on the LOCATE or LOCATEVM commands.
4. The FLASHCOPY command processors check to see if a CPHX command has been issued before issuing additional I/O for device numbers that were specified on the FLASHCOPY command.
5. For the VMRELOCATE command with the SYNCHRONOUS option, CPHX does the same thing as the VMRELOCATE CANCEL operand. This is only applicable when the SYNCHRONOUS option was used to start the command. As with CANCEL, CPHX can only be used to stop the command up until the time that the request is sent from the source system to start the virtual machine on the destination system.

## Responses

Response 1:

If you use CPHX to stop a LOCATEVM command that is taking too long, you see something like this:

```
locatevm 0-end count all data C179022DF
The data is located at 00001270.
#cp cphx
HCPLMN6790I LOCATEVM processing halted. The next location
that would have been processed is 0001CF00.
Ready;
```

If you have a large virtual machine, the LOCATEVM command in the above example could take quite a long time.

Response 2:

If your user ID has class A privileges, you can use the CPHX command to cancel any of the previously mentioned CP commands issued by other virtual machines. For example, someone may have requested that a service machine attach a set of real devices:

```
sm rscs cp attach 0100-01ff to *
Ready;
```

An ATTACH command may take a long time because of hardware problems on a controller. If you notice that an ATTACH command is taking an unusually long time, you can choose to cancel the remainder of the ATTACH command. If you do, you see something like this:

```
cphx rscs
Your request to halt RSCS's ATTACH command has been initiated.
Ready;
HCPHXC6792I User RSCS's ATTACH command halted.
```

The message that informs you of the successful cancelation of the ATTACH command arrives some time after the CPHX command execution completes. The ATTACH command processing only recognizes the CPHX request when it begins to attach a new device.

The RSCS virtual machine's console would reflect the following activity as a result of the CPHX command execution:

```
09:01:52 Location YORKTOWN(MAINT) executing: CP ATTACH 0100-01FF TO *
:
HCPHXC6793I User MAINT has halted your ATTACH command.
HCPATR6790I ATTACH processing halted. The next device
that would have been processed is 0108.
```

The example above assumes that you are user ID MAINT. The last message indicates the ATTACH processing had completed processing devices 0100 to 0107 and was canceled before it tried to attach device 0108.

CP notifies the operator ID of the cancellation by issuing a message like this one to the operator's console:

```
HCPHXC6791I User MAINT has halted the ATTACH command processed
by user RSCS.
```

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *operand*
- HCP020E Userid missing or invalid
- HCP045E *userid* not logged on
- HCP644E Unknown/unauthorized CP command: *command*

- HCP6790I {ATTACH|DELETE EDEVICE|FLASHCOPY|VARY} processing halted. The next device that would have been processed is {*rdev*|*vdev*|*edev*}.
- HCP6790I {LOCATE|LOCATEVM} processing halted. The next location that would have been processed is *address*.
- HCP6790I {VMDUMP|DIAG94} processing halted.
- HCP6791I User *userid* has halted the *command* command executed by user *userid*.
- HCP6792I User *userid*'s *command* command halted.
- HCP6793I User *userid* has halted your *command* command.
- HCP6898E User *userid* is not executing a command that can be halted.
- HCP6899E A halt request for user *userid* has already been made by user *userid*.

## CPLISTFILE

### Authorization

Privilege Class: A

### Purpose

Use CPLISTFILE to list information on the files on a minidisk that you identified to CP by using either a CPACCESS command or a CP\_ACCESS statement.

For more information on the CPACCESS command, see “CPACCESS” on page 89.

For more information on the [CP\\_ACCESS Statement](#), see *z/VM: CP Planning and Administration*.

### Operands

**fn**  
\*

is the file name of the file on which you want information. If you omit *fn* or specify an asterisk (\*), CP lists all file names. You can use generic file names to request a specific subset of files. A generic file name is a 1- to 8-character string with asterisks (\*) in place of 1 or more characters and percent signs (%) in place of exactly 1 character. For example:

```
cpllistfile hc%p* * *
```

lists all files that start with HC and have P as their fourth character.

**ft**  
\*

is the file type of the file on which you want information. If you omit *ft* or specify an asterisk (\*), CP lists all file types. You can use generic file types to request a specific subset of files. A generic file type

is a 1- to 8-character string with asterisks (\*) in place of 1 or more arbitrary characters and percent signs (%) in place of exactly 1 arbitrary character. For example:

```
cplistfile * con%%g *
```

caches all files whose file types start with CON and have G as their sixth (and last) character.

### ***fm*** **\***

is the file mode letter of the minidisk containing the files on which you want information. If you omit *fm*, CP lists the files on the minidisk that is accessed as file mode A (the default). If you specify an asterisk (\*), CP lists the files on all accessed disks.

### **Information**

tells CP to list the following information on each file in the list:

- File ID (file name, file type, and file mode)
- Format (fixed or variable)
- Logical record length
- Number of records in the file
- Date and time when the file was created or last updated
- Whether CP cached the file.

INFORMATION is the default.

### **Statistics**

tells CP to list the following information about each file:

- File ID (file name, file type, and file mode)
- Number of times the file has been opened and closed since you identified the minidisk to CP using the CPACCESS command (see “CPACCESS” on page 89).

**Note:** If CP cached the file, the number of times the file has been opened is one more than the number of times the file has been closed. For example, see the PVM and TCPIP LOGO files in the two responses that follow.

### **MEMBER *member***

tells CP that the files you are displaying are members of a CMS partitioned data set. The variable *member* is the name of the member within the CMS partitioned data set that you want displayed, and must be a 1- to 8-character alphanumeric string.

If you omit the MEMBER operand, CP does not display any of the members of the CMS partitioned data set. CP only displays the name of the CMS partitioned data set.

You can use generic member names to request a specific subset of members. A generic member name is a 1- to 8-character string with asterisks (\*) in place of 1 or more characters and percent signs (%) in place of exactly 1 character. For example:

```
cplistfile * * a information member qu%r*
```

lists all members that start with QU and have R as their fourth character.

### **SHOrtdate**

Specifies that dates in the response to this command will be displayed in mm/dd/yy format, where mm is the month, dd is the day of the month, and yy is the 2-digit year.

### **FULldate**

Specifies that dates in the response to this command will be displayed in mm/dd/yyyy, where mm is the month, dd is the day of the month, and yyyy is the 4-digit year.

### **ISOdate**

Specifies that dates in the response to this command will be displayed in yyyy-mm-dd format, where yyyy is the 4-digit year, mm is the month, and dd is the day of the month.

## Usage Notes

1. To see a list of the minidisks that CP has access to, use the QUERY CPDISK command. For more information, see [“QUERY CPDISKS” on page 824](#).
2. If no date operand is specified, the user's default date format setting will be used.

## Responses

Response 1:

If you want to see a list of all the LOGO files on CP's A-disk, enter the following:

```
cplistfile * logo a information fulldate
Filename Filetype FM Fmt LRecl   Records   Date       Time       Cache
DAVID    LOGO      A  F    78      15 09/05/1992 06:43:26 No
DEFAULT  LOGO      A  F    80      15 11/29/1992 06:42:14 No
EMILY    LOGO      A  F    80      15 02/14/1992 06:42:23 No
LDEV     LOGO      A  F    80      15 07/28/1992 06:41:48 No
LOCAL    LOGO      A  F    80      15 10/03/1992 06:41:40 No
MOD5     LOGO      A  F   132     15 10/03/1992 06:41:15 No
PVM      LOGO      A  F    78      15 11/29/1992 06:42:01 Yes
SNA      LOGO      A  F    78      15 09/05/1992 06:41:34 No
SVCDIR   LOGO      A  F    80      15 12/18/1992 22:06:27 No
SYSTEM   LOGO      A  F    80      15 11/29/1992 06:41:28 No
TCP/IP   LOGO      A  F    78      15 10/03/1992 06:42:07 Yes
08E4     LOGO      A  F    80      15 12/18/1992 06:41:21 No
08E6     LOGO      A  F    80      23 12/18/1992 06:41:54 No
Ready;
```

Response 2:

If you want to see a list of all the LOGO files on CP's A-disk and you want to know how many times each file has been opened and closed, enter the following:

```
cplistfile * logo a statistics
Filename Filetype FM      Opens    Closes
DAVID    LOGO      A         0         0
DEFAULT  LOGO      A         1         1
EMILY    LOGO      A         0         0
LDEV     LOGO      A         0         0
LOCAL    LOGO      A         1         1
MOD5     LOGO      A         2         2
PVM      LOGO      A        19        18
SNA      LOGO      A         1         1
SVCDIR   LOGO      A         1         1
SYSTEM   LOGO      A         0         0
TCP/IP   LOGO      A        21        20
08E4     LOGO      A         0         0
08E6     LOGO      A         0         0
Ready;
```

Response 3:

If you want to see a list of all the TXTLIB files on CP's A-disk that contain CMS partitioned data set members starting with the prefix IEA, enter the following:

```
cplistfile * txtlib a information member iea* shortdate
Filename Filetype FM Fmt LRecl   Records   Date       Time       Cache
CMSLIB   TXTLIB   B  F    80      131 12/20/96 13:12:29 No
  Member IEAXPSIM starts at record 2
  Member IEAXPALL starts at record 8
  Alias  IEAXKALL starts at record 8
  Member IEAXPDXR starts at record 102
  Alias  IEAXKDXR starts at record 102
Ready;
```

This response tells you that CP has one TXTLIB on its A-disk and that TXTLIB contains:

- 3 members whose names start with IEA at records 2, 8, and 102
- 2 aliases whose names starts with IEA for the two members at records 8 and 102.

Response 4:

If you want to see the above response with the date in mm/dd/yyyy format, enter the following:

```
cplistfile * txtlib a information member iea* fulldate
Filename Filetype FM Fmt LRecl   Records   Date       Time    Cache
CMSLIB   TXTLIB   B  F      80        131 12/20/1996 13:12:29 No
  Member IEAXPSIM starts at record 2
  Member IEAXPALL starts at record 8
  Alias  IEAXKALL starts at record 8
  Member IEAXPDXR starts at record 102
  Alias  IEAXKDXR starts at record 102
Ready;
```

Response 5:

If you want to see the above response with the date in yyyy-mm-dd format, enter the following:

```
cplistfile * txtlib a information member iea* isodate
Filename Filetype FM Fmt LRecl   Records   Date       Time    Cache
CMSLIB   TXTLIB   B  F      80        131 1996-12-20 13:12:29 No
  Member IEAXPSIM starts at record 2
  Member IEAXPALL starts at record 8
  Alias  IEAXKALL starts at record 8
  Member IEAXPDXR starts at record 102
  Alias  IEAXKDXR starts at record 102
Ready;
```

## Messages

# CPRELEASE

## Authorization

Privilege Class: A

## Purpose

Use CPRELEASE to release a disk that was previously accessed using the CPACCESS command or the CP\_ACCESS statement.

For more information on the CPACCESS command, see “CPACCESS” on page 89. For more information on the CP\_ACCESS Statement, see *z/VM: CP Planning and Administration*.

## Operands

### *fm*

is the file mode letter of the minidisk that you want CP to release.

### ASYNChronous

tells CP to schedule the command and lets you enter other commands before the CPRELEASE command completes. When the command is complete, CP displays the following:

```
CPRELEASE request for disk filemode completed
```

ASYNCHRONOUS is the default.

### SYNChronous

tells CP to process the command immediately and does not allow you to enter any other commands until the CPRELEASE command completes. CP must wait until all the files are closed before it can release a minidisk. If there are a large number of open files and you specify the SYNCHRONOUS option, you may be forced to wait for some time before you can enter any other commands.

## Usage Notes

1. When you enter a CPRELEASE command, CP removes from storage all the files on the minidisk that were cached into storage as a result of CPCACHE commands or a CPCACHE FILES file.

## Responses

Response 1:

If you specify the SYNCHRONOUS operand, you see something like this:

```
cprelease b synchronous
Disk B released
Ready;
```

Response 2:

If you specify the ASYNCHRONOUS operand or you choose it as the default by specifying nothing, you see something such as this:

## CPRELEASE

```
cprelease b asynchronous  
CPRELEASE request for disk B scheduled  
Ready;  
CPRELEASE request for disk B completed
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *operand*
- HCP6704E Missing token at end of line
- HCP6706E Invalid access mode - *string*
- HCP6706E Invalid disk mode - *filemode*
- HCP6731E CPRELEASE request for mode *filemode* already active

## CPTYPE

### Authorization

Privilege Class: A

### Purpose

Use CPTYPE to cause CP to display selected lines of a file on a minidisk that you identified to CP with either a CPACCESS command or a CP\_ACCESS statement.

For more information on the CPACCESS command, see “CPACCESS” on page 89. For more information on the CP\_ACCESS Statement, see *z/VM: CP Planning and Administration*.

### Operands

#### *fn*

is the file name of the file that you want to display.

#### *ft*

is the file type of the file that you want to display.

#### *fm*

is the file mode letter of the minidisk that you identified to CP by using the CPACCESS command or the CP\_ACCESS statement. If you omit *fm*, CP displays the specified file on the disk it has accessed as A (the default). If you specify an asterisk (\*), CP searches all the accessed minidisks and displays the first file found in the search hierarchy.

#### **MEMber** *member*

is the name of a member within the file that you want to display. Member is meaningful if your file is a CMS partitioned data set (for example, a TXTLIB), because this is the type of file that has members.

#### *start*

is the line number of the first record you want CP to display. You can specify any positive decimal number between 1 and the line number of the last record in the file. If this number is greater than the line number of the last record in the file, you receive an error message. If you do not specify a number, CP starts displaying the file at line 1 (the default).

#### *end*

is the line number of the last record you want CP to display. You can specify any positive decimal number between 1 and the line number of the last record in the file. If you do not specify a number, CP displays the file at the line specified by *start* and continues displaying until it reaches the end of the file.

## Usage Notes

1. If you specify the same line number for *start* and *end*, CP displays only that line.
2. CP limits the length of each output line to 130 characters.
3. Before you can use the CPTYPE command to display selected lines of a file on a minidisk, someone must have already issued a CPACCESS command or specified a CP\_ACCESS statement to identify the minidisk to CP. Although you do not have to have a link to that minidisk, your virtual machine must be capable of establishing one without a password. For more information on the CPACCESS command, see [“CPACCESS” on page 89](#). For more information on the [CP\\_ACCESS Statement](#), see *z/VM: CP Planning and Administration*.
4. To display a list of the minidisks that CP has access to, use the QUERY CPDISKS command. For more information, see [“QUERY CPDISKS” on page 824](#).

## Responses

CP displays the file on your terminal screen according to the information you specify.

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *operand*
- HCP2768E Missing file member name
- HCP6702E Error encountered while attempting to read records from *fn ft fm*

- HCP6704E Missing token at end of line
- HCP6706E Invalid file member name - *member*
- HCP6706E Invalid file mode - *fm*
- HCP6706E Invalid file name - *filename*
- HCP6706E Invalid file type - *ft*
- HCP6772E Not authorized to link disk without a password

## CPU

### Authorization

Privilege Class: G

### Purpose

Use CPU to do the following:

- Designate the virtual processor or processors to process the CP command specified
- Choose the default processor to run CP commands entered in response to CP read or prefixed by #CP.

### Operands

#### ALL

specifies that *command\_line* be run on all virtual processors currently defined in the principal configuration.

#### *cpuaddr*

identifies the address of the processor to run *command\_line*.

#### *cpuaddr1-cpuaddr2*

identifies a range of consecutive CPU addresses, designated by a nonwrapping pair of addresses separated by a hyphen (-) and not separated by blanks.

#### \*

specifies that the CP command requested should be run on the default target CPU. This option is useful to direct to the principal configuration a command issued from the adjunct configuration or issued via #CP while the adjunct is active.

The command can be directed to multiple CPUs using any combination of individual CPU addresses, ranges, and asterisk, separated by blanks. Commands are executed in the order the CPU addresses are listed. If a CPU address is included multiple times in the list, the subsequent references are ignored.

#### CMD

must be specified if CP would interpret the first token of the command line as a hexadecimal address.

For example, if you wish to specify that the DISPLAY PROGRAM STATUS WORDS command be processed on the CPU at address 1, do *not* specify *cpu 1 d psw* because CP would interpret the *d* as an address. Instead, enter *cpu 1 cmd d psw*.

#### *command\_line*

identifies the CP command you want to process.

When processing the CPU command, CP does not check the validity of the command entered with it. Only the processor receiving the CP command checks it for validity and errors.

### ***defcpuaddr***

identifies the address of the processor in the principal configuration that you want to process future commands issued from the console, unless they are overridden with a CPU command prefix. This is referred to as the default target CPU.

### **Usage Notes**

1. If *command\_line* is specified, it applies only to the specified virtual processors. If *defcpuaddr* is the only operand specified, future CP commands apply to that virtual processor until the next CPU command is issued.

### **Responses**

Response 1:

```
xx:
```

is prefixed to each output line to identify the processor whose execution of *command\_line* produced this line.

### **Messages**

- HCP001E Unknown CP command: *command*
- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid
- HCP1454E CPU *nn* does not exist.
- HCP1455E CPU *nn* is not started because it is in check-stop state.
- HCP1460E Only one of the CPU commands may specify multiple virtual CPUs when entering nested CPU commands.

## CPVLOAD

### Authorization

Privilege Class: B

### Purpose

Use CPVLOAD to load a file into your virtual machine's storage.

### Operands

#### *fname*

is the name of the file you want loaded.

#### *fmode*

is the type of the file you want loaded.

\*

tells CP to search the list of accessed disks for the file you want to load. This is the default if you do not specify a file mode.

#### *fmode*

is the mode of the CP-accessed minidisk where the file you want to load resides.

#### *location*

is the 31-bit address, in hexadecimal, where the file is to be loaded.

### Usage Notes

1. The specified file is loaded as a core image into virtual machine storage. The contents of the file are copied into virtual storage starting at the designated location and proceeding upward.
2. The file may be fixed or variable format and must have a logical record length less than 4,000 bytes.
3. Before you can use the CPVLOAD command to load a file into virtual storage, someone already must have issued a CPACCESS command or specified a CP\_ACCESS statement to identify the minidisk to CP. Although you do not have to link to that minidisk, your virtual machine must be capable of establishing one without a password. For more information on the CPACCESS command, see [“CPACCESS” on page 89](#). For more information on the CP\_ACCESS Statement, see [z/VM: CP Planning and Administration](#).
4. To display a list of the minidisks that CP has access to, use the QUERY CPDISKS command. For more information, see [“QUERY CPDISKS” on page 824](#).

### Responses

Response 1:

```
X'nnnnnnnn' bytes loaded
```

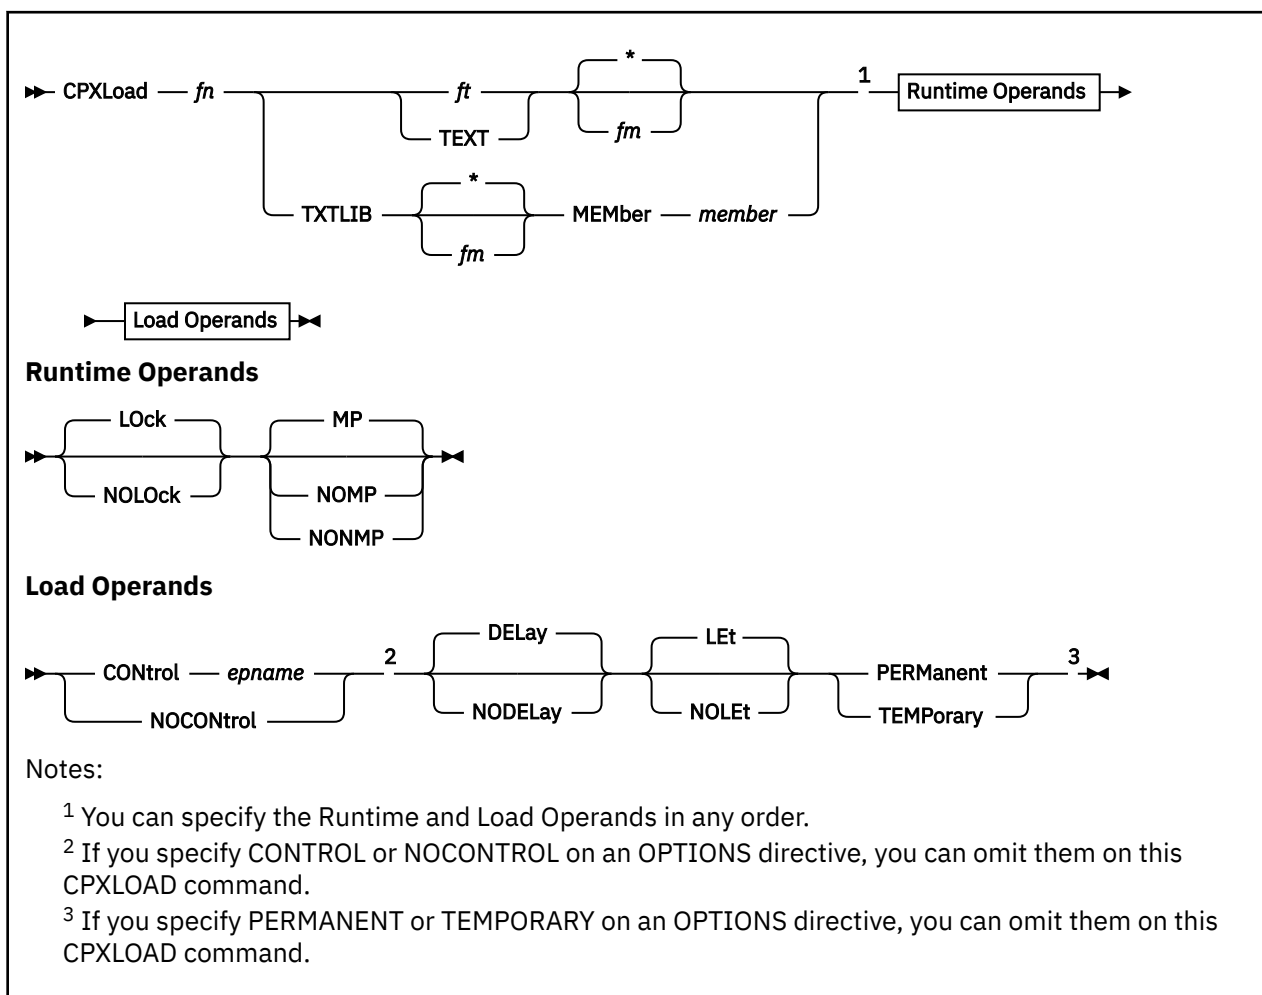

### Messages

- HCP6709E Too many items specified - *item*
- HCP6740E Insufficient storage to complete this request

## CPXLOAD

### Authorization

Privilege Class: A

### Purpose

Use CPXLOAD to load a file containing customer-written CP routines into the system execution space.

You can also load customer-written CP routines into the system execution space during initialization using the CPXLOAD configuration file statement. For more information on the [CPXLOAD Statement](#), see *z/VM: CP Planning and Administration*.

### Operands

***fn***

is the name of the file that you want loaded.

***ft***

is the file type (other than TEXT or TXTLIB) of the file that you want loaded.

This file may contain CPXLOAD directives, text records, or a combination of both. If the file contains text records, it must have a fixed record format (RECFM F) and a logical record length of 80 (LRECL

80). If the file does not contain text records, it can be any record format and must have a logical record length less than 4,000 (LRECL < 4000).

**TEXT**

tells CP that this is a text file that contains 1 or more CSECTs and can contain 1 or more CPXLOAD directives. Text files must have a fixed record format (RECFM F) and a logical record length of 80 (LRECL 80).

**TXTLIB**

tells CP that the file is a text library that contains 1 or more members. A TXTLIB member can contain 1 or more control sections (CSECTs) and can contain CPXLOAD directives. TXTLIB files must have a fixed record format (RECFM F) and a logical record length of 80 (LRECL 80).

**\***

tells CP to search the list of CP-accessed minidisks until it finds the first occurrence of the specified file that you want loaded. If you do not specify a file mode, \* is the default.

***fm***

is the file mode of the CP-accessed minidisk containing the file that you want loaded.

**MEMBER *member***

is the name of the member in the TXTLIB that you want loaded.

You can use generic member names to request a specific subset of files. A generic member name is a 1- to 8-character string with asterisks (\*) in place of 1 or more characters and percent signs (%) in place of exactly 1 character. For example:

```
hc%p* . . .
```

lists all members that start with HC and have P as their fourth character.

**LOCK****NOLOCK**

has no effect and is retained only for compatibility. All symbols are considered resident, which means they cannot be locked or unlocked.

**MP**

tells CP that the entry point is multiprocessor (MP) capable. This means that the entry point can be dispatched on any of the machine's processors. If omitted, MP is the default.

**NOMP****NONMP**

tells CP that the entry point is dispatched only on the master processor, because (in general) the entry point assumes that competitive routines are also not multiprocessor (MP) capable. Use NOMP or NONMP to prevent entry points from overlaying each other's chains of control blocks when you do not take the precaution of getting a system lock. For example, SPOOL routines are NOMP.

**CONTROL *epname***

tells CP to call the specified entry point after loading the customer-written CP routines and before processing a CPXUNLOAD request. You can load the customer-written CP routines containing the specified entry point either before or within this CPXLOAD request. The variable *epname* must be a 1- to 8-character string. The first character must be alphabetic or one of the following special characters: dollar sign (\$), number sign (#), underscore (\_), or at sign (@). The rest of the string can be alphanumeric characters, the 4 special characters (\$, #, \_, and @), or any combination thereof.

**Note:** Normally, if CP cannot find an entry point when processing an exit point routine, it ignores the unknown entry point and continues normal processing. This is not true when you specify the CONTROL *epname* operand. If CP cannot find the entry point you specify on CONTROL, CP will terminate processing your CPXLOAD command and will not load your customer-written CP routines into the system execution space.

For information about control entry points, see *z/VM: CP Exit Customization*.

**NOCONTROL**

tells CP not to call an entry point after loading the customer-written CP routine and before processing a CPXUNLOAD request.

**DElay**

This operand only has meaning on the CPXLOAD configuration file statement, where it tells CP not to process a CPXLOAD statement until after all CP\_ACCESS statements have been processed. It is included here, on the command, for compatibility with the CPXLOAD statement. If you specify DELAY, CP ignores the operand, issues informational message HCP2777I, and loads the CP routines immediately.

**NODElay**

This operand only has meaning on the CPXLOAD configuration file statement, where it tells CP to process a CPXLOAD statement immediately, without waiting for all CP\_ACCESS statements to be processed. It is included here, on the command, for compatibility with the CPXLOAD statement. If you specify NODELAY, CP ignores the operand, issues informational message HCP2777I, and loads the CP routines immediately.

**LEt**

tells CP to load the specified file and to ignore any records that are completely blank or that contain an unexpected value in column 1. This is meant to accommodate the noncommented information that can be left in a TEXT file by an assembler utility such as VMFASM. If omitted, LET is the default.

**NOLEt**

tells CP to stop loading the specified file when it encounters an unexpected value in column 1. Column 1 is expected to contain '\*' (to denote a comment), X'02' (to denote a TEXT record), or blank (to denote a possible CPXLOAD directive).

**PERManent**

tells CP that the customer-written CP routines being loaded are to remain a part of CP until a CP SHUTDOWN command is issued or a software-initiated restart (bounce) occurs. This means you cannot use the CPXUNLOAD command to remove these CP routines.

**TEMPorary**

tells CP that the customer-written CP routines being loaded can be unloaded in the future with a CPXUNLOAD command.

**Usage Notes**

1. When loading your files into storage, CP treats each control section (CSECT) independently for storage allocation. Also during loading, CP allocates one page of storage to each CSECT. There is one exception: if CP encounters a CSECT of zero length during CPXLOAD processing, that CSECT is deleted. If you need to load a zero-length CSECT, add an EXPAND directive to your input file. For example, if you had zero-length CSECT XXXDOG to load, you would add "EXPAND XXXDOG(8)" to your input file.
2. When invoking your files, CP treats each entry point in a CSECT independently for the MP attribute.
3. The customer-written CP routines that you are loading must be on a disk that CP has access to when the load operation is performed. If you have a CPXLOAD statement in your system configuration file that specifies the NODELAY operand, the customer-written CP routines must be on the parm disk because the minidisks specified on CP\_ACCESS statements are not available until the end of the initialization process. If your CPXLOAD statement specifies the DELAY operand, the customer-written CP routines can be a file on any disk, as long as you have specified a CP\_ACCESS statement for that disk in your system configuration file.
4. You can specify runtime and load operands on either the CPXLOAD command or the OPTIONS directive, or both. However, if you specify options on both and those options conflict, CP uses the options from the CPXLOAD command. For example, suppose you specify PERMANENT on the OPTIONS directive and TEMPORARY on the CPXLOAD command, CP will load the CP routines as temporary. For more information about the [OPTIONS Directive](#) and several other directives, see *z/VM: CP Exit Customization*.
5. To assign entry points and external symbols to an exit point and to enable or disable that exit point, use the ASSOCIATE EXIT command (see ["ASSOCIATE EXIT"](#) on page 20).
6. To assign an external symbol to a local message repository, use the ASSOCIATE MESSAGES or MSGS command (see ["ASSOCIATE MESSAGES / MSGS"](#) on page 24).

7. To display information about customer-written CP routines loaded by the CPXLOAD command, use the QUERY CPXLOAD command (see [“QUERY CPXLOAD”](#) on page 848).
8. To display information about external symbols you may have loaded, use the LOCATE SYMBOL command (see [“LOCATE SYMBOL”](#) on page 636).
9. To remove CPXLOADed files from the system execution space:
  - a. Use the DISASSOCIATE command (see [“DISASSOCIATE”](#) on page 324) to revoke all entry point and external symbol assignments made with the ASSOCIATE EXIT, MESSAGES, or MSGS commands or configuration file statements
  - b. Use the CPXUNLOAD command (see [“CPXUNLOAD”](#) on page 117) to unload the customer-written CP routines.

For more information about the ASSOCIATE EXIT Statement or ASSOCIATE MESSAGES / MSGS Statement, see *z/VM: CP Planning and Administration*.

10. For more information about loading customer-written CP routines into the system execution space, about runtime and load operands, and about CPXLOAD Directives, see *z/VM: CP Exit Customization*.
11. CPXLOAD provides the ability to load executable code, message repositories, and data modules dynamically. Only compiled files may be loaded. These compiled files would be the TEXT file output from the assembler or from the CMS GENMSG command.

## Responses

Response 1:

To permanently load a multiprocessor capable abend text deck, enter the following:

```
cpxload abend text * mp control kaos permanent
Loaded as identifier 7
Ready;
```

Note that CP assigns a load identifier (load ID) to the loaded CP routines. Please make a note of this number. If you ever want to unload these CP routines (using the CPXUNLOAD command), you will need to specify the load ID that CP assigned. If you do not know the load ID, use the ALL operand of the QUERY CPXLOAD command to display (among other things) the load IDs of all the CP routines loaded onto (and not yet unloaded from) the system.

The load ID that CP assigns is a 1- to 10-digit decimal number between 0 and 2,147,483,647. The first time you use the CPXLOAD command (or configuration file statement), CP assigns that set of customer-written CP routines a load ID of 0. CP increases the load ID by 1 for each subsequent CPXLOAD request. If all the CPXLOAD requests are successful, you will have a sequential list of loaded CP routines.

If one or more of the CPXLOAD requests are unsuccessful or you issue the CPXUNLOAD command to unload some customer-written CP routines, there will be one or more gaps in your sequential list of loaded CP routines. The next time you load some customer-written CP routines, CP ignores these gaps in the list and assigns the newly-loaded CP routines a load ID that is one more than the last assigned load ID.

For example, suppose you had customer-written CP routines loaded at IDs 0 through 7 and you unloaded the CP routines at IDs 2, 3, and 5. This means you still have CP routines loaded at IDs 0, 1, 4, 6, and 7. The next time you use the CPXLOAD command, CP will assign 8 as the load ID for those CP routines. CP will not try to fill in the gaps at 2, 3, or 5.

## CPXUNLOAD

### Authorization

Privilege Class: A

### Purpose

Use CPXUNLOAD to remove customer-written CP routines from the system execution space.

### Operands

#### ID *loadid*

is the identifier that CP assigned to these CP routines when you loaded them into the system execution space using the CPXLOAD command. The variable *loadid* must be a decimal number between 0 and 2147483647.

#### ASYNChronous

tells CP that you want to process other commands while this CPXUNLOAD command completes. ASYNCHRONOUS is the default.

#### SYNChronous

tells CP to prevent you from executing other commands until the CPXUNLOAD command completes.

### Usage Notes

1. To load customer-written CP routines into the system execution space, use the CPXLOAD command (see “CPXLOAD” on page 111) or the CPXLOAD configuration file statement. For more information about the [CPXLOAD Statement](#), see *z/VM: CP Planning and Administration*.
2. Before you unload the customer-written CP routines from the system execution space, use the DISASSOCIATE command (see “DISASSOCIATE” on page 324) to revoke all entry point and external symbol assignments made with the ASSOCIATE EXIT, MESSAGES, or MSGS commands or configuration file statements. For more information about the ASSOCIATE EXIT command, see “ASSOCIATE EXIT” on page 20. For more information about the ASSOCIATE MESSAGES or MSGS commands, see “ASSOCIATE MESSAGES / MSGS” on page 24. For more information about the [ASSOCIATE EXIT Statement](#) or [ASSOCIATE MESSAGES / MSGS Statement](#), see *z/VM: CP Planning and Administration*.
3. You can unload customer-written CP routines from the system execution space only if you specified the TEMPORARY operand of the CPXLOAD command or configuration file statement. For more information about the CPXLOAD command, see “CPXLOAD” on page 111. For more information about the [CPXLOAD Statement](#), see *z/VM: CP Planning and Administration*.
4. To unload customer-written CP routines from the system execution space, you must specify the load ID that CP assigned to the CP routines when loading them. CP assigns and displays this load ID in the response to your CPXLOAD command. If you cannot remember the load ID, use the QUERY CPXLOAD ALL command (see “QUERY CPXLOAD” on page 848).
5. For more information about unloading customer-written CP routines from the system execution space, see [Understanding the System Execution Space and CP Customization Methods](#) in *z/VM: CP Exit Customization*.

## Responses

Response 1:

To unload the customer-written CP routines that was assigned ID 92, enter the following:

```
cpxunload id 92
HCP2770I CPXUNLOAD for load ID 92 has been scheduled
Ready;
:
HCP2771I CPXUNLOAD for load ID 92 has been completed
```

Note that the Ready message in this response appears between the two messages. The virtual machine issuing this CPXUNLOAD command did not specify anything after the load ID, so this became an asynchronous command, by default. This means the virtual machine is free to issue other commands before CP unloads all the customer-written CP routines. When you specify SYNCHRONOUS, your virtual machine cannot perform other tasks until CP unloads all of the customer-written CP routines.

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP2769E CPXUNLOAD for load ID *loadid* has been rejected; the requested load ID was not found
- HCP2769E CPXUNLOAD for load ID *loadid* has been rejected; the requested load ID was loaded as PERMANENT
- HCP2769E CPXUNLOAD for load ID *loadid* has been rejected; the requested load ID is still in use by a system service
- HCP2769E CPXUNLOAD for load ID *loadid* has been rejected; the request was denied by the control entry point
- HCP6704E Missing token at end of line
- HCP6706E Invalid string - *string*

## DEACTIVE CONV

### Authorization

Privilege Class: B

### Purpose

Use the DEACTIVE CONV command to deactivate a conversation between transaction programs that is being managed by the local VM node.

To deactivate a collection management conversation between nodes, use the DEACTIVE ISLINK command (see [“DEACTIVE ISLINK”](#) on page 120).

There are two types of conversations in the Communication Services (CS) collection:

- Conversations between nodes are used for communications management and CS collection control. These conversations are called collection management conversations (CMP conversations).
- The other type of conversations in the CS collection are conversations between user transaction programs and resource transaction programs. These types of conversations are called APPC conversations (a reference to the program's use of the assembler language or CPI Communications programming interface to APPC/VM).

### Operands

#### *convid*

Is the hexadecimal conversation identifier of a specific conversation managed by the local VM node. To determine the conversation ID, enter the QUERY CONV command (see [“QUERY CONV”](#) on page 810).

### Responses

Response 1:

```
Conversation convid is deactivated.
```

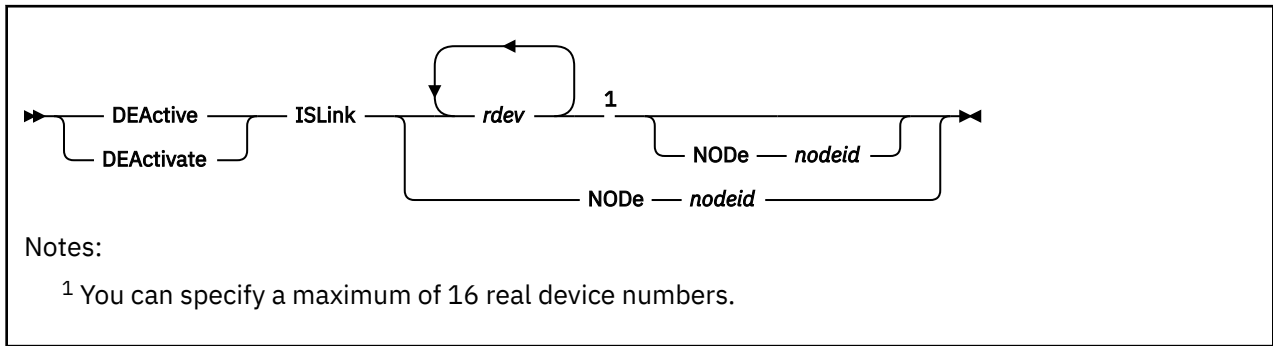

#### *convid*

Identifies the conversation ID of the conversation that is deactivated.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid
- HCP2706I Conversation *convid* deactivated by user *userid*
- HCP2728E Conversation *convid* does not exist.
- HCP2729E Conversation *convid* is for collection management. Conversation not deactivated.

## DEACTIVE ISLINK

### Authorization

Privilege Class: B

### Purpose

Use the DEACTIVE ISLINK command to deactivate active conversations on one or more devices.

To deactivate a conversation between transaction programs, use the DEACTIVE CONV command.

### Operands

#### *rdev*

Identifies one to sixteen real device numbers to be deactivated.

When specified with NODe *nodeid*, devices are deactivated only if the link configuration matches *nodeid*.

#### **NODe** *nodeid*

Specifying NODe *nodeid* without an *rdev* deactivates all devices.

### Usage Notes

1. The system operator receives all informational and error messages, but not immediate command responses.
2. When you deactivate all remaining devices associated with an ISLINK, that ISFC link to a neighboring node is disabled. The affected link may be your only connection to this neighbor. It might also be the only connection to other nodes in the ISFC collection. Losing access to a node in the ISFC collection may terminate IUCV or APPC communication with those nodes. For example, a local user editing a file in a Shared File System directory residing on a remote node would lose access to that file while this link is disabled. Even if ISFC can access these remote resources through another ISFC link, IUCV and APPC sessions will be terminated by this disruption and the guest will have to take action to regain access to the remote node.
3. Avoid using DEACTIVATE ISLINK to remove a link device from an ISFC logical link while a VMRELOCATE MOVE command is in progress. Removing a link device interferes with the relocation and can cause operations to time out, terminating the relocation.

### Responses

Response 1:

```
Link rdev deactivated.
```

***rdev***

is the link address that has been deactivated.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid
- HCP2701I Link *linkname* went down.
- HCP2703I Node *nodeid* deleted from collection.
- HCP2706I Link *linkname* deactivated by user *userid*.
- HCP2720E Link device *rdev* not found.
- HCP2720E Node *nodeid* not found.
- HCP2738E Deactivate in progress for link *linkname* -- command rejected.
- HCP2746E Deactivate failed. Node *node1* was specified on the command, but link device *rdev* is connected to node *node2*.

## DEFINE

---

### Purpose

Use the DEFINE commands to:

- Change the configuration of your virtual machine
- Change the configuration of your operating system
- Add a new alias for an existing CP command on your system
- Add a new CP command to your system
- Add a new version of an existing CP command to your system
- Add a new DIAGNOSE code to your system
- Add a new guest LAN to your system.

### Usage Notes

(General for DEFINE)

1. SET IMSG OFF suppresses informational messages for this command.
2. When you use the DEFINE command to alter the configuration of your virtual machine, the changes are temporary and are in effect only for the current session.
3. When you use the DEFINE command to alter the real I/O configuration of the processor, the changes are temporary and are in effect only until the next power-on reset (POR). If you want the changes to be permanent, you must update your I/O configuration program (IOCP) file.
4. Defaults for some real printer attributes (for example CHARS) are not set when a virtual printer is created with the DEFINE command.

- HCP6873E PCI function *rpfid* has been created but is in definition error and has not been added to the configuration.
- HCP9300E A system soft abend *code* has occurred on CPU *nnnn* for user *userid*.

## DEFINE ALIAS

### Authorization

Privilege Class: A

### Purpose

Use DEFINE ALIAS to define a new alias for an existing CP command on the system.

You can also define a new alias during initialization using the DEFINE ALIAS configuration file statement. For more information, see [DEFINE ALIAS Statement in z/VM: CP Planning and Administration](#).

### Operands

#### *alias*

is the name of the alias that you are defining. The variable *alias* must be a 1- to 12-character string.

#### *command*

is the name of the existing CP command for which you are creating an alias. The variable *command* is a 1- to 12-character string.

#### **Query SUBCmd *subcommand***

tells CP the name of the existing CP QUERY subcommand for which you are creating an alias. The variable *subcommand* is a 1- to 12-character string.

#### **Query Virtual SUBCmd *subcommand***

tells CP the name of the existing CP QUERY VIRTUAL subcommand for which you are creating an alias. The variable *subcommand* is a 1- to 12-character string.

#### **Set SUBCmd *subcommand***

tells CP the name of the existing CP SET subcommand for which you are creating an alias. The variable *subcommand* is a 1- to 12-character string.

#### **ABBRlength *nn***

is the length of the smallest acceptable abbreviation of the alias that you are defining. The variable *nn* is a decimal number between 1 and the length of the full alias name.

### **DISable**

tells CP not to activate this alias until you enable it. (For more information about enabling aliases, see Usage Note “5” on page 129.) If omitted, DISABLE is the default.

### **ENable**

tells CP to immediately activate this alias.

### **IBMclass \***

tells CP to define aliases for all versions of the specified command or subcommand. If omitted, IBMCLASS \* is the default.

### **IBMclass c**

tells CP to define an alias for a specific version of the specified command or subcommand. The variable *c* can be any 1 of the following:

#### **A**

this is a system-control command to be used by the primary system operator.

#### **B**

this is a command for operational control of real devices.

#### **C**

this is a command to alter system storage.

#### **D**

this is a command for system-wide control of spool files.

#### **E**

this is a command to examine system storage.

#### **F**

this is a command for service control of real devices.

#### **G**

this is a general-use command used to control the functions of a virtual machine.

#### **O**

(zero) this command has no specific IBM class assigned.

## Usage Notes

1. You can create many aliases for one command, but you cannot create an alias for an alias. For example, the CP MSG command is actually an alias for the CP MESSAGE command:

```
MSG ----> MESSAGE
```

You can create another alias for the MESSAGE command:

```
MSG ----> MESSAGE <---- TELL
```

But you cannot create an alias for MSG:

```
TELL ----> MSG ----> MESSAGE
```

2. If you specify the QUERY, QUERY VIRTUAL, or SET operands, you are creating an alias for a subcommand, not a command. For example, suppose you created alias TUBE for the CP QUERY VIRTUAL GRAF command. To invoke your new alias, you would enter QUERY VIRTUAL TUBE, not QUERY TUBE or just TUBE.
3. When specifying an alias name, you can use special characters in the name. However, we do not recommend that you use the pattern matching characters (\* and %). You can use these characters to define aliases, but they may seem confusing when you issue other commands that allow you to use the pattern matching characters because CP will interpret the % or \* in your alias name as a pattern matching character.

CP places no restriction on the use of special characters such as \*, %, comma, (, ), blank, /, :, \$, #, and @ in command names. However, some External Security Managers (EMs) restrict their use. Please consult your ESM documentation for information on restricted characters.

4. If you try to define a minimum abbreviation that matches the abbreviation for an existing command, subcommand, or alias CP rejects your DEFINE command. For example, if you created a "QUEUE" alias with a minimum abbreviation of 2, CP would reject your QUEUE alias because "QU" is an abbreviation for the QUERY command. In this case, you would need to specify a minimum abbreviation greater than or equal to 4 because the first 3 characters of QUERY and QUEUE are identical.
5. If you do not specify the ENABLE operand, the new alias is initially in a disabled state. To activate an alias after defining it, use the ENABLE COMMAND or CMD command (see [“ENABLE COMMAND / CMD”](#) on page 460).

Note that both the alias you define and its base command must be enabled for the alias to work. For example, if you define alias SHOWIT for the existing command DISPLAY, DISPLAY is considered the base command. DISPLAY must also be enabled for the alias SHOWIT to work.

6. To deactivate an alias after defining it, use the DISABLE COMMAND or CMD command (see [“DISABLE COMMAND / CMD”](#) on page 313).

If you specify the name of an alias on DISABLE COMMAND, then just the alias is disabled. If you specify the name of the base command on DISABLE COMMAND then you disable the entire function. That means that the base command is in a disabled state and every alias you have defined for that command is treated as if it were also disabled.

7. To obtain information such as the enable/disable status and the name of the base command for the alias you have defined, use the QUERY CPCMDS command (see [“QUERY CPCMDS”](#) on page 817).
8. Once defined, an alias name cannot be used again. An alias cannot be modified or eliminated; it can only be disabled. Only a SHUTDOWN or RESTART IPL will eliminate an alias.
9. For more information about creating an alias, see [Defining an Alias Command](#) in *z/VM: CP Exit Customization*.

## Responses

Response 1:

To define GOODNIGHT as an alias for the CP SHUTDOWN command and make it available immediately, enter the following:

```
def alias goodnight for shutdown abbrevlength 5 enable
Ready;
```

Response 2:

To define TELL as an alias for the IBM class <ANY> version of the CP MESSAGE command and make it available immediately, enter the following:

```
define alias tell for message ibmclass 0 enable
Ready;
```

Response 3:

To define NUKE as an alias for all of the IBM class versions of the CP PURGE command and make it available immediately, enter the following:

```
define alias nuke for purge ibmclass * enable
Ready;
```

## Messages

For the list of general messages for the DEFINE command, see [“Messages”](#) on page 122.

## DEFINE CFLINK

### Authorization

Privilege Class: A, B, G

### Purpose

DEFINE CFLINK allows a coupled guest or system operator to create links between coupling facilities.

### Operands

#### *msgprocid1*

specifies the sending coupling facility user ID for the new link.

#### *vdev*

specifies the device number of the first message device in the sending coupling facility. This must be a hexadecimal number from X'0000' to X'FFFE'.

#### *msgprocid2*

specifies the receiving coupling facility for the new link.

#### DEVICES *n*

specifies the number of message devices that the sending virtual machine (coupling guest or coupling facility) can process; *n* must be between 2 and 8. The default is 2.

### Usage Notes

1. A class G only user must be coupled to both the sending and receiving coupling facilities. There also must either be no SPECIAL MSGP statements in the *msgprocid1* directory entry, or *msgprocid2* must appear on one of the SPECIAL MSGP statements in the *msgprocid1* directory entry.
2. A class A or class B user can couple any two coupling facilities regardless of whether they are coupled to the coupling facilities in question and regardless of the presence of SPECIAL MSGP statements in the sending coupling facility's directory entry.
3. A coupling facility can have links to up to seven other coupling facilities.
4. There can be up to two links (channel path IDs) from *msgprocid1* (the sender) to *msgprocid2* (the receiver). In the sender, the first link uses the next available channel path ID in range (E0..E6) and the second uses the next available channel path ID in range (A0..A6). In the receiver, the first link uses the next available channel path ID in range (F0..F6) and the second uses the next available channel path ID in range (B0..B6).
5. The *vdev* chosen must be a hexadecimal number low enough for the addition of *vdev* plus the number of DEVICES minus 1 with a result less than or equal to X'FFFF'.
6. Device numbers X'*vdev*' and X'*vdev*' plus the number of DEVICES minus 1 must be available in the sending coupling facility.
7. If DEVICES is specified without *n*, message HCP026E is displayed.
8. If DEVICES is specified with a device count that is not within the 2 to 8 range, message HCP002E is displayed.
9. If *msgprocid2* is not in z/Architecture mode, CP forces DEVICES to 2 no matter what else was specified.

## Examples

Create a link between CFVM1 and CFVM2, with two message devices in CFVM1 at device numbers 400–401:

```
define cflink cfvm1 vdev 400 cfvm2
```

If CFUSER1 is coupled to both CFVM1 and CFVM2, then CFUSER1 can create a second link between CFVM1 and CFVM2 as follows:

```
define cflink cfvm1 vdev 800 cfvm2
```

**Note:** This creates two more message devices in CFVM1 at addresses 800 and 801.

If CFVM2 was an z/Architecture mode machine, the operator or CFUSER1 could request that more than two devices (up to 8 are allowed) be put in CFVM1 as follows:

```
define cflink cfvm1 vdev 400 cfvm2 devices 6
```

## Messages

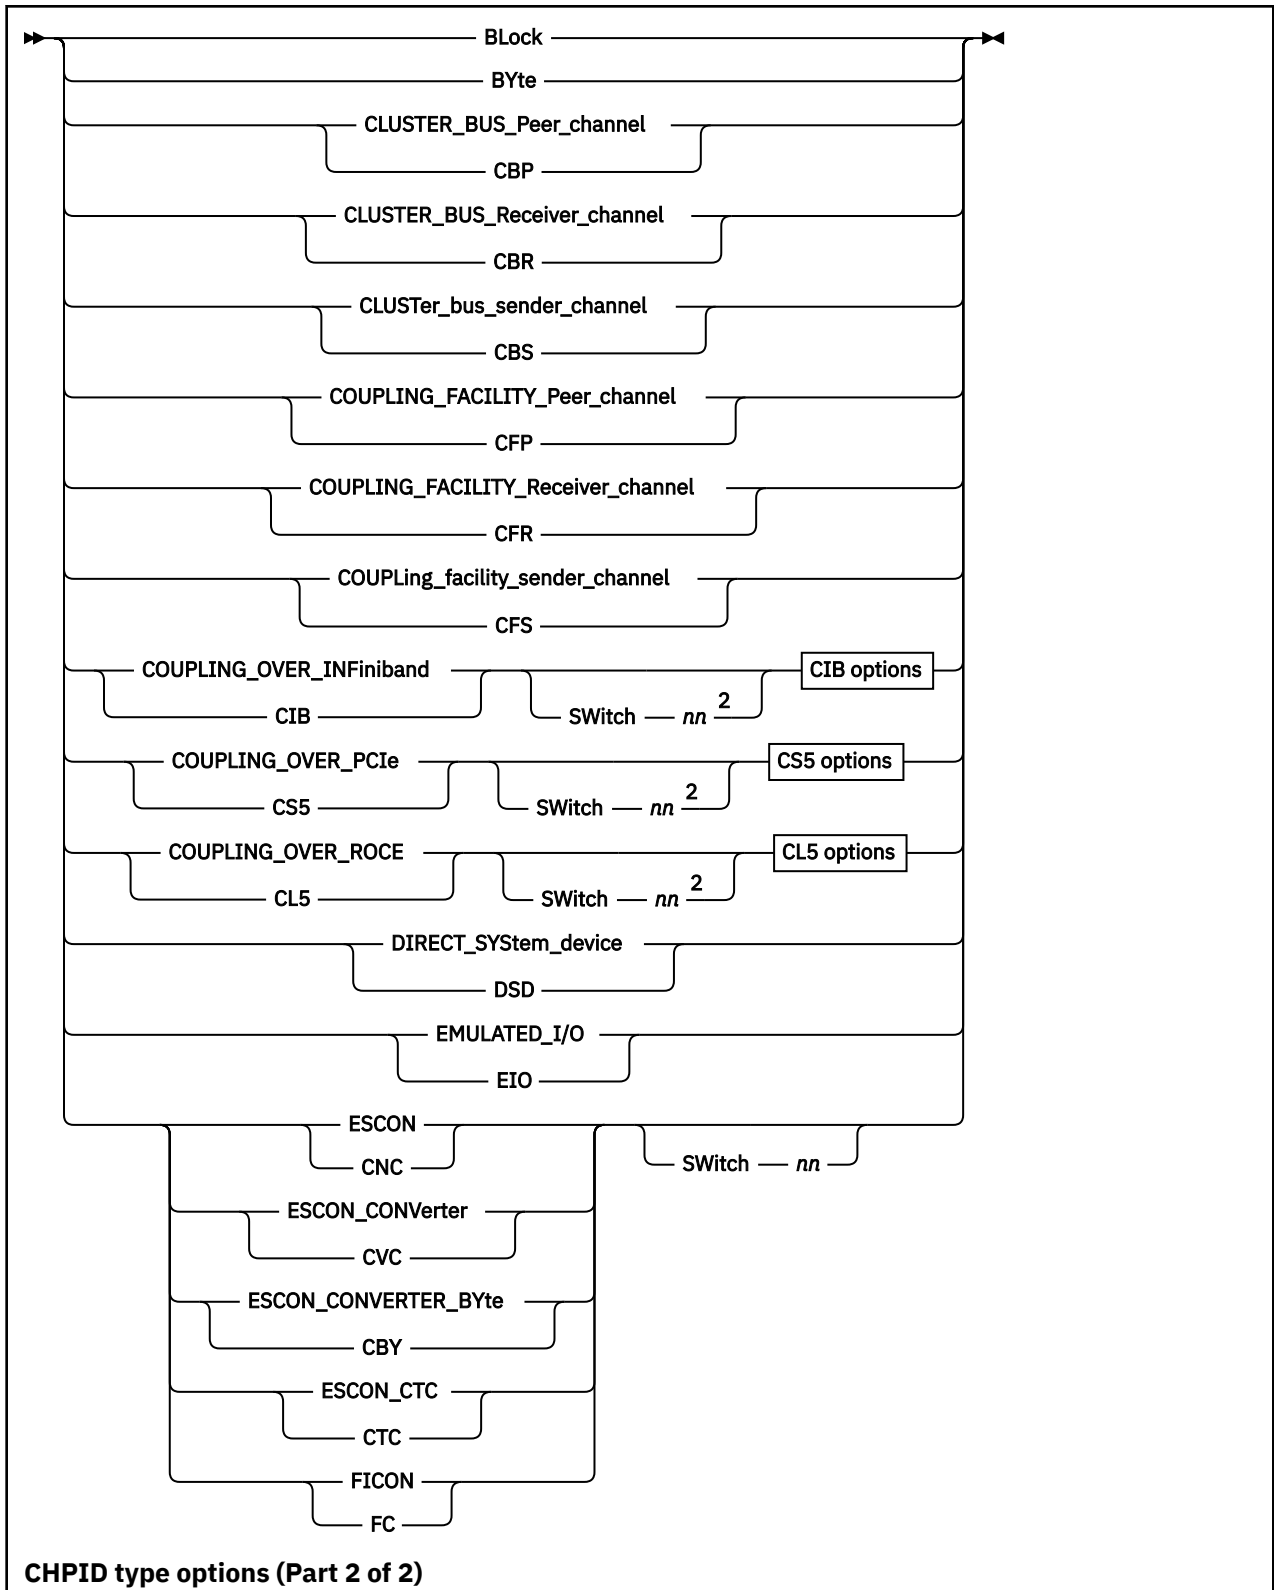

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

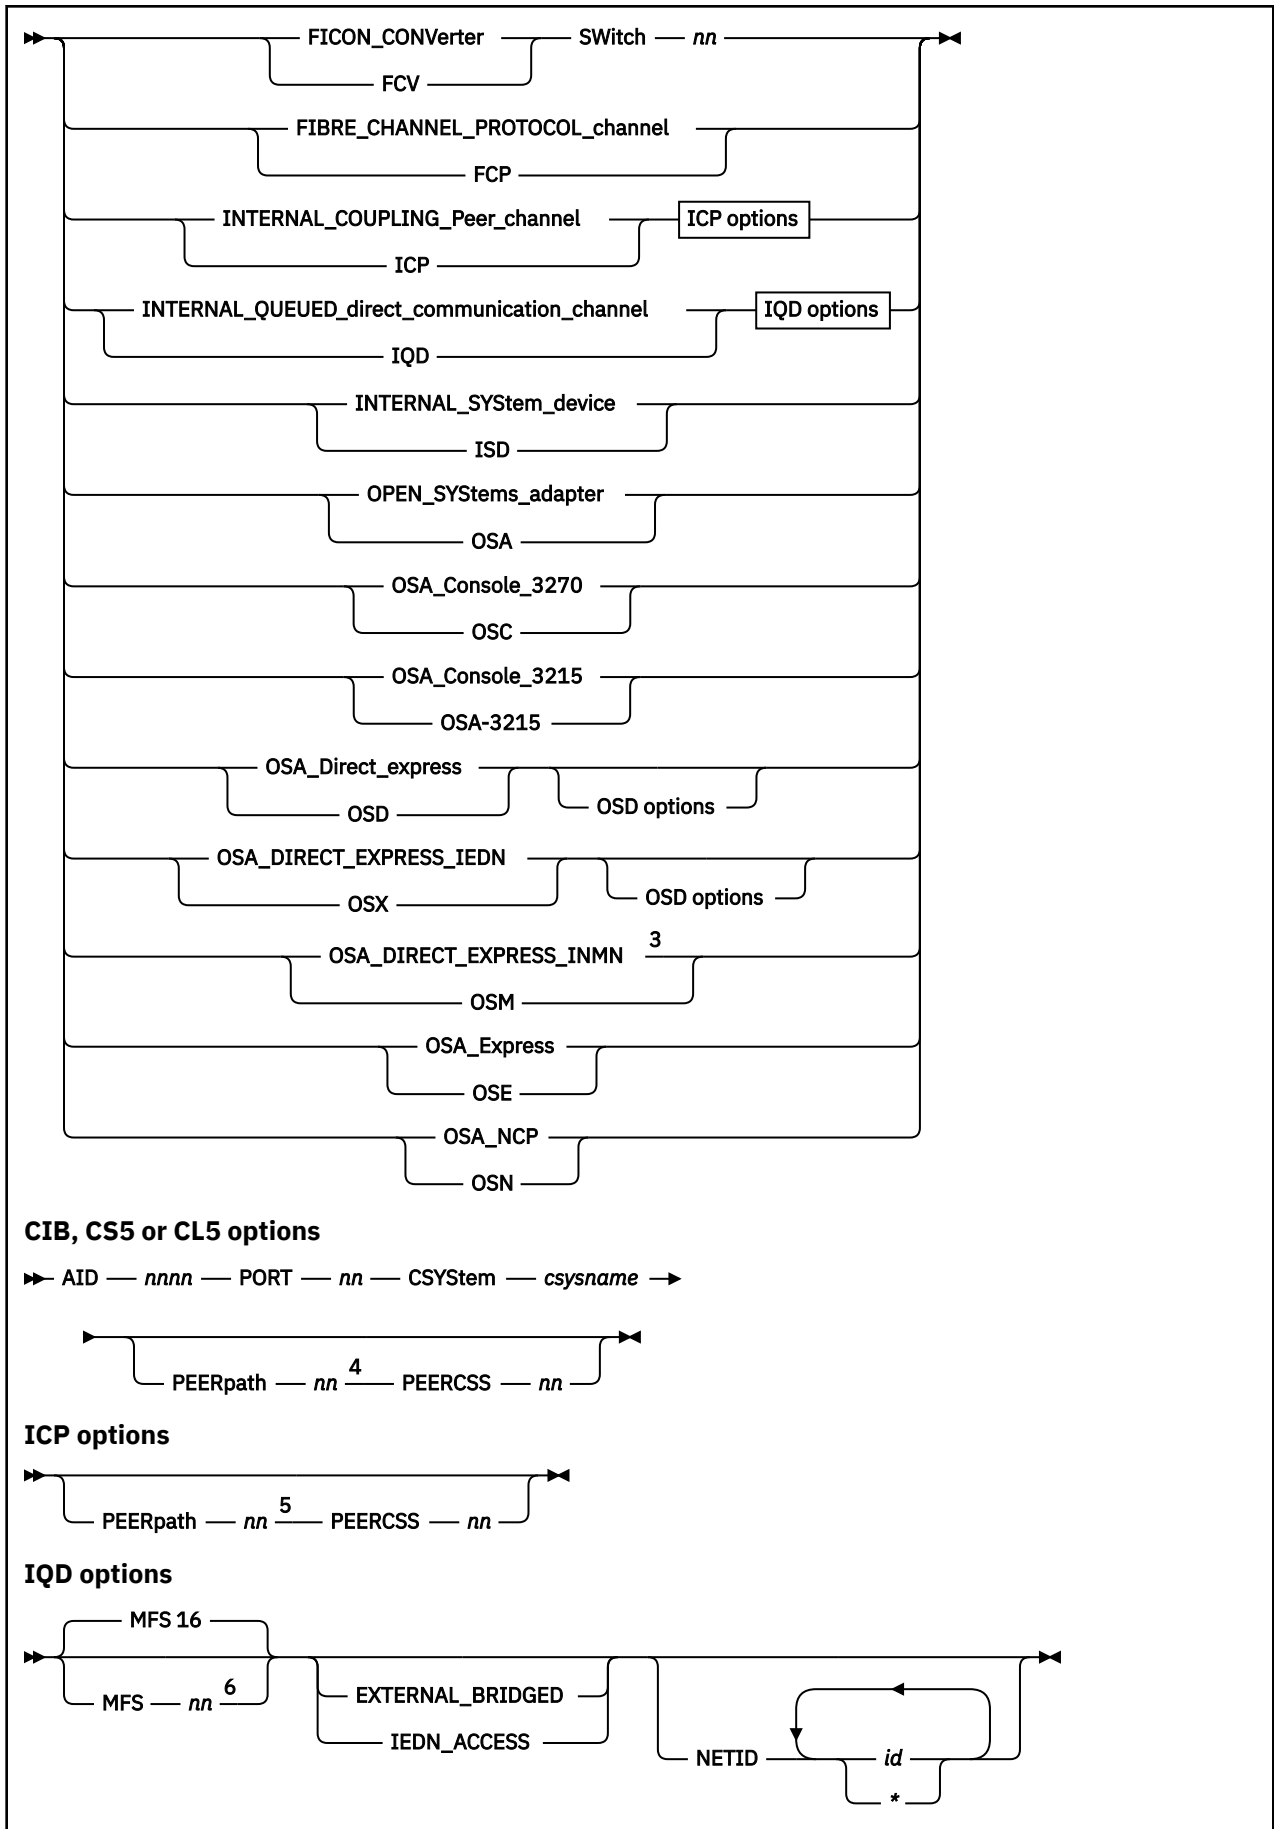

Messages:

- HCP002E Invalid operand — *operand*

## DEFINE CHPID / PATH

**OSD options**

**Configuration and management options**

**Case 1**

**Case 2**

**Case 3**

**Case 4**

**Pname(s)**

**Notes:**

- 1 This operand is required for some CHPID types. See explanation below.
- 2 This parameter is ignored for point-to-point links.
- 3 Priority queuing is always disabled for the Open Systems Adapter Direct Express INMN (OSM) channel paths.
- 4 You must specify this parameter when *csysname* specifies a name other than this system's name or when defining the second path of a pair of connected CIB, CS5 or CL5 paths.
- 5 You must specify this parameter when defining the second path of a pair of connected ICP paths.
- 6 The maximum frame size (MFS) for an IQD path must be a value of 16, 24, 40 or 64 kilobytes.
- 7 This operand is valid only for CBP, CBS, CFP, CFS, CIB, CNC, CS5, CL5, CTC, DSD, EIO, FC, FCP, FCV, ICP, IQD, ISD, OSA, OSC, OSD, OSE, OSM, OSN, and OSX channel paths.
- 8 This operand is valid only for CNC, FC, or FCV switched channel paths.
- 9 The maximum number of logical partition names you can specify depends on the capabilities of your machine.

**Authorization**

Privilege Class: B

## Purpose

Use DEFINE CHPID or PATH to define a new channel path identifier (CHPID) to the I/O configuration.

## Operands

### *nn*

is the number representing the logical channel path (CHPID) that you are defining. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

### **PCHID *nnnn***

is the physical channel ID associated with the channel you are defining. The variable *nnnn* must be a 1- to 4-digit hexadecimal number between X'0000' and X'FFFF'. Your machine likely supports a lower maximum value. Only PCHIDs that are physically installed on your machine should be entered.

**Note:** This parameter is valid and required only when your machine supports multiple logical channel subsystems. However, this parameter does not apply to InfiniBand host communication adapters (HCAs) or to internal channel-path type of INTERNAL\_COUPLING\_PEER\_CHANNELS (ICP) because there are no physical channel paths associated with them. Unlike ICP channels, this parameter is required when INTERNAL\_QUEUED\_DIRECT\_COMMUNICATION\_CHANNELS (IQD) CHPIDs are being defined to specify a virtual channel identifier on machines that support them.

### **CSS *nn***

is the channel-subsystem ID where the channel path is to be defined. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'. Your machine might support a lower maximum value. See Usage Note [“10” on page 141](#).

**Note:** This parameter and other parameters that identify different channel-subsystem IDs require that the logical channel-subsystem facility be installed.

### **TYPe**

introduces the channel type, defined by the immediately following parameter.

### **BLock**

tells CP that this is a parallel multiplexor channel that interleaves blocks of data.

### **BYte**

tells CP that this is a parallel multiplexor channel that interleaves bytes of data.

### **CLUSTER\_BUS\_Peer\_channel**

#### **CBP**

tells CP that this is a cluster bus peer channel path.

### **CLUSTER\_BUS\_Receiver\_channel**

#### **CBR**

tells CP that this is a cluster bus receiver channel path.

### **CLUSTER\_bus\_sender\_channel**

#### **CBS**

tells CP that this is a cluster bus sender channel path that connects to a cluster bus receiver channel path.

### **COUPLING\_FACILITY\_Peer\_channel**

#### **CFP**

tells CP that this is a coupling facility peer channel path.

### **COUPLING\_FACILITY\_Receiver\_channel**

#### **CFR**

tells CP that this is a coupling facility receiver channel path.

### **COUPLing\_facility\_sender\_channel**

#### **CFS**

tells CP that this is a coupling facility sender channel path that connects to a coupling facility receiver channel path.

**COUPLING\_OVER\_INFiniband****CIB**

tells CP that this is a coupling over InfiniBand channel path.

**COUPLING\_OVER\_PCIE****CS5**

tells CP that this is a coupling over PCIe channel path.

**COUPLING\_OVER\_ROCE****CL5**

tells CP that this is a coupling over RoCE channel path.

**AID *nnnn***

is the adapter identifier of an InfiniBand host communication adapter (HCA) through which a CIB, CS5 or CL5 channel path is defined. The variable *nnnn* must be a 1- to 4-digit hexadecimal number between X'0000' and X'FFFF'. Your machine might support a lower maximum value. Only adapter identifiers for adapters that are physically installed on your machine should be entered.

**PORT *nn***

is the port number on an InfiniBand host communication adapter (HCA) where a CIB, CS5 or CL5 channel path is defined. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'. Your adapter might support a lower maximum value. Only port numbers for ports that are physically installed on your adapter should be entered.

**CSYSstem *csysname***

is the name of the target system to which a CIB, CS5 or CL5 CHPID connects. It is the name you would see after issuing the QUERY LSYSTEM command in a z/VM system running on that target machine. The name is established via an IOCP configuration definition, HCD configuration definition (in z/OS or z/VM), or the z/VM SET LSYSTEM operator command on the target machine. The variable *csysname* must be a 1- to 8-character string.

**DIRECT\_SYStem\_device****DSD**

tells CP that this is a channel path to a direct system device.

**EMULATED\_I/O****EIO**

tells CP that this is an emulated I/O channel path.

**ESCON****CNC**

tells CP that this channel uses the Enterprise Systems Connection (ESCON) channel to control unit I/O interface to transmit data through optical cables.

**ESCON\_CONVerter****CVC**

tells CP that this is an ESCON channel that attaches to an ESCON converter in block mode.

**ESCON\_CONVERTER\_BYte****CBY**

tells CP that this is an ESCON channel that attaches to an ESCON converter in byte mode.

**ESCON\_CTC****CTC**

tells CP that this ESCON channel path provides channel-to-channel adapter communications.

**FICON****FC**

tells CP that this channel uses the Fibre Connection (FICON) channel to control unit interface to transmit data through optical cables.

**FICON\_CONVerter****FCV**

tells CP that this is a FICON channel that attaches to an ESCON Director with a FICON Bridge card.

**SWitch *nn***

is a number identifying the ESCON or FICON switch to which the channel paths you are defining are connected. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

**FIBRE\_CHANNEL\_PROTOCOL\_channel****FCP**

tells CP that this is a SCSI fibre channel protocol (FCP) path.

**INTERNAL\_COUPLING\_Peer\_channel****ICP**

tells CP that this is an internal coupling peer channel path.

**PEERpath *nn***

is the "peer channel path", the number representing the channel-path identifier (CHPID) as known in another machine, or central processing complex (CPC), to which the channel path being defined is connected. The second-to-be-defined path of a pair of connected ICP or CIB paths must specify this parameter. This parameter must also be specified for a CIB path whenever the *csysname* parameter specifies a CPC name other than the name of the system where this command is being executed. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

**Note:** If you mistakenly define two connected ICP or CIB paths without defining their association with this parameter, you must delete one of the paths and then redefine it using this parameter.

**PEERCSS *nn***

identifies the channel subsystem where the "peer channel path" is defined. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'. Your machine might support a lower maximum value.

**INTERNAL\_QUEUED\_direct\_communication\_channel****IQD**

tells CP that this is an internal-queued-direct-communication channel. When this channel type is selected, the PCHID operand is also required to be specified to indicate a virtual channel ID on machines that support them.

**MFS *nn***

is the maximum frame size (in kilobytes) to be used by the internal-queued-direct-communication channel being defined. If an MFS value is not specified, the default value of 16 will be used. If an MFS value is specified, the variable *nn* must be a 2-digit decimal number with a value of 16, 24, 40, or 64.

**EXTERNAL\_BRIDGED**

identifies that the specified CHPID can be bridged to a z/VM virtual switch.

**IEDN\_ACCESS**

identifies a single IQD CHPID as a CHPID that is managed by the Unified Resource Manager. When IEDN\_ACCESS is specified, EXTERNAL\_BRIDGED is assumed.

**INTERNAL\_SYSTEM\_device****ISD**

tells CP that this is a channel path to an internal system device.

**OPEN\_SYSTEMS\_adapter****OSA**

tells CP that this is an Open Systems Adapter (OSA) channel path.

**Note:** When defining OSA channels, you should remain in configuration mode while defining the channel path, control unit, and device. If you exit configuration mode before issuing these three DEFINE commands, CP will not add this OSA device to your I/O configuration. For details see the *Planning for the System/390 Open Systems Adapter Feature* book, GC23-3870.

**OSA\_Console\_3270****OSC**

tells CP that this is an OSA Integrated Console Controller (OSA-ICC) channel path (also known as an OSA 3270 console channel path).

**OSA\_Console\_3215****OSA-3215**

dynamically defines an OSC (OSA 3270 console) CHPID for use as a 3215 console.

**OSA\_Direct\_express****OSD**

tells CP that this is an Open Systems Adapter Direct Express (OSD) channel path.

**OSA\_DIRECT\_EXPRESS\_IEDN****OSX**

tells CP that this is an Open Systems Adapter Direct Express IEDN (OSX) channel path.

**PQ\_ON****PQ\_OFF**

tells CP whether or not outbound priority queuing as supported by the QDIO interface is to be used. If PQ\_OFF is specified, then priority queuing is disabled. By not exploiting this function for an OSD channel, the channel can support four (4) times as many queues. For details, refer to Usage Note “11” on page 141. When the option is unspecified, the default is PQ\_ON, which enables priority queuing.

**NETID id****NETID \***

is the network identifier associated with a port of the OSD or IQD channel. A maximum of four network ID's can be specified. The order of the network IDs corresponds to the order of the ports of the channel. An asterisk '\*' can be used as a placeholder that indicates that there is not a network ID associated with a particular port. Each *id* must be a 1- to 16-digit character string.

**OSA\_DIRECT\_EXPRESS\_INMN****OSM**

tells CP that this is an Open Systems Adapter Direct Express INMN (OSM) channel path.

**OSA\_Express****OSE**

tells CP that this is an Open Systems Adapter Express (OSE) channel path.

**OSA\_NCP****OSN**

tells CP that this is an Open Systems Adapter NCP (OSN) channel path.

**DEDICATED\_NOT\_REConfigurable**

tells CP that this is an unshared channel path which can only be configured or deconfigured to the logical partition specified on the ACCESS\_LIST operand.

**DEDICATED\_REConfigurable**

tells CP that this is an unshared channel path which can only be configured to one of the logical partitions specified on the ACCESS\_LIST operand at a time. Later, you can use the MODIFY CHPID or PATH command to reconfigure this channel path to one of the other logical partitions specified on the ACCESS\_LIST operand.

**SHARED**

tells CP that this is a shared channel path which can be concurrently configured to any or all of the logical partitions specified on the ACCESS\_LIST operand. Only the partitions specified in the access list will have access to the defined CHPID. Multiple logical partitions can have initial access to the channel path at device initialization.

**Note:** This operand is valid only for CBP, CBS, CFP, CFS, CIB, CL5, CNC, CS5, CTC, DSD, EIO, FC, FCP, FCV, ICP, IQD, ISD, OSA, OSC, OSD, OSE, OSM, OSN, and OSX channel paths.

**ACCess\_list pname**

specifies the name(s) of the logical partition(s) in which the channel path can be configured in the specified or implied channel-subsystem image. The maximum number of logical partition names you can specify depends on the capabilities of your machine. Each *pname* must be a 1- to 8-digit character alphanumeric string. See Usage Note “1” on page 140 for more information on the maximum number of logical partitions you can specify.

**INITIAL\_access pname**

specifies the name(s) of the logical partition(s) that will have initial access to this channel path in the specified or implied channel-subsystem image. Each pname must be a 1- to 8-digit character alphanumeric string. See Usage Note “1” on page 140 for more information on the maximum number of logical partitions you can specify.

**MANaged**

indicates that the channel path being defined is to be managed by one or more z/OS systems in other logical partitions comprising an I/O cluster. A managed channel path is shared among all logical partitions having access to it, but none have initial access. z/OS dynamically reassigns the channel path within the I/O cluster according to the workload demands within the cluster.

**Note:** This operand is valid only for CNC, FC, or FCV switched channel paths.

**IOcluster iocname**

is the name of the I/O cluster to which the managed channel path is assigned. The variable *iocname* must be a 1- to 8-character alphanumeric string.

**Note:** This operand is valid only for EMIF-capable machines.

**Usage Notes**

1. Specifying Logical Partition Numbers:

- a. When you specify DEDICATED\_NOT\_RECONFIGURABLE, DEDICATED\_RECONFIGURABLE, or SHARED, you must specify at least one logical partition name for ACCESS\_LIST, and you can optionally choose to specify logical partition names for INITIAL\_ACCESS. How many logical partition names you can specify depends upon which operand you choose and the capabilities of your machine; see Table 12 on page 140.

<i>Table 12. Maximum Number of Logical Partition Names</i>		
<b>Operand</b>	<b>ACCESS_LIST</b>	<b>INITIAL_ACCESS</b>
DEDICATED_NOT_RECONFIGURABLE	1	1
DEDICATED_RECONFIGURABLE	MAX	1
SHARED	MAX	MAX

- b. The number of logical partitions that you specify for ACCESS\_LIST must always be greater than or equal to the number of logical partitions you specify for INITIAL\_ACCESS, because the INITIAL\_ACCESS logical partition names are a subset of the ACCESS\_LIST logical partition names. If you specify a logical partition name for INITIAL\_ACCESS, you must also specify that same logical partition name in the ACCESS\_LIST list.

2. Devices attached to your system communicate with the system through control units and channel paths. Thus, before you dynamically define a new device to your system, you must first dynamically define one or more control units for that device (if they do not already exist) and one or more channel paths (if they do not already exist).

If you need to physically define any channel paths, control units, or devices, use the following commands in the following order:

- a. To define channel paths, use the DEFINE CHPID or PATH command.
- b. To define control units, use the DEFINE CU or CNTLUNIT command. (See “DEFINE CU / CNTLUNIT” on page 161.)
- c. To define devices, use the DEFINE DEVICE or IODEVICE command. (See “DEFINE DEVICE / IODEVICE” on page 167.)

If you do not define the channel paths, control units, and devices correctly and in the proper order, CP will issue appropriate error messages.

3. After successfully entering this command, you will have changed the software's view of the I/O configuration and part of the hardware's view: the I/O configuration in the hardware system area

(HSA). You should also change the other part of the hardware's view: the active I/O configuration data set (IOCDS) file on the support element (SE) hard disk.

To change the IOCDS file on the SE hard disk, you must:

- a. Update the IOCP source file.
  - b. Run the IOCP utility (see [“IOCP” on page 2203](#)) against the updated IOCP file. If the IOCP utility runs without errors, it downloads the new IOCDS file to the SE hard disk.
  - c. Issue the SET IOCDS\_ACTIVE command (see [“SET IOCDS\\_ACTIVE” on page 1525](#)) to make the new IOCDS file the active file that the machine will use during the next power-on reset (POR).
4. For more information about defining channel paths in your I/O configuration, see [z/VM: I/O Configuration](#).
  5. To delete an existing channel path ID on the system, use the DELETE CHPID or PATH command. (See [“DELETE CHPID / PATH” on page 259](#).)
  6. To change the definition of an existing reconfigurable channel path ID on the system, use the MODIFY CHPID or PATH command. (See [“MODIFY CHPID / PATH” on page 679](#).) There is no MODIFY command to change the definitions of the other types of channel paths. If you need to change their definitions, you must:
    - a. Delete the existing channel path definition, using the DELETE CHPID or PATH command.
    - b. Redefine the channel path definition, using the DEFINE CHPID or PATH command.
  7. To display the status of a specific logical channel path and the devices with that logical channel path installed, or to display the type of a specific logical channel path, use the QUERY CHPID command. (See [“QUERY CHPID” on page 791](#).)
  8. To display the physical status of all of CP's defined channel paths, use the QUERY CHPIDS command. (See [“QUERY CHPIDS” on page 796](#).)
- Note:** If the channel path is in single channel service (SCS) mode, it will appear as "not configured" in the display.
9. To display the logical and physical status of the channel paths installed on one or more devices, use the QUERY PATHS command. (See [“QUERY PATHS” on page 1064](#).)
  10. On a machine with multiple logical channel-subsystem images, the DEFINE PATH and DEFINE CHPID commands define the channel path in the single specified channel-subsystem image. If the channel path is a type that can span multiple logical channel-subsystem images, then MODIFY PATH or MODIFY CHPID commands must be entered for each additional channel-subsystem image in which you want to define the channel path.
  11. When defining an OSD channel or an OSX channel, the user has the option of specifying whether or not to use the outbound priority queuing function supported by the QDIO interface. This option is similar to the CHPARM keyword on the IOCP CHPID statement for these types. If the option is exploited (PQ\_ON), then the maximum number of subchannels allowed on the defined OSD or OSX channel will be offset by the number of outbound priority queues. Since 3 subchannels are necessary per TCP/IP stack, 480 subchannels will yield a total of 160 stacks. 160 is the default maximum number of stacks with PQ\_ON.

Configurations that require many virtual machines to share the same OSD or OSX CHPID might need more than the default limit. When it is anticipated that more than 160 TCP/IP stacks will be required for a single OSD or OSX CHPID, then the PQ\_OFF option should be specified. By disabling the priority queues, the maximum number of subchannels increases to 1920. This allows 640 TCP/IP stacks to be supported per OSD or OSX CHPID. It should be noted that disabling priority queues may impact the performance of non-z/VM TCP/IP stacks and some z/VM virtual switch configurations that may be sharing subchannels on the OSD or OSX CHPID. This is because priority queues will no longer be available for their use. The z/VM TCP/IP stack does not make use of priority queues.

A CHPID defined for use by a z/VM Type IVL virtual switch must be configured with PQ\_ON to insure IVL network stability and availability. The IVL virtual switch exploits OSA-Express features priority queuing capabilities to insure IVL management transmissions are delivered to the IVL network ahead of any error recovery production traffic. In addition, a z/VM Type QDIO virtual switch can optionally

## DEFINE CHPID / PATH

exploit priority queuing by turning PRIQueuing ON. If you are planning on exploiting priority queuing on a z/VM virtual switch, then PQ\_ON must be specified.

**Note:** The outbound priority queuing function is always disabled (PQ\_OFF) for OSM channel paths.

### Responses

Response 1:

To define a switched ESCON channel path, enter the following:

```
define chpid 9 type escon switch 1
Channel path configuration change completed successfully
Ready;
```

Response 2:

To define a dedicated-reconfigurable FICON channel path, enter the following:

```
define chpid 1f type ficon dedicated_rec acc vm1 vm3 vm5 init vm1
Channel path configuration change completed successfully
Ready;
```

Response 3:

To define a shared channel path to an open systems adapter, enter the following:

```
define chpid 09 type osa shared access_list boston initial boston
Channel path configuration change completed successfully
Please remember to define a control unit and devices for an OSA
channel path
Ready;
```

Note that CP issues an extra message for OSA devices, because you should define the associated OSA control units and devices before leaving configuration mode.

Response 4:

To define a shared FICON channel path in a channel-subsystem image, enter the following:

```
def chpid 43 pchid 81 css 2 type ficon shared acc vm1 vm2 vm3 init vm1
Channel path configuration change completed successfully
Ready;
```

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE COMMAND / CMD

### Authorization

Privilege Class: A

### Purpose

Use DEFINE COMMAND or DEFINE CMD to define a new CP command or a new version (by IBM class) of an existing CP command on the system.

You can also define a new CP command during initialization using the DEFINE COMMAND or DEFINE CMD configuration file statements. For more information, see [DEFINE COMMAND / CMD Statement in z/VM: CP Planning and Administration](#).

### Operands

#### **command**

is the name of the command that you are defining. The variable *command* is a 1- to 12-character string.

#### **Query SUBCmd *subcommand***

tells CP the name of the CP QUERY subcommand that you are defining. The variable *subcommand* is a 1- to 12-character string.

#### **Query Virtual SUBCmd *subcommand***

tells CP the name of the CP QUERY VIRTUAL subcommand that you are defining. The variable *subcommand* is a 1- to 12-character string.

### **Set SUBCmd *subcommand***

tells CP the name of the CP SET subcommand that you are defining. The variable *subcommand* is a 1- to 12-character string.

### **ABBRlength *nn***

is the length of the smallest acceptable abbreviation of the command or subcommand that you are defining. The variable *nn* is a decimal number between 1 and the length of the full command or subcommand name.

### **AFTer\_logon**

tells CP that the command version you are defining will only be issued by users after they log onto the system. Most CP commands fall into this category. The default is AFTER\_LOGON.

### **BEFore\_logon**

tells CP that the command you are defining will only be issued by users before they log onto the system. For example, the CP DIAL command can only be used before logon.

**Note:** If you specify BEFORE\_LOGON, you must specify PRIVCLASSANY because CP cannot check privilege classes before a user logs on. Thus, you cannot specify BEFORE\_LOGON with the PRIVCLASSES or IBMCLASS operands.

### **ANYTime**

tells CP that the command version you are defining can be issued by users both before and after they log onto the system. For example, many systems let users issue the CP MESSAGE or MSG commands before and after logon.

**Note:** If you specify ANYTIME, you must specify PRIVCLASSANY because CP cannot check privilege classes before a user logs on. Thus, you cannot specify ANYTIME with the PRIVCLASSES or IBMCLASS operands.

### **AUDIT**

tells the external security manager (ESM) to audit the command that you are defining. When you audit a command, the ESM logs each attempt by users to issue this command.

### **DISAble**

tells CP not to call the entry points and external symbols associated with this CP command until you enable it. (For more information about enabling CP commands, see Usage Note [“4”](#) on page 146.) If omitted, DISABLE is the default.

### **ENable**

tells CP to immediately start calling the entry points and external symbols associated with this CP command.

### **EPName *name***

tells CP the name of the entry point that contains the code to process the command. The variable *name* must be a 1- to 8-character string. The first character must be alphabetic or one of the following special characters: dollar sign (\$), number sign (#), underscore (\_), or at sign (@). The rest of the string can be alphanumeric characters, the 4 special characters (\$, #, \_, and @), or any combination thereof.

**Note:** If you are defining a new command, you must specify EPNAME. If you are defining a new version of an existing command, specifying EPNAME is optional. This is because CP only allows one entry point per command, regardless of how many versions that command has. So, when you define a new version of an existing command, CP already knows the entry point name.

The QUERY and SET commands are the only exceptions, because they have subcommands. Note that CP only allows one entry point per subcommand, regardless of how many versions that subcommand has.

### **MAC**

tells CP to enable mandatory access control (MAC) for the command that you are defining. When MAC is enabled for your command, the external security manager (ESM) compares the security label of the user who issued your command to the security label of the resource or user that your command will affect. If you want the ESM to dynamically turn MAC on or off for this command, specify the VMAC operand.

**PRIVCLASSANY**

tells CP that users with any privilege class can issue the command that you are defining.

**PRIVclasses classes**

tells CP that only users with 1 or more of the specified privilege classes can issue the command that you are defining. The variable *classes* is 1 or more privilege classes in the range A through Z, 1 through 6, or an asterisk (\*). Privilege class \* indicates all privilege classes (A-Z and 1-6).

**Note:**

1. If you want more than one privilege class, specify your classes in one string of characters. Do not separate the classes with blank spaces. For example, specify "privclasses abc123", not "privclasses a b c 1 2 3".
2. If you specify PRIVCLASSES, you must also specify IBMCLASS. You can specify these 2 operands in any order.

**IBMclass c**

tells CP what type of command you are defining. The variable *c* can be any 1 of the following:

**A**

this is a system-control command to be used by the primary system operator.

**B**

this is a command for operational control of real devices.

**C**

this is a command to alter system storage.

**D**

this is a command for system-wide control of spool files.

**E**

this is a command to examine system storage.

**F**

this is a command for service control of real devices.

**G**

this is a general-use command used to control the functions of a virtual machine.

**Note:** If you specify IBMCLASS, you must also specify PRIVCLASSES. You can specify these 2 operands in any order.

**PROC**

tells CP that, after performing the initial privilege class checks, your command processor will be responsible for any further calls to the external security manager (ESM) for the command that you are defining.

**PROT**

tells the external security manager (ESM) to protect the command that you are defining. When protection is enabled for your command, the ESM checks an access list to ensure that the user who issued your command is authorized to do so. If you want the ESM to dynamically turn protection on or off for your command, specify the VPROT operand.

**SILENTly**

tells CP that the responses from the command you are defining can be suppressed by invoking it using the SILENTLY command. For more information, see [“SILENTLY” on page 1798](#).

**Note:** Response suppression is supported only for the ATTACH, DETACH, and GIVE commands.

**VMAC**

gives the external security manager (ESM) the power to dynamically turn mandatory access control (MAC) on or off. If you specify MAC and VMAC for this command, you are enabling MAC and allowing the external security manager (ESM) to dynamically disable MAC. If you specify VMAC and you do not specify MAC for this command, you are disabling MAC and allowing the ESM to dynamically enable MAC.

CP places no restriction on the use of special characters such as \*, %, comma, (, ), blank, /, :, \$, #, and @ in command names. However, some External Security Managers (ESMs) restrict their use. Please consult your ESM documentation for information on restricted characters.

11. If you try to define a minimum abbreviation that matches the abbreviation for an existing command, subcommand, or alias, CP rejects your DEFINE command. For example, if you created a "QUEUE" command with a minimum abbreviation of 2, CP would reject your QUEUE command because "QU" is an abbreviation for the QUERY command. In this case, you would need to specify a minimum abbreviation greater than or equal to 4 because the first 3 characters of QUERY and QUEUE are identical.
12. Once defined, commands, subcommands, aliases, and Diagnose codes cannot be deleted. They may be altered in various appropriate ways, but they remain in existence until a SHUTDOWN or RESTART IPL is done.
13. MODIFY COMMAND RESET will not allow a RESET to occur if the resulting command versions would have different EPNAMEs. This can occur if you change the EPNAME for a command then add a new version for that command. To avoid this restriction, you should add new versions of a command before changing the EPNAMEs associated with the command.
14. The DEFINE COMMAND or DEFINE DIAGNOSE commands should not be used on a system with an active External Security Manager (ESM); unpredictable results could occur. To safely define a CP command add the DEFINE COMMAND or DEFINE DIAGNOSE statement to the SYSTEM CONFIG file and re-IPL the system. This allows the command and diagnose additions to control structures to be made prior to activating the ESM.
15. For more information about user-defined commands, see [z/VM: CP Exit Customization](#).

## Responses

Response 1:

To define a new command, TELL, with:

- 3 versions:
  - Privilege class A, IBM class A, issued after logon
  - Privilege class B, IBM class B, issued after logon
  - Any privilege class, no IBM class, issued before and after logon,
- No minimum abbreviation, and
- The same entry point and syntax as the CP MESSAGE command,

enter the following:

```
define cmd tell epname hcpxmngms ibmclass a privclasses a
Ready;
define command tell ibmclass b privclasses b
Ready;
define command tell anytime privclassany
Ready;
```

**Important Note:** Normally, it is not a good practice to define a CP command that has the same name as a command, exec, or function belonging to another z/VM subsystem. (This newly-defined command will interfere with the CMS TELL command.) However, in this case, we thought we would show you an example of how to create a "synonym" for a common CMS command that could be used by novice z/VM users when they accidentally drop out of their CMS session into CP.

Response 2:

To define 2 new commands, CONTINUE and RESUME, which behave like the CP BEGIN command, enter the following:

```
define cmd continue abbr 4 epname hcpcmcbe ibmclass g priv g
Ready;
```

## DEFINE COMMAND / CMD

```
define command resume epname hcpcmcbe ibmclass g priv g  
Ready;
```

In this example, the CONTINUE and RESUME commands:

- Have the same entry point and syntax as the CP BEGIN command,
- Are IBM class G,
- Are privilege class G, and
- Can only be issued after logon.

Additionally, the CONTINUE command has a minimum abbreviation of 4 (CONT) and the RESUME command has no minimum abbreviation.

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE CONSOLE

### Authorization

Privilege Class: G

### Purpose

Use DEFINE CONSOLE to add a system console to your virtual machine configuration.

### Operands

*vdev*

**AS** *vdev*

identifies the virtual device number of the console you are defining.

**3215**

**3270**

identifies the virtual console device type. Type 3215 is the default.

### Usage Notes

1. If a terminal is controlled by a VTAM service machine with a level lower than 3.1.1., the console cannot be defined as a 3270. If you attempt to do so, the console is defined as a 3215, and an error message is displayed.
2. Only one virtual console is permitted. You receive an error message if you already have a virtual console defined.
3. The default spool file class given to spool files created on the virtual console is class T.
4. Any time you enter the DEFINE CONSOLE command, you define the console mode for your display. This becomes the console mode for the duration of the session or until you reenter DEFINE CONSOLE or enter TERMINAL CONMODE. For more information on the console mode setting and its significance to the programs that you run in your virtual machine, see [“TERMINAL CONMODE” on page 1928](#).
5. For additional information, see [“Usage Notes” on page 122](#).

### Responses

Response 1:

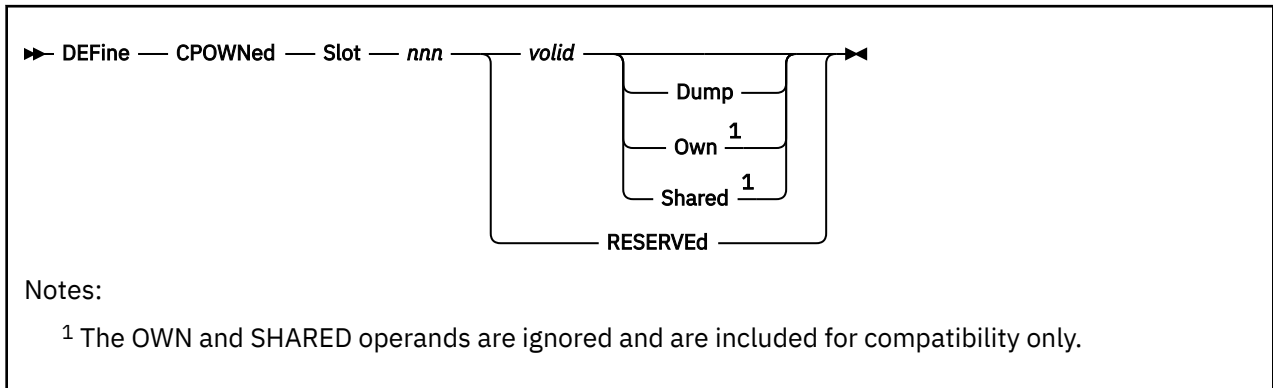

```
CONSOLE vdev DEFINED
```

confirms the virtual console definition.

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE CPOWNEDED

### Authorization

Privilege Class: A

### Purpose

Use DEFINE CPOWNEDED to define new entries or to change existing entries in the list of CP-owned DASD volumes. You can also use the CP\_OWNED statement in the system configuration file to modify the CP-owned volume list. For more information on the CP\_OWNED statement, see the *z/VM: CP Planning and Administration* book.

### Operands

#### Slot *nnn*

specifies the number of the slot in the CP-owned volume list that you are defining or changing. The number *nnn* cannot exceed the number of slots available in the CP-owned volume list. You can use the QUERY CPOWNEDED command to find the number of slots that were defined at IPL time. For more information on the QUERY CPOWNEDED command, see [“QUERY CPOWNEDED”](#) on page 834.

#### *valid*

specifies the volume to add to the CP-owned volume list. You cannot specify the same volume identifier in more than one slot in the CP-owned volume list.

#### Dump

tells CP to reserve the spool space on the specified volume exclusively for dumps.

#### Own

is ignored and is included for compatibility only. In an SSI cluster, volume ownership is determined by the ownership information recorded on the volume.

#### Shared

is ignored and is included for compatibility only. In an SSI cluster, volume ownership is determined by the ownership information recorded on the volume.

#### RESERVED

tells CP to disassociate the slot from a specific volume and make it available for allocation.

### Usage Notes

1. Unless the system configuration has been updated, all definitions from the DEFINE CPOWNEDED commands will be lost at the next system initialization. Always consider updating the system configuration file before issuing the DEFINE CPOWNEDED commands.
2. Use the QUERY CPOWNEDED command to display the CP-owned volume list and the number of available slots. For more information, see [“QUERY CPOWNEDED”](#) on page 834.

3. You cannot replace an existing entry in the CP-owned volume list if the volume being replaced has not been detached from the system. For more information, see the DETACH (Real Device) command.
4. A volume can be defined as a CP-owned volume only if it is not currently attached to SYSTEM.
5. A slot may not be changed to reserved status unless the volume associated with the slot is not attached to the system.
6. In an SSI cluster, when a volume with SPOOL extents is defined as CP-owned on a member of the cluster and the ATTACH command is issued, the attach process will automatically attach the volume to the other active members where the device is online and not already attached. Also, if the volume is not in the CP-owned list on another active member where the device is being attached, the attach process will automatically add the volume to the CP-owned list on that member.
7. See *z/VM: CP Planning and Administration* for information on allocating space for CP hardabend dumps including recommendations from IBM.

## Responses

Response 1:

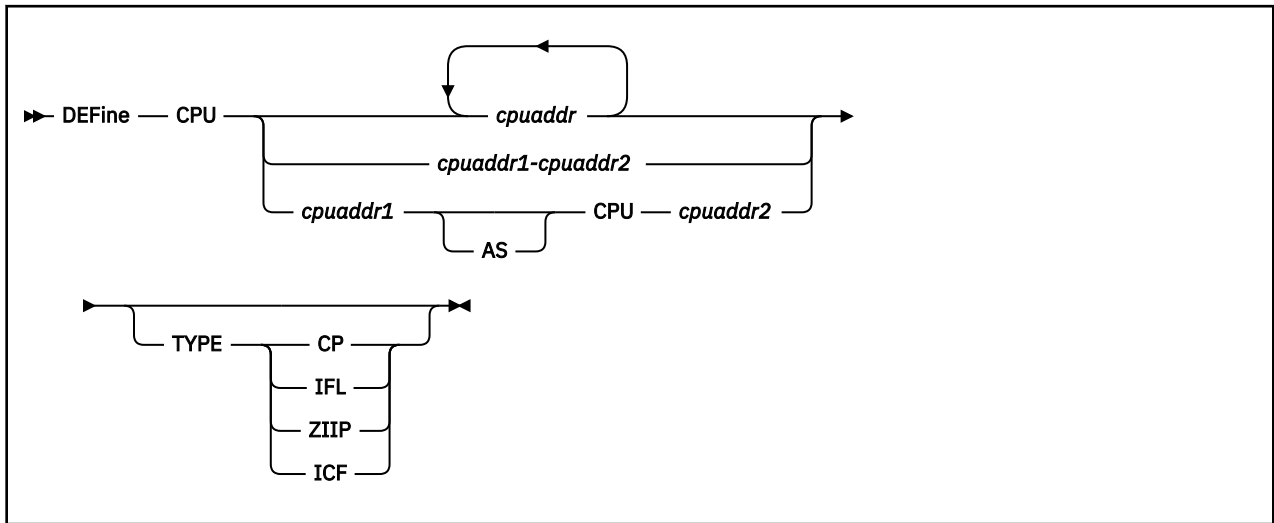

To add the shared volume ESAPG1 to the CP-owned DASD volume list in the empty slot 10, enter:

```
define cowned slot 10 esapg1 shared
Ready;
```

## Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE CPU

### Authorization

Privilege Class: G

### Purpose

Use DEFINE CPU to do the following:

- Add one or more processors to your virtual machine
- Change the address of a defined virtual processor.
- Change the type of a defined virtual processor.

### Operands

#### **cpuaddr**

defines a virtual processor for your virtual machine configuration at the address you specify for *cpuaddr*. You can specify multiple addresses in a list or in range form. If you specify a list of addresses, separate each address from the others by at least one blank. If you specify a range of addresses, specify the first and last addresses in the range and put a hyphen between them. The processor addresses can be any value from 0 to 3F; the initial address of your base processor is specified in your system directory entry, or it defaults to 0.

#### **cpuaddr cpuaddr**

identifies a list of addresses or ranges delimited by blanks.

#### **cpuaddr1-cpuaddr2**

specifies a nonwrapping pair of addresses separated by a hyphen (-) and not separated by any blanks.

#### **cpuaddr1 AS CPU cpuaddr2**

changes the address of the processor currently defined at *cpuaddr1* to the address *cpuaddr2*.

#### **TYPE**

specifies the type of virtual CPU being defined. If no type is specified when defining a new CPU, it defaults to the type of the primary virtual CPU.

If no type is specified when redefining an existing virtual CPU (for example, changing the CPU address), the type of the virtual CPU does not change. Each command to define or redefine virtual CPU(s) must result in a valid virtual CPU configuration. Valid types are:

#### **CP**

indicates the central processor.

**IFL**

indicates the IBM Integrated Facility for Linux.

**ZIIP**

indicates the IBM z Integrated Information Processor.

**ICF**

indicates the Internal Coupling Facility.

Valid virtual configurations are shown in the tables below:

*Table 13. ESA/390 or General Logical Partition*

Primary Real CPU Type	VCONFIG Mode	Primary Virtual CPU Type	Valid Virtual CPU Types
CP	ESA390, GENERAL ***	CP	CP, zIIP **
CP	CF *	CP	CP
CP	LINUX	IFL	IFL
CP	LINUX	CP	CP
CP	VM	CP	CP, zIIP, IFL, ICF **

*Table 14. LINUX Only Logical Partition*

Primary Real CPU Type	VCONFIG Mode	Primary Virtual CPU Type	Valid Virtual CPU Types
CP	LINUX	CP	CP
CP	LINUX	IFL	IFL
IFL	LINUX	IFL	IFL

*Table 15. z/VM Logical Partition*

Primary Real CPU Type	VCONFIG Mode	Primary Virtual CPU Type	Valid Virtual CPU Types
CP	ESA390, GENERAL ***	CP	CP, zIIP **
CP	CF *	ICF	ICF
CP	LINUX	IFL	IFL
CP	LINUX	CP	CP
CP	VM	CP	CP, zIIP, IFL, ICF **

where: \* indicates OPTION CFVM was specified in the user directory entry

\*\* indicates that zIIPs are supported as secondary virtual CPU types as long as they are supported on the underlying machine model

\*\*\* VCONFIG modes ESA390 and GENERAL are functionally equivalent, which means that the same virtual CPU types can be defined in an ESA390 mode virtual machine and in a GENERAL mode virtual machine

**Usage Notes**

1. Your system directory entry specifies the maximum number of processors you can define for your virtual machine.

## DEFINE CPU

2. If your system directory entry contains multiple CPU statements and/or DEFINE CPU commands (on directory COMMAND statements) that specify a virtual multiprocessing configuration, that configuration is created for you at logon time. If your directory entry does not specify additional processors, your virtual machine logs on as a uniprocessor. Once logged on, you can use DEFINE CPU to modify your virtual configuration.
3. Any CPUs defined with the CPU statement in your directory entry will default to the same type as your primary real processor.
4. The following actions will result in a System Clear:
  - Changing the type of an existing CPU.
  - Changing the address of a CPU in a multi-CPU-type virtual configuration.
5. Each DEFINE CPU command must result in a valid virtual CPU configuration. Because of this, the order of multiple DEFINE CPU commands is important.
6. To make changes to a virtual configuration, including changing virtual CPU types and the virtual configuration mode, the best approach is to:
  - a. Issue the DEFINE CPU command to change all CPU types to CP.
  - b. Issue the SET VCONFIG MODE command to change the virtual configuration mode.
  - c. Issue the DEFINE CPU command to change the CPU types to the desired types.
7. The virtual configuration mode of a Coupling Facility virtual machine cannot be changed.
8. All future CP responses are prefaced with the number of the CPU that issues the responses. This continues as long as you have the virtual multiprocessor configuration.
9. A user that is assigned to a resource pool cannot change the CPU type of its base CPU because the base CPU defines the user's primary CPU type, and the primary CPU type must match the CPU type being limited by the resource pool. These CPU types matched when the user was put into the resource pool and must continue to do so. As long as the user's logical configuration remains valid, a user assigned to a resource pool can define additional CPUs or change the type of the non-base CPUs. The QUERY VIRTUAL CPUS command can be used to determine the user's base CPU number and type.
10. For additional information, see ["Usage Notes" on page 122](#).

## Responses

Response 1:

```
xx: CPU nn DEFINED
```

confirms that the processor has been defined.

Response 2:

```
xx: CPU nn REDEFINED AS TYPE yyyy
```

confirms that the processor has been redefined to a new type.

**xx**

identifies the number of the CPU responding to you.

**nn**

identifies the number of the CPU currently defined or redefined.

**yyyy**

identifies the type of the redefined CPU.

Response 3:

```
xx: STORAGE CLEARED - SYSTEM RESET
```

indicates that a system-reset-clear has been performed.

## Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

Messages:

- HCP5780E Adjunct does not support the DEFINE CPU command
- HCP6849E DEFINE CPU cannot change the CPU type of the base CPU for a userid in a resource pool

## DEFINE CPUPOOL

---

### **Purpose**

DEFINE CPUPOOL has been superseded by DEFINE RESPOOL. See [“DEFINE RESPOOL” on page 205](#).

## DEFINE CRYPTO

►► DEFine — CRYPTo — APVIRTual ◄◄

### Authorization

Privilege Class: G

### Purpose

Use DEFINE CRYPTO APVIRTUAL command to create a virtualized crypto resource through which the virtual machine can use the system's pool of shared crypto resources.

### Usage Notes

1. The DEFINE CRYPTO APVIRTUAL command requires a virtual machine to be enabled to access the shared crypto resources. A CRYPTO APVIRTUAL directory statement must be included in the directory entry of the virtual machine requesting shared use of crypto resources.
2. The DEFINE CRYPTO APVIRTUAL command allows a general user to regain access to the system's shared crypto resources after the virtual resource has been detached.
3. Use the DETACH CRYPTO APVIRTUAL command to remove a virtual machine's access to the system's shared crypto resources.
4. If DEFINE CRYPTO APVIRTUAL is issued when there are no crypto resources in the shared pool, the virtual machine will still be given access to the system's shared crypto resources if they become available.
5. For information on planning and managing crypto resources on a z/VM system, see [Crypto Planning and Management in z/VM: CP Planning and Administration](#).

### Responses

Response 1:

The following is the response if there are resources in the shared crypto pool.

```
Crypto APVIRTUAL defined
```

Response 2:

The following is the response if there are no resources in the shared crypto pool.

```
Crypto APVIRTUAL defined, however, there are
currently no shared AP crypto resources available.
```

### Messages

## DEFINE CRYPTO

- HCP1745E Crypto APVIRTUAL cannot be defined because you do not have authorization to access shared crypto resource on this system.
- HCP1746E Crypto APVIRTUAL cannot be defined because you already have access to dedicated crypto resources.

## DEFINE CTCA

### Authorization

Privilege Class: G

### Purpose

Use DEFINE CHANNEL-TO-CHANNEL ADAPTER (CTCA) to define a CTCA for your virtual machine configuration.

### Operands

#### CTCa

indicates you are defining a channel-to-channel adapter for your virtual machine.

#### 3088

indicates you are defining a channel-to-channel adapter for your virtual machine to emulate a 3088 device.

#### SCTC

indicates you are defining a channel-to-channel adapter for your virtual machine to emulate an ESCON CTCA in Standard mode.

#### BCTC

indicates you are defining a channel-to-channel adapter for your virtual machine to emulate an ESCON CTCA in Basic mode.

#### CNC

indicates you are defining a channel-to-channel adapter for your virtual machine to emulate an ESCON CTCA with no controller (the CNC device must be coupled to an SCTC or BCTC adapter to be fully functional).

#### FCTC

indicates you are defining a channel-to-channel adapter for your virtual machine to emulate a FICON CTCA.

#### *vdev*

#### **AS** *vdev*

identifies the virtual device number of the CTCA you are defining.

#### *userid*

#### **USER** *userid*

identifies the user that you will permit to connect to this CTCA using the COUPLE command. If you do not specify *userid*, you are not restricting any user ID from connecting.

#### \*

can be used to specify your own user ID.

### Usage Notes

1. For general usage notes for the DEFINE COMMAND, see [“Usage Notes” on page 122](#).

### Responses

Response 1:

```
CTCA vdev DEFINED
```

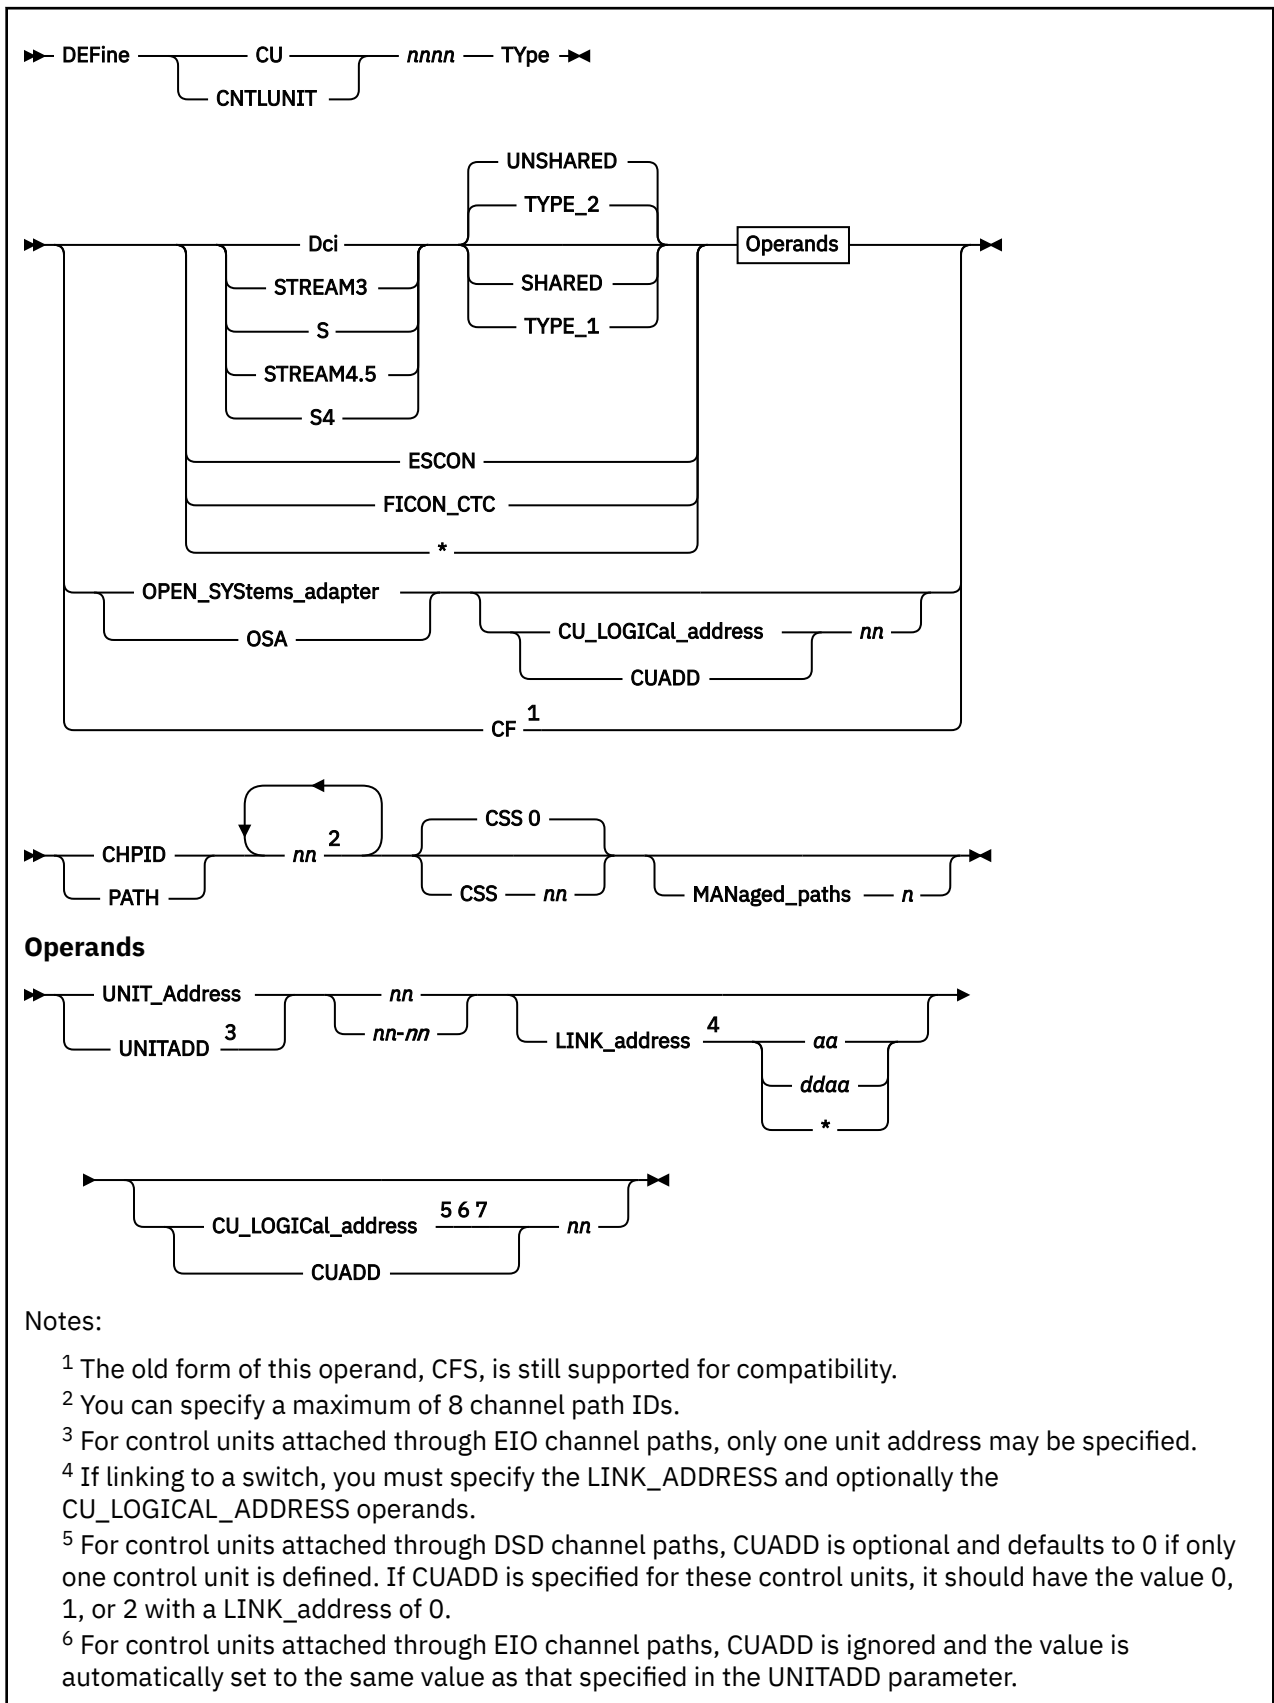

confirms the definition of the virtual channel-to-channel adapter.

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE CU / CNTLUNIT

<sup>7</sup> For FICON CTCs on a shared channel path, the CUADD parameter specifies the MIF-ID number of the destination partition; that is, the remote end of the CTC connection for the control unit being defined. Use the QUERY LPAR command to find the MIF-ID for the LPAR. A control unit must be defined for each destination partition on the shared channel path. For FICON CTCs on non-shared channel paths, the destination partition is implicit in the channel-path definition and should not be specified here.

## Authorization

Privilege Class: B

## Purpose

Use DEFINE CU or CNTLUNIT to define a new control unit to the I/O configuration.

**Note:** DEFINE CU and DEFINE CNTLUNIT are dynamic I/O commands. Dynamic I/O configuration is only supported on IBM Z servers. If your system is not running on one of these servers, your command will not complete successfully.

## Operands

### *nnnn*

is the number of the control unit that you are defining. The variable *nnnn* must be a 1- to 4-digit hexadecimal number between X'0000' and X'FFFE'.

### **T**Ype

is the control unit type. Valid types are:

### **D**ci

tells CP that this control unit uses the directed-coupled interlock (DCI) protocol. DCI protocol is a method of data transfer up to 1.5 megabytes per second. DCI protocol requires the sender to raise a signal on the interface along with the byte of data being transferred. The signal and data must be maintained until the receiver acknowledges receipt of the data.

### **S**TREAM3

#### **S**

tells CP that this control unit uses a method of data transfer up to 3 megabytes per second. This protocol does not interlock data streaming between sender and receiver. Once the data transfer begins, the sender does not wait for acknowledgment from the receiver before sending the next byte of data. The control unit determines the actual data transfer rate.

### **S**TREAM4.5

#### **S**4

tells CP that this control unit uses a method of data transfer up to 4.5 megabytes per second. This protocol does not interlock data streaming between sender and receiver. Once the data transfer begins, the sender does not wait for acknowledgment from the receiver before sending the next byte of data. The control unit determines the actual data transfer rate.

### **U**NSHARED

#### **T**YPE\_2

tells CP that this control unit supports concurrent multiple I/O requests. This means that this control unit is synonymous with a Type 2 control unit.

### **S**HARED

#### **T**YPE\_1

tells CP that this control unit only supports one I/O request at a time. This means that this control unit is synonymous with a Type 1 control unit.

**ESCON**

tells CP that this control unit uses the Enterprise Systems Connection (ESCON) channel to control unit I/O interface to transmit data through optical cables. Also specify this operand for control units attached through direct-system-device (DSD), emulated-I/O (EIO), FICON converter (FCV) or internal-system-device (ISD) channel paths.

**FICON\_CTC**

tells CP that the control unit is a channel-to-channel (CTC) adapter on a FICON channel path. At least one of the two sides of a FICON CTC connection must have a FICON CTC control unit defined. If a FICON CTC control unit is defined on both sides (which is recommended), the two connected channels determine which side acts as the control unit at any given time. For a FICON CTC control-unit definition to be effective, the FICON CTC facility must be installed in the host with the control-unit definition

**\***

indicates that the correct TYPe will be chosen automatically. Automatic selection applies to control units attached through DSD, EIO, CNC, CVC, CBY, CTC, FC, FCP, FCV, IQD, ISD, OSC, or OSN channel paths.

**OPEN\_SYSTEMS\_adapter****OSA**

tells CP that this control unit connects to an Open Systems Adapter (OSA), OSA Direct Express (OSD), OSA-Express (OSE), OSA Direct Express IEDN (OSX), or OSA Direct Express INMN (OSM) channel path.

**Notes:**

1. Before you have a working OSA configuration, you should define the channel paths, the device, and the control unit. See the *Planning for the System/390 Open Systems Adapter Feature GC23-3890*.
2. Only 1 CU per OSA CHPID per logical partition is allowed.

**CF**

tells CP that this control unit connects to coupling facility channel paths. Coupling facility channel paths include coupling facility sender (CFS), coupling facility receiver (CFR), coupling facility peer (CFP), cluster bus sender (CBS), cluster bus receiver (CBR), cluster bus peer (CBP), or internal coupling peer (ICP) channel paths.

**UNIT\_Address nn****UNIT\_Address nn-nn****UNITADD nn****UNITADD nn-nn**

is the last 2 digits of a device address or number (or a range of addresses or numbers). Each *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

**LINK\_address aa****LINK\_address ddaa****LINK\_address \***

Each link-address value you specify identifies a port on a destination switch (ESCON or FICON director) to which the control unit is connected.

The LINK\_address operand must be specified when one or more of the channel paths to the control unit are switched paths; that is, when any of the paths traverse an ESCON or FICON director and for an ESCON director the path through the director is not dedicated. When all of the channel paths are unswitched (including dedicated paths through an ESCON director), the LINK\_address operand is optional.

For an unswitched FICON channel path, the end nodes determine the link addresses used at each end. Thus you cannot specify a numeric link address to be used. If you specify a LINK\_address operand value for an unswitched FICON channel path (for example, because other paths to the control unit are switched and a "placeholder" value is required), you must specify an asterisk (\*) as the link-address value.

When any link addresses are required to be specified (for example, when one or more of the channel paths is a switched path), you must provide a link address for each channel-path identifier (PATH or CHPID) that you specified, in the same order. When no link addresses are required to be specified

(i.e., when all of the channel paths are unswitched paths), the link address for each ESCON channel path is determined by the hardware processor, and the link address for each FICON channel path is negotiated between the hardware endpoints.

The link address is a one or two digit hexadecimal value for control units connected to an ESCON channel. The link address is a one, two, three, or four digit hexadecimal value for control units connected to a FICON channel. Leading zeroes can be omitted, except that an actual *dd* value of zero (see below) must be specified with at least one digit.

**aa**

is the one-byte port-area address in an ESCON or FICON director to which the control unit is connected. This address must be a one or two digit hexadecimal number between X'01' and X'FE' for ESCON directors, and between X'00' and X'FF' for FICON directors.

Link addresses for channel paths having dedicated (unswitched) connections through an ESCON director can be arbitrary within the above-specified range, but it is recommended that the actual port-area address be used.

**ddaa**

is the first two bytes of a standard three-byte fibre-channel port address. The third byte of a standard port address is used for fibre-channel arbitrated loops, which are not supported for FICON channels and therefore you do not specify. This two-byte form of the link address is required when the channel path is a FICON channel path that traverses more than one FICON director to reach any of the channel-path's destination control units.

This means that if the channel path traverses more than one FICON director to reach this control unit, a two-byte link address is required. In addition, if the channel path traverses only one FICON director to reach this control unit, but the same channel path traverses more than one FICON director to reach some other control unit, a two-byte link address is required for that channel path in all control-unit definitions in which the channel path appears. That is, once a two-byte link address is required for any control unit on a channel path, a two-byte link address is required for all control units on that channel path.

**dd**

is the switch address (or domain identifier) of the destination FICON director (for example, the switch to which the control unit is directly connected), and *aa* is the port-area address within that FICON director. The link address must be a three to four digit hexadecimal number between X'0000' and X'FFFF'.

One-byte and two-byte link addresses can be mixed within the LINK\_address operand, according to the requirements for each channel path. You can choose to use a two byte link address when only a one byte address is required as long as the FICON director is configured with the high-integrity attributes (see the *IOCP User's Guide* for more information).

**CU\_LOGICAL\_address nn**

**CUADD**

is the logical address of the control unit that you are defining. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FE'. If omitted, the default is X'00'.

For control units attached through DSD channel paths, CUADD is optional and defaults to 0 if only one control unit is defined. If CUADD is specified for these control units, it should have the value 0, 1, or 2 with a LINK\_address of 0.

For control units attached through EIO channel paths, CUADD is ignored and the value is automatically set to the same value as that specified in the UNITADD parameter.

For control units attached through CNC, CTC, FCV, or IQD channel paths, the variable *nn* must be a 1 to 2-digit hexadecimal number between X'00' and X'0F'.

**CHPID nn**

**PATH nn**

is the value that uniquely identifies the path from this control unit to the system. You can specify up to 8 channel path IDs (CHPIDs). Each *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'. All channel paths must be in the same channel-subsystem image. .

**Note:** You cannot specify managed channel paths.

### CSS *nn*

is the channel-subsystem ID of the specified channel paths. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'.

**Note:** This parameter and other parameters that identify different channel-subsystem IDs require the logical channel-subsystem facility to be installed.

### MANaged\_paths *n*

is the maximum number of managed channel paths that can be attached to the specified control unit. The variable *n* must be a 1-digit decimal number from 1 to 7.

**Note:** The actual managed paths cannot be specified in the control-unit definition; only the maximum number of managed channel paths can be specified. The managed paths will be associated with specific control units automatically by z/OS's dynamic-channel-path-management function. When a maximum number of managed paths is specified, the channel paths named in the CHPID/PATH operand must all be shared and of the type CNC, FC, or FCV. Also, the number of paths specified with the CHPID/PATH operand when added to the maximum number of managed paths specified cannot exceed 8.

## Usage Notes

1. Devices attached to your system communicate with the system through control units and channel paths. Thus, before you dynamically define a new device to your system, you must first dynamically define one or more control units for that device (if they do not already exist) and one or more channel paths (if they do not already exist).

If you need to physically define any channel paths, control units, or devices, use the following commands in the following order:

- a. To define channel paths, use the DEFINE CHPID or PATH command. (See [“DEFINE CHPID / PATH”](#) on page 132.)
- b. To define control units, use the DEFINE CU or CNTLUNIT command.
- c. To define devices, use the DEFINE DEVICE or IODEVICE command. (See [“DEFINE DEVICE / IODEVICE”](#) on page 167.)

If you do not define the channel paths, control units, and devices correctly and in the proper order, CP will issue appropriate error messages.

2. After successfully entering this command, you will have changed the software's view of the I/O configuration and part of the hardware's view: the active I/O configuration in the hardware system area (HSA). You should also change the other part of the hardware's view: the active I/O configuration data set (IOCDS) file on the support element (SE) hard disk.

To change the IOCDS file on the SE hard disk, you must:

- a. Update the IOCP source file.
- b. Run the IOCP utility against the updated IOCP file. If the IOCP utility runs without errors, it downloads the new IOCDS file to the SE hard disk.
- c. Issue the SET IOCDS\_ACTIVE command to make the new IOCDS file the active file that the processor will use during the next power-on reset (POR).

For more information, see [“IOCP”](#) on page 2203 and [“SET IOCDS\\_ACTIVE”](#) on page 1525.

3. For more information about defining control units in your I/O configuration, see [z/VM: I/O Configuration](#).
4. To change the definition of an existing control unit on the system, use the MODIFY CU or CNTLUNIT command. (See [“MODIFY CU / CNTLUNIT”](#) on page 688.)
5. To delete an existing control unit on the system, use the DELETE CU or CNTLUNIT command. (See [“DELETE CU / CNTLUNIT”](#) on page 263.)

6. On a machine with multiple logical channel-subsystem images, the DEFINE CU and DEFINE CNTLUNIT commands define the control unit on channel paths within the single specified channel-subsystem image. If the control unit is connected to channel paths in more than one channel-subsystem image, then MODIFY CU or MODIFY CNTLUNIT commands must be entered to define the control unit's connections to each group of channel paths in the additional channel-subsystem images.

### Responses

Response 1:

To define an Open Systems Adapter (OSA) control unit, enter the following:

```
def cu 1210 type OSA chpid 42
Control unit configuration change completed successfully
Ready;
```

Response 2:

To define an ESCON control unit, enter the following:

```
def cu 900 type escon unit_addr 0-1f link_addr f cu_logic 9 chpid 9
Control unit configuration change completed successfully
Ready;
```

Response 3:

To define a FICON control unit to a channel-subsystem image, enter the following:

```
def cu 4343 type * unitadd 81 chpid 7 9 42 css 1
Control unit configuration change completed successfully
Ready;
```

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE DEVICE / IODEVICE

**Partitions**

►► PARTition — *pname* <sup>1</sup>►►

Notes:

<sup>1</sup> The maximum number of logical partition names you can specify depends on the capabilities of your machine.

**Authorization**

Privilege Class: B

**Purpose**

Use DEFINE DEVICE or IODEVICE to define one or more new real devices to the I/O configuration.

**Operands**

*rdev*

*rdev1-rdev2*

is the real device number (or range of real device numbers) of the device that you are defining to CP. Each *rdev* must be a 1- to 4-digit hexadecimal number between X'0000' and X'FFFF'.

**UNIT\_Address *nn***

**UNITADD *nn***

is the last 2 digits of a device address or number. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

**Note:** If you are specifying a range of devices (*rdev1-rdev2*), the unit address that you specify is the starting address associated with the first device in the range.

**TType CF**

tells CP that the specified devices are attached to a control unit that connects to coupling facility channel paths. Coupling facility channel paths include coupling facility sender (CFS), coupling facility receiver (CFR), coupling facility peer (CFP), cluster bus sender (CBS), cluster bus receiver (CBR), cluster bus peer (CBP), or internal coupling peer (ICP) channel paths.

**CU\_number *nnnn***

**CUNUMBR *nnnn***

is the number of the control unit associated with the device that you are defining. You can specify up to 8 control unit numbers. Each *nnnn* must be a 1- to 4-digit hexadecimal number between X'0000' and X'FFFE'.

**CSS *nn***

is a channel-subsystem ID previously defined for one or more channel paths to the specified control unit. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'.

**Note:** This parameter and other parameters that identify different channel-subsystem IDs require that the logical channel-subsystem facility be installed.

**SS *nn***

is the subchannel set with which this device is associated. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'03'.

**Note:** This parameter requires that the multiple-subchannel-set facility be installed.

**UNIT 3745**

tells CP that this device is a simulated 3745 device.

**UNIT OSN**

tells CP that this device is an OSA NCP device.

**Note:** When UNIT 3745 or UNIT OSN is specified, the corresponding unit-address values must be in the range from X'00' to X'FE'.

**CTCa EXTended**

tells CP that this device is an extended mode channel-to-channel adapter (CTCA).

**CTCa BASic**

tells CP that this device is a basic mode channel-to-channel adapter (CTCA).

**NOTDASD**

tells CP that this device is not a direct access storage device (DASD).

**DASD**

tells CP that this device is a direct access storage device (DASD).

**NOPREferred\_channel\_path**

tells CP that there is no preferred channel path.

**PREFerred\_channel\_path *nn***

tells CP to use this channel path to initiate I/O requests before trying any other channel paths from the device that you are defining. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

**Note:** A preferred path must not be specified for a device connected to a control unit for which z/OS-managed paths are being used. Although the command will not prevent you from doing so, the use of preferred paths in a managed-path environment will adversely affect z/OS's ability to manage channel-path workloads.

**NOSTATus\_verification**

tells CP that the status verification facility is not active for this device, and so the channel subsystem will not check the device's status.

**STATus\_verification**

tells CP that the status verification facility is active for this device, causing the channel subsystem to check the device's status every time this device announces its status.

**NOTIME\_Out**

tells CP that the I/O interface time out function is not active. This parameter should not be specified if the device is being defined on a CHPID with TYPE=BYTE.

**TIME\_Out**

tells CP that the I/O interface time out function is active for the following I/O interfaces between the channel and I/O device:

- 4 second time out for initial selection
- 30 second time out for data transfer.

**SENSEd**

tells CP to use the information returned from a sense ID request to determine the device class or type at device initialization.

**NOTSENSEd**

tells CP not to use the information returned from a sense ID request to determine the device class or type at device initialization.

**PARTition *pname***

specifies the name(s) of the logical partition(s) which will have access to the device(s) being defined in the specified or implied channel-subsystem image. The maximum number of logical partition names you can specify depends on the capabilities of your processor. Each *pname* must be a 1- to 8-character alphanumeric string.

**Note:** When defining CTC devices, only specify a PARTition list that includes partitions in which they will be used. If "extra" partitions are specified, then the CTC subchannels defined for those extra partitions unnecessarily use Hardware System Area (HSA) storage.

## Usage Notes

1. Devices attached to your system communicate with the system through control units and channel paths. Thus, before you dynamically define a new device to your system, you must first dynamically define one or more control units for that device (if they do not already exist) and one or more channel paths (if they do not already exist).

If you need to physically define any channel paths, control units, or devices, use the following commands in the following order:

- a. To define channel paths, use the DEFINE CHPID or PATH command. (See [“DEFINE CHPID / PATH” on page 132.](#))
- b. To define control units, use the DEFINE CU or CNTLUNIT command. (See [“DEFINE CU / CNTLUNIT” on page 161.](#))
- c. To define devices, use the DEFINE DEVICE or IODEVICE command.

If you do not define the channel paths, control units, and devices correctly and in the proper order, CP will issue appropriate error messages.

2. Before you add a new device to the system, you should decide whether you want CP to immediately initialize that device. If CP initializes a new device when you add it to the system, you can begin using that device immediately. If CP does not initialize the new device, you must vary the device online using the VARY (real device) command (see [“VARY \(Real Device\)” on page 2063](#)) before anyone can use that device.
3. To display whether CP initializes new real devices as they are added to a running system, use the QUERY NEW\_DEVICES command. (See [“QUERY NEW\\_DEVICES” on page 1033.](#))
4. To define or change the way CP initializes new real devices as they are added to a running system:
  - During initialization, use the ENABLE or DISABLE NEW\_DEVICES\_INITIALIZED\_WHEN\_ADDED operands of the FEATURES statement in your system configuration file. For more information, see [FEATURES Statement](#) in *z/VM: CP Planning and Administration*.
  - After initialization, use the SET NEW\_DEVICES command. (See [“SET NEW\\_DEVICES” on page 1581.](#))
5. To change whether CP uses the sense ID information at device initialization, use the SENSED or NOTSENSED operands of the SET DEVICES command. (See [“SET DEVICES” on page 1490.](#))
6. After successfully entering this command, you will have changed the software's view of the I/O configuration and part of the hardware's view: the active I/O configuration in the hardware system area (HSA). You should also change the other part of the hardware's view: the active I/O configuration data set (IOCDS) file on the support element (SE) hard disk.

To change the IOCDS file on the SE hard disk, you must:

- a. Update the IOCP source file.
- b. Run the IOCP utility against the updated IOCP file. If the IOCP utility runs without errors, it downloads the new IOCDS file to the SE hard disk.
- c. Issue the SET IOCDS\_ACTIVE command to make the new IOCDS file the active file that the processor will use during the next power-on reset (POR).

For more information, see [“IOCP” on page 2203](#) and [“SET IOCDS\\_ACTIVE” on page 1525.](#)

## Responses

Response 1:

To define 16 real DASDs in two logical partitions with a preferred channel path, enter the following:

```
def dev 300-30f unit_addr 0 cu 300 dasd preferred 3 par vm1 vm5
Device configuration change completed successfully
Ready;
```

Response 2:

To define 16 real DASDs in two logical partitions in a channel-subsystem image, enter the following:

```
def dev 4300-430F unitadd 80 cu 8100 css 3 dasd par vm1 vm2
Device configuration change completed successfully
Ready;
```

Response 3:

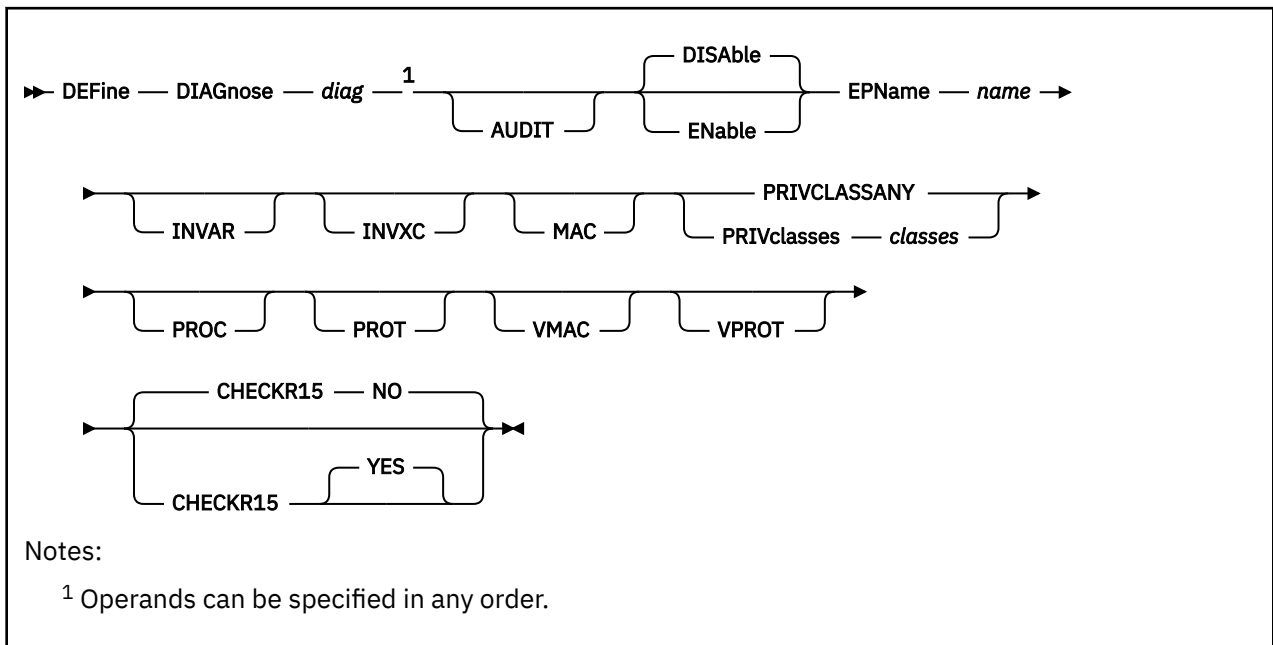

To define 16 real DASDs in two logical partitions in a channel-subsystem image and subchannel set, enter the following:

```
def dev 8180-818F unitadd 80 cu 8100 css 3 ss 1 dasd par vm1 vm2
Device configuration change completed successfully
Ready;
```

## Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE DIAGNOSE

### Authorization

Privilege Class: A

### Purpose

Use DEFINE DIAGNOSE to define a new DIAGNOSE code on the system.

You can also define a new DIAGNOSE code during initialization using the DEFINE DIAGNOSE configuration file statement. For more information, see [DEFINE DIAGNOSE Statement in z/VM: CP Planning and Administration](#).

### Operands

#### *diag*

is the number of the DIAGNOSE code that you are defining. The variable *diag* is a hexadecimal number between X'0' and X'3FC' and must be a multiple of 4. The recommended variable range is a value between X'100' and X'1FC' because that is the range of diagnose codes reserved for customer use. All other DIAGNOSE code numbers are reserved for IBM use.

#### **AUDIT**

tells the external security manager (ESM) to audit the DIAGNOSE code that you are defining. When you audit a DIAGNOSE code, the ESM logs each attempt by users to issue this DIAGNOSE code.

#### **DISABLE**

tells CP not to call the entry points and external symbols associated with this DIAGNOSE code until you enable it. (For more information about enabling DIAGNOSE codes, see Usage Note “3” on page 174.) If omitted, DISABLE is the default.

#### **ENABLE**

tells CP to immediately start calling the entry points and external symbols associated with this DIAGNOSE code.

#### **EPName *name***

tells CP the name of the entry point that contains the code to process the DIAGNOSE code that you are defining. The variable *name* must be a 1- to 8-character string. The first character must be

alphabetic or one of the following special characters: dollar sign (\$), number sign (#), underscore (\_), or at sign (@). The rest of the string can be alphanumeric characters, the 4 special characters (\$, #, \_, and @), or any combination thereof.

**INVAR**

tells CP not to process this DIAGNOSE code if the virtual machine issuing the DIAGNOSE code is in host access register mode.

**INVXC**

tells CP not to process this DIAGNOSE code if the virtual machine issuing the DIAGNOSE code is in Enterprise System Architecture/Extended Configuration (ESA/XC) mode or in z/XC mode.

**MAC**

tells CP to enable mandatory access control (MAC) for the DIAGNOSE code that you are defining. When MAC is enabled for your DIAGNOSE code, the external security manager (ESM) compares the security label of the virtual machine that issued your DIAGNOSE code to the security label of the resource or user that your DIAGNOSE code will affect. If you want the ESM to dynamically turn MAC on or off for this DIAGNOSE code, specify the VMAC operand.

**PRIVCLASSANY**

tells CP that users with any privilege class can issue the DIAGNOSE code that you are defining.

**PRIVclasses classes**

tells CP that only users with 1 or more of the specified privilege classes can issue the DIAGNOSE code that you are defining. The variable *classes* is 1 or more privilege classes in the range A through Z, 1 through 6, or an asterisk (\*). Privilege class \* indicates all privilege classes (A-Z and 1-6).

**Note:** If you want more than one privilege class, specify your classes in one string of characters. Do not separate the classes with blank spaces. For example, specify "privclasses abc123", not "privclasses a b c 1 2 3".

**PROC**

tells CP that, after performing the initial privilege class checks, your DIAGNOSE code processor will be responsible for any further calls to the external security manager (ESM) for the DIAGNOSE code that you are defining.

**PROT**

tells the external security manager (ESM) to protect the DIAGNOSE code that you are defining. When protection is enabled for your DIAGNOSE code, the ESM checks an access list to ensure that the user who issued your DIAGNOSE code is authorized to do so. If you want the ESM to dynamically turn protection on or off for your DIAGNOSE code, specify the VPROT operand.

**VMAC**

gives the external security manager (ESM) the power to dynamically turn mandatory access control (MAC) on or off.

**VPROT**

gives the external security manager (ESM) the power to dynamically turn DIAGNOSE code access protection on or off. If you specify PROT and VPROT for this command, you are enabling protection and allowing the external security manager (ESM) to dynamically disable that protection. If you specify VPROT and you do not specify PROT for this command, you are disabling protection and allowing the ESM to dynamically enable that protection.

**CHECKR15 YES**

indicates that the diagnose router should check register 15 upon return from the diagnose handler.

**CHECKR15 NO**

indicates that the diagnose router should not check register 15 upon return from the diagnose handler.

**Usage Notes**

1. If you do not specify the ENABLE operand, a new DIAGNOSE code is initially in a disabled state after being defined. CP treats disabled DIAGNOSE codes as if they were never defined. If you try to use a disabled DIAGNOSE code in a program, CP will give you a program check specification exception.

## DEFINE DIAGNOSE

2. To load the DIAGNOSE processing code into the system execution space, use the CPXLOAD command (see [“CPXLOAD”](#) on page 111).
3. To activate a new DIAGNOSE code after defining it, use the ENABLE DIAGNOSE command (see [“ENABLE DIAGNOSE”](#) on page 463).
4. To change the definition of an existing DIAGNOSE code after initialization, use the MODIFY DIAGNOSE command (see [“MODIFY DIAGNOSE”](#) on page 697).
5. To display information about a DIAGNOSE code (status, entry point name, and privilege class), use the QUERY DIAGNOSE command (see [“QUERY DIAGNOSE”](#) on page 885).
6. To display the address of the CP DIAGNOSE code table block for a DIAGNOSE code, use the LOCATE DGNBK command (see [“LOCATE DGNBK”](#) on page 608).
7. To deactivate a DIAGNOSE code after defining it, use the DISABLE DIAGNOSE command (see [“DISABLE DIAGNOSE”](#) on page 316).
8. Once defined, DIAGNOSE codes cannot be deleted. They may be altered in various appropriate ways, but they remain in existence until a SHUTDOWN or RESTART IPL is done.
9. To remove the DIAGNOSE processing code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD”](#) on page 117).
10. Many external security managers (ESMs) do not support DIAGNOSE codes above X'03FC'. For this reason, CP does not support DIAGNOSE codes above X'03FC'. The DIAGNOSE codes between X'0000' and X'03FC' are divided as follows:

**X'0000' to X'00FC'**

Reserved for IBM use

**X'0100' to X'01FC'**

Reserved for customer use

**X'0200' to X'03FC'**

Reserved for IBM use.

11. When CHECKR15 YES is specified, the diagnose router will check register 15 on return from the diagnose handler. If register 15 contains:

**RC = 0**

Processing was successful. Complete the guest instruction.

**RC = 4**

Processing failed due to a condition which would cause a guest program check. Simulate guest program interruption passed in R0.

**RC = 8**

Nullify the instruction.

**RC = 12**

Present the machine check then nullify the instruction. R2 will contain the address of the MCRBK which will contain the machine check information.

**RC = 16**

Generate machine check for processing damage, then go to HCPENDOP to terminate the instruction.

**RC = 20**

Present the machine check, then go to HCPENDOP to terminate the instruction. R2 will contain the address of the MCRBK, which contains machine check information.

**RC = 24**

Issue error message or soft abend for paging I/O error, then nullify the instruction. R1 has the message or abend number.

If a return code is invalid (negative, not a multiple of 4 or too big ( RC > 24 )), then a soft abend will occur.

12. The DEFINE COMMAND or DEFINE DIAGNOSE commands should not be used on a system with an active External Security Manager (ESM); unpredictable results could occur. To safely define a CP

command add the DEFINE COMMAND or DEFINE DIAGNOSE statement to the SYSTEM CONFIG file and re-IPL the system. This allows the command and diagnose additions to control structures to be made prior to activating the ESM.

13. For more information about user-defined DIAGNOSE codes, see [Defining and Modifying Commands and Diagnose Codes in z/VM: CP Exit Customization](#).

## Responses

Response 1:

To define a general purpose DIAGNOSE code (X'10C') that will be processed by entry point HCPSRC00, enter the following:

```
define diagnose 10c epname hcpsrc00 privclasses g
Ready;
```

Response 2:

To define DIAGNOSE code X'100' and make it available to users with privilege classes C or E, enter the following:

```
define diagnose 100 epname qwerty privclasses ce
Ready;

enable diagnose 100
Ready;

query diagnose 100
Code Status EPName PrivClasses
0100 Enabled QWERTY CE
Ready;
```

Response 3:

To define DIAGNOSE code X'18C' and make it available to all users, enter the following:

```
define diagnose 18c epname hcpsrc00 privclassany
Ready;

enable diagnose 18c
Ready;

query diagnose 18c
Code Status EPName PrivClasses
018C Enabled HCPSRC00 <ANY>
Ready;
```

## Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE EXIT

### Authorization

Privilege Class: A

### Purpose

Use DEFINE EXIT to dynamically define a new exit point in CP.

You can also dynamically define a new CP exit point during system initialization using the DEFINE EXIT configuration file statement. For more information, see [DEFINE EXIT Statement in z/VM: CP Planning and Administration](#).

### Operands

#### *exit*

is the number of the exit point you are defining. This value must be a hexadecimal number between X'0' and X'FFFF'. The recommended value is between X'F000' and X'FFFF', because that range is reserved for customer use. All other exit numbers are reserved for IBM, vendor, or general use.

#### **AT** *entry + offset instruction*

identifies the location of the exit point you are defining and the instruction that is located at the exit point. The variable *entry* must be a 1-to-8-character string. The first character must be alphabetic or one of the following special characters: \$ (dollar sign), # (number sign), \_ (underscore), or @ (at sign). The rest of the string can be alphabetic or numeric characters, the four special characters (\$, #, \_, or @), or any combination. The variable *offset* must be a 1-to-4-character even hexadecimal number between X'0' and X'FFFE'. The variable *instruction* must be a 2-, 4-, or 6-character hexadecimal number.

#### **NORESolve**

tells CP to resolve the entry points associated with this exit number the first time they are called. This is the default.

#### **RESolve**

tells CP to resolve the entry points associated with this exit number when the association is first established. Any existing associated entry points are resolved immediately.

#### **PARM** *parameter*

is a list of one or more parameters to be supplied to the exit. Five kinds of tokens can be used to define a parameter:

1. Addresses: strings up to eight characters long, consisting of the hexadecimal digits 0 through 9 and A through F.
2. General Registers: strings beginning with G or R, followed by a decimal number between 0 and 15 or a hexadecimal digit, designating the contents of a general register.
3. Indirection: a percent sign (%), which causes the contents of an address or the contents of an address in a register to be used instead of the address or register contents itself.

4. Arithmetic: a plus sign (+) or minus sign (-).
5. Displacement: strings of up to four hexadecimal digits.

Each parameter string specifies how to combine these tokens to generate a parameter value to be passed to an exit routine. The following is a Backus-Naur definition of the syntax of a parameter:

```
<parameter> ::= <anchor> | <anchor><vector>
<anchor> ::= <reg> | 0...FFFFFFFF | <anchor>%
<vector> ::= <modifier> | <vector>% | <vector><modifier>
<modifier> ::= +<disp> | -<disp> | +<reg> | -<reg>
<reg> ::= G<digit> | R<digit>
<digit> ::= 0...15 | 0...9, A...F
<disp> ::= 0...7FFF
```

## Usage Notes

1. To load the exit processing code into the system execution space, use the CPXLOAD command (see [“CPXLOAD” on page 111](#)).
2. To assign entry points or external symbols to an exit point, use the ASSOCIATE EXIT command (see [“ASSOCIATE EXIT” on page 20](#)).
3. To activate a new exit after defining it, use the ENABLE EXITS command (see [“ENABLE EXITS” on page 465](#)).
4. To change the definition of an existing dynamic exit point, or to remove the exit point from the system, use the MODIFY EXIT command (see [“MODIFY EXIT” on page 700](#)).
5. To display information about an exit (status, entry point name, and parameters), use the QUERY EXITS command (see [“QUERY EXITS” on page 907](#)).
6. Exit numbers are allocated as follows:
  - X'0000' to X'7FFF' are reserved for IBM use.
  - X'8000' to X'FFFF' are reserved for vendor and general use.
  - X'F000' to X'FFFF' are reserved for private customer use.
7. The RESOLVE option ensures that the entry names associated with an exit point are defined.
8. Each exit is passed a parameter list that begins with three standard parameters, as described in [z/VM: CP Exit Customization](#). Additional parameters, specified by the PARM operand, are optional and follow the first three in the order in which they are specified.
9. Errors (for example, addressing exceptions) during evaluation of user-defined parameters when an exit is being invoked cause CP to abend.
10. For more information about user-defined exits, see [z/VM: CP Exit Customization](#).

## Examples

### Example 1:

To define an exit that will be entered every time a MESSAGE command is issued, enter the following:

```
define exit f422 at hcpxmgms + 4 41700000
Ready;
```

### Example 2:

To define exit X'F800', pass it two additional parameters, and associate it with entry point QWERTY, enter the following:

```
define exit f800 at hcplpg + 7ce 41204028 parm g1+8% g4
Ready;

associate exit f800 epname qwerty
Ready;

enable exits f800
Ready;
```

## DEFINE EXIT

```
query exits f800
Exit Status      Calls      Returns Seconds
F800 Enabled      0          0 0.000000
      Location      Instruction Resolution
      HCPLOG +0FCE 41204028  NORESOLVE
      Defined by: MAINT on 09/03/98 at 13:27:54
      PARM R1+8%
      R4
      EPNAME      Attempts      Calls Seconds
      QWERTY      0            0 0.000000
Ready;
```

## Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE GRAF

### Authorization

Privilege Class: G

### Purpose

Use DEFINE GRAF to add a display station to your virtual machine configuration.

### Operands

*vdev*

**AS** *vdev*

identifies the virtual device number of the display you are defining.

**3270**

identifies the virtual device type of the display you are defining. This is the default.

### Usage Notes

1. After the display station is defined, you can enter DIAL from a real display station to logically connect the display station to your virtual machine.
2. For additional information, see [“Usage Notes” on page 122](#).

### Responses

Response 1:

```
GRAF vdev DEFINED
```

confirms the definition of the virtual display station.

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE HYPERPAVALIAS

### Authorization

Privilege Class: G

### Purpose

Use DEFINE HYPERPAVALIAS to define one or more virtual HyperParallel Access Volume (HyperPAV) aliases that will reside in the same pool as the specified base HyperPAV.

### Operands

#### AS *vdev*

#### *vdev*

is the virtual device number of the HyperPAV alias you are defining.

#### *vdev1-vdev2*

is the range of virtual device numbers of the HyperPAV aliases you are defining.

#### FOR BASE *basedev*

is the device number of an existing virtual base HyperPAV.

### Usage Notes

1. The number of virtual HyperPAV aliases cannot exceed the number of real HyperPAV aliases in the pool to which the base is assigned.
2. There can only be 254 aliases per pool, and there is a limit of 16,000 pools per system.
3. The base *vdev* specified on the command must be a virtual HyperPAV base device that is defined as a full-pack (0-END) minidisk or a 1-END minidisk.

### Responses

Response 1:

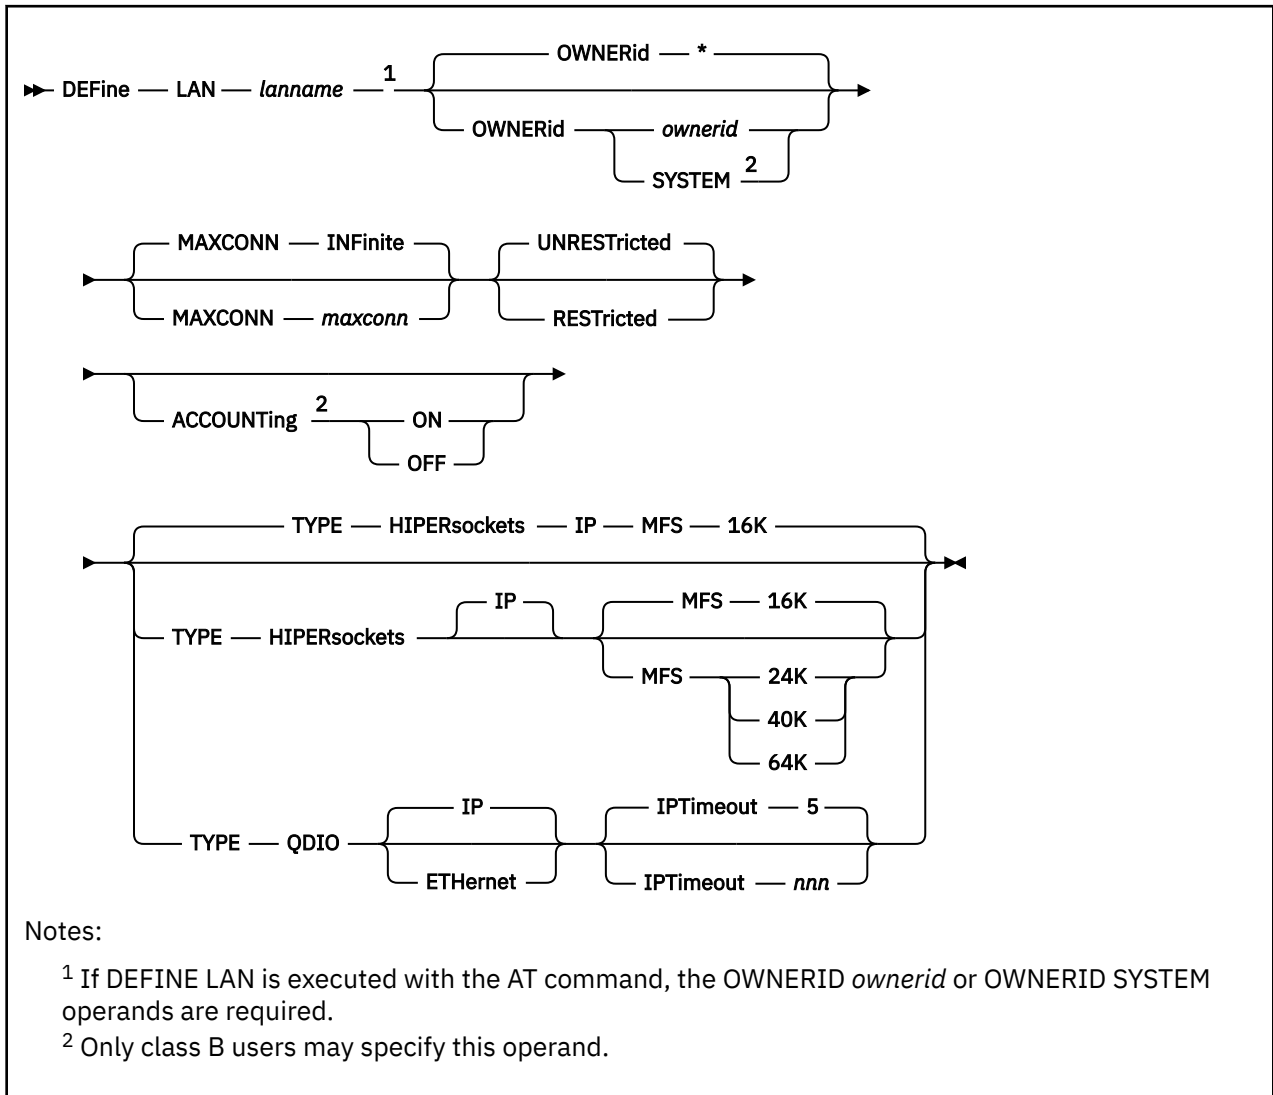

```
DASD vdev DEFINED
```

confirms that the device has been created.

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE LAN

### Authorization

Privilege Class: B, G

### Purpose

Use DEFINE LAN to create a guest LAN which can be shared among virtual machines on the same VM system. Each guest LAN is identified by a unique combination of *ownerid* and *lanname*. A VM user can create a simulated network interface card (NIC) and connect it to this LAN segment.

The SET LAN command can be used to modify attributes of the guest LAN.

You can also define a LAN during system initialization using the DEFINE LAN configuration file statement.

The Class B form of the command allows the invoker to create a LAN for another user (for example, OWNERID SYSTEM) and specify whether accounting is on or off for the LAN being defined.

For more information, see [“SET LAN”](#) on page 1536, [“COUPLE”](#) on page 83, [“DEFINE NIC”](#) on page 194, [DEFINE LAN Statement in z/VM: CP Planning and Administration](#), and [Virtual Networking Options in z/VM: Connectivity](#).

## Operands

### *lanname*

is the name of the new emulated LAN (Local Area Network). The *lanname* is a single token (1-8 alphanumeric characters). The combination of *ownerid* and *lanname* will identify this LAN for subsequent commands.

### **OWNERid \***

#### **OWNERid *ownerid***

#### **OWNERid SYSTEM**

establishes the owner of the new LAN. When OWNERID \* is specified, the owner is the invoker. This is the default.

The Class G form of the command only accepts \* or the user ID of the invoker. This creates a TRANSIENT LAN.

The Class B form of the command also accepts OWNERID SYSTEM (creating a PERSISTENT LAN), or any other user ID (creating a TRANSIENT LAN).

### **MAXCONN INFinite**

#### **MAXCONN *maxconn***

sets the maximum number of simultaneous adapter connections permitted at any given time. When MAXCONN is specified as INFINITE, there is no limit on the number of connections. Any other value, *maxconn*, limits the number of simultaneous connections to a decimal number in the range of 1–1024 (inclusive).

If MAXCONN is omitted, the default is MAXCONN INFinite.

### **RESTRicted|UNRESTRicted**

sets the type of authorization required to connect to this LAN. Options are:

#### **RESTRicted**

Defines a LAN with an access list to restrict connections. The LAN owner will use the **SET LAN** command to GRANT or REVOKE access to specific VM users (by userid). The **COUPLE** command will only allow authorized users (those on the access list) to connect a simulated adapter to a RESTRICTED network.

#### **UNRESTRicted**

Defines a LAN with no access list. When CP is in control of the LAN, connections to this LAN are not restricted by user ID. All users connected to this LAN will be able to use PROMISCUOUS Mode. If an External Security Manager (ESM) is in control of the LAN, the ESM may restrict access.

When neither option is specified, the default is to define an **UNRESTRicted** LAN.

### **ACCOUNTing ON**

#### **ACCOUNTing OFF**

Allows a Class B user to control whether accounting records are created for the LAN being defined. The default setting may be changed by the VMLAN statement in the system configuration file, and queried by QUERY VMLAN.

### **TYPE HIPERsockets**

defines a guest LAN for use by simulated HiperSockets adapters. A HiperSockets LAN can only accept connections from a simulated HiperSockets adapter.

If **TYPE** is omitted, the default is **TYPE HIPERSOCKETS**.

### **MFS 16K**

### **MFS 24K**

### **MFS 40K**

### **MFS 64K**

sets the Maximum Frame Size (MFS) for adapters on this network. When an adapter is connected to this LAN, it will adopt the network MFS. The MFS value determines the amount of storage to be allocated for internal structures, and limits the effective MTU size (Maximum Transmission Unit) for the coupled adapters. For general internet communications, a lower MFS is probably better. However,

a high MFS may provide higher data transfer rates for applications that are capable of using larger packet sizes.

If MFS is omitted, the default for HiperSockets is 16K. The MFS operand is not valid for QDIO but the effective MFS is 8992 for a QDIO adapter.

### TYPE QDIO

defines a guest LAN for use by simulated QDIO adapters. A QDIO LAN can only accept connections from a simulated QDIO adapter.

### IP | Ethernet

indicates whether the transport for the LAN is ETHERNET or IP. The ETHERNET transport type is Data Link (Layer 2) based, where the ETHERNET frame is used as a point of reference for source and destination Media Access Control (MAC) addresses in transporting ETHERNET frames on the LAN. The IP transport type is Network (Layer 3) based, where the IP packet is used as the point of reference for source and destination IP addresses in transporting IP packets on the LAN. See the usage notes for more detail.

### IPTimeout *nnn*

indicates the length of time in minutes that a transient IP address table entry remains in the IP address table for the virtual network. A transient entry is an entry added to the virtual network by one guest on behalf of another. This operand has no meaning for ETHERNET networks.

*nnn* is a number from 1 to 240. 5 minutes is the default value.

## Usage Notes

1. The Class G form of the **DEFINE LAN** command only allows the invoker to create a guest LAN that belongs to the invoker. That is, *ownerid* must be the user ID of the invoker, or an asterisk (\*).
2. The Class B form of the **DEFINE LAN** command allows the invoker to create a guest LAN that belongs to another user (or to **SYSTEM**).
3. A **PERSISTENT** LAN can only be destroyed by the **DETACH LAN** command. When a guest LAN is created for ownerid SYSTEM, it is automatically classified as a **PERSISTENT** LAN.
4. A **TRANSIENT LAN** can be destroyed by the **DETACH LAN** command, or by elimination of all references. When a guest LAN is created for a user (any userid other than SYSTEM) it is automatically classified as a **TRANSIENT** LAN. During LOGOFF processing, any **TRANSIENT** LAN with no active connections will be destroyed. If active connections exist, the "orphaned" LAN will continue to be functional until the last adapter is uncoupled. However, if the owner completes LOGON before the last adapter is uncoupled, the LAN is no longer "orphaned" and it will survive the removal of the last adapter.
5. The **VMLAN** statement in SYSTEM CONFIG (or the **SET VMLAN** command) may restrict the number of guest LANs on the system. Use the **QUERY VMLAN** command to determine what limit is in effect.
6. **DEFINE LAN** statements can be added to the SYSTEM CONFIG file to automatically create guest LANs during CP system initialization. Every guest LAN defined in the SYSTEM CONFIG file is classified as a **PERSISTENT** LAN.
7. A Class B user can use the **SET LAN** and **DETACH LAN** commands to operate on a LAN segment that belongs to another user (e.g. a SYSTEM-owned LAN).
8. When a RESTRICTED LAN is defined, the owner (as determined by the DEFINE command) is automatically added to the access list unless the owner is SYSTEM. SYSTEM will not be automatically added to the access list. The owner can use the **SET LAN** command to grant and revoke access to the LAN.
9. SET LAN cannot be used to change the type of transport. The LAN will need to be redefined.
10. The TYPE QDIO guest LAN supports two modes of operation for data transport in support of both TCP/IP and non-IP based applications. In deciding which mode to deploy for your network, some things to consider about deploying an ETHERNET virtualized LAN segment are:
  - Do your servers or applications need to have their own unique MAC addresses (load balancers)?
  - Do you plan to deploy non-IP based applications on your network (SNA or NetBIOS, for example)?

## DEFINE LAN

- Do you want to build a virtual LAN segment that operates closely to its physical counterpart?

The key attributes of each transport mode with their operational characteristics are as follows:

- ETHERNET (Layer 2)
  - Supports all applications that deploy ETHERNET (IEEE 802).
  - ETHERNET frames are transported on the LAN segment.
  - All destinations are identified by MAC address.
  - MAC addresses are locally administered by the LAN administrator through z/VM CP commands or configuration statements.
  - Each host connection is identified by a single MAC address.
  - This is a Link Layer transport, in which all hosts maintain their respective ARP caches.
  - VLAN tagging resides within the ETHERNET frames per IEEE 802.1Q specifications.
- IP (Layer 3)
  - Supports IP for TCP/IP applications only.
  - IP packets are transported on the LAN segment.
  - All destinations are identified by IP addresses.
  - IP address assignments are set by the host running in the guest virtual machine.
  - Each host may have more than one IP address (multi-homed).
  - This is Link Layer independent (that is, no MAC addresses).
  - VLAN tagging resides in internal QDIO headers.

A guest LAN operates in only one mode for a given instance. For example, if the LAN is configured as IP, then all communications on the LAN segment must be IP based. The same is also true when the LAN is configured in ETHERNET mode.

### Examples

#### 1. DEFINE LAN - Class G:

To create a user LAN named QNET that will allow up to 16 connections, enter:

```
cp define lan qnet type qdio maxconn 16
LAN VMUSERX QNET is created
```

#### 2. DEFINE LAN - Class B:

To create a SYSTEM LAN named INEWS that will allow up to 100 connections and will not have accounting records created, enter:

```
cp define lan inews ownerid system maxconn 100 accounting off
LAN SYSTEM INEWS is created
```

Note that this must be done by a user with Class B privileges since the LAN is not owned by the invoker and the ACCOUNTING option is specified.

### Responses

Response 1:

```
LAN ownerid lanname is created
```

is the normal response for this command.

### General Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## Messages

Messages:

- HCP013E Conflicting option - *option*
- HCP2782E LAN *ownerid lanname* not created; a detach is in progress for a VSWITCH with that name
- HCP2782E LAN *ownerid lanname* not created; this name already in use
- HCP2784E LAN *ownerid lanname* not created; the system LAN limit has been reached
- HCP2784E LAN *ownerid lanname* not created; VMLAN limit has been reached
- HCP2795E You are not authorized to DEFINE LAN *lanname* for OWNERID *ownerid*
- HCP2795E You are not authorized to override LAN ACCOUNTING
- HCP2796E LAN *ownerid lanname* not created; user *ownerid* is not logged on

## DEFINE LINE

### Authorization

Privilege Class: G

### Purpose

Use DEFINE LINE to add a virtual communication line to your virtual machine configuration.

### Operands

*vdev*

**AS** *vdev*

identifies the virtual device number of the line you are defining.

**IBM1**

identifies the virtual device type of the line you are defining. This is a 2741, 3767, or equivalent device. This is the default.

**TELE2**

identifies the virtual device type of the line you are defining. This is a 3101, 3151, 3161, 3162, 3163, or equivalent device.

### Usage Notes

1. After the line is defined, you must enter DIAL from a real device to logically connect the line to your virtual machine.
2. For additional information, see [“Usage Notes” on page 122](#).

### Responses

Response 1:

```
LINE vdev DEFINED
```

confirms the definition of the virtual communication line.

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE LPAR

### Authorization

Privilege Class: B

### Purpose

Use the DEFINE LPAR command to define a logical partition to the I/O configuration.

### Operands

#### *pname*

specifies the name of the logical partition to be defined. *pname* must be a 1-character to 8-character alphanumeric string.

**Note:** The first character of *pname* must be alphabetic and the following names cannot be used: PHYSICAL, REC, SYSTEM, PRIMnnn (where nnn are decimal digits).

#### **CSS** *nn*

is the channel-subsystem ID associated with the logical partition that is being defined. The variable *nn* must be a 1-digit to 2-digit hexadecimal number between X'00' and X'0F.'

#### **MIF\_id** *mm*

is the MIF-ID within the specified CSS associated with the logical partition that is being defined. The variable *mm* must be a 1-digit to 2-digit hexadecimal number between X'01' and X'0F.'

### Usage Notes

1. The specified CSS and MIF-ID combination must be an available reserved slot in the configuration in order for a logical partition to be defined to it. An available reserved logical partition slot is created by:
  - Specifying it with the RESOURCE statement in the IOCP file.
  - Deleting a logical partition definition with the DELETE LPAR command.
2. This command requires that the logical-channel-subsystem facility and logical-partition-configuration facility be installed on your system.

### Examples

To define logical partition VMSYSONE to CSS 1 with a MIF-ID of 3, enter the following:

```

define lpar vmsysone css 1 mif 3
Logical partition configuration change completed successfully
Ready;
  
```

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE MDISK

### Authorization

Privilege Class: A

The user must be the primary system operator or the user's OPTION directory statement must include the DEVMAINT option.

**Note:** When the command is controlled by an external security manager (ESM), such as RACF, the ESM will check the authorization. Only privilege class A is required. No additional checks for the primary system operator or the user's OPTION directory statement are done.

### Purpose

Use DEFINE MDISK to define a minidisk on the following media:

- A system volume
- The DASD volume that is attached to the system

### Operands

*vdev*

**AS** *vdev*

identifies the virtual device number of the minidisk you are defining.

**start**

is a decimal number that defines the cylinder (CKD/ECKD) or block (FBA) on the real DASD that is cylinder 0 or block 0 for this minidisk.

Generally, ECKD user minidisks must begin with cylinder 1 or higher and FBA user minidisks must begin with block 32 or higher. If the SALIPL utility was used to install a copy of the Stand-Alone Program Loader (SAPL), then FBA user minidisks must begin with block 208 or higher.

**count**

**END**

defines the size of the minidisk.

The variable *count* is a decimal number that defines the number of cylinders or blocks to make up the minidisk.

END defines the minidisk to extend to the end of the real DASD.

**valid**

identifies the volume serial number (1- to 6-alphanumeric characters long) of the real DASD volume against which the MDISK is being defined.

### Usage Notes

1. The minidisk that you define remains available until you log off or detach the virtual device on which it resides. Use this command only for disaster recovery because it provides access to any area of a DASD volume without requiring more authorization.
2. You can define a minidisk as a full-pack minidisk. You must define the starting cylinder number as zero and include all DASD volume primary cylinders and some or all of its alternate cylinders.

3. Minidisks that are created by using the DEFINE MDISK command have cache access if they are on a cached control unit.
4. Minidisks must not be defined on PAGE, SPOL, TDSK, or on DRCT allocation areas.
5. FBA minidisks intended to be eligible for minidisk mapping and minidisk caching must start and end on a 4 K boundary. They must be defined with a number of blocks that comprise a complete number of pages (a multiple of 8 blocks) because partial pages are not formatted by ICKDSF CPVOLUME.
6. A minidisk, including a temporary disk, is not eligible for minidisk cache if it has been defined with greater than 32767 cylinders. This does not apply to FBA devices. It applies only to ECKD devices.
7. If you define a minidisk as virtual device number 192, the following special rules apply when you IPL CMS:
  - If 192 is unformatted, CMS formats it and accesses it as file mode D.
  - If 192 is CP-formatted, CMS reformats it for CMS use and accesses it as file mode D.
  - If 192 is CMS-formatted and accessed as a file mode other than D, CMS reaccesses it as file mode D.

When CMS accesses a 192 minidisk as file mode D, any minidisk or SFS directory that is already accessed as D is released.
8. When linking to a minidisk that has at least one cylinder that is the target of a persistent FlashCopy relationship, warning message HCP116I is issued. The link is not prevented when a FlashCopy relationship exists.
9. Minidisk cache is not supported for a minidisk that is defined on an Extended Address Volume (EAV) DASD, such as the 3390-0E, because of the large number of cylinders that are supported by that device.
10. For additional information, see [“Usage Notes” on page 122](#).

## Responses

Response 1:

```
DASD vdev DEFINED
```

confirms the definition of the DASD.

### **vdev**

identifies the virtual device number of the minidisk you define.

Response 2:

When minidisks that are in a FlashCopy relationship are defined, you see something like this:

```
DEFINE MDISK 200 100 100 PACK01
HCPLNS116I WARNING: Cylinders 50 through 59 of minidisk 0200 are the
HCPLNS116I          target of FlashCopy relationship 4AF7DB61.
Ready; T=0.01/0.01 14:48:25

DEFINE MDISK 300 100 100 PACK02
HCPLNS116I WARNING: Cylinders 50 through 59 of minidisk 0300 are the
HCPLNS116I          target of FlashCopy relationship 4AF7BDB3.
Ready; 0.01/0.01 14:48:29
```

- HCP2880E *userid vaddr* is not linked, CSE LINK I/O error, code *cc*.

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE MSGPROC

### Authorization

Privilege Class: G

### Purpose

Use the DEFINE MSGPROC command to define a virtual message processor and associated message devices in the issuer's virtual I/O configuration. This command establishes a coupling connection between a CFUSER defined user ID and the specified CF Service Machine running under z/VM.

### Operands

#### *msgprocid*

specifies the user ID of a z/VM Virtual Machine that is defined to run as a Coupling Facility. CP will establish a coupling connection between the user ID that issues this command and the user ID specified by *msgprocid*.

#### VDEvice *vdev*

is the virtual device number of the base message device that you are defining to CP. The device number must be a 1 to 4 digit hexadecimal number between X'0000' and X'FFFC'. The virtual device number specified will be the first of four consecutive device numbers created. If the specified device number is not valid or if it or any of the next three consecutive device numbers are already defined, this command will fail.

#### DEVices *n*

specifies the number of message devices to be created in the coupling guest. The number of devices (*n*) must be an even number between 4 and 16 inclusive; the default is 4.

#### SINGLE\_message\_path

will force only a single message path to be created for each message device. By default this command will create two message paths per message subchannel. Specifying SINGLE will turn off multi-path simulation when communicating with the Message Processor being defined.

### Usage Notes

1. The user must be authorized to issue this command via the CFUSER operand on the OPTION directory statement in the user directory. Without authorization, the MSGProc operand is rejected as not valid.
2. The SPECIAL directory statement allows the system administrator to restrict which message processors that a user is allowed to define. If SPECIAL directory statements are used to define the message processors for the user, then the user can specify only those *msgprocid*s on the DEFINE MSGPROC command. Specifying a *msgprocid* not defined by the SPECIAL directory entry causes the operand to be rejected as not valid.

## DEFINE MSGPROC

3. The *msgprocid* must be set up and authorized to run as a CF Service Machine via the CFVM operand on the OPTION directory statement in the user directory.
4. The CF Service Machine that you specified must be active and running prior to issuing this command. If the CF Service Machine is not running disconnected, no message devices will be defined.
5. A single coupled guest can connect to a maximum of 8 different CF Service Machines at the same time.
6. The *vdev* chosen must be a hexadecimal number low enough for the addition of *vdev* plus the number of DEVICES minus 1 with a result less than or equal to X'FFFF'.

You can only have one connection with each CF SVM. Therefore, if you want to change the *vdev* number from one you have already defined, you need to use the DETACH MSGPROC command to first detach the virtual message processor and then DEFINE MSGPROC command to define a new message processor.

7. When DEVICES *n* is used, specify between 4 and 16 inclusive; this device count must be even. If DEVICES is not specified, the default is 4.

You can have only one connection with each CF SVM. Therefore, if you already have defined a device using the default 4 and want to define a different device number, you need to use the DETACH MSGPROC command to first detach the virtual message processor and then use DEFINE MSGPROC command to define a new message processor.

8. If *msgprocid* is not z/Architecture mode, CP forces the DEVICES value to 4 no matter what was specified. The only indication of this is when confirmation message HCP2804I is displayed containing the actual device count that was used.
9. To display information about virtual message processors in your I/O configuration, use the QUERY VIRTUAL MSGPROC command.
10. To display information about the virtual message devices within your I/O configuration, use the QUERY VIRTUAL MSGDEVICES command.
11. To restart a virtual message processor that is within your I/O configuration, use the RESTART MSGPROC command.
12. To remove all message facility capability from your virtual machine, use the SET MSGFACIL OFF command.
13. To detach a virtual message processor and associated virtual message devices, use the DETACH MSGPROC command.
14. CHPIDs 8X and CX are used for the message devices. 'X' depends on when the connection was established between the coupling guest and the coupling facility relative to when other connections were made. A conflict exists when an OSA device is attached to a CFVM user and the OSA's CHPID is the same as that of a message device associated with the CFVM. When this happens, the following MVS errors are received when trying to bring the OSA online:

```
IEE103I UNIT 0420      NOT BROUGHT ONLINE
IEE763I NAME= IOSVDSE0 CODE= 0000000800000000
IOS576I OSA DEVICES REQUIRE AN OSA CHANNEL PATH BUT
TYPE 0B FOUND TYPE=COUPLING FACILITY SENDER
```

15. For more information, see the DEFINE command.

## Responses

Response 1:

To define a connection with four message devices and two Message Paths to a CF Service Machine user ID CFCC1, enter the following:

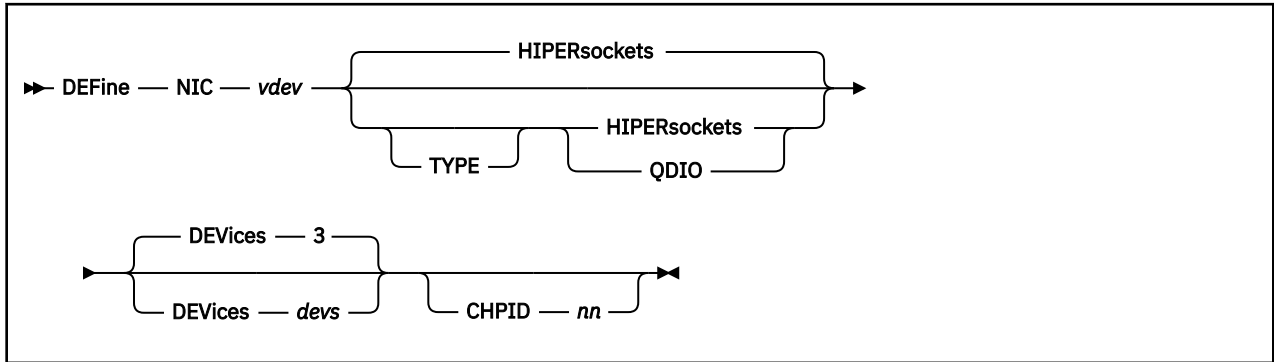

```
def msgp cfcc1 vdev 700
HCP2804I Message devices 0700-0703 defined and coupled to CFCC1.
Ready;
```

## Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE NIC

### Authorization

Privilege Class: G

### Purpose

Use the DEFINE NIC command to install a simulated network interface card (NIC) in the invoker's virtual machine configuration. A successful definition creates a contiguous range of virtual OSA-type devices which all belong to the same simulated adapter. After the network interface card (NIC) is installed, use the **COUPLE** command to connect the adapter to a guest LAN or virtual switch. VM guests connected to the same LAN segment or virtual switch can exchange messages using the same communication software that they would use to drive a physical network adapter.

For more information on the COUPLE command, see [“COUPLE” on page 83](#).

### Operands

#### *vdev*

specifies the base virtual device address for the new adapter. The network interface card (NIC) is represented by a series of I/O devices in your virtual machine configuration. CP messages and responses will use this first device address, the base device address, to refer to the adapter.

#### TYPE

specifies the type of NIC adapter to be created, specifically the hardware and protocol that the adapter is to emulate.

#### **HIPERsockets**

defines this adapter as a simulated HiperSockets NIC. This adapter will function like the HiperSockets internal adapter (device model 1732-05). A HiperSockets NIC can function without a guest LAN connection, or it can be coupled to a HiperSockets guest LAN.

You will receive an error if you attempt to connect a simulated HiperSockets adapter to a virtual switch.

#### **QDIO**

defines this adapter as a simulated QDIO NIC. This adapter will function like OSA-Express (QDIO) adapter (device model 1732-01). A QDIO NIC is functional only when it is coupled to a QDIO guest LAN or a QDIO virtual switch.

#### **DEVICES 3**

#### **DEVICES *devs***

determines the number of virtual devices associated with this adapter. For a simulated HiperSockets adapter, *devs* must be a decimal value between 3 and 3,072 (inclusive). For a simulated QDIO adapter, *devs* must be a decimal value between 3 and 240 (inclusive). The **DEFINE NIC** command will create a range of virtual devices from *vdev* through *vdev+devs-1* to represent this adapter in your virtual machine configuration.

If the **DEVices** operand is omitted, the default is **3** for any adapter type.

### CHPID *nn*

is the two-digit hexadecimal number that represents the CHPID number the invoker wants to allocate for this simulated adapter. If the requested CHPID number is available, all of the virtual devices belonging to this adapter will share the same CHPID number.

### TYPE

This is an optional keyword that you can specify with HIPERsockets or QDIO.

## Usage Notes

1. The CP User Directory can be used to automatically define a simulated network interface card (NIC) during LOGON processing. The **NICDEF** statement supports device type **HIPERs** (to create a simulated HiperSockets adapter) or **QDIO** (to create a simulated QDIO adapter).
2. The HiperSockets adapter is functional immediately after it is defined, but it can only communicate with its own internal LAN until it is connected to a guest LAN by the COUPLE command. If an attempt is made to connect to a guest LAN via the NICDEF statement or the COUPLE command, the default internal LAN is destroyed and the adapter becomes "LAN NOTREADY" whenever it is uncoupled.
3. The virtual devices created by the DEFINE NIC command cannot be moved or detached by virtual device number. Each device will retain its assigned virtual device number until the virtual adapter is destroyed by the DETACH NIC command (or by LOGOFF processing).
4. The **CHPID** *xx* operand allows the invoker to request a specific CHPID number for this adapter. If the designated real CHPID number *xx* is available on the LPAR, it will be allocated for the adapter, and assigned to each virtual device that is created as part of this virtual adapter.

This option is useful if you need to configure a virtual environment with predictable CHPID numbers for your simulated adapters. It is also useful if you need to carry certain attributes associated with the real CHPID to the virtual adapter. An example would be the NETID associated with an OSD CHPID used as a VSWITCH uplink port. These attributes would be picked up by the internal discovery code run by the guest operating system using the virtual adapter.

See ["Channel path usage" on page 195](#) for more details about how this command interacts with real CHPIDs on the LPAR and how the CHPID option can make that interaction more predictable.

5. z/VM supports virtual QDIO networking connections comprised of one read control device, one write control device, and up to eight data devices. This provides the ability to configure up to ten virtual devices per host QDIO connection.

## Channel path usage

It is important to have a good understanding of how a Channel Path ID (CHPID) is associated with the set of simulated NIC devices created with a single invocation of this command. A CHPID is a required element for the virtual devices created by this command. If the CHPID operand is not specified on this command, VM will automatically assign a CHPID. Except for guests defined with the OPTION CHPIDV user directory statement, a VM guest's set of CHPIDs is directly related to the VM LPAR's real set of CHPIDs. That is, the VM LPAR's real set of CHPIDs pass-through to the guest.

Since the devices created by this command have no real device counterpart, VM uses an algorithm to assign a CHPID to these virtual devices that can coexist with VM's *real* set of CHPIDs. This algorithm first looks for a CHPID that is unassigned in both VM's *real* set of CHPIDs and the guest's set of CHPIDs. This lookup starts at *real* CHPID 0 and increases to 255 (xFF) until a match is found. If an unassigned CHPID is **not** found, a new lookup will start attempting to find a *real*, assigned CHPID that fulfills these requirements:

1. It has the same type needed by the devices created by this command.
2. It is a CHPID not already assigned to the guest.

This lookup also starts at real CHPID 0 and increases to 255 (xFF) until a match is found. The DEFINE NIC command will fail if a match is **not** found.

This algorithm usually works seamlessly unless a dynamic I/O event occurs that impacts the *real* CHPID picked up and assigned to devices created by this command. For example, if *real* CHPID 0 is assigned to guest virtual NICs 600-602, and a later dynamic I/O event adds *real* CHPID 0 with a non-compatible type, like a FICON CHPID, the guest using these virtual devices will likely start to experience error conditions. The errors likely will be experienced later when the guest operating system (OS) executes self-discovery code and notices the incompatible CHPID type. For example, a previously-working, second-level VM guest might start to encounter VSWITCH initialization errors on a re-IPL.

If a guest experiences a CHPID conflict due to a dynamic I/O change, one can detach the virtual devices with the conflicting CHPID, using the DETACH NIC command, and issue a DEFINE NIC command again to let VM locate a new *real* CHPID to associate with the virtual devices. This will likely also require a guest reboot or recycle of the guest's network interface.

The best way to avoid these CHPID conflicts is to keep a free set of CHPIDs available that can be used with the CHPID operand on each invocation of this command. The rule is that each invocation of DEFINE NIC must have a new available CHPID for the guest; note, however, that the same *real* CHPIDs can be used across different guests. The privileged Q CHPIDS command will display the *real* CHPID layout used by a VM LPAR. The guest OS will likely also have a means for determining its CHPID layout. For example, a second-level VM system can use the same Q CHPIDS command second-level.

If it is not possible to keep a free set of *real* CHPIDs available, remember that assigned CHPIDs can also be used if they are a compatible type. For example, an "Open Systems Adapter Direct Express" CHPID can be used for a DEFINE NIC with the TYPE QDIO operands. An "Internal Queued Direct Communications" (IQDC) CHPID can be used for a DEFINE NIC with the default TYPE HIPERSOCKETS operands. The type associated with a *real* CHPID can be determined using the privileged Q CHPID command with TYPE operand.

It should be noted that use of the OPTION CHPIDV user directory statement for a guest will avoid the pass-through of the real CHPID set to the guest. However, although use of CHPIDV completely virtualizes a guest's CHPID set, it should only be specified when a guest is going to be relocated and should not be specified for a z/OS guest.

### Examples

Create a simulated HiperSockets adapter with (3) devices.

```
cp define nic 500 hipersockets devices 3
NIC 0500 is created; devices 0500-0502 defined
```

```
cp define nic 5120 qdio devices 16
NIC 5120 is created; devices 5120-512F defined
```

### Responses

Response 1:

```
NIC vdev is created; devices vdev-lastdev defined
```

#### *vdev*

is the base device address

#### *lastdev*

is the last device address in the range created for this adapter ( $lastdev = vdev + devs - 1$ ).

This is the normal response for this command.

### Messages

For the list of general messages for the DEFINE command, see ["Messages" on page 122](#).

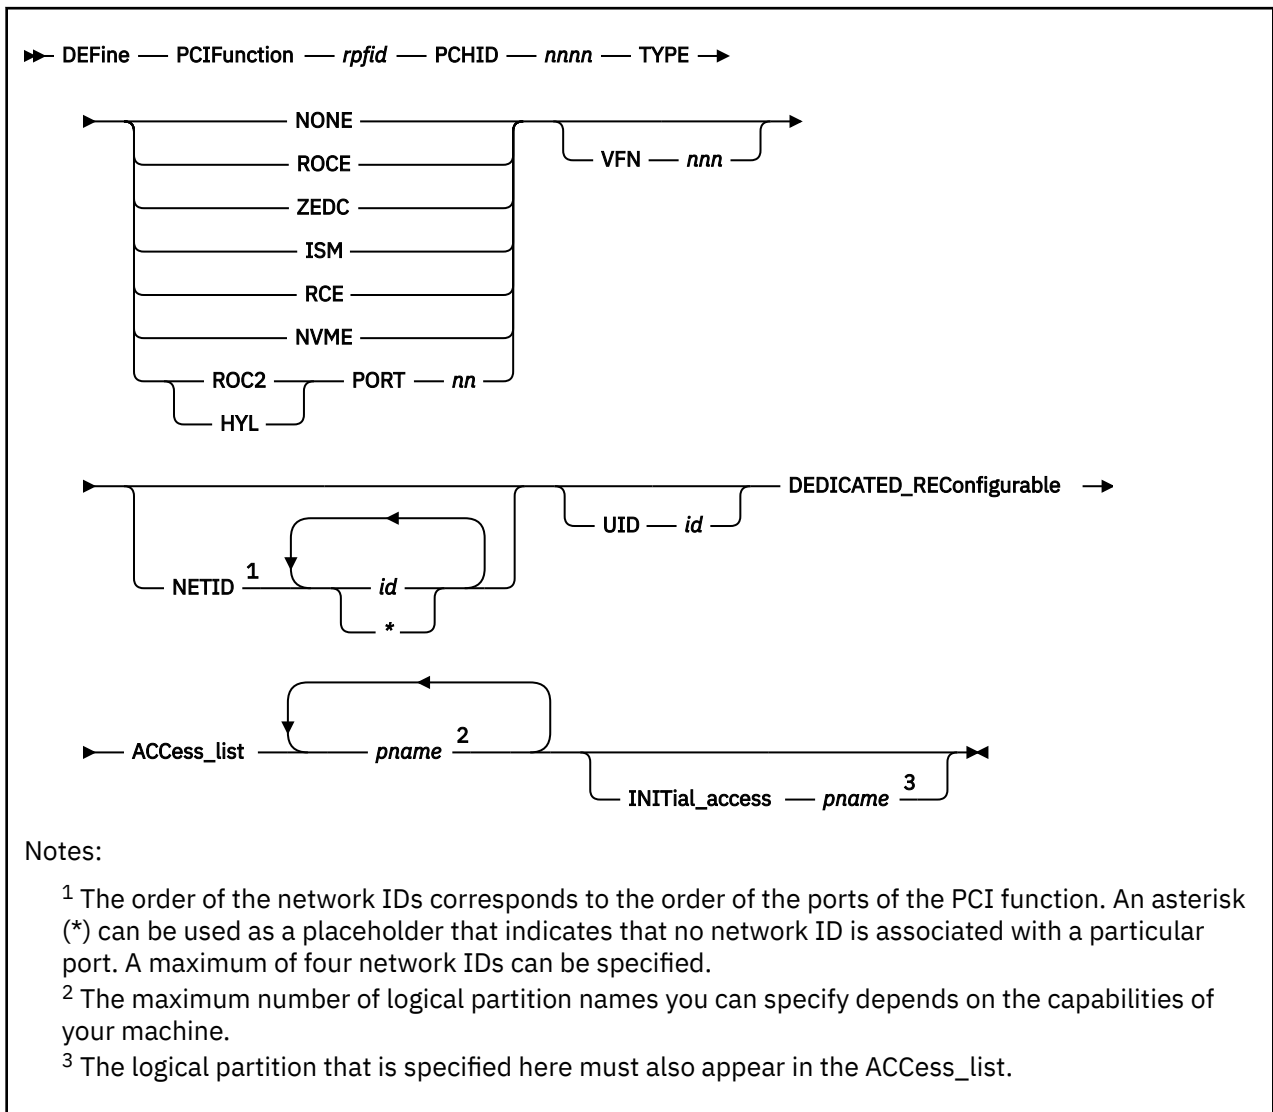

Messages:

- HCP013E Conflicting option - *option*

- HCP2794E NIC *vdev* not created; *devs* is outside the valid range of *mindevs* to *maxdevs*
- HCP2797E NIC *vdev* not created; CHPID *nn* is already in use

- HCP2797E NIC *vdev* not created; Unsupported type.

# DEFINE PCIFUNCTION

## Authorization

Privilege Class: B

## Purpose

Use DEFINE PCIFUNCTION to define a real PCI function to the I/O configuration.

## Operands

### *rpfid*

is the real function identifier of the PCI function you are defining to the I/O configuration. The *rpfid* must be a 1- to 8-digit hexadecimal number between X'00000000' and X'7FFFFFFF'. The maximum value of the *rpfid* is model-dependent and your machine likely supports a lower maximum value.

## DEFINE PCIFUNCTION

### **PCHID *nnnn***

is the physical channel ID associated with the PCI function you are defining. The variable *nnnn* must be a 1- to 4-digit hexadecimal number between 'X'0000' and 'X'FFFF'. Your machine likely supports a lower maximum value. Only PCHIDs that are physically installed on your machine should be entered.

**Note:** When TYPE ISM is specified, the PCHID operand is a virtual channel ID and must be in the range of 'X'7C0' to 'X'7FF'.

### **TYPE NONE**

### **TYPE ROCE**

### **TYPE ZEDC**

### **TYPE ISM**

### **TYPE ROC2**

### **TYPE RCE**

### **TYPE HYL**

### **TYPE NVME**

indicates the type of PCI function that is being defined. The NONE operand is required on systems that do not support the TYPE operand. The ROC2 operand is used to define RoCE Express 2 and RoCE Express 3 PCI functions.

### **PORT *nn***

is the physical port associated with the PCI function you are defining. The variable *nn* must be a 1- to 2-digit decimal number in the range 1 - 15.

### **VFN *nnn***

is the virtual function number associated with the PCI function you are defining. The variable *nnn* must be a 1- to 3-digit decimal number in the range 1 - 256. Your machine likely supports a lower maximum value.

**Note:** If a virtual function number is specified for a PCHID, all definitions for that PCHID must specify a virtual function number. Some systems require the VFN operand to be specified and reject a request with return code 010D if it is not specified.

### **NETID *id***

### **NETID \***

is the network identifier associated with a port of the PCI function. A maximum of four network IDs can be specified. The order of the network IDs corresponds to the order of the ports of the PCI function. An asterisk (\*) can be used as a placeholder that indicates that no network ID is associated with a particular port. Each *id* must be a 1- to 16-digit character string.

### **UID *id***

is the user-defined identifier to be associated with this PCI function and other PCI functions that are deemed equivalent by the user. Each *id* must be an integer in the range 1 - 65535 . This field is model-dependent and the command fails if the system does not support the UID for real PCI functions.

### **DEDICATED\_REConfigurable**

tells CP that this is an unshared PCI function which can only be configured to one of the logical partitions specified on the ACCESS\_LIST operand at a time.

### **Access\_list *pname***

specifies one or more names of the logical partition(s) in which the PCI function can be configured. The maximum number of logical partition names you can specify depends on the capabilities of your machine. Each *pname* must be a 1- to 8-digit character alphanumeric string.

### **INITial\_access *pname***

specifies the name of the logical partition that has initial access to this PCI function.

**Note:** When a logical partition is specified with the INITial\_access parameter, it must also be specified as part of the ACCESS\_list.

## Usage Notes

1. Specifying Logical Partition Names:

- a. When you specify DEDICATED\_RECONFIGURABLE you must specify at least one logical partition name for ACCESS\_LIST, and you can optionally choose to specify a logical partition name for INITIAL\_ACCESS. However, after the command runs successfully, the PCI function appears in standby state (offline) to all active partitions that are specified in the ACCESS LIST. The PCI function appears in standby state whether a partition is specified on the INITIAL ACCESS list or not. How many logical partition names you can specify depends upon the capabilities of your machine; see [Table 16 on page 201](#).

Table 16. Maximum Number of Logical Partition Names		
Operand	ACCESS_LIST	INITIAL_ACCESS
DEDICATED_RECONFIGURABLE	MAX	1

2. After successfully entering this command, the software's view of the I/O configuration is changed. The hardware's view of the active I/O configuration in the hardware system area (HSA) is also changed. You must also change the hardware's view of the active I/O configuration data set (IOCDS) file on the support element (SE) hard disk.

To change the IOCDS file on the SE hard disk, you must complete the following steps:

- a. Update the IOCP source file.
  - b. Run the IOCP utility against the updated IOCP file. If the IOCP utility runs without errors, it downloads the new IOCDS file to the SE hard disk.
  - c. Issue the SET IOCDS\_ACTIVE command to make the new IOCDS file the active file that the processor uses during the next power-on reset (POR).
3. For more information about defining real PCI functions in your I/O configuration, see [z/VM: I/O Configuration](#).
  4. To change the definition of an existing PCI function on the system, use the MODIFY PCIFUNCTION command.
  5. To delete an existing PCI function on the system, use the DELETE PCIFUNCTION command.
  6. To display the status of one or more real PCI functions, use the QUERY PCIFUNCTION command.

**Note:** The QUERY PCIFUNCTION command displays the status of the PCI function only if you issue the QUERY command in a logical partition (LP) that has access to the PCI function.

7. All virtual functions for a PCHID that specify NETID values must use the same values for each port of the function. The DEFINE command fails with hex return code 0320 if the specified NETIDs do not match the existing settings.

## Responses

Response 1:

The following command and response shows a successful definition of a dedicated-reconfigurable PCI function with three logical partitions.

```
def pcif 43 pchid 8181 dedicated_rec access vm1 vm3 vm5 init vm1
PCI function configuration change completed successfully
Ready;
```

## Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

Messages:

- HCP1006E Command processing cannot complete because the system does not support the Dynamic-I/O-for-I/O-adapters facility.

## DEFINE PCIFUNCTION

- HCP1006E Command processing cannot complete because the system does not support the Utility-String facility.
- HCP6806E Dynamic I/O change request for PCI function failed with return code *nnnn*
- HCP6873E PCI function *rpfid* has been created but is in definition error and has not been added to the configuration.

## DEFINE RELODOMAIN

### Authorization

Privilege Class: A

### Purpose

Use to define or dynamically alter a named subset of the SSI membership known as a relocation domain. The domain specifies the set of systems among which a guest may relocate. The domain imposes a common set of architectural characteristics that ensures a guest is presented with a consistent architecture whatever member of the domain the guest runs in. When a user first logs on, its default associated domain is the entire SSI. (An exception is that the domain for a multi-configuration virtual machine is the singleton domain of its execution member.) A VMRELOCATE statement may be coded in the user's directory entry to assign the user to a domain other than the default at login time.

### Operands

#### **domain\_name**

The eight-character name of the domain. The reserved word "SSI" is excluded from use because it is predefined as the domain which includes all members of the SSI. Also, the names of SSI member systems are predefined as singleton domains and may not be modified by this command. The name may consist of up to eight characters using only A-Z and 0-9.

#### **MEMbers membername**

A list of one or more SSI member system names comprising the domain.

### Usage Notes

1. The QUERY SSI command may be used to determine the list of members in the SSI which can be included as members in a relocation domain.
2. The QUERY RELODOMAIN command may be used to determine the list of members in a particular relocation domain.
3. Changing the member list of an existing domain might result in changing the virtual architecture level (VAL) of that domain. If additional features are added to the VAL (for example, if the only member of the domain on an older machine type is removed, leaving all newer machine types), then guests assigned to this domain may begin to use the added features (that is, features available only on the newer machine types). Conversely, if the change results in removal of features from the VAL (such as adding an older machine type into the domain), this removal will not take effect for an active guest until its next IPL. In the interim, the guest will continue to have access to the former feature set; however, it will be excluded from relocating to any newly added member system (on the older machine type) that lacks those features.
4. For information about [Using Relocation Domains](#), see *z/VM: CP Planning and Administration*.

### Responses

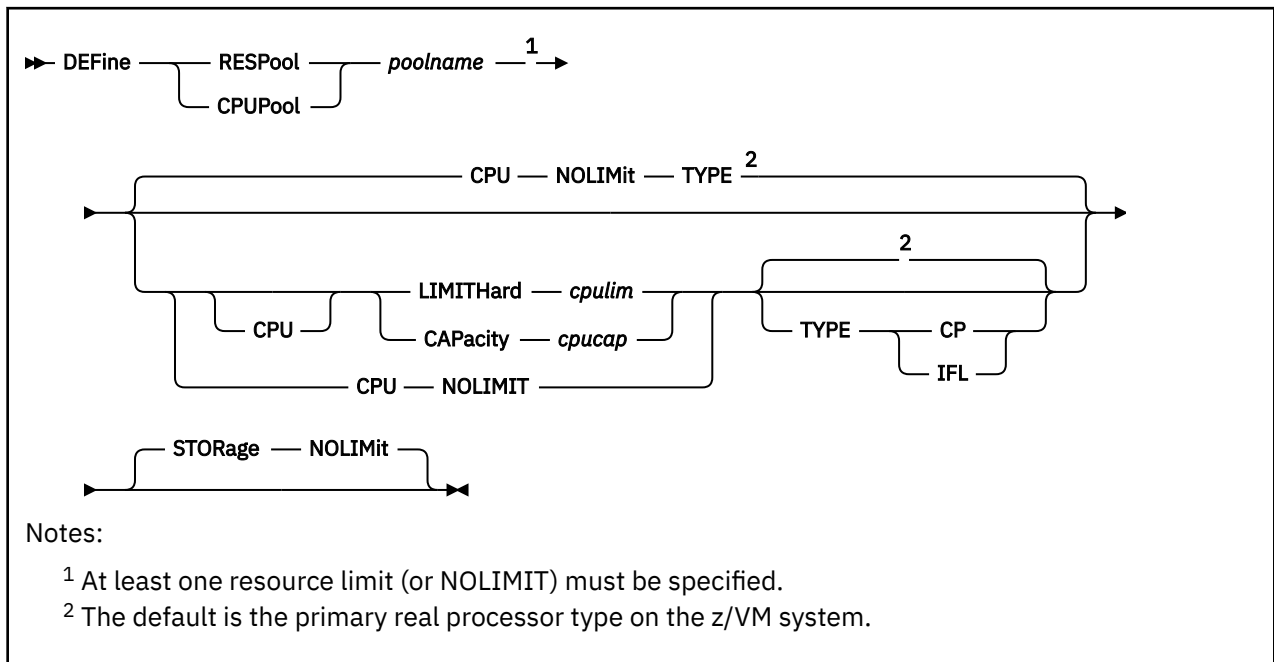

Responses issued by DEFINE RELODOMAIN

This system is not a member of an SSI cluster.

### Messages

## DEFINE RESPOOL

### Authorization

Privilege Class: A

### Purpose

Use DEFINE RESPOOL to add a new resource pool to your system configuration. After a pool has been created, it remains until the next time z/VM is IPLed or the DELETE RESPOOL command is issued to remove it. For compatibility with prior releases, CPUPOOL is accepted as a synonym for RESPOOL.

### Operands

#### *poolname*

is the 1- to 8-character name of the pool to be created. The pool name is a single alphanumeric token that identifies a pool of resources that can be associated with guests who are to be limited.

#### CPU LIMITHard *cpulim*

#### LIMITHard *cpulim*

sets the enforcement of hard limiting for the defined pool such that the pool does not receive more than *cpulim* percent of the shared logical cores of the type specified on the TYPE operand. Here, "logical core" refers to a logical CPU when multithreading is not enabled, or to a set of logical processors (threads) currently dispatched on a physical processor core when multithreading is enabled. The *cpulim* value is a decimal whole number (no decimal place) from 1 to 100, followed by a percent sign (for example, 2% or 80%).

#### CPU CAPacity *cpucap*

#### CAPacity *cpucap*

sets the enforcement of CPU capacity limiting for the defined pool such that it does not receive an amount of processor power greater than the equivalent of *cpucap* real cores of the type specified on the TYPE operand (although the number of logical cores of that type in use simultaneously by the group can exceed *cpucap*). The *cpucap* value is a decimal number (up to two decimal places) from 0.01 to 999 (for example, 2.5 or 8).

## DEFINE RESPOOL

### TYPE

specifies the type of virtual CPU being limited. If no type is specified when a resource pool is defined, it defaults to the primary real processor type on the z/VM system. The valid CPU types are:

### CP

indicates a central processor.

### IFL

indicates an IBM Integrated Facility for Linux processor.

### CPU NOLIMit

prevents the enforcement of CPU capacity limiting for the defined pool.

### STORAge NOLIMit

prevents the enforcement of memory limiting for the defined pool.

## Usage Notes

1. The DEFINE RESPOOL command can limit only CP and IFL CPU types and is intended to create a pool for groups of guests that use only these types of CPUs, such as a group of Linux virtual machines that use only IFLs.
2. CPU limiting can work only when CONSUMPTION limiting is in effect on the z/VM system. This setting (SET SRM LIMITHARD CONSUMPTION) is the default. As a result, a pool can be created only if the system is set to CONSUMPTION limiting. While a pool exists, the SRM LIMITHARD setting cannot be changed.
3. A pool exists from the time the DEFINE RESPOOL command is issued until the z/VM system shuts down or a DELETE RESPOOL command is issued for it. The pool must be defined before SCHEDULE commands to assign guests to the pool are issued. If a permanent pool is desired, add the DEFINE RESPOOL command to the AUTOLOG1 profile or add a COMMAND statement to the AUTOLOG1 directory entry. This will ensure that the pool is created early in the IPL process, before guests permanently assigned to the pool (that is, via SCHEDULE commands in their directory entries) are logged on.
4. This command offers two very different methods for limiting CPU resources:
  - The LIMITHARD method determines the resources available to the pool based on how many shared logical cores of the specified type are online to the z/VM system. Logical processors dedicated to guest virtual CPUs are ignored. This method uses a specific percentage of the shared CPU resources for the pool, and the amount of CPU resources available to the pool will change whenever a VARY PROCESSOR command is issued to change the number of online shared cores.

**Attention:** CP always assumes that every logical core can run to 100% busy, regardless of the LPAR's entitlement and regardless of the availability of excess power on the CPC. For example, if the system has five shared logical IFL cores, CP assumes that the shared IFL CPU resource has a total capacity of 500%. If a pool is defined with a LIMITHARD 50% setting for TYPE IFL, the pool will be allowed to run to 250% busy (that is, consume up to 2.5 cores of power). If PR/SM is limiting the LPAR's five logical IFL cores to 280% total capacity, CP will still allow the pool to run to 250% busy. In that case, CP is really allowing the pool to consume  $(250/280) = 89\%$  of the scheduled IFL CPU resource.

- The CAPACITY method sets a specific CPU processor power limit for the pool. As long as the CPU CAPACITY limit is less than the amount of CPU resource of that type on the z/VM system, the amount of CPU available to the pool does not change when the VARY PROCESSOR command is issued, or if the CPU affinity of an IFL-limiting pool toggles between the on and suppressed settings. For example, a pool with a CAPACITY of 0.8 IFL cores will retain that limit regardless of the number of IFL cores on the system. If there are no IFL cores on the system, this pool will be running with CPU affinity suppressed and will be limited to 0.8 CP cores.

The only time a system change can affect the resources given to a pool with a CAPACITY limit is if the CAPACITY value is greater than the resources of that type on the system before or after the change. For example, say that the limit for LINGRP1 is 3.5 IFLs but there are only 2 IFL cores varied online. In this case, the CAPACITY limit is greater than the amount of shared CPU resource on the z/VM system, so the pool runs as if there is no CPU limit, and the LINGRP1 users can use all of the IFL cores available (2.0) without exceeding their limit. If another IFL core is varied online, this pool can now use more CPU resource (up to the available 3.0 IFLs). If a fourth IFL core is varied online, this pool will be limited to 3.5 IFL cores, and that limit will remain if more IFL cores are added.

5. You are allowed to define a resource pool with virtual CPU type IFL when there is no IFL core on that z/VM system. Users assigned to this pool are required to have CPU affinity on and will run with CPU affinity suppressed while on the z/VM system with no IFL cores. All users in the pool need to use the same underlying CPU resource for pooling to work, which is why all users assigned to a pool must have CPU affinity on. Based on the availability of IFL cores, z/VM will toggle the users and the pool together between CPU affinity on and CPU affinity suppressed.
6. If pools are used in an SSI environment, compatible pools should be defined on all members of the SSI cluster where users assigned to the resource pool could log on or be relocated. A user who is assigned to a pool can be relocated only to another member of the SSI cluster where a compatible pool exists. Compatible pools have the same pool name and the same type of virtual CPU. If a guest is being relocated between a system with IFLs and one without them, CPU affinity will be adjusted on the destination system so that the CPU affinity settings for the guest and the pool are identical.
7. After a pool has been created, use the SCHEDULE command to assign users to and remove users from the pool. When a guest is in a pool, its primary CPU type cannot be changed with the DEFINE CPU command, and its CPU affinity cannot be turned off with the SET CPUAFFINITY command.
8. When APAR VM65680 is applied and multithreading is enabled, prorated core time is used in the pool limiting calculation for all pools. When multithreading is not enabled or APAR VM65680 is not applied, raw CPU time is used instead. For an explanation of the different measures of CPU time, see [Simultaneous Multithreading \(SMT\) in z/VM: Performance](#).
9. LIMITHARD 100% is equivalent to and reported as CPU NOLIMIT.
10. Share settings control access to CPU power on a system-wide, per-processor-type basis, but they have no bearing or influence on how the power associated with a RESPOOL is distributed to its members. When the RESPOOL limit is reached, all members of the pool are put onto the limit list for a while, and then, after a delay sufficient to compensate for any excess use, they are all removed. The scheduler makes no effort to distribute the power of the RESPOOL to its members in accordance with the members' share settings.

## Responses

Response 1:

```
Resource pool poolname is created
```

confirms that the resource pool has been created.

specifies a 3800 Model 3 printer in Model 1 compatibility mode.

#### **vdev**

#### **AS vdev**

is the virtual device number for the spooling device you are defining.

#### **SIZE *width length***

specifies the physical characteristics of the paper to be loaded into the 3800 printer. The variable *width* is the hexadecimal width code of the paper. The variable *length* is the decimal length of the paper.

Specify *length* as a whole number using half-inches. If *width* and *length* are not specified, 14-7/8 x 11 inches is assumed. The default value of *width* is X'0F'. The default value of *length* is 22 (11 inches).

The following is a list of form width codes available; all other values are rejected.

<b>Code</b>	<b>Width in Inches</b>	<b>Width in Millimeters (ISO)</b>
01	6 - 1/2	165
02	Reserved	180
04	8 - 1/2	215
06	9 - 1/2	235

Code	Width in Inches	Width in Millimeters (ISO)
07	9 - 7/8	250
08	10 - 5/8	270
09	11	280
0A	12	305
0B	Reserved	322
0D	13 - 5/8	340
0E	14 - 3/10	363
0F	14 - 7/8	378

**4WCGM****2WCGM**

specifies the number of writable character generation modules (WCGMs) assumed for the virtual 3800 printer. A WCGM is a 64-position portion of 3800 character generation storage that holds the scan elements of 1 character set. A 3800 can have either 2 or 4 WCGMs. If neither is specified, the default is 4WCGM.

**Note:** Specifying 3800-3 with 2WCGM results in an error message.

**CFS****BTS**

specifies the stacker for the virtual 3800 printer. You can choose either CFS (continuous forms stacker) or BTS (burster trimmer stacker). If neither is specified, the default is CFS.

**NODATCK****DATCK**

specifies the desired handling of certain virtual 3800 data checks. If neither is specified, the default is NODATCK.

If you specify DATCK, all 3800 data checks are reflected to the virtual machine (provided the BLOCK DATA CHECK CCW has not been issued). If you specify NODATCK, only data checks that occur because of invalid translate table specifications or unmatched FCB codes are reflected to the virtual machine.

**Note:** DATCK should be specified only when absolutely necessary, as it severely increases the overhead associated with simulation of WRITE and SKIP CCWs to the virtual 3800. In general, the reflection of data checks because of overprinting and invalid EBCDIC codes is not necessary.

**Usage Notes**

1. Avoid using device addresses that can be mistaken for device types (such as 1403 and 3203). When it encounters a device address that is the same as an IBM device type, CP assumes that you are specifying a device type and not a device address.
2. If you define a virtual 3211 printer, it supports the CP command LOADVFCB and the INDEX feature.
3. The default classes given to spool files created on this device are as follows:
  - Class A reader
  - Class A printer
  - Class A punch.
4. Virtual printers, consoles, and punches are created with the default option NOEOF.
5. Defaults for some real printer attributes (for example CHARS) are not set when a virtual printer is created with the DEFINE command.
6. The maximum data length for a VAFP spool file is 32767 bytes. See the RSCS library for information on RSCS logical record length restrictions.

## DEFINE (Spooling Device)

7. There is no Channel Command Word (CCW) validation performed for VAFP devices. Therefore, spool files for VAFP devices may contain CCWs that do not appear for other devices (for example: SENSE ID and READ FCB). Specifically, when performing CCW I/O operations to a VAFP printer, most CCWs in the channel program are treated as a write operation CCW. The exceptions are X'08' which is treated as a transfer in channel command, X'03' with a byte count of one which is treated as a no operation instruction, and X'04' which is treated as a sense command.

The flags in the CCW flag field (for example, command chaining and data chaining flags) will be respected for VAFP devices as they are for other virtual printers with one exception. The SKIP flag will be ignored because most CCWs are treated as write operations by these devices. The SKIP flag will be preserved in the CCW that is placed in the spool file.

8. VAFP spool files with skip to channel other than 1 will not be rejected.
9. There is no corresponding real device type for a VAFP.
10. VAFP spool files are intended for use by AFP printers and real printers managed by RSCS. VAFP printers are not intended for normal use as a virtual printer.

Print files created on VM using the VAFP support can be chosen for printing by the CP real printer system. Care must be taken by the application which creates these files. If the file is to be printed on a VM system printer, the application must only use standard impact printer CCWs to create the file.

11. Files created on a VAFP device can be read by the virtual card reader using either an assembler I/O instruction or DIAGNOSE code X'A8'. However, the data in these files may be truncated. With respect to the read operation, these files are treated like a file created on a virtual 3800 printer. That is, the file is treated as if it has a logical record length of 204 and the records are truncated at that point. The data in these files can be accessed without truncation by using DIAGNOSE X'14' or the IUCV \*SPL system service.
12. For more information, see [“Usage Notes” on page 122](#).

### Examples

```
define reader as 00c
```

You can specify the operands after *vdev* in any order and repeatedly. However, the last specification of a repeatedly defined operand is the one used. For example, if you enter:

```
define 3800 as 00a cfs datck size 07 22 2wcgm bts
```

BTS is the value used instead of CFS because it was specified after CFS.

### Responses

Response 1:

```
type vdev DEFINED
```

confirms that the device has been defined.

#### **type**

identifies a reader, printer, or punch.

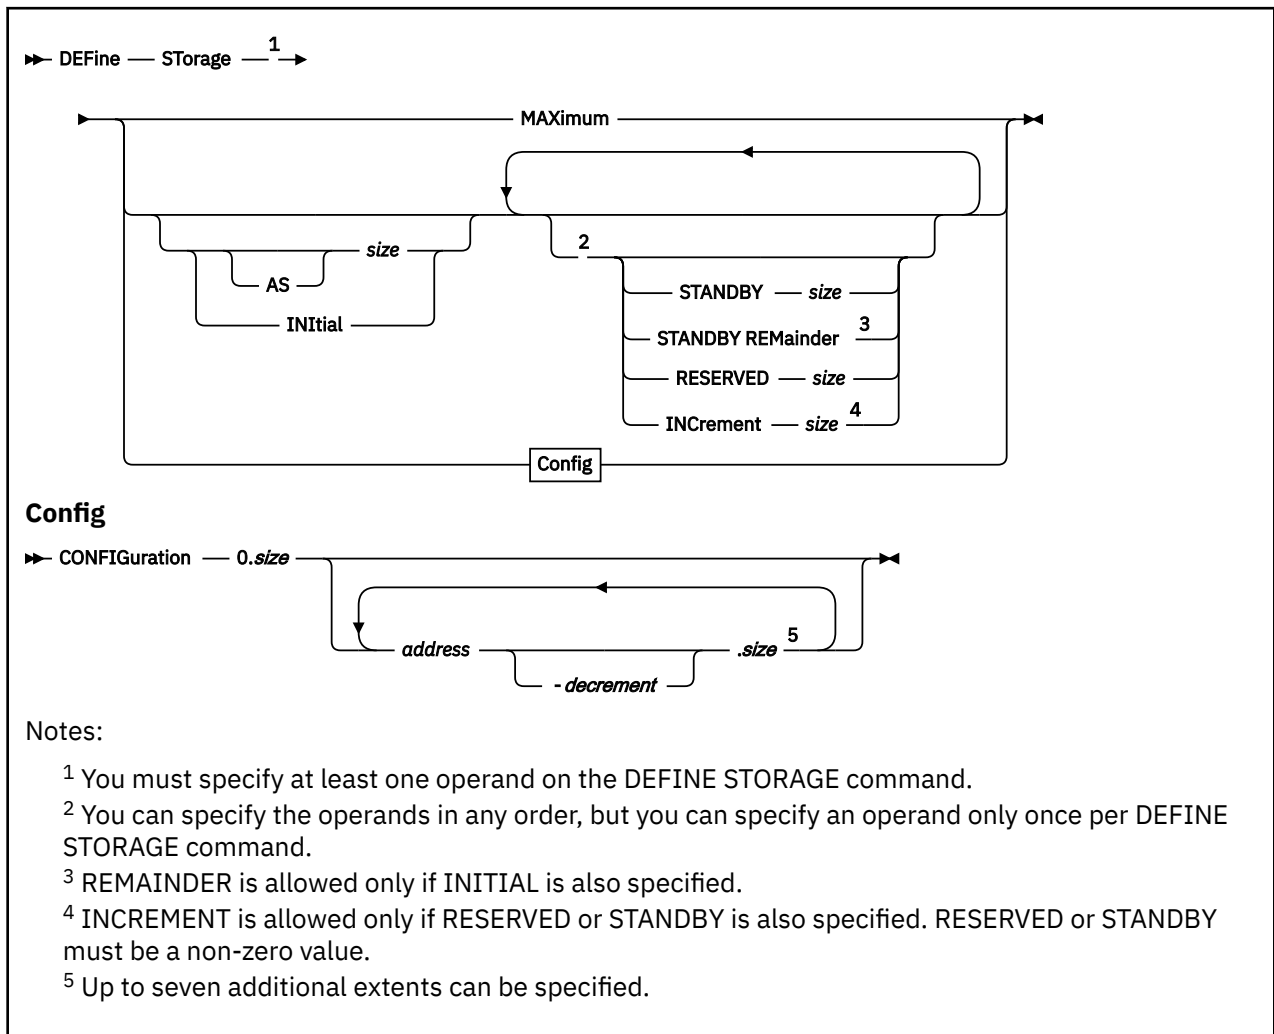

#### **vdev**

identifies the virtual number of the spool device.

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE STORAGE

### Authorization

Privilege Class: G

### Purpose

Use DEFINE STORAGE to change the storage size of your virtual machine.

### Operands

#### MAXIMUM

specifies that the maximum size of virtual machine storage as defined on the MAXSTORAGE statement, if any, or defined in the USER directory entry for the virtual machine, is to be the online storage size of your virtual machine. No other keywords can be specified, because when MAXIMUM is specified, the RESERVED and STANDBY storage sizes are 0.

#### AS size

specifies the online storage size of your virtual machine. When the RESERVED or STANDBY operand is also specified, the AS size might be adjusted upward because of the storage-increment size specified by the INCREMENT operand, or as determined by CP. The sum of the AS or INITIAL, RESERVED, and STANDBY storage sizes cannot exceed the maximum storage size specified for the virtual machine in the CP directory.

## DEFINE STORAGE

See usage note [“8” on page 217](#) for an example that demonstrates how the AS size might be adjusted by CP.

### **INITIAL**

specifies that the initial size of virtual machine storage as defined on the STORAGE statement, if any, or defined in the USER directory entry for the virtual machine, is to be the online storage size of your virtual machine. When the RESERVED or STANDBY operand is also specified, the INITIAL size might be adjusted upward because of the storage-increment size specified by the INCREMENT operand, or as determined by CP. The sum of the AS or INITIAL, RESERVED, and STANDBY storage sizes cannot exceed the maximum storage size specified for the virtual machine in the CP directory.

IBM recommends that you use INITIAL in a DEFINE STORAGE command with the STANDBY REMAINDER option specified.

See usage note [“14” on page 218](#) to understand in which situations using INITIAL causes a system-reset-clear function to be performed.

### **STANDBY size**

specifies the standby storage size of your virtual machine.

The STANDBY size might be adjusted upward by CP because of the storage-increment size specified by the INCREMENT operand, or as determined by CP. The sum of the AS or INITIAL, RESERVED, and STANDBY storage sizes cannot exceed the maximum storage size specified for the virtual machine in the CP directory. You can specify a STANDBY storage size of 0.

See usage note [“1” on page 216](#) for more information about using STANDBY storage, and see usage note [“8” on page 217](#) for an example of how the STANDBY storage size might be adjusted by CP.

### **STANDBY REMAINDER**

specifies that the STANDBY storage size should be calculated. The INITIAL keyword must be specified when you specify STANDBY REMAINDER. When you specify STANDBY REMAINDER, the STANDBY storage is equal to the maximum storage size (from the CP directory) minus the initial storage size (from the CP directory) and the RESERVED value specified on the DEFINE STORAGE command. The STANDBY size might be adjusted upward or downward by CP because of the storage-increment size specified by the INCREMENT operand, or as determined by CP. The sum of the AS or INITIAL, RESERVED, and STANDBY storage sizes cannot exceed the maximum storage size specified for the virtual machine in the CP directory.

See usage note [“13” on page 218](#) for examples of using the STANDBY REMAINDER keyword.

### **RESERVED size**

specifies the reserved storage size of your virtual machine.

The RESERVED size might be adjusted upward by CP because of the storage-increment size specified by the INCREMENT operand, or as determined by CP. The sum of the AS or INITIAL, RESERVED, and STANDBY storage sizes cannot exceed the maximum storage size specified for the virtual machine in the CP directory. You can specify a RESERVED storage size of 0.

See usage note [“14” on page 218](#) to understand in which situations using RESERVED causes a system-reset-clear function to be performed.

### **INCREMENT size**

specifies the size of a unit of storage that can be added or removed by an operating system running in a virtual machine. The minimum size is 1 MB and must be a power of 2. If necessary, CP adjusts the value up or down to conform to the architected requirements.

See usage note 8 for an example demonstrating how the INCREMENT size might be adjusted by CP.

When no standby or reserved storage is defined for the virtual machine, by default or because the STANDBY and RESERVED operands are set to 0, the INCREMENT operand is not allowed. In this case, the increment size reflected to a second-level operating system is 1 MB.

See usage note [“14” on page 218](#) to understand in which situations using INCREMENT causes a system-reset-clear function to be performed.

**size**

is the size of the storage you are defining (when CONFIGURATION is not specified). The *size* value is of the form *nu*, where *n* is a 1- to 7-digit decimal number and *u* is the 1-character storage unit suffix (see Table 17 on page 215). For the AS value, *n* must be greater than 0. For the RESERVED or STANDBY value, a size of 0 is valid.

Table 17. Maximum Input Values for Storage Units

Storage unit (powers of 2)	Suffix ( <i>u</i> )	Maximum input value ( <i>n</i> )
Kilobytes	K	2096128
Megabytes	M	9999999
Gigabytes	G	9999999
Terabytes	T	9999999
Petabytes	P	16384
Exabytes	E	16

**Notes:**

1. The K suffix is provided for upward compatibility only; a K specification is rounded up to a MB value. The maximum specification is 2096128K (2047 MB). The K suffix is not valid with a CONFIGURATION specification.
2. The maximum input value of 9999999 for the M, G, or T suffix is not a size limit but the physical limit of the operand (7 digits plus suffix). If the maximum input value for one of these suffixes does not allow you to define the amount of storage you want, you need to use a larger storage unit.
3. An XC virtual machine cannot address more than 2047 MB of storage in its base address space.

**CONFIGURATION**

allows you to define multiple, noncontiguous storage extents. You can also define a single extent just as you would without CONFIGURATION, for example:

```
DEF STOR 64M
DEF STOR CONFIG 0.64M
```

The advantage of CONFIGURATION is that it provides more detail in the command response and in the output of the QUERY VIRTUAL STORAGE command.

**0.size**

is the size of the first extent you are defining (when CONFIGURATION is specified), which always starts at address 0. The *size* value is of the form *nu*, where *n* is a 1- to 7-digit decimal number and *u* is the 1-character storage unit suffix (see Table 17 on page 215).

**address**

is the starting address of the extent you are defining. The *address* value is of the form *nu*, where *n* is a 1- to 7-digit decimal number and *u* is the 1-character storage unit suffix (see Table 17 on page 215). The first address must be zero. Subsequent extent start specifications must specify a higher address than the ending address of the last extent plus one (contiguous extents are not valid).

**.size**

is the size of the extent you are defining. The *size* value is of the form *nu*, where *n* is a 1- to 7-digit decimal number and *u* is the 1-character storage unit suffix (see Table 17 on page 215).

**-decrement**

is subtracted from the extent starting *address* specified to calculate the actual extent start address you are defining. The *decrement* value is of the form *nnnu*, where *nnnn* is a 1- to 4-digit decimal number and *u* is the 1-character storage unit suffix (see Table 17 on page 215). The *decrement*:

- Cannot be larger than the *address*
- Cannot cause overlap or abutment of a previous extent specification.

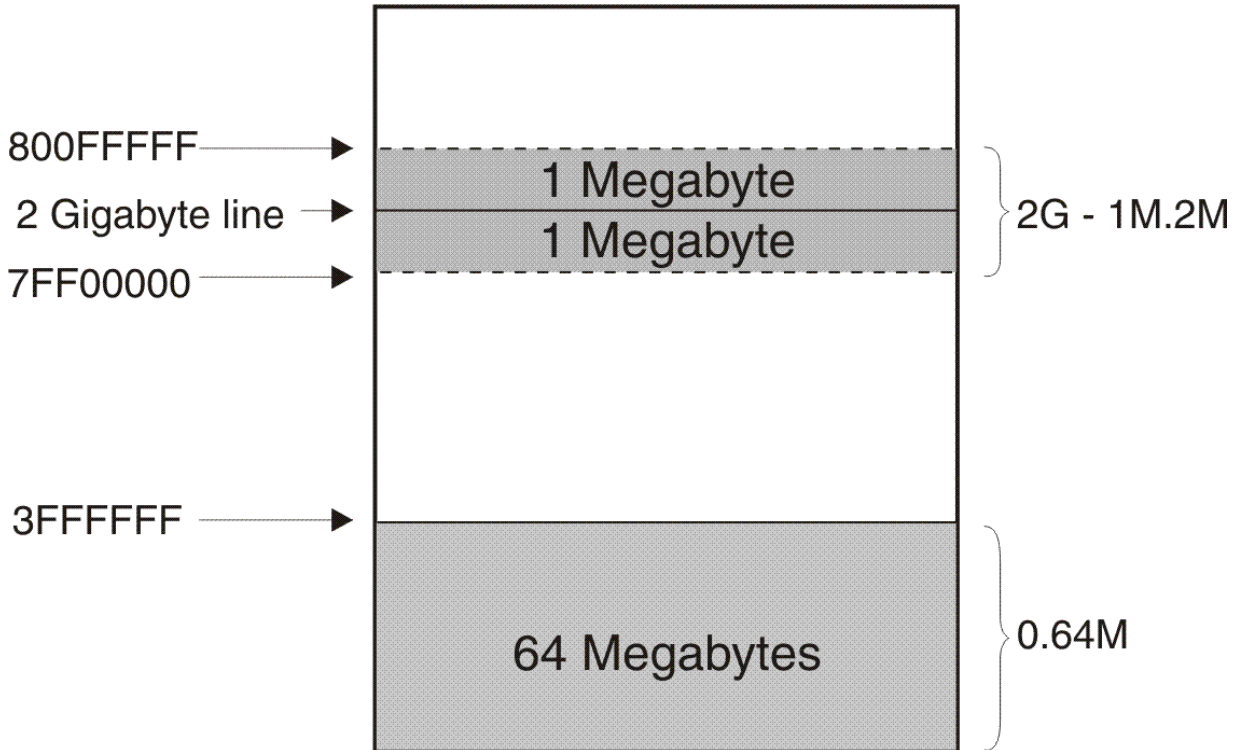

## DEFINE STORAGE

- Must use a unit of measure smaller than the one used for *address*

The *decrement* value helps to determine addresses of higher values, especially when they cross boundaries, for example:

```
DEF STOR CONFIG 0.64M 2G-1M.2M
```

This would define the 66 MB of storage shown below without you having to know (or type in) the address that is 1 MB below the 2 GB line:

The response would be:

```
def stor config 0.64m 2g-1m.2m
STORAGE = 66M
Storage Configuration:
0.64M 2G-1M.2M
Extent Specification          Address Range
-----
          0.64M              0000000000000000 - 0000000003FFFFFF
          2G-1M.2M          000000007FF00000 - 00000000800FFFFF
Storage cleared - system reset.
```

See Response 3 for a detailed definition of the information.

## Usage Notes

1. The STANDBY operands allow you to define standby storage before you IPL a guest operating system in the virtual machine.

This allows a second-level operating system to exploit the dynamic storage reconfiguration (DSR) capabilities of the architecture. For example, the operator of a second-level z/VM system can issue the SET STORAGE command to convert standby storage to configured storage, thereby increasing the size of the storage configuration, or convert configured storage to standby storage to reduce the size of the storage configuration. These changes can be seen first-level in the QUERY VIRTUAL STORAGE command response values for STORAGE= and STANDBY=.

2. AS specified alone (without a RESERVED or STANDBY value) defines the online storage size of the virtual machine. If the online storage size is changed, or if reserved or standby storage was previously

defined, a system-reset-clear function is performed. If reserved or standby storage was previously defined, their sizes are set to zero.

3. RESERVED specified alone (without an AS or STANDBY value) defines the reserved storage size of the virtual machine but does not change the online size or standby size. You can specify a reserved storage size of 0, with or without an AS or STANDBY value. A system-reset-clear function is performed when a RESERVED value is specified. Use of RESERVED is not recommended unless directed by IBM.
4. STANDBY specified alone (without an AS or RESERVED value) takes the standby amount of storage from the reserved storage size or returns it. That is, the RESERVED value is implicitly adjusted opposite to the STANDBY value, so that their sum remains unchanged. When you specify only the STANDBY value, it cannot be set to greater than the sum of the current STANDBY and RESERVED values. No system-reset-clear function is performed when a STANDBY value is specified alone.
5. If more than one option is specified, a new virtual machine configuration is defined containing the respective storage areas:
  - If the AS option is not specified, its value is the previously configured amount. If a virtual machine has changed the amount of its real storage (for example, if the operator of a second-level z/VM system has issued the SET STORAGE command or a Linux guest has issued a chmem command), the response for a DEFINE STORAGE or QUERY VIRTUAL STORAGE command at first level will reflect the updated amount of online configured and STANDBY storage for the virtual machine.
  - If AS is specified and either the RESERVED or STANDBY option is not specified, the respective value is assumed to be zero.

If any storage size is different from the current configuration, a system-reset-clear function is performed.

6. If the DEFINE STORAGE command performs a system-reset-clear function, it is as though the SYSTEM CLEAR command had been processed. The effects of this system-reset-clear function are described in the description of the CLEAR operand of the SYSTEM command. (See “SYSTEM” on page 1911.) Because a system-reset-clear function sets all of your virtual machine storage to binary zeros, you must repeat your IPL procedure to continue operation.
7. A DEFINE STORAGE command that results in a system-reset-clear function will fail when issued while a VMRELOCATE of the virtual machine is in progress.
8. A storage increment is the unit in which an operating system can add or remove storage. If the INCREMENT operand is not specified on the DEFINE STORAGE command, CP determines the increment size. When no standby or reserved storage is defined for the virtual machine, the increment size is set to 1 MB. Otherwise, the increment size must be a power of 2 in megabytes and no less than 1/512th of the AS size, or 1/512th of the sum of the STANDBY plus RESERVED sizes, whichever is larger. If the increment size you specify does not adhere to these rules, CP adjusts the value, along with the AS or INITIAL, RESERVED, and STANDBY sizes, to be multiples of the increment size. The resulting values are displayed in the DEFINE STORAGE command response. For example, in the following command, all values are adjusted:

```
DEFINE STORAGE 1M STANDBY 3G RESERVED 543G INCREMENT 3M
STORAGE = 2G MAX = 15E INC = 2G STANDBY = 4G RESERVED = 544G
```

where:

- The INCREMENT size is adjusted downward to a power of 2, namely 2 MB.
- The INCREMENT size is adjusted again to 1/512th of the AS size, and made a power of 2; in this case it remains 2 MB.
- The INCREMENT size is adjusted again to 1/512th of STANDBY + RESERVED, and made a power of 2, specifically 2 GB.
- The AS size must be adjusted to at least the INCREMENT size, and must be a multiple of the INCREMENT size, specifically 2 GB.
- The STANDBY size must be adjusted to at least the INCREMENT size, and must be a multiple of the INCREMENT size, specifically 4 GB

## DEFINE STORAGE

- The RESERVED size must be adjusted to at least the INCREMENT size, and must be a multiple of the INCREMENT size, specifically 544 GB.

If any adjustment causes the sum of the AS or INITIAL, RESERVED, and STANDBY sizes to exceed the maximum storage size specified for the virtual machine in the CP directory, the command fails and message HCP0094E is issued.

9. If the increment size you specify on the DEFINE STORAGE command using the INCREMENT operand, or the increment size determined by the DEFINE STORAGE command, is less than 128 MB, a second-level z/VM system running in the virtual machine will apply a dynamic storage reconfiguration (DSR) unit size of 128 MB in place of the storage-increment size. When this occurs, the increment size (INC=) displayed using the QUERY STORAGE command on the second-level z/VM system is different from the increment size (INC=) displayed by the QUERY VIRTUAL command first-level.

Because storage must be added or removed from an operating system's storage configuration in units of the storage-increment size, z/VM's usage of the DSR unit size as the effective storage-increment size, can make a portion of a virtual storage configuration unusable by a second-level z/VM system. In addition, storage values that normally round up to a storage-increment multiple, will be rounded down when insufficient CONFIGURED or STANDBY storage exists to round up.

10. The CONFIGURATION option with more than one extent is primarily for testing. Do not confuse this with loading discontinuous saved segments. Directory limits apply to the sum of the extent sizes.
11. When a second-level z/VM system comes up with the STORE=*n* IPL parameter in a virtual machine whose storage was defined with a DEFINE STORAGE CONFIGURATION command, and the STORE=*n* value falls outside of a storage extent, the highest storage address online after IPL is equal to the value that would have resulted if the STORE=*n* value had been specified.
12. For general usage notes for the DEFINE command, see [“Usage Notes” on page 122](#).
13. An example of using the STANDBY REMAINDER keyword follows:

- With this directory entry:

```
USER ANYONE SECRET18 6G 48G ABCDEFG
```

with this command:

```
DEFINE STORAGE INITIAL STANDBY REMAINDER RESERVED 16G
```

the response would be:

```
STORAGE = 6G MAX = 48G INC = 128M STANDBY = 26G RESERVED = 16G
```

14. A system-reset-clear function is performed when any of these conditions are met:

- The INCREMENT, INITIAL, or RESERVED operand is specified.
- The requested AS size is different than the current configured value.
- The requested configuration has neither STANDBY nor RESERVED storage, but the current configuration has STANDBY storage, RESERVED storage, or both. For example:

Given the current memory configuration of:

```
STORAGE = 16G MAX = 32G INC = 32M STANDBY = 5G RESERVED = 5G
```

with this command:

```
DEFINE STORAGE 16G
```

the response would be:

```
STORAGE = 16G  
Storage cleared - system reset
```

- The requested configuration has STANDBY storage, but the current configuration has no STANDBY storage. For example:

Given the current memory configuration of:

```
STORAGE = 16G
```

with this command:

```
DEFINE STORAGE 16G STANDBY 5G
```

the response would be:

```
STORAGE = 16G MAX = 32G INC = 32M STANDBY = 5G RESERVED = 0
Storage cleared - system reset
```

- The requested configuration's sum of STANDBY and RESERVED storage is different from the current configuration's sum of STANDBY and RESERVED storage. For example:

Given the current memory configuration of:

```
STORAGE = 16G MAX = 32G INC = 32M STANDBY = 5G RESERVED = 5G
```

with this command:

```
DEFINE STORAGE 16G STANDBY 7G
```

the response would be:

```
STORAGE = 16G MAX = 32G INC = 32M STANDBY = 7G RESERVED = 0
Storage cleared - system reset
```

## Responses

Response 1 is displayed when the DEFINE STORAGE command contains only the AS, INITIAL, or MAXIMUM operand:

```
STORAGE = nu
```

where:

### **STORAGE = nu**

specifies the size of virtual machine storage.

Response 2 is displayed when the DEFINE STORAGE command contains the STANDBY operand, the RESERVED operand, or both:

```
STORAGE = nu MAX = nu INC = nu STANDBY = nu RESERVED = nu
```

where:

### **STORAGE = nu**

specifies the size of online (assigned) virtual machine storage.

### **MAX = nu**

specifies the maximum size of virtual machine storage as defined in the user directory entry for the virtual machine. You cannot use the DEFINE STORAGE command to increase the virtual machine's total storage beyond this amount.

### **INC = nu**

specifies the size of the virtual machine storage increment.

### **STANDBY = nu**

specifies the amount of virtual machine storage in standby state that is available to be configured online.

### **RESERVED = nu**

specifies the amount of virtual machine storage in reserved state that can be defined online or as standby. Use of RESERVED is not recommended unless directed by IBM.

## DEFINE STORAGE

Response 3 is displayed when the DEFINE STORAGE command results in a system-reset-clear function:

```
STORAGE CLEARED - SYSTEM RESET
```

Response 4 is displayed when the DEFINE STORAGE command contains the CONFIGURATION operand:

```
STORAGE = nu
Storage Configuration:
configspec

Extent Specification                Address Range
-----
          0.ssssssssssssu 00000000_00000000 - endadres_endadres
boundaryaddressu.ssssssssssssu begadres_begadres - endadres_endadres
boundaryadru-nnnnu.ssssssssssssu begadres_begadres - endadres_endadres
```

where:

### **STORAGE = nu**

specifies the size of online (assigned) virtual machine storage, including the configuration extents.

### **configspec**

is the storage configuration specification input used on the DEFINE STORAGE CONFIGURATION command that defines the current storage configuration.

### **Extent Specification**

specifies the information supplied by the QUERY VIRTUAL STORAGE command. Each configuration extent is listed on a separate line:

#### **boundaryaddressu**

#### **boundaryadru**

is the boundary address as specified in the DEFINE STORAGE CONFIGURATION command, where *u* is the 1-character storage unit suffix.

#### **sssssssssssssu**

is the extent size, 1 - 14 decimal digits followed by the 1-character storage unit suffix.

#### **nnnnu**

is the decrement specified in DEFINE STORAGE CONFIGURATION used to modify the extent start boundary address, expressed as 1 - 4 decimal digits followed by the 1-character storage unit suffix (which must be a smaller storage unit than that used for the start address it modifies). The decrement is subtracted from the base start boundary specification to determine the effective extent start boundary address.

### **Address Range**

specifies the extent information converted to beginning and ending addresses:

#### **begadres\_begadres**

is the 16-digit extent start address expressed in hexadecimal format (always ends in X'00000', a megabyte boundary). Underscores are used for readability if SET UNDERSCORE ON has been issued.

#### **endadres\_endadres**

is the 16-digit extent end address expressed in hexadecimal format (always ends in X'FFFFFF', 1 less than a megabyte boundary). Underscores are used for readability if SET UNDERSCORE ON has been issued.

## Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

Messages:

- HCP093E RESERVED (*resize*) exceeds hardware maximum (*maxsize*)
- HCP093E STANDBY (*stbysize*) exceeds hardware maximum (*maxsize*)
- HCP093E STANDBY (*stbysize*) plus RESERVED (*resize*) exceeds hardware maximum (*maxsize*)

- HCP093E Storage size (*storsize*) exceeds hardware maximum (*maxsize*)
- HCP093E Storage size (*storsize*) plus RESERVED (*ressize*) exceeds hardware maximum (*maxsize*)
- HCP093E Storage size (*storsize*) plus STANDBY (*stbysize*) exceeds hardware maximum (*maxsize*)
- HCP093E Storage size (*storsize*) plus STANDBY (*stbysize*) plus RESERVED (*ressize*) exceeds hardware maximum (*maxsize*)
- HCP094E Storage size (*storsize*) plus STANDBY (*stbysize*) plus RESERVED (*ressize*) exceeds directory maximum (*maxsize*)
- HCP096E Configuration extent (*extent*) exceeds maximum allowed on this processor (*maxsize*). Storage configuration remains unchanged.
- HCP098E Insufficient storage available to satisfy STANDBY request
- HCP099E {STANDBY|RESERVED|INCREMENT} option conflicts with current storage configuration

## DEFINE SUBSTITUTE

### Authorization

Privilege Class: A

### Purpose

Use DEFINE SUBSTITUTE to define which virtual machine is actually used as the target for IUCV communication requests addressed to a specified *alias* user identifier.

### Operands

#### *alias*

is the substitute to be defined. The *alias* may not be the user identifier of a virtual machine that is defined in the CP User Directory.

#### *userid*

specifies the user identifier for which the substitute is to be set or cleared.

#### OFF

removes the substitute for the user.

### Usage Notes

1. A substitute may be used to refer to a virtual machine by another name (user identifier) for the purposes of inter-machine communication using IUCV. Any communications addressed to the substitute will be redirected to the specified virtual machine.
2. A substitute may be defined or removed for a virtual machine regardless of whether it is logged on. If a substitute is removed, existing IUCV communication paths that were established using it are not affected.

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE (Temporary Disk)

### Authorization

Privilege Class: G

### Purpose

Use DEFINE (temporary disk) to increase virtual workspace by attaching temporary disks to your virtual machine. A temporary disk is private (cannot be shared by another virtual machine).

### Operands

#### T2314, T2319, or T3310

All above DASD are accepted for compatibility but result in a message indicating that the temporary disk is not defined because space is not available.

#### T3380, T3390, T9336, or TFB-512

All above DASD add a temporary virtual disk to your virtual machine configuration. The 4 digits following the T correspond to the virtual device type. TFB-512 indicates that any supported FBA device is acceptable.

#### AS *vdev*

##### *vdev*

is the virtual device number of the temporary disk you are defining.

#### CYL *ncyl*

##### *ncyl*

is the size of this temporary disk in cylinders (valid only for CKD and ECKD disks).

#### BLK *nblk*

##### *nblk*

is the size of this temporary disk in blocks (valid only for FBA disks).

### Usage Notes

1. Temporary disk space is assigned from a pool of DASD resources; therefore, you should always format your temporary disk space before you use it.
2. The temporary disk may be slightly larger than the size requested because of CP's implementation of system temporary disk space management.
3. Using ICKDSF is the preferred method for formatting a DASD device if it is to be used by CP (such as an IPL device). The CMS FORMAT command should be used to format a DASD device if it is to be used as a CMS disk.

## DEFINE (Temporary Disk)

4. Temporary disks created with this command have cache access if they are on a cached control unit.
5. A minidisk, including a temporary disk, is not eligible for minidisk cache if it has been defined with greater than 32767 cylinders. This does not apply to FBA devices. It applies only to ECKD devices.
6. If you define a temporary disk as virtual device number 192, the following special rules apply when you IPL CMS:
  - If 192 is unformatted, CMS formats it and accesses it as file mode D.
  - If 192 is CP-formatted, CMS reformats it for CMS use and accesses it as file mode D.
  - If 192 is CMS-formatted and accessed as a file mode other than D, CMS reaccesses it as file mode D.When CMS accesses a 192 minidisk as file mode D, any minidisk or SFS directory already accessed as D is released.
7. For more information, see [“Usage Notes” on page 122](#).

### Responses

```
DASD vdev DEFINED
```

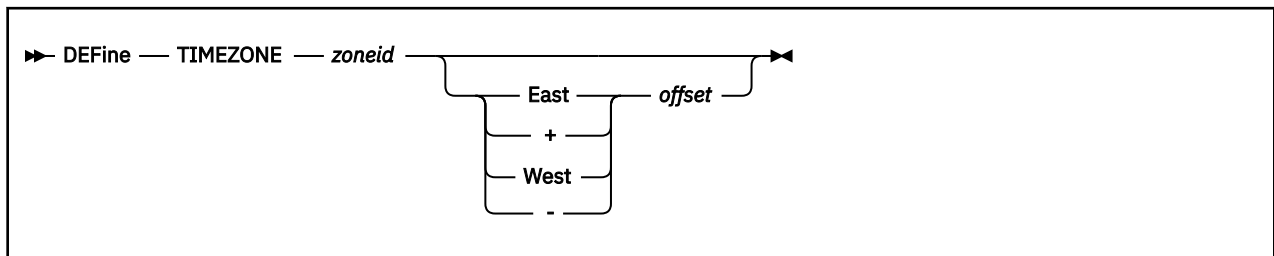

confirms the definition of the temporary disk.

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE TIMEZONE

### Authorization

Privilege Class: A

### Purpose

Use DEFINE TIMEZONE to define a new time zone or change an existing time zone definition.

To activate a time zone, use the SET TIMEZONE command. To display the defined time zones, use the QUERY TIMEZONES command. For more information, see [“SET TIMEZONE” on page 1738](#) and [“QUERY TIMEZONES” on page 1222](#).

### Operands

#### *zoneid*

is the time zone ID you wish to define or change. The time zone ID must be an alphanumeric string of 1-4 characters. GMT (Greenwich Mean Time) and UTC (Coordinated Universal Time) are reserved time zone IDs.

#### **East**

+

indicates that the time zone is east of longitude 0. CP adds the specified *offset* to UTC to define the time zone ID. EAST is the same as +.

#### **West**

-

indicates that the time zone is west of longitude 0. CP subtracts the specified *offset* from UTC to define the time zone ID. WEST is the same as -.

#### *offset*

is the time difference between UTC and the zone ID you are defining. You can specify the offset in either of the following formats:

*hh:mm:ss*

*hh.mm.ss*

where *hh* is the hour, *mm* are the minutes, and *ss* are the seconds. You can separate the hour from the minutes and seconds using either a colon (:) or a period (.), but you cannot use both in one offset definition. You must specify at least a 1-digit number for the hour; everything else is optional. However, if you want to specify seconds, you must specify the hour and the minutes. If you want to specify the minutes, you must specify the hour.

For example, if you want to specify an offset of 5 hours, no minutes, and no seconds, all of the following are valid offsets:

```

5
05
5:0
05.00

```

## DEFINE TIMEZONE

```
5.0.0  
05:00:00
```

### Usage Notes

1. If you specify an existing time zone ID, CP changes the specified time zone definition to reflect the new direction and offset from UTC.
2. If you change the time zone definition for the zone ID that is currently in effect, you do not affect the local time on your system. To put the change into effect, use the SET TIMEZONE command. For more information on the SET TIMEZONE command, see [“SET TIMEZONE” on page 1738](#).
3. You can also define and set time zones in the system configuration file by using the TIMEZONE\_DEFINITION and TIMEZONE\_BOUNDARY statements. For more information, see [TIMEZONE\\_DEFINITION Statement](#) and [TIMEZONE\\_BOUNDARY Statement](#).

### Responses

Response 1:

When you enter the DEFINE TIMEZONE command, CP responds with information on the newly defined or changed time zone ID. For example:

```
define timezone est west 05.00.00  
Time zone EST has been defined as 05.00.00 west of UTC.  
Ready;
```

shows that you have defined or changed the time zone ID EST to be 5 hours west of UTC.

### Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

Messages:

- HCP0987E DEFINE TIMEZONE not valid - STP timezone in use

## DEFINE (Virtual Device)

### Authorization

Privilege Class: G

### Purpose

Use DEFINE (virtual device) to change the device number of any device in your virtual machine configuration.

### Operands

#### **vdev1**

is the device number of an existing virtual device.

#### **AS vdev2**

#### **vdev2**

is the new virtual device number.

### Usage Notes

1. Avoid using device addresses that can be mistaken for device types (such as 1403 and 3203). When it encounters a device address that is the same as an IBM device type, CP assumes that you are specifying a device type and not a device address. To avoid potential confusion and errors, use the REDEFINE command.
2. Virtual paging subsystem devices cannot be redefined. This is done to protect the integrity of the user virtual paging subsystem.
3. Devices that are part of a virtual network adapter cannot be redefined. Virtual network adapters are defined with the DEFINE NIC command.
4. If the existing virtual device is part of a Concurrent Copy (CONCOPY) session for your virtual machine, the CONCOPY session is terminated in the storage control associated with the device.
5. If you change the virtual device number of your console while spooling your console, the spool file device number will also change.
6. If you define a minidisk as virtual device number 192, the following special rules apply when you IPL CMS:
  - If 192 is an unformatted temporary minidisk or virtual disk in storage, CMS formats it and accesses it as file mode D.
  - If 192 is a CP-formatted temporary minidisk or virtual disk in storage, CMS reformats it for CMS use and accesses it as file mode D.
  - If 192 is a CMS-formatted temporary minidisk, virtual disk in storage, or permanent minidisk accessed as a file mode other than D, it is released.
  - If 192 is an unformatted or CP-formatted permanent minidisk, CMS does not automatically format, reformat, access, or reaccess it.

When CMS accesses a 192 minidisk as file mode D, any minidisk or SFS directory already accessed as D is released.

7. For more information, see [“Usage Notes” on page 122](#).

### Responses

Response 1:

```
type vdev2 DEFINED
```

confirms that the device number has been changed.

#### **type**

is device type you defined. The *type* values are:

#### **Type**

#### **Meaning**

#### **CONS**

Console

#### **CTCA**

Channel-to-channel adapter

#### **CTLR**

3745 Communications Controller

#### **DASD**

Direct access storage device

#### **DEV**

Any other device

#### **GRAF**

Display graphic device

#### **LINE**

Communication line

#### **MSC**

Mass Storage Controller

#### **OSA**

Open Systems Adapter

#### **PRT**

Printer

#### **PUN**

Card punch

#### **RDR**

Card reader

#### **SWCH**

Dynamic Switching Device

#### **TAPE**

Magnetic tape

#### **vdev2**

identifies the new device number.

Response 2:

```
Redefining vdev1 has caused the termination of  
CONCOPY session(s) on device(s): vdev...
```

indicates that Concurrent Copy (CONCOPY) sessions have been terminated during the process of changing the existing virtual device number.

#### **vdev1**

is the existing virtual device number that you are changing.

#### **vdev...**

is a list of the virtual device numbers that are part of the terminated CONCOPY sessions.

## Messages

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

## DEFINE (Virtual Disk in Storage)

### Authorization

Privilege Class: E, G

### Purpose

Use DEFINE to create a virtual disk in storage attached to your virtual machine. A virtual disk in storage created using this command is temporary, private (cannot be shared by another virtual machine), and simulates an FBA minidisk, which is defined in 512-byte blocks. The virtual disk in storage is destroyed when you detach it or log off.

### Operands

*vdev*

**AS** *vdev*

is the virtual device number to be assigned to the virtual disk in storage.

*nnnnnnn*

**BLK** *nnnnnnn*

is the size of the virtual disk in storage in 512-byte blocks. The maximum size is 4194296 blocks.

### Usage Notes

1. A virtual disk in storage is allocated from system storage, not mapped to a real DASD. Therefore, defining a virtual disk in storage does not require having a real FBA DASD in your system configuration.
2. A virtual disk in storage must be formatted before it can be used. Using ICKDSF is the preferred method for formatting the virtual disk in storage if it is to be used as a system disk by a guest (such as VSE) or a second-level CP. The CMS command FORMAT should be used to format the virtual disk in storage if it is to be used as a CMS disk.
3. Virtual disks in storage are allocated in 8-block pages. Therefore, the size of the virtual disk in storage that is created may be rounded up to the nearest page. You can use all of the blocks in the created virtual disk in storage.
4. If you define a virtual disk in storage as virtual device number 192, the following special rules apply when you IPL CMS:
  - If 192 is unformatted, CMS formats it and accesses it as file mode D.
  - If 192 is CP-formatted, CMS reformats it for CMS use and accesses it as file mode D.
  - If 192 is CMS-formatted and accessed as a file mode other than D, CMS reaccesses it as file mode D.

When CMS accesses a 192 minidisk as file mode D, any minidisk or SFS directory already accessed as D is released.
5. This command will fail if issued when VMRELOCATE is in progress.
6. For more information, see [“Usage Notes” on page 122](#).

### Responses

Response 1:

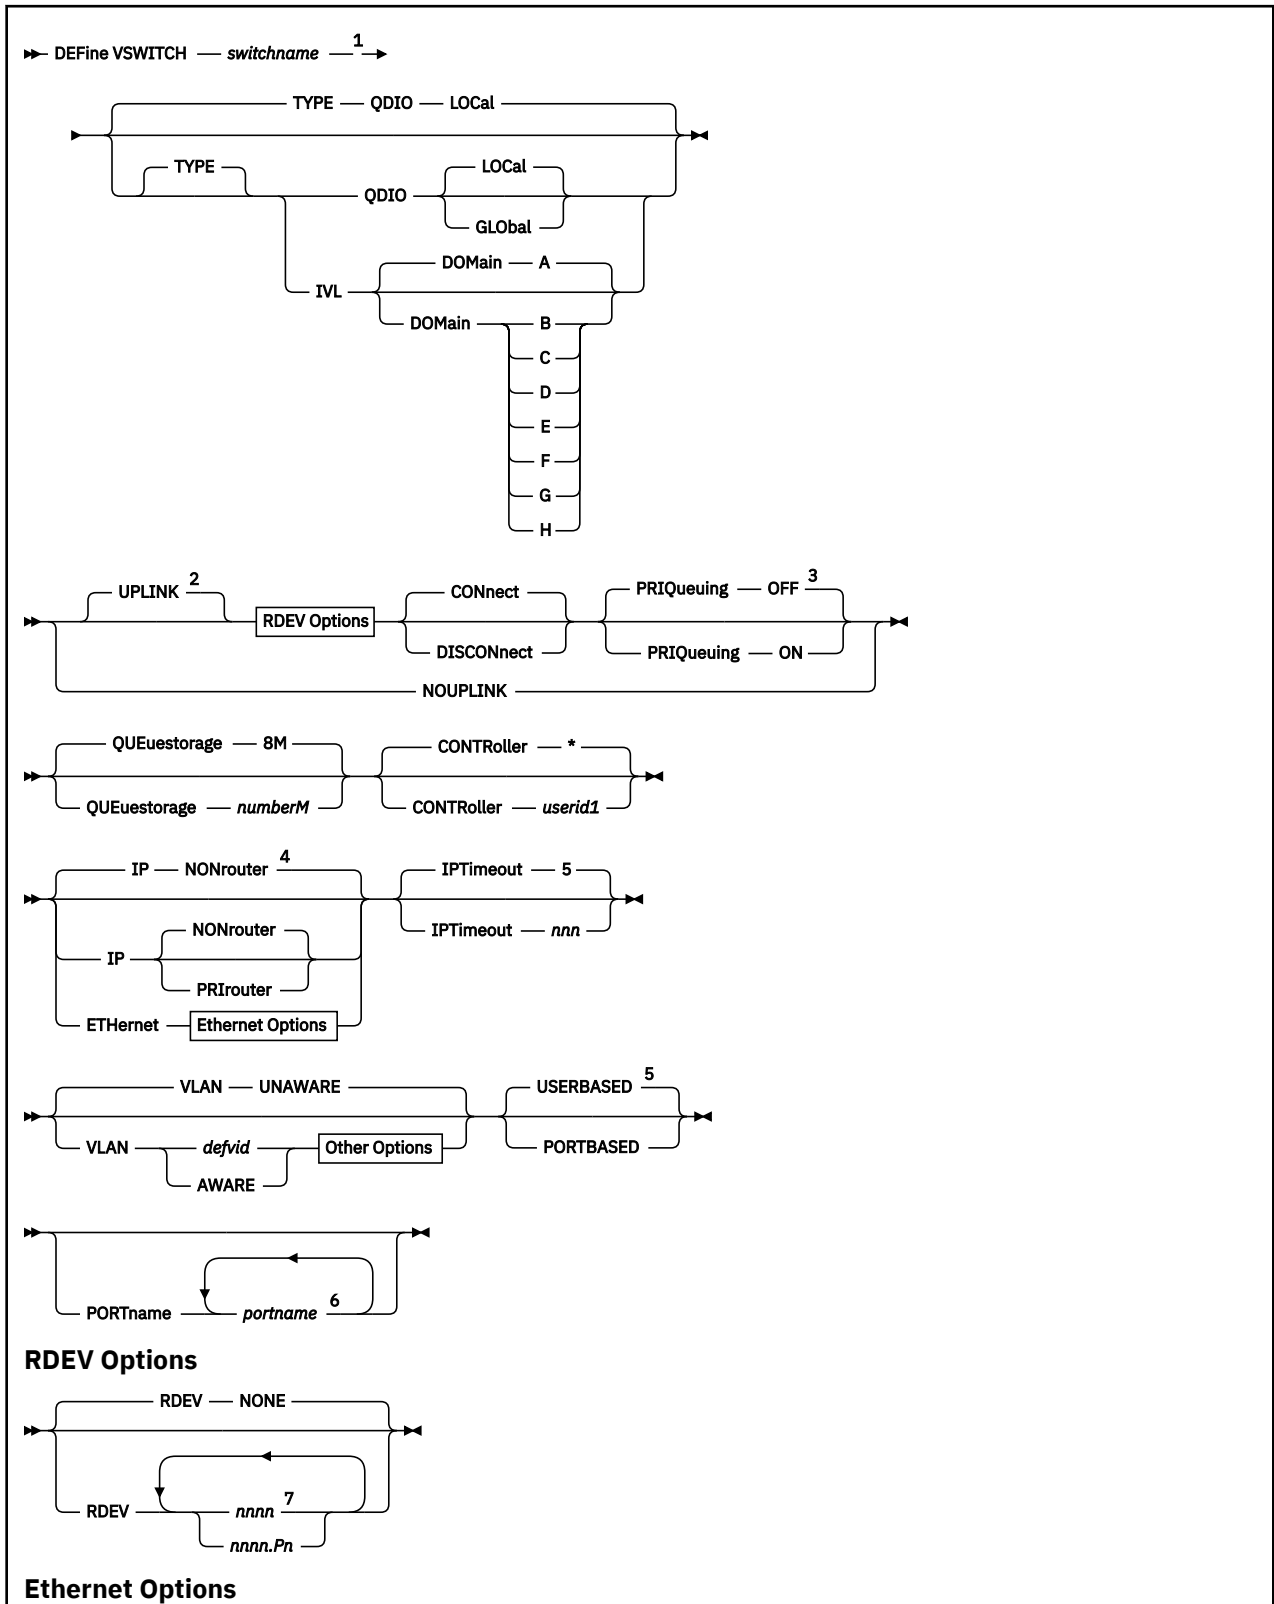

```
DASD vdev DEFINED
```

confirms the creation of the virtual disk in storage.

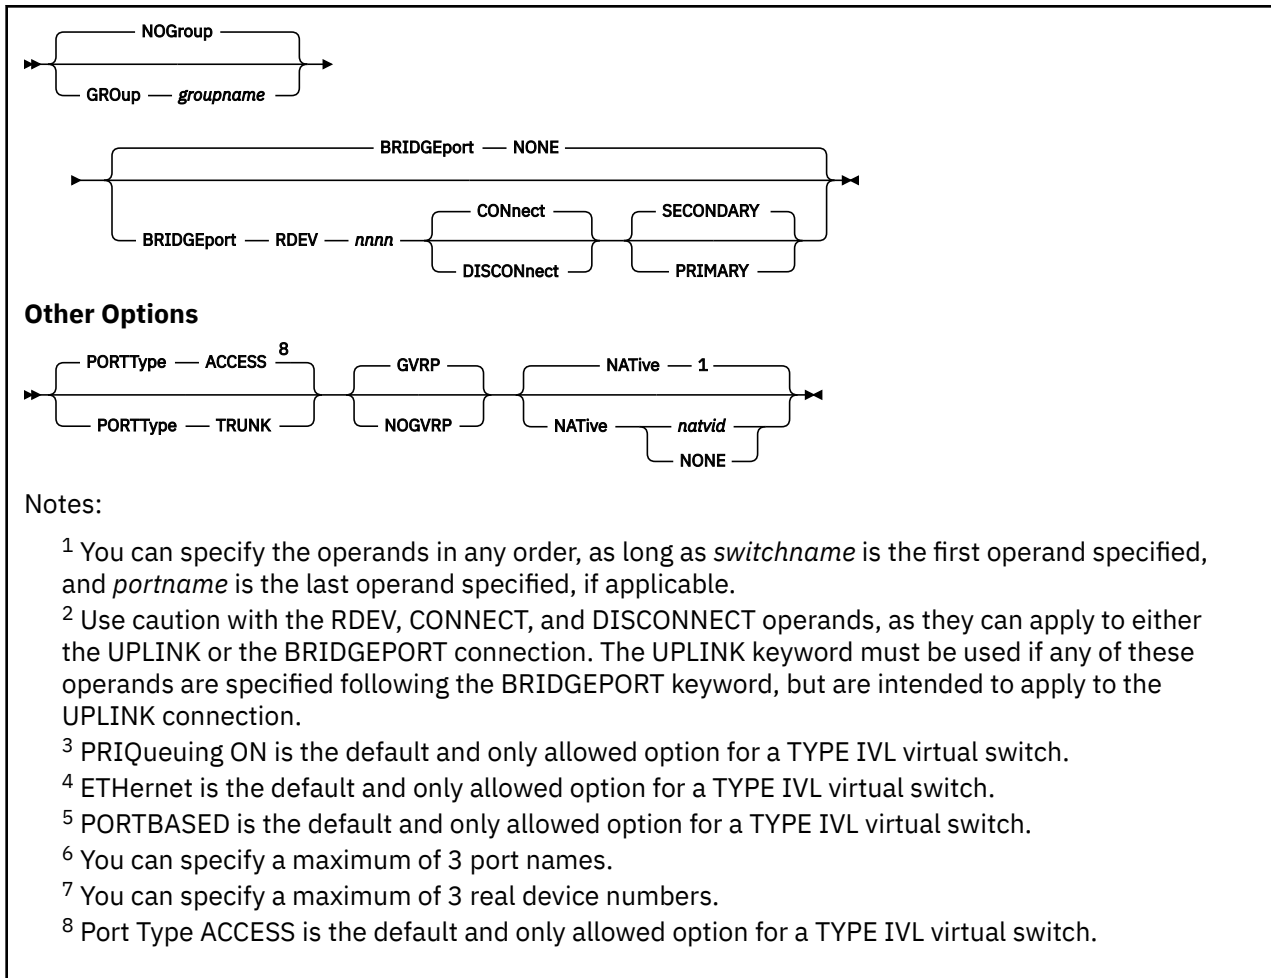

### **Messages**

For the list of general messages for the DEFINE command, see [“Messages” on page 122](#).

# DEFINE VSWITCH

## Authorization

Privilege Class: B

## Purpose

Use the DEFINE VSWITCH command to create a CP system-owned switch (a virtual switch) to which virtual machines can connect. Each switch is identified by a *switchname*. A z/VM user can create the appropriate QDIO network interface card (NIC) and connect it to this switch. For information about related commands, see [“COUPLE” on page 83](#) and [“DEFINE NIC” on page 194](#). For more information about [Virtual Networking Options](#), see *z/VM: Connectivity*.

The SET VSWITCH command can be used to modify attributes of the virtual switch. See [“SET VSWITCH” on page 1757](#) for more information on this command.

You can also define a virtual switch during system initialization using the DEFINE VSWITCH configuration file statement. For more information about the [DEFINE VSWITCH Statement](#), see *z/VM: CP Planning and Administration*.

## Operands

### *switchname*

is the name of the new virtual switch. The *switchname* is a single token (1–8 alphanumeric characters) that identifies this virtual switch for subsequent commands.

### TYPE

specifies the type of virtual switch to be created, specifically the hardware and protocol the virtual switch will emulate.

**QDIO**

defines a simulated Ethernet or IP virtual switch. A QDIO virtual switch creates a network comprised of both simulated QDIO devices residing on the same z/VM system, with real network devices located on an external or physical network. A QDIO type virtual switch can only accept connections from a simulated QDIO adapter. External connectivity to network devices on a physical network is achieved using the RDEV or GROUP keywords.

**IVL**

defines an Inter-VSwitch Link which provides the communication facility to implement an IVL Domain. An IVL domain is a grouping of up to 16 systems running z/VM connected by an IVL LAN segment. All the active members within an IVL domain provide control operations that support the creation and management of shared virtual networking components such as Shared Port Groups. The IVL virtual switch provides communication infrastructure to exchange control information and data necessary to manage global networking objects that can span multiple systems running z/VM. The IVL virtual switch must be defined with external connectivity (using the RDEV or GROUP keywords) and its UPLINK connection must remain operational in order to support global networking objects.

Only one IVL virtual switch may be created on a system running z/VM.

Guest NICs may not be coupled to an IVL virtual switch.

**DOMain [A | B | C | D | E | F | G | H]**

defines the domain to which the IVL virtual switch belongs. See [“19” on page 243](#) for more information about an IVL virtual switch.

**GLobal**

identifies this virtual switch as a member of a global virtual switch. A global virtual switch is a collection of virtual switches that share the same name and the same networking characteristics. This collection of virtual switches spans multiple systems running z/VM but logically operates as a single switch.

Global virtual switches using a shared port group must reside on LPARs in the same CEC.

See [usage note 18](#) for more information about a global virtual switch.

**LOCal**

LOCAL means that the virtual switch is not a member of a global virtual switch.

**UPLINK**

enables and specifies connectivity for a virtual switch UPLINK port. The UPLINK port is a special port that typically is used to connect the virtual switch to a physical switch, essentially bridging the virtual switch's simulated network to a physical network.

**RDEV *nnnn*****RDEV *nnnn.Pn***

is a real device number or a real device number and OSA-Express port number to be used as an UPLINK port to connect the virtual switch to the appropriate model OSA-Express device. The device selected must be compatible to the type of virtual switch created. Connectivity to the physical network will be prevented when the specified device doesn't match the virtual switch's type.

Specify each real device number as a hexadecimal number between X'0001' and X'FFFD'. If specifying a real device and an OSA-Express port number, specify the real device number as a hexadecimal number between X'0001' and X'FFFD' followed by a period (.), the letter 'P' (or 'p') followed by the port number as a hexadecimal number between X'0' and X'F'. For example, to specify port 1 for RDEV 300, specify "300.P1". The value of the port number depends on how many ports the OSA-Express hardware adapter supports. If the port number is not specified, it will default to port 0.

You can specify a maximum of three real device numbers. If you specify more than one device number, each must be separated from the others by at least one blank. When the virtual switch has been defined with the GROUP attribute, any devices identified by the RDEV keyword are used for failover in the event of a real switch failure of the link aggregation group. Failover in this environment will be to a single OSA-Express device connected to a second real switch.

Each real device number represents a trio of devices. For example, specifying **RDEV 111 222 333** means that the first devices, 111-113, are used to provide the connection to the real hardware LAN segment. When issuing the VSWITCH command without the GROUP attribute, if there is a problem with the connection, devices 222-224 are used next to provide the connection, and if those devices fail to connect, devices 333-335 are used. This feature provides dynamic recovery for OSA-Express device failures when issuing the VSWITCH command without the GROUP attribute or for real switch failure when issuing the VSWITCH command with the GROUP attribute. (Failure of an OSA in an aggregated group is automatically handled by the virtual switch; that is, the virtual switch will transfer the data flow to the remaining OSAs in the group.)

RDEV NONE means that the virtual switch should not be connected to the real LAN segment when defined with NOGROUP. When the virtual switch has been defined with GROUP, RDEV NONE means that there is no link aggregation group failover in the event the real switch should fail.

The RDEV operand may not be used to specify device numbers when the virtual switch is configured to use a shared port group. MAC address takeover is managed by the shared port group to maintain connectivity following a failure.

### **CONNECT**

indicates that the currently configured virtual switch UPLINK port must be activated, and traffic may flow through the specified UPLINK ports device(s).

### **DISCONNECT**

indicates that the currently configured virtual switch UPLINK port must not be activated, and that no traffic is to flow through the specified UPLINK ports device(s).

A virtual switch can be functional without a connection to a real LAN segment, and traffic flows only between virtual machines coupled to the virtual switch.

### **PRIQUEUING**

enables or disables guest priority queuing support on all outbound data transmissions from the virtual switch uplink port to an external network. Priority queuing is a capability of the OSA-Express feature where multiple output queues are defined for a single network connection with each queue weighted by a priority on how often it gets serviced by the OSA-Express feature. The highest priority queue is serviced first and more often followed by the next highest priority and so on. No queue is starved and all will get serviced at some point by the OSA-Express feature. See [Virtual Switch Priority Queuing Function](#) in *z/VM: Connectivity* for more information on virtual switch exploitation of priority queuing.

If PRIQUEUING is to be enabled on a virtual switch, then the OSA-Express features configured to the virtual switch's uplink port must be configured by IOCP to enable the feature within the adapter (PQ\_ON). (See ["DEFINE CHPID / PATH"](#) on page 132 for more information.)

### **OFF**

The virtual switch will not exploit priority queuing. A single input queue is established for inbound transmissions from the external network and a single output queue is established for outbound transmissions. All outbound data to the external network is transmitted with equal priority. This is the default for TYPE QDIO virtual switches.

The OFF option is not allowed for a TYPE IVL virtual switch.

### **ON**

The virtual switch will exploit priority queuing. If the customer configured the OSA-Express features used by a virtual switch uplink port for priority queuing via IOCP (PQ\_ON), then z/VM will establish one input queue and four output queues when activating its network connection. This will allow z/VM to transmit data to the external network at four different priorities. CP will use the highest priority queue for control and management traffic. The other three queues (low, normal and high) can be used for virtual NICs' network connections. This is the default for TYPE IVL virtual switches.

For an IVL virtual switch, z/VM will attempt to establish an active network connection with the first OSA device specified. For migration reasons, if the OSA-Express features (used by the IVL virtual switch uplink port) are configured without priority queuing (PQ\_OFF), z/VM will establish an active

## DEFINE VSWITCH

network connection, and force priority queuing off. A warning message will be displayed to inform the customer to configure priority queuing via IOCP.

If the OSA-Express features used by a non-IVL virtual switch uplink port are configured without priority queuing (PQ\_OFF), z/VM will not establish an active network connection, and an error message will be displayed.

The policy used to select which priority a specific datagram is transmitted to the external network is determined by the type of virtual switch.

For an IVL virtual switch, the priority of outbound transmissions is handled by z/VM. IVL management traffic will be queued and transmitted on a high priority queue, and encapsulated production data failover traffic will be sent on a lower priority queue. The default for TYPE IVL virtual switches is PRIQueuing ON so that IVL network management data and encapsulated production data can be prioritized appropriately. Only an OSA-Express feature configured for priority queuing should be used on an IVL virtual switch's uplink port.

For all other virtual switch types, the priority can be set to low, normal or high for all packets sent from a guest NIC's network connection to an external network via the SET VSWITCH command. See the PQUPLINKTX operand on [“SET VSWITCH” on page 1757](#) for more information.

### NOUPLINK

indicates the virtual switch will never have connectivity to a physical network through the UPLINK port. This option removes the UPLINK port from the virtual switch. Once the UPLINK port is removed, it can never be added back to the virtual switch.

Defining a virtual switch UPLINK port with either the RDEV or GROUP operands while also removing the UPLINK port with the NOUPLINK operand will cause the command to fail.

The NOUPLINK option is not allowed for a TYPE IVL virtual switch.

### QUEuestorage *numberM*

indicates the upper limit of the amount of fixed storage CP and Queued Direct I/O Hardware Facility will use for buffers for each OSA-Express data device.

*number* defines the maximum number of megabytes of storage that can be consumed for QDIO queues on a single OSA port. When multiple OSA devices are defined in a link aggregation group, then each OSA port within the group will use the specified amount of storage. Fixed storage is allocated as needed based on network traffic, until the maximum of *numberM* are allocated.

*number* is a number from 1 to 8. 8 is the default value.

### CONTRoller \*

#### CONTRoller *userid1*

identifies the z/VM user ID that controls the OSA-Express device connected at the device number identified by *rdev*. CONTROLLER \* means CP selects from any of the eligible z/VM TCP/IP stacks. See usage note [“3” on page 239](#) for more information about the function of a controller.

If you specify multiple real devices on the RDEV keyword, or through the GROUP keyword, then specify CONTROLLER \*, or allow it to default. The controller functions are then spread across multiple z/VM TCP/IP stacks, providing more flexibility in case of a failure. You can also specify a pool of specific controllers to be chosen from by specifying a list of user IDs after the CONTROLLER keyword with the SET VSWITCH command or the MODIFY VSWITCH statement.

### IP

#### ETHernet

indicates whether the transport for the virtual switch is ETHERNET or IP. The ETHERNET transport type is Data Link (Layer 2) based, where the ETHERNET frame is used as a point of reference for source and destination Media Access Control (MAC) addresses in transporting ETHERNET frames on the LAN. The IP transport type is Network (Layer 3) based, where the IP packet is used as the point of reference for source and destination IP addresses in transporting IP packets on the LAN.

If this option is omitted for a type QDIO virtual switch, then the transport is set to IP NONROUTER. For an IVL virtual switch the ETHERNET setting is used. An IVL virtual switch can function correctly only

at the Data Link (layer 2) level. Specifying anything other than ETHERNET for an IVL virtual switch will cause the command to fail.

#### **NONrouter**

indicates that the OSA-Express device identified by the RDEV keyword will not act as a router to the virtual switch. If a datagram is received at this device for an unknown IP address, the datagram will be discarded. This is the default.

#### **PRIrouter**

indicates that the OSA-Express device identified by the RDEV keyword will act as a primary router to the virtual switch. If a datagram is received at this device for an unknown IP address, the datagram will be passed to the virtual switch.

#### **GRoup *groupname***

indicates that the virtual switch UPLINK port is to be configured to use IEEE 802.3ad Link Aggregation. The *groupname* is a single token (1-8 alphanumeric characters) that identifies the group. Use the SET PORT GROUP command to specify the attributes of the group and the OSA-Express devices that will make up the group. This option can only be specified when the virtual switch has been defined with the ETHERNET transport attribute. **NOGROUP** means that the virtual switch will not use Link Aggregation. The port group must be defined using the SET PORT GROUP command before creating a GLOBAL virtual switch. For a LOCAL virtual switch, if the group specified has not been defined, it will be created with this command.

#### **NOGROUP**

means that the virtual switch will not use Link Aggregation.

#### **BRIDGEport**

configures and specifies connectivity for a virtual switch Bridge Port. The Bridge Port is a special port that is used to connect the virtual switch to a HiperSockets CHPID, essentially bringing the HiperSockets CHPID to the virtual switch's simulated and physical networks.

Configuring a virtual switch Bridge Port is only supported when the Bridge facility is supported by the processor, the virtual switch transport type is ETHERNET, and the virtual switch TYPE is QDIO. Additionally, the ISOLATION feature cannot be used when the virtual switch has a Bridge Port.

Only guest operating systems running in a virtual machine under z/VM and exploiting QDIO Enhanced Buffer State Management (QEBSM) are eligible to be bridged from the HiperSockets CHPID to the virtual switch's simulated and physical networks.

#### **NONE**

specifies that the virtual switch does not have a Bridge Port.

#### **RDEV *nnnn***

is a real device number to be used as a Bridge Port to connect the virtual switch to a HiperSockets CHPID. Only devices that have been configured with the HiperSockets CHPID parameter EXTERNAL\_BRIDGED can be specified. Use these parameters on the DEFINE CHPID command or the appropriate CHPARM in the IOCP (x4 for EXTERNAL\_BRIDGED).

The device selected must be compatible to the type of virtual switch created; for example EXTERNAL\_BRIDGED for a QDIO type virtual switch. Connectivity to the HiperSockets CHPID will be prevented when the specified device does not match the virtual switch's type.

You must specify a single real device number as a hexadecimal number between X'0001' and X'FFFD'. The real device number specified represents a trio of devices. For example, specifying BRIDGEPORT RDEV 508 means the devices, 508-50A, are used to provide the connection to the HiperSockets CHPID.

#### **CONnect**

indicates that the device identified by the RDEV keyword will be immediately activated, allowing the connection to be used as the active or standby Bridge Port.

#### **DISCONnect**

indicates that the device identified by the RDEV keyword will be placed in the inactive state. If this connection is the active Bridge Port connection, another virtual switch with a Bridge Port on the same CHPID in standby state will take over the active Bridge Port connection.

### SECONDARY

indicates that this virtual switch should be assigned a role as a SECONDARY Bridge Port for the HiperSockets CHPID. This is the default. See usage note [“17” on page 242](#) for more information about the SECONDARY Bridge Port role.

### PRIMARY

indicates that this virtual switch must be assigned the role as the PRIMARY Bridge Port for the HiperSockets CHPID. See usage note [“17” on page 242](#) for more information about the PRIMARY Bridge Port role.

### IPTimeout *nnn*

indicates the length of time in minutes that a transient IP address table entry remains in the IP address table for the virtual network. A transient entry is an entry added to the virtual network by one guest on behalf of another. This operand has no meaning for ETHERNET networks.

*nnn* is a number from 1 to 240. 5 minutes is the default value.

### VLAN

used to enable and configure IEEE standard 802.1Q VLAN support for the virtual switch being defined. A VLAN-aware virtual switch provides VLAN controls at the user level (with SET VSWITCH GRANT, SET VSWITCH PORTNUMBER and SET VSWITCH VLANID commands) that cannot be overridden by a guest host. If this option is omitted for a type QDIO virtual switch, then the virtual switch is set to VLAN UNAWARE.

### UNAWARE

indicates the virtual switch does not support IEEE standard 802.1Q. All frames flow within the virtual switch regardless of presence or absence of Virtual Local Area Network (VLAN) tags. Any VLAN tags present in the frames will be ignored within the switch (however the guest hosts may perform VLAN filtering at the virtual NIC level).

### *defvid*

defines the virtual switch as a VLAN-aware switch supporting IEEE standard 802.1Q. The *defvid* defines the default VLAN ID to be assigned to guest ports when no VLAN ID is coded on the SET VSWITCH GRANT VLAN command, MODIFY VSWITCH GRANT VLAN statement, the SET VSWITCH PORTNUMBER command, the SET VSWITCH VLANID command, or through an ESM. It is a number from 1 to 4094.

### AWARE

defines the virtual switch as a VLAN-aware switch supporting IEEE standard 802.1Q without a default VLAN ID. When a virtual switch is specified as VLAN AWARE, one or more VLAN IDs must be assigned to each guest port by either a SET VSWITCH GRANT VLAN command, MODIFY VSWITCH GRANT VLAN statement, the SET VSWITCH PORTNUMBER command, the SET VSWITCH VLANID command, or through an ESM. Failure to assign an explicit VLAN ID causes all untagged frames transmitted from the port to be discarded. In the case of a VLAN-unaware guest using a PORTTYPE ACCESS all outbound frames will be discarded until a VLAN ID is set for the port.

### PORTType ACCESS

defines the default porttype attribute for guests authorized for the virtual switch. For PORTTYPE ACCESS, the guest is unaware of VLAN IDs and sends and receives only untagged traffic.

### PORTType TRUNK

defines the default porttype attribute for guests authorized for the virtual switch. For PORTTYPE TRUNK, the guest is VLAN aware and sends and receives tagged traffic for those VLANs to which the guest is authorized. If the guest is also authorized to the *natvid*, untagged traffic sent or received by the guest is associated with the native VLAN ID (*natvid*) of the virtual switch.

PORTTYPE TRUNK is not allowed for a TYPE IVL virtual switch.

### GVRP

indicates that the VLAN IDs in use on the virtual switch should be registered with GVRP-aware switches on the LAN. This provides dynamic VLAN registration and VLAN registration removal for networking switches. This eliminates the need to manually configure the individual port VLAN assignments.

**NOGVRP**

Do not register VLAN IDs with GVRP-aware switches on the LAN. When NOGVRP is specified VLAN port assignments must be configured manually.

**NATive *natvid*****NATIVE NONE**

the *natvid* option is available only on a VLAN-aware switch. When *natvid* is a number from 1 to 4094, this operand defines the native VLAN ID that is to be associated with untagged frames received and transmitted by the virtual switch. NATIVE NONE causes all untagged frames to be discarded, instead of being delivered with a native VLAN ID. If this option is omitted, 1 is used as the *natvid* for a type QDIO virtual switch.

**USERBASED**

operational differences between USERBASED and PORTBASED VSwitches have been eliminated.

USERBASED specifies that user based rules will be applied when relocating a guest in an SSI. A user-defined port may or may not be preserved over a relocation. Port numbers assigned by z/VM will not be preserved. New port numbers will be assigned on the destination system. If portnumber predictability across an SSI is required, use the PORTBASED option on the VSwitch in each SSI member.

Refer to [What Is the Difference Between a Port Based and User Based Virtual Switch?](#) in *z/VM: Connectivity* for more information.

**PORTBASED**

operational differences between USERBASED and PORTBASED VSwitches have been eliminated.

PORTBASED specifies that port based rules will be applied when relocating a guest in an SSI. User-defined port numbers will be preserved over a relocation. Port numbers assigned by z/VM will not be preserved. In this case a new port number will be allocated on the destination system.

Refer to [What Is the Difference Between a Port Based and User Based Virtual Switch?](#) in *z/VM: Connectivity* for more information.

**PORTname *portname***

is a 1- to 8-character name that identifies the OSA-Express adapter. You can specify a maximum of three port names. Multiple port names are used when different port names are needed for the multiple *rdevs* specified on the RDEV operand. See usage note [“10” on page 241](#) for more information.

**Note:** The PORTNAME operand is ignored when the GROUP operand is used.

**Usage Notes**

1. The DEFINE VSWITCH command creates a virtual switch. The SET VSWITCH command can be used to modify a virtual switch by authorizing users to use the switch. Authorization to a virtual switch may also be provided by an External Security Manager.
2. Accounting is set for the switch based on the default accounting state as set by the SET VMLAN ACCOUNT SYSTEM command or configuration statement. If accounting is turned on after the virtual switch is defined, the virtual switch will need to be redefined for accounting to take effect.
3. A virtual switch's connection to a real hardware LAN segment is not operational until an eligible z/VM TCP/IP stack is selected to be the controller for the OSA-Express device. CP selects an eligible z/VM TCP/IP stack to be the controller by either:
  - If CONTROLLER *userid1* is specified on the DEFINE or SET VSWITCH commands or the DEFINE or MODIFY VSWITCH System Configuration statements, with either a single user ID or a list of user IDs, only those user IDs are selected.
  - If CONTROLLER \* is specified or allowed to default, CP selects from any eligible z/VM TCP/IP stacks.

A z/VM TCP/IP stack becomes eligible when:

## DEFINE VSWITCH

- The TCPIP MODULE running in the controller is at a release level that supports the function required for the virtual switch. It is recommended that the VSWITCH controller be at the same release level as CP, although all supported releases are allowed.
- An IUCV \*VSWITCH statement is included in its CP directory entry.
- The TCP/IP VSWITCH CONTROLLER statement is coded, and has defaulted to be ON or is explicitly set to ON in the TCP/IP configuration file or through an OBEYFILE command.
- The stack has completed initialization.
- The stack has virtual device numbers available for CP to attach the control device.

The virtual device range used by CP is specified in the VSWITCH CONTROLLER TCP/IP configuration statement. If no VDEV range is specified, CP uses the virtual device number (*vdev*) that matches the *rdev* number specified on the DEFINE VSWITCH or SET VSWITCH command. See the [VSWITCH CONTROLLER Statement](#) in *z/VM: TCP/IP Planning and Customization* for more information.

**Note:** Do not code DEVICE and LINK TCP/IP configuration statements for the device. Do not attach the device to a TCP/IP controller virtual machine. These steps are handled by DEFINE VSWITCH processing when a controller is selected.

If an eligible stack is not found, or none of the *rdevs* are operational, you receive a message, and the virtual switch operates in a local LAN environment.

4. The virtual switch supports two modes of operation for data transport in support of both TCP/IP and non-IP based applications. In deciding which mode to deploy for your network, some things to consider about deploying an ETHERNET virtualized LAN segment are:
  - Do your servers or applications need to have their own unique MAC addresses (load balancers)?
  - Do you plan to deploy non-IP based applications on your network (SNA or NetBIOS, for example)?
  - Do you want to build a virtual LAN segment that operates closely to its physical counterpart?

The key attributes of each transport mode with their operational characteristics are as follows:

- **ETHERNET (Layer 2)**

- Supports all applications that deploy ETHERNET (IEEE 802).
- ETHERNET frames are transported on the LAN segment.
- All destinations are identified by MAC address.
- MAC addresses are locally administered by the LAN administrator through z/VM CP commands or configuration statements.
- Each host connection is identified by a single MAC address.
- This is a Link Layer transport, in which all hosts maintain their respective ARP caches.
- VLAN tagging resides within the ETHERNET frames per IEEE 802.1Q specifications.
- When GROUP attribute is specified, the frames can be transported as part of the IEEE 802.3ad standard.
- When a Bridge Port is defined the virtual switch provides physical LAN connectivity for the target HiperSocket channel.

- **IP (Layer 3)**

- Supports IP for TCP/IP applications only.
- IP packets are transported on the LAN segment.
- All destinations are identified by IP addresses.
- IP address assignments are set by the host running in the guest virtual machine.
- Each host may have more than one IP address (multi-homed).
- This is Link Layer independent (that is, no MAC addresses), and ARP processing is offloaded onto the OSE-Express adapter.
- VLAN tagging resides in internal QDIO headers.

- All hosts share the OSA-Express MAC address.

A virtual switch operates in only one mode for a given instance. For example, if the switch is configured as IP, then all communications on the LAN segment must be IP based. The same is also true when the switch is configured in ETHERNET mode. These transport modes affect the method of data transfer for the virtual switch. The other operations of the switch, such as guest authorization, failover, controller configuration, and so on, function the same for both modes.

5. The IP transport type is IPv4 only. In order to support IPv6 through the virtual switch UPLINK port, the ETHERNET transport is required.
6. SET VSWITCH cannot be used to change the type of transport. The virtual switch will need to be redefined.
7. Use the QUERY CONTROLLER command output to find the z/VM TCP/IP stacks that are the virtual switch controllers. Use the QUERY VSWITCH command to display information about the virtual switch.
8. CP manages the devices used to control a virtual switch's connection to a real LAN segment through an OSA-Express device. CP attaches the devices to the z/VM TCP/IP virtual machine. CP also defines devices of type VSWITCH-OSD to the z/VM TCP/IP stack, concatenating *switchname* with *vdev* and "DEV" to form the device name and *switchname* with *vdev* and "LINK" to form the link names. These names appear in the TCP/IP query and trace information.

DEVICE and LINK statements must not be included in the TCP/IP configuration file for these devices.

The port number specified by *nnnn.Pnn* will be used by the TCP/IP stack (controller) when initializing the device. If the port number is not specified, it will default to port 0. If the port number is not supported, initialization of the device will be terminated.

9. Multiple real devices and portnames can be specified on the RDEV and PORTNAME parameters. This feature allows failover to an alternate real device in the event of a failure with the current OSA-Express device or link aggregation group. All real devices specified must be active and connected to the same hardware LAN in order to effectively and dynamically failover to an alternate device. In addition, the alternate devices must be defined on separate CHPIDs. If your OSA-Express device requires a portname, specify one portname for each real device number.
10. When the real device identified by one of the *rdevs* is started using the VSWITCH command with the NOGROUP attribute, TCP/IP assigns the port name as the hardware adapter name. If an adapter name was already assigned by a previous connection, then the port name must be the same as assigned by any other connection in order to share the adapter. This includes sharing the OSA-Express adapter with this logical partition or all other partitions.

The PORTNAME operand is optional. However, some levels of the OSA-Express adapters require that the PORTNAME operand is specified. When such an adapter is in use and the PORTNAME operand is omitted, an error message is displayed during switch initialization.

If the device is already started, you must stop it by issuing the SET VSWITCH *switchname* DISCONNECT command before changing the port name.

11. PRIROUTER is required only when IP forwarding (routing) nodes will be coupled to the switch. Router nodes provide connectivity for their LAN segments (remote nodes) through their switch connection. When Router nodes are deployed, their switch connection must be configured as PRIROUTER. In addition to this, the switch itself must also be configured as PRIROUTER to the OSA-E adapter. This will insure delivery of datagrams destined for LAN segments that are connected through routers coupled to a switch. Only one connection on each OSA-Express card can be designated as PRIROUTER. If the switch is successful in establishing PRIROUTER on the OSA-Express card, no other node (or switch) sharing the same OSA-Express card will be able to act as PRIROUTER. If another connection has already been established as PRIROUTER, the switch will be left with NONROUTER status (which is reflected in the QUERY VSWITCH response).
12. NONROUTER is the default mode for the switch. Every node is directly coupled to the switch and the associated IP destinations are registered with the OSA-Express connection. This is the most efficient way to use the virtual switch. In this mode, packets with an unrecognized IP destination are automatically sent out through the switch connection.

## DEFINE VSWITCH

13. For a VLAN aware virtual switch, you should specify the same native VLAN ID (*natvid*) as specified in your configuration of any physical switches in your network. Most hardware manufacturers use a default of 1.
14. SET VSWITCH cannot be used to change the VLAN awareness attribute. To change the attribute, detach the virtual switch and define it again with the correct attribute.
15. If the virtual switch is defined as VLAN UNAWARE, any attempts to define a VLAN membership will fail. When the CP access list is used, SET or MODIFY VSWITCH GRANT with VLAN membership list fails. In addition, SET or MODIFY VSWITCH VLANID fails and SET or MODIFY VSWITCH PORTNUMBER with VLAN members fails. When an ESM is used, the COUPLE command fails if a VLAN list is returned by the ESM.
16. SET VSWITCH cannot be used to change the USERBASED/PORTBASED attribute. The virtual switch will need to be redefined.
17. A virtual switch's Bridge Port can be configured to take on the role as either the PRIMARY or as a SECONDARY Bridge Port for the HiperSockets CHPID. SECONDARY is the default role assigned when defining a virtual switch with a Bridge Port. A single PRIMARY Bridge Port and up to four SECONDARY Bridge Ports can be defined per HiperSockets CHPID.

A functional virtual switch configured for the PRIMARY role is always selected as the *active* Bridge Port connection. Functional virtual switches configured with the SECONDARY role provide backup (standby) capability in the event of failure on the part of the active Bridge Port connection.

The first virtual switch Bridge Port successfully connecting to the HiperSockets CHPID (whether PRIMARY or SECONDARY) will take on the responsibility as the active Bridge Port connection. When the active Bridge Port connection is a virtual switch with a SECONDARY role, then its responsibility as the active Bridge Port connection will be relinquished to a connection made by a virtual switch requesting the PRIMARY role.

18. A Global virtual switch is a collection of virtual switches that share the same networking characteristics. This collection of virtual switches spans multiple systems running z/VM but logically operates as a single switch.

Virtual switches defined with the same name and the GLOBAL option are said to be members of the same global virtual switch when they reside in systems running z/VM that belong to the same IVL domain. (Definition and activation of an IVL virtual switch allows a system running z/VM to join an IVL domain. See [usage note 20](#) for more information about the IVL virtual switch.)

The following conditions must be fulfilled in order to create or change a global virtual switch member:

- The system's IVL virtual switch must be defined and its UPLINK port connected. In other words, the system must be an active member of an IVL domain.

Creation of Global virtual switches specified in the SYSTEM CONFIG file will be deferred until the IVL virtual switch UPLINK port connects the system to the IVL domain. Message HCP3178I will be displayed for each deferred Global virtual switch.

- If any other virtual switch exists in the IVL domain with the same name the following attributes must match or the DEFINE VSWITCH or SET VSWITCH will fail with message HCP3170E.
  - TYPE QDIO
  - IP or ETHERNET
  - ISOLATION
  - VEPA
  - VLAN AWARE or UNAWARE
  - NATIVE *natvid*
  - USERBASED or PORTBASED
- The following additional restrictions exist if a global virtual switch is configured to use a shared port group:
  - RDEV *device\_addr* is not allowed

19. A virtual switch defined to be TYPE IVL is an Inter-VSwitch Link which provides communication infrastructure to exchange control information and data necessary to manage global networking objects that can span multiple systems running z/VM.

A single IVL virtual switch accommodates all inter-LPAR control traffic for a system. This virtual switch is defined by the system administrator using a CP command or a statement in the System Configuration file. The DEFINE VSWITCH specifies the RDEV or GROUP operand to configure OSA-Express adapters to provide the required connectivity to systems running z/VM in other LPARs so they can all join the same IVL domain.

An IVL domain is a group of systems running z/VM that have each defined an IVL VSwitch with an UPLINK port configured and connected to the same external LAN segment. Configuration of an IVL virtual switch defines the system's IVL domain membership.

These domains allow isolation of global networking traffic through the enumeration of different domain letters A-H. Each is assigned a separate, reserved multicast MAC address. For example, communications for default Domain A is assigned to 03-FF-FF-FF-FF-01. (MAC address prefix 03-FF-FF is reserved for IVL communications for all systems running z/VM.)

The VLAN associated with a VLAN-aware IVL virtual switch can be modified using the IVLPORT VLAN operand on the SET VSWITCH command. Up to 8 IVL domains can be defined per VLAN.

Note that up to 16 systems can be members of the same IVL domain.

When a global virtual switch is in use the IVL virtual switch UPLINK port must remain operational in order to support full function for a global virtual switch that spans multiple systems.

See [IVL \(Inter-VSwitch Link\) Overview](#) in *z/VM: Connectivity* for more information.

## Examples

1. To define a switch named BIGANG that connects to a real LAN through device fd00, specify the following:

```
define vswitch bigang rdev fd00
```

2. To define a switch named ETH1 that will use Link Aggregation, specify the following commands:

```
set port group eth1grp join b c d
define vswitch eth1 ethernet group eth1grp
```

3. To define a switch named LINPROD that uses OSA-Express hardware ports, specify the following:

```
define vswitch linprof rdev 9c00.p0 9d00.p1 9e00
```

In the above example, device 9e00 will connect to port 0 on the OSA-Express.

4. To define a switch named ETH0 that connects to a real LAN through device 1e1b and to a HiperSockets CHPID through device 7000, specify the following:

```
define vswitch eth0 type qdio rdev 1e1b ethernet bridgeport rdev 7000
```

## Responses

Response 1:

```
VSWITCH SYSTEM switchname is created
```

This is the normal response for this command.

## Messages

For the list of general messages for the DEFINE command, see [“Messages”](#) on page 122.

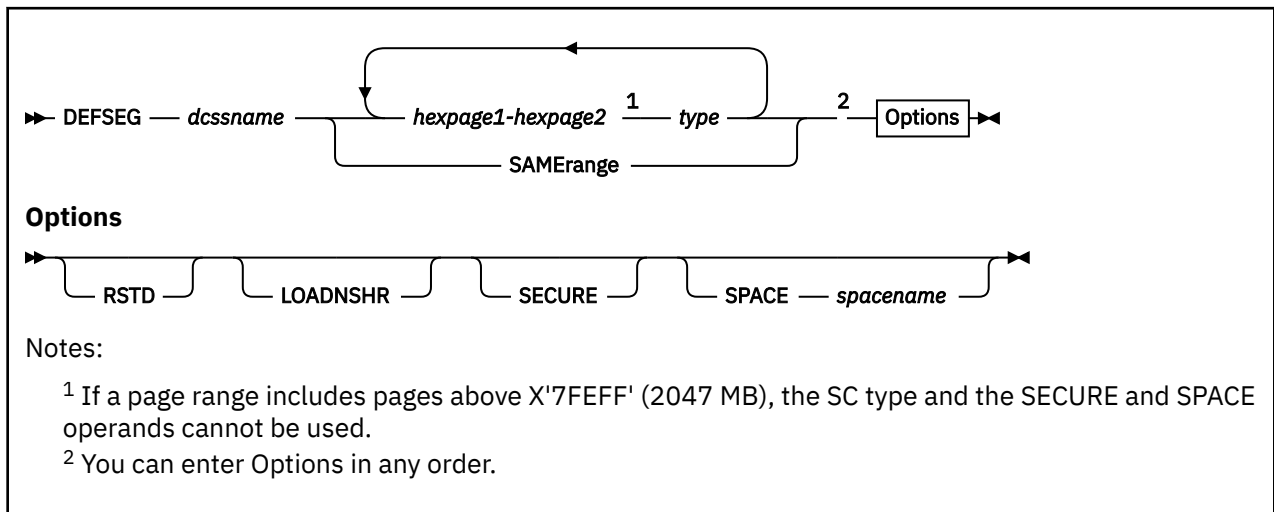

Messages:

## DEFINE VSWITCH

- HCP013E Conflicting option - *option*
- HCP025E Storage missing or invalid
- HCP2768E Missing switchname
- HCP2782E VSWITCH SYSTEM *switchnm* not created; a detach is in progress for a VSWITCH with that name
- HCP2782E VSWITCH SYSTEM *switchnm* not created; this name is already in use
- HCP2782E VSWITCH SYSTEM *switchnm* is not created; an IVL virtual switch already exists.
- HCP2784E VSWITCH *switchnm* not created; VMLAN limit has been reached
- HCP2838I Device *device* specified for VSWITCH *vswitchname* BRIDGEPORT is not a bridge-capable HiperSockets device.
- HCP2838I Device *device* specified for VSWITCH *vswitchname* is not compatible with the VSWITCH type.
- HCP2838I Device *device* specified for VSWITCH *vswitchname* is not configured for priority queuing.
- HCP2846E The [PORTTYPE | GVRP | NATIVE] option is not allowed for a VLAN UNAWARE virtual switch
- HCP2853E VSWITCH SYSTEM *switchname* not created; device limit exceeded.
- HCP2854E VSWITCH SYSTEM *switchname* not created; No MACID is available.
- HCP2854E VSWITCH SYSTEM *switchname* not created; SSI cluster mode is not stable.
- HCP2856E VSWITCH SYSTEM *switchname* not created; port group *groupname* is already in use.
- HCP3001E Device *device* is defined for both port group *groupname* and VSWITCH SYSTEM *switchname*.
- HCP3045E The Bridge facility is not supported by this processor.
- HCP3160E Virtual switch *switchnm* cannot be configured with the RDEV operand specifying back up devices.
- HCP3161E [ DEFINE VSWITCH | SET VSWITCH ] is not performed; a port group defined with the SHARED option can be used only with a virtual switch defined with the GLOBAL option.
- HCP3167E [ DEFINE VSWITCH *switchnm* | SET VSWITCH *switchnm* | SET PORT GROUP *groupname* ] failed. The IVL virtual switch does not exist or its UPLINK port is not connected.
- HCP3170E VSWITCH *systemname.switchname* [is not created | is not changed]. The virtual switch defined on *systemname* [ conflicts with the [ IP | ETHERNET | ISOLATION | VEPA | VLAN AWARE | VLAN UNAWARE | NATIVE VLAN | USERBASED | PORTBASED ] attribute ].
- HCP3170E VSWITCH *systemname.switchname* [is not created | is not changed]. An internal error occurred.
- HCP3170E VSWITCH *systemname.switchname* [is not created | is not changed]. The virtual switch defined on *systemname* [ is currently not responding | is currently in synchronization ].
- HCP3173E Device *device* is reserved for system use.
- HCP3178E [ VSWITCH SYSTEM *switchnm* | PORT GROUP *groupname* ] creation is deferred. The IVL virtual switch does not exist or its UPLINK port is not connected.
- HCP3186E [ DEFINE VSWITCH GROUP | SET PORT GROUP | SET VSWITCH GROUP ] for shared port group *groupname* not performed; devices on OSA PCHID *pchid* do not exist or are not available.
- HCP3194I Creating [ VSWITCH *switchnm* | PORT GROUP *groupname* ] now that the IVL Virtual switch is connected.
- HCP3196E VSWITCH *vswname* is not created; the port group must be defined before creating the associated GLOBAL vswitch.
- HCP3199E [DEFINE VSWITCH | SET VSWITCH] not performed; uplink port group *portgroup* on this system is not equivalent to other IVL members sharing the same port group.
- HCP3221E VSWITCH not created; usage of shared port group *groupname* would exceed the maximum number of virtual switches allowed by a single system sharing the same port group.
- HCP3230I Priority Queuing is not enabled for device *device* for VSWITCH SYSTEM *switchname*.

- HCP3230I Priority Queuing is not enabled for VSWITCH SYSTEM *switchname*. No eligible controllers support priority queuing.
- HCP6706E Invalid groupname - *groupname*
- HCP6706E Invalid portname - *portname*
- HCP6706E Invalid switchname - *switchname*

## DEFSEG

### Authorization

Privilege Class: E

### Purpose

Use DEFSEG to define a skeleton system data file (class S, SDF) for a discontinuous saved segment (DCSS). A DCSS has the following attributes:

- It can be loaded at an address above a virtual machine's defined storage size.
- It can include page ranges that are not contiguous.

By using the SPACE operand, you can define special types of DCSSs called segment spaces and member saved segments. Therefore the terms *discontinuous saved segment* and *DCSS* generally refer to saved segments which are not segment spaces or member saved segments.

The skeleton file consists of a descriptor page containing all information necessary to preserve the saved segment with the SAVESEG command. You cannot access the saved segment until it has been saved.

### Operands

#### *dcssname*

is the name of the saved segment (a 1- to 8-character alphanumeric string). When the SPACE operand is used, *dcssname* is known as the member name and must be different from the *spacename* name.

#### *hexpage1-hexpage2*

is a range of pages to be saved. *hexpage1* and *hexpage2* are the numbers of available pages. When they are the same, only that page is saved. The range may be contained in a single 1 MB segment, or it may comprise a contiguous area in two or more segments. You may use multiple page ranges to define a 1 MB segment. However, the page descriptor codes of all page ranges in the same segment must have the same shared or exclusive attribute. (See the description of the *type* parameter for information about descriptor codes.)

Define only those pages whose data must be saved. Any page or pages in a segment not explicitly defined in a page range on the DEFSEG command defaults to the "no data saved" attribute. If other pages in the segment have been defined with the shared attribute (page descriptor codes SR, SW, SN and SC), pages not specified on the command line become shared read-only pages whose data are not saved. No page descriptor code corresponds to this state; it has the same attributes as the state defined by page descriptor code SC, except that CP does not write into these pages.

If other pages in the segment have been defined with the exclusive attribute (page descriptor codes ER, EW, and EN), any pages not specified on the command line become exclusive read/write pages whose data are not saved. This corresponds to page descriptor code EN.

The page ranges of a member saved segment cannot overlap with the specified page ranges of another member saved segment associated with the same segment space. Areas not specified (defaulted to "no data saved") may be taken by another member saved segment. If the member uses these pages but doesn't need the data from the pages saved, the range with the EN or SN attribute type must be specified. Also, this member saved segment's range descriptor code cannot conflict with those of an existing member that has ranges defined in the same segment of storage.

The page number is a hexadecimal value less than or equal to X'7FFFFFFF' (512 GB). The following list shows examples of how hexadecimal storage addresses translate into hexadecimal page numbers:

<b>Storage Address</b>	<b>Page Number</b>
0000000xxx	0
0000001xxx	1
0000022xxx	22
0000333xxx	333
0004444xxx	4444
007F800xxx	7F800
0080000xxx	80000
7F8000Fxxx	7F8000F
0100000xxx	100000

If a page range includes pages above X'7FEFF' (2047 MB), the SC page range descriptor and the SPACE and SECURE operands cannot be used on the same DEFSEG command.

The maximum size of a saved segment is 2047 MB.

### **type**

refers to the page descriptor code of the page range in the saved segment. It indicates the type of virtual machine access permitted to pages in the range.

The first character is either E for exclusive access or S for shared access. Sharing of storage between virtual machines is based on 1 MB segments, so all 256 pages in any one segment must be either exclusive or shared.

The second character of the page descriptor code defines the storage protection characteristics of the page. These character designators are:

#### **R**

Indicates that page protection is used to make the page range read-only.

#### **W**

Means that the page is not protected, and users have read/write access.

#### **N**

Stands for "read/write, no data saved," meaning that the page is treated as a new page when the user refers to it. The contents of, and storage keys for, "no data saved" pages are not saved by the SAVESEG command.

#### **C**

Stands for "CP-writable, virtual machine read-only, no data saved," meaning virtual machines have read-only access to these pages, but CP services may change the data in the pages.

The contents of storage keys for "no data saved" pages are not saved by the SAVESEG command.

Valid page descriptor codes are:

**Code****Meaning****EW**

Exclusive read/write access.

**EN**

Exclusive read/write access, no data saved.

**ER**

Exclusive read-only access.

**SW**

Shared read/write access.

**SN**

Shared read/write access, no data saved.

**SR**

Shared read-only access.

**SC**

CP writable pages, shared read-only access by virtual machine, no data saved.

**Note:** The SC page descriptor code cannot be used with the LOADNSHR operand.

The user must define all pages in segment zero in ranges with an exclusive page descriptor code (EW, ER, or EN). The system rejects the DEFSEG command if the user defines any pages in segment zero with a shared access page descriptor code.

**SAMERange**

specifies that this member saved segment definition is the same as one specified by a previous DEFSEG. This operand is mutually exclusive with the *hexpage1-hexpage2* operands. When you specify SAMERANGE, you also must specify SPACE.

You do not have to specify SAVESEG if you use DEFSEG with the SAMERANGE operand for a class A member saved segment. However, if the member saved segment you are referring to is a class S file, you must still use SAVESEG to save the file.

SAMERANGE makes it easier to create overlaying segment spaces by using the same member for both segment spaces.

If you use this operand in the same DEFSEG command with a name in *spacename* that does not exist, the member that you specify must be a class S (skeleton) file.

You must have either a class S or class A file with the same *dcssname* when you use this operand. If you have both class A and class S files, the command uses the information in the class S file.

**RSTD**

indicates a restricted saved segment. The user must have a corresponding NAMESAVE directory statement to access this saved segment. If any member of a segment space is defined with the restricted operand (that is, the SPACE operand is used), the entire segment space is then restricted. This means that the restricted *spacename* is that which must be used on the NAMESAVE directory statement. If you didn't specify SPACE, then *dcssname* is restricted. If you use the RSTD operand, make sure that you use the NAMESAVE directory statement to allow authorization.

If you used the SAMERANGE operand, you can use RSTD. This affects the authorization of the segment space that you specified in the DEFSEG definition. The name specified in *spacename* must be used on the NAMESAVE directory statement.

The RSTD operand cannot be used with the LOADNSHR operand.

**LOADNSHR**

indicates that any user may load a nonshared copy of the saved segment. No NAMESAVE directory authorization is required. If any member saved segment is defined with LOADNSHR, a nonshared copy of the space itself or any member may be loaded by any user.

The LOADNSHR operand cannot be used with the RSTD operand. It also cannot be used with the SC page range descriptor code.

### SECURE

indicates that the user ID that created the saved segment will be the only user ID allowed to use SPXTAPE DUMP or SPXTAPE LOAD for that file.

### SPACE

specifies the definition of a segment space. Use this operand to make the *dcssname* that you are defining a member of this segment space.

#### *spacename*

is the name of the segment space (a 1- to 8-character alphanumeric string). You must specify this if you use the SPACE operand. The *spacename* must be different from any *dcssname* known to CP.

## Usage Notes

1. CP can process only one DEFSEG or SAVESEG command at a time. If CP is already processing a DEFSEG or SAVESEG command, processing of a subsequent DEFSEG or SAVESEG command is delayed. The SAVESEG command writes all page ranges, except those defined as EN or SN, to the associated system data file. The amount of time it takes for the command to complete is directly proportional to the amount of data to be written.
2. Defining a saved segment at a high storage address that will be shared by many virtual machines might affect real storage availability. For each virtual machine, CP creates dynamic address translation (DAT) tables to reference the virtual machine storage. DAT tables include page tables, segment tables, and higher level (region) tables.

CP keeps the page tables in page management blocks (PGMBKs). Each 8 KB PGMBK references 1 MB of virtual machine storage. For shared page ranges within a saved segment that is loaded shared, the associated segment table entries will point to the same page tables. However, for a saved segment that is loaded nonshared, or for exclusive page ranges within a saved segment, unique page tables are created for each user. PGMBKs might be pageable; as such, their impact on real storage depends on how frequently the MBs of storage they reference are used.

Segment tables and region tables are allocated from host real storage and are not pageable:

- To reference the page tables for a primary address space or data space up to 2 GB, 1 - 4 contiguous frames are allocated for the segment table, one frame for each 512 MB of storage.
- For a primary address space larger than 2 GB, multiple segment tables are created, plus one or more region tables to reference the segment tables. Each region table occupies 1 - 4 contiguous frames. If needed, multiple levels of region tables are created.

Because CP dynamically expands the size of a virtual machine to incorporate a saved segment loaded at an address outside the virtual machine, the DAT tables for the virtual machine also expand. However, addresses between the top of the virtual machine and the bottom of the saved segment are not addressable by the virtual machine.

3. Pages either defined as, or defaulted to, the no data saved attribute are initialized to a page of zeros when first referred to. If the pages are in an exclusive saved segment, changes are seen only by the one user. If the pages are in a shared saved segment, any changes previously made by any sharing user (if allowed) are visible to all other users sharing that same page.
4. Storage keys are not saved for pages defined as, or defaulted to, the "no data saved" attribute. When first referred to, they have keys of zero.
5. A segment space has a range that may span one or more physical MB boundaries. The beginning address of a segment space is rounded down to the nearest MB boundary of the member having the lowest page value. The ending address of a segment space is rounded up to the last address of the last page within the MB occupied by the member having the highest page value.
6. Each member saved segment has a range that may span one or more pages. The beginning address of a member saved segment is determined by its lowest page value. The ending address is determined by the last address of the highest page value.

7. A segment space can include up to 64 member saved segments. A member saved segment can belong to up to 64 segment spaces.
8. Segment zero must always have the exclusive access attribute "Ex". If a shared ("Sx") page descriptor code is used for any pages in segment zero, the command is rejected.
9. Saved segments are loaded through DIAGNOSE code X'64'. You can also use the CMS SEGMENT command or macro, which call DIAGNOSE code X'64'. However, CMS does not support saved segments above 2047 MB. A DCSS that contains pages above 2047 MB can be loaded only through DIAGNOSE code X'64', using a 64-bit subcode.
10. A CP DCSS (defined as type SC) contains CP-writable pages, to which virtual machine users have just read-only access. CP writes data into these pages, which may then be referred to by virtual machines. Serialization of data in the CP-writable pages, if desired, must be arranged between the CP function providing the data and the virtual machines referring to it. A CP DCSS cannot be loaded in nonshared (exclusive) mode by DIAGNOSE X'64'.
11. Only one skeleton (class S) file can exist with a specific name. If one already exists and a second DEFSEG command is issued specifying the same name, the command is rejected.
12. Each segment name may be used for only one of the following: a segment space, a member saved segment, or a DCSS.
13. Defining members that use undefined areas within other members of the same segment space is not recommended. However, in support of multiple products requiring both shared and exclusive segment types and to minimize storage use, definition of members with interleaved ranges is supported.
14. You can use the SAMERANGE operand only with the SPACE operand.  
**Note:** You *cannot* use the SAMERANGE operand with a *dcssname* containing SW, SN, EW, or EN page types.
15. A DEFSEG with a SAMERANGE operand can be the first definition of a segment space only if the specified member is a class S file.
16. A DEFSEG with a SAMERANGE operand does not need a corresponding SAVESEG if the member saved segment is already saved. If the member saved segment is not saved, you need to use the SAVESEG command.
17. A member of a segment space cannot overlap any of the ranges specified for an existing member within the same segment space. Also, the members cannot have conflicting descriptor codes for ranges defined within the same segment of storage.
18. You cannot specify a DEFSEG with the SAMERANGE operand for a segment space that already has a member saved segment with that name.
19. Putting a member name in a directory statement has no effect; use the segment space name.
20. Processing of a DEFSEG command might be delayed if DIAGNOSE code X'64' is concurrently performing the initial load of a large DCSS.
21. If a new version of a NSS or DCSS is created and a previous version (with the same filename) exists and had a reserved storage setting (as established by the SET RESERVED command), the reserved storage setting is not inherited by the new version of the NSS or DCSS. If you want reserved storage for the new version, you must explicitly enter the SET RESERVED command for the new NSS or DCSS after it is saved using SAVESYS or SAVESEG.

#### Security Notes:

1. When RSTD is specified (indicating a restricted saved segment), only those users whose directory entries contain a NAMESAVE statement specifying the name of the restricted system data file are allowed to load this saved segment. If RSTD was specified **without** the SPACE operand, the directory entries must contain a NAMESAVE statement specifying the same DCSS name as *dcssname*. If RSTD was specified **with** the SPACE operand, the directory entries must contain a NAMESAVE statement specifying the segment space name as *spacename*. This allows an installation to ensure data integrity by restricting access to saved segments that contain shared writable storage (defined with the SW

and SN page descriptor codes) or to CP DCSSs (defined with the SC page descriptor code), which may contain sensitive data.

- Virtual machines that share read/write pages, defined with the SW and SN page descriptor codes, are responsible for the integrity of the shared data. The operating system that uses these shared writable pages should ensure that these virtual machines are properly protected from one another.

## Examples

```
defseg userseg 100-1ff sr rstd
defseg seg1 1000-1fff en 2000-2fff sr 3000-3fff er
defseg ppa 700-721 sr space group1
defseg ppb 722-7A1 sr space group1
defseg ppc 7A2-7F0 sr space group1
defseg ppx 700-721 sr rstd space group1a
defseg ppb same space group1a
defseg ppc same space group1a
defseg ppd 700-740 sr space group3
defseg ppe 741-779 sr space group3
defseg ppe 7A0-7FF sr space group3
defseg seg5 800-8FF sr loadnshr
defseg ppg 700-738 sr space group4 loadnshr
defseg ppe same space group4
```

For more explanations and examples, see [z/VM: Saved Segments Planning and Administration](#).

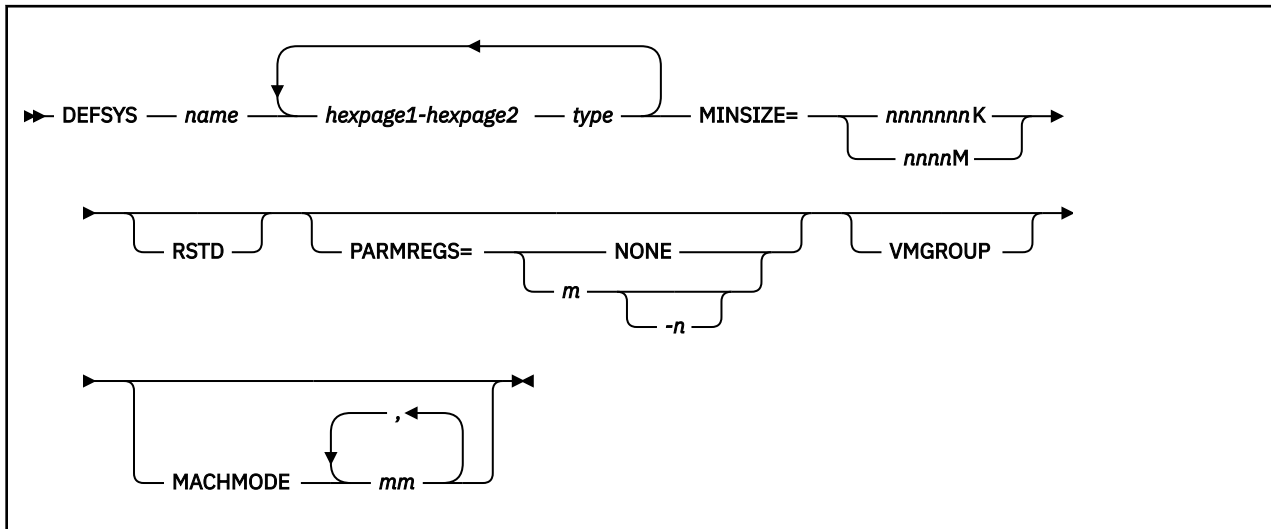

## Messages

- HCP002E Invalid operand - *operand*

- HCP1369E *name* is already defined in segment space *name*.
- HCP1371E *name* is not defined as a member saved segment.
- HCP8161E CONFLICT BETWEEN OPERANDS *operand* AND *operand*

## DEFSYS

### Authorization

Privilege Class: E

### Purpose

Use DEFSYS to define a skeleton system data file (Class S, SDF) for a named saved system (NSS).

The skeleton file consists of a descriptor page that contains all information that is necessary to preserve the NSS with the SAVESYS command.

**Note:** Users cannot access the NSS until it has been saved.

### Operands

#### *name*

is the name of the NSS (a 1- to 8-character alphanumeric string).

**Important:** If you specify a name that is the hexadecimal number of a device, that device is IPLed instead of the NSS.

LOADDEV and DUMPDEV are reserved keywords and cannot be used as NSS names.

#### *hexpage1-hexpage2*

is a range of pages to be saved. *hexpage1* and *hexpage2* are the page numbers of available pages. When they are the same, only that page is saved. The range can be contained in a single 1 MB segment, or it can comprise a contiguous area in two or more segments. You can use multiple page ranges to define a 1 MB segment. However, the page descriptor codes of all page ranges in the same segment must have the same shared or exclusive attribute. (See the description of the *type* operand for information about page descriptor codes.)

Define only those pages whose data must be saved. Any page or pages in a segment that is not explicitly defined in a page range on the DEFSYS command defaults to the "no data saved" attribute. If other pages in the segment were defined with the shared attribute (page descriptor codes SR, SW, SN and SC), pages that are not specified on the command line become shared read-only pages whose data is not saved. No page descriptor codes correspond to this state; it has the same attributes as the state defined by page descriptor code SC except that CP does not write into these pages.

If other pages in the segment were defined with the exclusive attribute (page descriptor codes ER, EW and EN), any pages not specified on the command line become exclusive read/write pages whose data is not saved. This corresponds to page descriptor code EN.

The page number is a hexadecimal value less than or equal to X'7FEFF' (2047 MB). The following list shows examples of how hexadecimal storage addresses translate into hexadecimal page numbers:

Storage Address	Page Number
00000xxx	0
00001xxx	1
00022xxx	22
00333xxx	333
04444xxx	4444
3E6FFxxx	3E6FF
7F800xxx	7F800

**type**

refers to the 2-character page descriptor code of the page range in the NSS. It indicates the type of virtual machine access that is permitted to pages in the range.

The first character is either E for exclusive access or S for shared access. Sharing of storage between virtual machines is based on 1 MB segments, so that all 256 pages in any one segment must be either exclusive or shared.

The second character of the page descriptor code defines the storage protection characteristics of the page. These character designators are:

**R**

Indicates that page protection is used to make the page range read-only.

**W**

Means that the page is not protected, and users have read/write access.

**N**

Stands for "read/write, no data saved," meaning that the page is treated as a new page when the user refers to it. The contents of, and storage keys for, no-data-saved pages are not saved by the SAVESYS command.

**C**

Stands for "CP-writable, virtual machine read-only, no data saved," meaning virtual machines have read-only access to these pages, but CP services can change the data in the pages.

The contents of and storage keys for no-data-saved pages are not saved by the SAVESYS command.

Valid page descriptor codes are:

**Code**

**Meaning**

**EW**

Exclusive read/write access.

**EN**

Exclusive read/write access, no data saved.

**ER**

Exclusive read-only access.

**SW**

Shared read/write access.

**SN**

Shared read/write access, no data saved.

**SR**

Shared read-only access.

**SC**

CP-writable pages, shared read-only access by virtual machine, no data saved.

Any page ranges defined in segment zero must have an exclusive page descriptor code (EW, ER, or EN). If any pages in segment zero are defined with a shared access page descriptor code, the command is rejected.

**MINSIZE=nnnnnnnK****MINSIZE=nnnnM**

indicates the minimum storage size of the virtual machine into which the NSS can be loaded. The operand *nnnnnnnK* is the storage size in decimal kilobytes; *nnnnM* is the storage size in decimal megabytes.

**Options****RSTD**

indicates a restricted NSS. The user must have a corresponding NAMESAVE directory statement to access this NSS.

**PARMREGS=*m*****PARMREGS=*m-n*****PARMREGS=NONE**

specifies a range of general purpose registers to contain the IPL parameter string when the NSS receives control from the control program.

The operands *m* and *n* are decimal values from 0 to 15. If you specify two registers, *n* must be greater than or equal to *m*. If only one register is required, you can specify PARMREGS=*m*.

NONE specifies that no parameters can be passed to this NSS.

**Note:** If you want to use the AUTOOCR, BATCH, NOSPROF, INSTSEG, or SAVESYS parameters of the IPL command, you must have **PARMREGS=0-15** in the DEFSYS command for the CMS NSS.

**VMGROUP**

specifies that a user who IPLs this NSS becomes a member of a virtual machine group that is identified by the name of the NSS.

**MACHMODE *mm***

specifies the set of virtual machine modes in which this NSS can be saved and IPLed.

The operand *mm* is a list of one or more virtual machine modes, separated by commas with no intervening blanks. Each entry in this list is one of the virtual machine mode designators ESA, XA, XC, or Z. ESA designates ESA/390 mode, although a guest can switch the virtual machine to z/Architecture mode. XA is supported for compatibility and is functionally equivalent to ESA. XC designates ESA/XC mode, although a guest can switch the virtual machine to z/XC mode. Z designates a guest that runs only in z/Architecture mode.

If more than one machine mode is specified with this operand, the NSS is known as a multimode NSS. Special considerations apply regarding the information that is saved by the SAVESYS command and restored by the IPL command for a multimode NSS; see the description for the SAVESYS command for these special considerations. However, for purposes of determining if the NSS is multimode or not, the designations XA and ESA are considered synonyms. If both are specified, the pair is treated as a single machine mode specification rather than two. That is, specifying 'MACHMODE XA,ESA' does not result in the NSS being considered a multimode NSS.

**Usage Notes**

1. CP can process only one DEFSYS or SAVESYS command at a time. If CP is already processing a DEFSYS or SAVESYS command, processing of a subsequent DEFSYS or SAVESYS command is delayed. The SAVESYS command writes all page ranges, except those defined as EN or SN, to the

associated system data file. The amount of time it takes for the command to complete is directly proportional to the amount of data to be written.

2. Defining an NSS at a high storage address that will be shared by many virtual machines might affect real storage availability. For each virtual machine, CP creates dynamic address translation (DAT) tables to reference the virtual machine storage. DAT tables include page tables, segment tables, and higher level (region) tables.

CP keeps the page tables in page management blocks (PGMBKs). Each 8 KB PGMBK references 1 MB of virtual machine storage. For shared page ranges within an NSS, the associated segment table entries will point to the same page tables. However, for exclusive page ranges within an NSS, unique page tables are created for each user. PGMBKs might be pageable; as such, their impact on real storage depends on how frequently the MBs of storage they reference are used.

Segment tables and region tables are allocated from host real storage and are not pageable:

- To reference the page tables for a primary address space or data space up to 2 GB, 1 - 4 contiguous frames are allocated for the segment table, one frame for each 512 MB of storage.
- For a primary address space larger than 2 GB, multiple segment tables are created, plus one or more region tables to reference the segment tables. Each region table occupies 1 - 4 contiguous frames. If needed, multiple levels of region tables are created.

Because CP dynamically expands the size of a virtual machine to incorporate an NSS loaded at an address outside the virtual machine, the segment table for the virtual machine might also expand.

3. Page zero should always be saved for an operating system. If it is not saved, certain information might be lost. IBM recommends that page zero is saved with the exclusive write (EW) page descriptor code.
4. Segment zero should always have the exclusive access attribute (EW, EN, or ER). If a shared page descriptor code (SW, SN, SR, or SC) is used for any pages in segment zero, the command is rejected.
5. Pages that are either defined as, or defaulted to, the no-data-saved attribute are initialized to a page of zeros when first referred to. If the pages are in an exclusive segment, changes are seen only by the one user. If the pages are in a shared segment, any changes that are previously made by any sharing user are visible to all other users sharing that same page.
6. A CP NSS (SC mode) contains CP-writable pages, to which virtual machine users have just read-only access. CP writes data into these pages, which can then be referred to by virtual machines. Serialization of data in the CP-writable pages can be arranged between the CP function that provides the data and the virtual machines that reference the data.
7. NSSs are loaded by using the IPL command. The use of the PARMREGS values is described with the IPL command.
8. When the user refers to any pages either defined as, or defaulted to, no-data-saved, the user gets a new page. A new page is assigned as a full frame of zeros, just as any page that does not have a copy that is backed on auxiliary storage.
9. Storage keys are not saved for pages that are either defined as, or defaulted to, no-data-saved. When these pages are first referred to, they have keys of zero. The virtual machine can set the keys for writable storage.
10. Each segment has an associated address range of 1 MB, regardless of the number of pages specified.
11. The maximum amount of storage available to a virtual machine is 2047 MB. To specify this value for MINSIZE, enter either '2047M' or '2096128K'.
12. If you do not specify the MACHMODE operand, the NSS can be saved (through the SAVESYS command) regardless of the saver's MACHINE value. However, the NSS can be IPLed only when the IPLer has the same MACHINE value as the saver.

If you specify the MACHMODE operand, the NSS can be saved or IPLed only when the SAVESYS or IPL command is issued by a guest whose MACHINE value is specified on the MACHMODE operand.

13. Virtual machines that are designated as XA virtual machines (for example, by SET MACHINE XA) and virtual machines that are designated as ESA virtual machines are equivalent. Both designations cause

the virtual machines to operate as ESA virtual machines. The virtual machine mode designations XA and ESA can be considered synonyms. Therefore:

- NSSs that are defined by specifying MACHMODE ESA can also be saved when a virtual machine has been designated as an XA virtual machine.
  - NSSs that are defined by specifying MACHMODE XA can also be saved when a virtual machine has been designated as an ESA virtual machine.
  - An NSS that can be IPLed when a virtual machine has been defined as an ESA virtual machine can also be IPLed when a virtual machine has been defined as an XA virtual machine.
  - An NSS that can be IPLed when a virtual machine has been defined as an XA virtual machine can also be IPLed when a virtual machine has been defined as an ESA virtual machine.
14. Processing of a DEFSYS command might be delayed if DIAGNOSE code X'64' is concurrently performing the initial load of a large DCSS.
  15. The NSS name "\_0\_\_\_1\_\_" is reserved for IBM use.
  16. The reserved storage setting is not inherited by the new version of the NSS or DCSS if the following conditions are true:
    - A new version of a NSS or DCSS is created.
    - A previous version (with the same filename) exists.
    - The previous version had a reserved storage setting (as established by the SET RESERVED command).

If you want reserved storage for the new version, you must explicitly enter the SET RESERVED command for the new NSS or DCSS after it is saved by using SAVESYS or SAVESEG.

#### Security Notes:

1. When RSTD is specified, only those users whose directory entries contain a NAMESAVE statement that specifies the same *name* as the DEFSYS operand are allowed to IPL the NSS. This restriction allows the installation to ensure data integrity by restricting access to NSSs that might contain sensitive data:
  - NSSs that contain shared writable storage (defined with the SW and SN page descriptor codes)
  - CP NSS (defined with the SC page descriptor code), which may contain sensitive data
2. Virtual machines that share read/write pages, which are defined with the SW and SN page descriptor codes, are responsible for the integrity of the shared data. The operating system that uses these shared writable pages should ensure that these virtual machines are properly protected from one another.

#### Examples

```
CP DEFSYS CMS 0-D EW 20-23 EW F00-13FF SR MINSIZE=3M
MACHMODE XA,ESA,XC PARMREGS=0-15

defsys wss 0-8 ew 300-5ff sw 600-fff sn minsize=4m rstd

defsys newsys 0-4 ew e-21 ew 800-86f sr minsize=256k parmregs=0-15
machmode esa,xc
```

## DELETE CHPID / PATH

### Authorization

Privilege Class: B

### Purpose

Use DELETE CHPID or PATH to delete an existing channel path identifier (CHPID) from the I/O configuration.

### Operands

**nn**

is the number of the channel path ID that you want to delete. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

**CSS nn**

is the channel-subsystem ID from which the channel path is to be deleted. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'. See Usage Note “2” on page 259.

**Note:** This parameter and other parameters that identify different channel-subsystem IDs require that the logical channel-subsystem facility be installed.

### Usage Notes

1. Before you can delete a channel path from your I/O configuration, you must:
  - a. Delete all of the devices attached to all the control units attached to that channel path using the DELETE DEVICE or IODEVICE command. (See “DELETE DEVICE / IODEVICE” on page 265.)
  - b. Delete all of the control units attached to that channel path using the DELETE CU or CNTLUNIT command (see “DELETE CU / CNTLUNIT” on page 263) or use the MODIFY CU or CNTLUNIT command (see “MODIFY CU / CNTLUNIT” on page 688) to delete channel path access.
  - c. Take that channel path logically offline using the VARY PATH command. (See “VARY PATH” on page 2053.)
  - d. Take that channel path physically offline using the VARY CHPID command. (See “VARY CHPID” on page 2046.)
2. On a machine with multiple logical channel-subsystem images, the DELETE CHPID and DELETE PATH commands are effective only for channel paths in a single channel-subsystem image. To delete channel paths that are in more than one channel-subsystem image, you must first enter MODIFY CHPID or MODIFY PATH commands to remove all but one channel-subsystem image. Then a DELETE CHPID or DELETE PATH command can be entered.
3. After successfully entering this command, you will have changed the software's view of the I/O configuration and part of the hardware's view: the active I/O configuration in the hardware system area (HSA). You should also change the other part of the hardware's view: the active I/O configuration data set (IOCDS) file on the support element (SE) hard disk.

To change the IOCDS file on the SE hard disk, you must:

- a. Update the IOCP source file.

## DELETE CHPID / PATH

- b. Run the IOCP utility against the updated IOCP file. If the IOCP utility runs without errors, it downloads the new IOCDS file to the SE hard disk.
- c. Issue the SET IOCDS\_ACTIVE command to make the new IOCDS file the active file that the processor will use during the next power-on reset (POR).

For more information, see [“IOCP” on page 2203](#) and [“SET IOCDS\\_ACTIVE” on page 1525](#).

4. For more information about deleting channel paths from your I/O configuration during initialization, see [Dynamically Deleting Channel Paths \(CHPIDs\) in z/VM: I/O Configuration](#).
5. To define a new channel path ID on the system, use the DEFINE CHPID or PATH command. See [“DEFINE CHPID / PATH” on page 132](#).
6. To change the definition of an existing reconfigurable channel path ID on the system, use the MODIFY CHPID or PATH command. (See [“MODIFY CHPID / PATH” on page 679](#).) There is no MODIFY command to change the definitions of the other types of channel paths. If you need to change their definitions, you must:
  - a. Delete the existing channel path definition, using the DELETE CHPID or PATH command.
  - b. Redefine the channel path definition, using the DEFINE CHPID or PATH command.
7. To display the status of a specific logical channel path and the devices with that logical channel path installed, or to display the type of a specific logical channel path, use the QUERY CHPID command. (See [“QUERY CHPID” on page 791](#).)
8. To display the physical status of all 256 of the machine's channel paths, use the QUERY CHPIDS command. (See [“QUERY CHPIDS” on page 796](#).)

**Note:** If the channel path is in single channel service (SCS) mode, it will appear as "not configured" in the display.
9. To display the logical and physical status of the channel paths installed on one or more devices, use the QUERY PATHS command. (See [“QUERY PATHS” on page 1064](#).)

## Responses

Response 1:

To delete channel path ID 32 from the I/O configuration, enter the following:

```
delete chpid 32
Channel path configuration change completed successfully
Ready;
```

Response 2:

To delete channel path ID 43 from the I/O configuration when it is currently defined only in channel-subsystem image 3, enter the following:

```
delete chpid 43 css 3
Channel path configuration change completed successfully
Ready;
```

## Messages

- HCP1006E Command processing cannot complete because the system does not support the logical-channel-subsystem facility.
- HCP6805E Cannot find RDEV for TYPE 1 subchannel
- HCP6806E Dynamic I/O change request [for channel path|for control unit|for device] failed with return code *nnnn*
- HCP6809E This processor does not support dynamic I/O changes
- HCP6815E Command failed in the channel subsystem

- HCP6816E Dynamic I/O changes are not allowed {on this system|for CSS *nn*}
- HCP6818E Delete command failed. Channel path *nn* is physically available
- HCP6819E A dynamic I/O command is currently executing for user *userid*

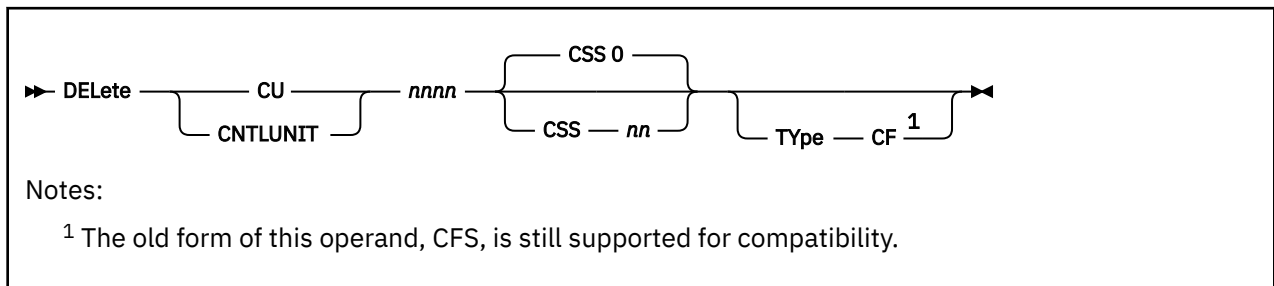

## DELETE CPUPOOL

---

### **Purpose**

DELETE CPUPOOL has been superseded by DELETE RESPOOL. See [“DELETE RESPOOL” on page 276](#).

## DELETE CU / CNTLUNIT

### Authorization

Privilege Class: B

### Purpose

Use DELETE CU or CNTLUNIT to delete an existing control unit from the I/O configuration.

### Operands

#### *nnnn*

is the number of the control unit that you want to delete. The variable *nnnn* must be a 1- to 4-digit hexadecimal number between X'0000' and X'FFFE'.

#### **CSS** *nn*

is the channel-subsystem ID from which the control unit is to be deleted. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'. See Usage Note “2” on page 263.

**Note:** This parameter and other parameters that identify different channel-subsystem IDs require that the logical channel-subsystem facility be installed.

#### **TYpe** **CF**

tells CP that this control unit is connected to coupling facility channel paths. Coupling facility channel paths include coupling facility sender (CFS), coupling facility receiver (CFR), coupling facility peer (CFP), cluster bus sender (CBS), cluster bus receiver (CBR), cluster bus peer (CBP), or internal coupling peer (ICP) channel paths.

### Usage Notes

1. Before you can delete a control unit, you must delete all devices attached to that control unit. To delete a device from a control unit, use the DELETE DEVICE or IODEVICE command. (See “DELETE DEVICE / IODEVICE” on page 265.)
2. On a machine with multiple logical channel-subsystem images, the DELETE CU and DELETE CNTLUNIT commands are effective only for control units in a single channel-subsystem image. To delete control units that are in more than one channel subsystem image, you must first enter MODIFY CU or MODIFY CNTLUNIT commands to remove all but one channel-subsystem image. Then a DELETE CU or DELETE CNTLUNIT command can be entered.
3. After successfully entering this command, you will have changed the software's view of the I/O configuration and part of the hardware's view: the active I/O configuration in the hardware system area (HSA). You should also change the other part of the hardware's view: the active I/O configuration data set (IOCDS) file on the support element (SE) hard disk.

To change the IOCDS file on the SE hard disk, you must:

- a. Update the IOCP source file.

## DELETE CU / CNTLUNIT

- b. Run the IOCP utility against the updated IOCP file. If the IOCP utility runs without errors, it downloads the new IOCDs file to the SE hard disk. For more information, see [“IOCP” on page 2203](#).
  - c. Issue the SET IOCDs\_ACTIVE command to make the new IOCDs file the active file that the processor will use during the next power-on reset (POR). For more information, see [“SET IOCDs\\_ACTIVE” on page 1525](#).
4. For more information about deleting control units from your I/O configuration during initialization, see [z/VM: I/O Configuration](#).
  5. To define a new control unit on the system, use the DEFINE CU or CNTLUNIT command. (See [“DEFINE CU / CNTLUNIT” on page 161](#).)
  6. To change the definition of an existing control unit on the system, use the MODIFY CU command. (See [“MODIFY CU / CNTLUNIT” on page 688](#).)

## Responses

Response 1:

To delete control unit 300 from the I/O configuration, enter the following:

```
delete cu 300
Control unit configuration change completed successfully
Ready;
```

Response 2:

To delete control unit 43 from the I/O configuration when it is currently defined only in channel-subsystem image 3, enter the following:

```
delete cu 43 css 3
Control unit configuration change completed successfully
Ready;
```

- HCP6816E Dynamic I/O changes are not allowed {on this system|for CSS *nn*}
- HCP6819E A dynamic I/O command is currently executing for user *userid*

## DELETE DEVICE / IODEVICE

### Authorization

Privilege Class: B

### Purpose

Use DELETE DEVICE or IODEVICE to delete one or more existing real devices from the I/O configuration.

### Operands

**rdev**

**rdev1r-dev2**

is the real device number (or range of real device numbers) of the device that you want to delete. Each *rdev* must be a 1- to 4-digit hexadecimal number between X'0000' and X'FFFF'.

**UNIT\_Address nn**

**UNITADD nn**

is the starting unit address associated with the device that you want to delete. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

**TYpe CF**

tells CP that the specified devices are attached to a control unit that connects to coupling facility channel paths. Coupling facility channel paths include coupling facility sender (CFS), coupling facility receiver (CFR), coupling facility peer (CFP), cluster bus sender (CBS), cluster bus receiver (CBR), cluster bus peer (CBP), or internal coupling peer (ICP) channel paths.

**CU\_number nnnn**

**CUNUMBR nnnn**

is the number of one of the control units associated with the device that you are deleting. The variable *nnnn* must be a 1- to 4-digit hexadecimal number between X'0000' and X'FFFE'.

**CSS nn**

is the channel-subsystem ID from which the device is to be deleted. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'.

**Note:** This parameter and other parameters that identify different channel-subsystem IDs require that the logical channel-subsystem facility be installed.

**SS nn**

is the subchannel set with which this device is associated. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'03'.

**Note:** This parameter requires that the multiple-subchannel-set facility be installed.

## Usage Notes

1. Before you delete one or more real devices from your I/O configuration, they must all be offline and their corresponding subchannels must also be offline. To take a device offline, use the VARY (Real Device) command. To take a subchannel offline, use the VARY SUBCHANNEL command. For more information, see [“VARY \(Real Device\)” on page 2063](#) and [“VARY SUBCHANNEL” on page 2067](#).
2. On a machine with multiple logical channel-subsystem images, the DELETE DEVICE and DELETE IODEVICE commands delete the device with respect to the control unit's connection to channel paths within the single specified logical channel-subsystem image. To delete devices from more than one logical channel-subsystem image, you must enter a separate DELETE DEVICE or DELETE IODEVICE command for each logical channel-subsystem image from which you want the devices deleted.
3. When you delete one or more real devices from your I/O configuration, CP also deletes their corresponding real device blocks (RDEVs). If you want to delete the RDEV but do not want to change the I/O configuration, use the DELETE RDEVICE command. (See [“DELETE RDEVICE” on page 274](#).)
4. After successfully entering this command, you will have changed the software's view of the I/O configuration and part of the hardware's view: the active I/O configuration in the hardware system area (HSA). You should also change the other part of the hardware's view: the active I/O configuration data set (IOCDS) file on the support element (SE) hard disk.

To change the IOCDS file on the SE hard disk, you must:

- a. Update the IOCP source file.
  - b. Run the IOCP utility against the updated IOCP file. If the IOCP utility runs without errors, it downloads the new IOCDS file to the SE hard disk. For more information, see [“IOCP” on page 2203](#).
  - c. Issue the SET IOCDS\_ACTIVE command to make the new IOCDS file the active file that the processor will use during the next power-on reset (POR). For more information, see [“SET IOCDS\\_ACTIVE” on page 1525](#).
5. To define a new device on the system, use the DEFINE DEVICE or IODEVICE command. (See [“DEFINE DEVICE / IODEVICE” on page 167](#).)
  6. To change the definition of an existing device on the system, use the MODIFY DEVICE or IODEVICE command. (See [“MODIFY DEVICE / IODEVICE” on page 693](#).)
  7. To display the status of one or more real devices, use the QUERY (Real Device) command. (See [“QUERY \(Real Device\)” on page 1114](#).)

## Responses

Response 1:

To delete four real devices from your I/O configuration, enter the following:

```
delete device 300-303 unit_address 00 cu_number 300
Device configuration change completed successfully
RDEV 0300 deleted
RDEV 0301 deleted
RDEV 0302 deleted
RDEV 0303 deleted
Ready;
```

Response 2:

To delete four real devices in channel-subsystem image 3 and subchannel set 0 from your I/O configuration, enter the following:

```
delete device 440-443 unit_address 00 cu_number 400 css 3 ss 0
Device configuration change completed successfully
RDEV 0440 deleted
RDEV 0441 deleted
RDEV 0442 deleted
RDEV 0443 deleted
Ready;
```

## Messages

- HCP1006E Command processing cannot complete because the system does not support the logical-channel-subsystem facility.
- HCP1006E Command processing cannot complete because the system does not support the multiple-subchannel-set facility.

## DELETE EDEVICE

### Authorization

Privilege Class: B

### Purpose

Use DELETE EDEVICE to delete one or more emulated device definitions from the system.

### Operands

*rdev*

*rdev1-rdev2*

specifies the emulated devices that you want to delete. An emulated device in the active configuration can be entered as a 4-digit hexadecimal device number between X'0000' and X'FFFF'. For an emulated device in the active or standby configuration, the device can be a 5-digit hexadecimal number between X'00000' and X'3FFFF'. The leading digit specifies the subchannel set where the device is to be deleted. A range of devices cannot span subchannel sets.

### Usage Notes

1. Before you can delete an emulated device, you must vary offline the real device and subchannel that is associated with the emulated device. To VARY a device offline, use the VARY (Real Device) command. To VARY a subchannel offline, use the VARY SUBCHANNEL command.
2. To display the status of one or more real devices, use the QUERY (Real Device) command.
3. To display information about one or more emulated devices, use the QUERY EDEVICE command.
4. To define an emulated device, use the following commands:
  - a. SET EDEVICE command with the proper device characteristics, and the
  - b. VARY (Real Device) command to bring the device online.
5. You must delete all the aliases for an emulated device before you delete the base device.
6. You cannot delete the initial base for an emulated device until all aliases and any other bases are deleted.
7. The deletion of an NVME EDEVICE can be delayed for a device-specific interval to allow the NVME controller sufficient time to shut down.

### Responses

Response 1:

When you delete an emulated device 300 from your system, the command and response is as follows:

```
delete edevice 300
EDEV 300 was deleted.
Ready;
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP009E Invalid range - *range*
- HCP040E Device *rdev* does not exist
- HCP6704E Missing token at end of line
- HCP6790I *rdev1* processing halted. The next device that would have been processed is *rdev2*.
- HCP6833E Device *rdev* is not subchannel offline
- HCP8702E Device *rdev* is defined as a real device.
- HCP8704E EDEV *rdev* was not deleted because the device could not be unloaded.
- HCP8704E EDEV *rdev* was not deleted because there are alias devices defined.
- HCP8704E EDEV *rdev* was not deleted because there are other base devices defined.

## DELETE LPAR

### Authorization

Privilege Class: B

### Purpose

Use the DELETE LPAR command to delete a logical partition from the I/O configuration.

### Operands

#### *pname*

specifies the name of the logical partition you are deleting. *pname* must be a 1-character to 8-character alphanumeric string.

**Note:** The first character of *pname* must be alphabetic and the following names cannot be used: PHYSICAL, REC, SYSTEM, PRIMnnn (where nnn are decimal digits).

#### *CSS nn*

is the channel-subsystem ID associated with the logical partition that is being deleted. The variable *nn* must be a 1-digit to 2-digit hexadecimal number between X'00' and X'0F.'

#### *MIF\_id mm*

is the MIF-ID within the specified CSS associated with the logical partition that is being deleted. The variable *mm* must be a 1-digit to 2-digit hexadecimal number between X'01' and X'0F.'

### Usage Notes

1. Once a logical partition is successfully deleted with this command, the MIF-ID within the CSS becomes an available slot in the configuration in which a logical partition can be subsequently defined.
2. This command requires that both the logical-channel-subsystem facility and the logical-partition-configuration facility be installed on your system.

### Examples

To delete logical partition VMSYSONE that is associated with CSS 1 and MIF-ID 3, enter the following:

```

delete lpar vmsysone css 1 mif 3
Logical partition configuration change completed successfully
Ready;
  
```

### Messages

- HCP864E Partition *pname* is not configured in CSS *nn*, MIF-ID *mm*
- HCP1006E Command processing cannot complete because the system does not support the logical-partition-configuration facility
- HCP6805E Cannot find RDEV for TYPE 1 subchannel
- HCP6806E Dynamic I/O change request for logical partition failed with return code *nnnn*
- HCP6809E This processor does not support dynamic I/O changes
- HCP6815E Command failed in channel subsystem

- HCP6816E Dynamic I/O changes are not allowed for CSS *nn*
- HCP6819E A dynamic I/O command is currently executing for user *userid*

## DELETE PCIFUNCTION

```
▶▶ DELEte — PCIFunction — rpfid ▶▶
```

### Authorization

Privilege Class: B

### Purpose

Use DELETE PCIFUNCTION to delete a real PCI function from the I/O configuration.

### Operands

#### *rpfid*

is the real function identifier of the PCI function you are deleting from the I/O configuration. The *rpfid* must be a 1- to 8-digit hexadecimal number between X'00000000' and X'7FFFFFFF'. The maximum value of the *rpfid* is model dependent and your machine likely supports a lower maximum value.

### Usage Notes

1. Before you delete a PCI function from your I/O configuration, and the PCIF is configured to the z/VM system you are issuing the DELETE command from, it must be offline before the DELETE PCIF is issued. To take a PCI function offline, use the VARY OFF PCIFUNCTION command. If the PCI function is attached to a guest, then the DETACH PCIFUNCTION command must be issued before the VARY OFF PCIFUNCTION command.
2. If a PCIF is to be deleted from the I/O configuration and the PCIF is configured to a different z/VM system in the I/O configuration than the z/VM system where the command is issued, the PCIF will be forcefully detached from any users and forcefully varied offline. So care must be used when using the DELETE PCIF command.
3. After successfully entering this command, you will have changed the software's view of the I/O configuration and part of the hardware's view: the active I/O configuration in the hardware system area (HSA). You should also change the other part of the hardware's view: the active I/O configuration data set (IOCDS) file on the support element (SE) hard disk.

To change the IOCDS file on the SE hard disk, you must:

- a. Update the IOCP source file.
  - b. Run the IOCP utility against the updated IOCP file. If the IOCP utility runs without errors, it downloads the new IOCDS file to the SE hard disk.
  - c. Issue the SET IOCDS\_ACTIVE command to make the new IOCDS file the active file that the processor will use during the next power-on reset (POR).
4. For more information about deleting PCI functions from your I/O configuration, see [Adding, Deleting, or Changing a PCI Function in z/VM: I/O Configuration](#).
  5. To define a PCI function to the system, use the DEFINE PCIFUNCTION command.
  6. To change the definition of an existing PCI function on the system, use the MODIFY PCIFUNCTION command.
  7. To display the status of one or more real PCI functions, use the QUERY PCIFUNCTION command.

### Responses

Response 1:

To delete a PCI function from your configuration, enter the following:

```
del pcif 43
PCI function configuration change completed successfully
Ready;
```

## Messages

- HCP1006E Command processing cannot complete because the system does not support the Dynamic-I/O-for-I/O-adapters facility.
- HCP6805E Cannot find RDEV for TYPE 1 subchannel
- HCP6806E Dynamic I/O change request for PCI function failed with return code *nnnn*
- HCP6809E This processor does not support dynamic I/O changes
- HCP6815E Command failed in the channel subsystem
- HCP6818E Delete command failed. PCI function *rpfid* is not offline.
- HCP6819E A dynamic I/O command is currently executing for user *userid*

## DELETE RDEVICE

### Authorization

Privilege Class: B

### Purpose

Use DELETE RDEVICE to delete one or more real device control blocks (RDEVs) on the system. An RDEV is a piece of storage associated with a real device that contains information about that device's features and status. Thus, when you issue the DELETE RDEVICE command, you are actually deleting a piece of storage, not an actual real device.

To delete an actual real device, use the DELETE DEVICE or IODEVICE command (see [“DELETE DEVICE / IODEVICE”](#) on page 265).

### Operands

*rdev*

*rdev1-rdev2*

is the number of the real device whose RDEV you want to delete. A real DASD in the active configuration can be entered as a 4-digit hexadecimal device number between X'0000' and X'FFFF'. For a real DASD in the active or standby configuration, the device can be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is to be deleted. A range of devices cannot span subchannel sets.

### Usage Notes

1. Before you can delete a real device control block (RDEV), you must take the device and subchannel associated with this RDEV offline. To take a device offline, use the VARY (Real Device) command (see [“VARY \(Real Device\)”](#) on page 2063). To take a subchannel offline, use the VARY SUBCHANNEL command (see [“VARY SUBCHANNEL”](#) on page 2067).
2. To display the status of one or more real devices, use the QUERY (Real Device) command (see [“QUERY \(Real Device\)”](#) on page 1114).

**Note:** The QUERY (Real Device) command displays the status of the device only if you issue the QUERY command in the logical partition that owns the device. If you issue the QUERY command in one of the other logical partitions, CP gives you a message stating that the device does not exist.

3. To create a real device control block, use the:
  - a. SET RDEVICE command (see [“SET RDEVICE”](#) on page 1627) with the proper device characteristics, and
  - b. VARY (Real Device) command (see [“VARY \(Real Device\)”](#) on page 2063) to bring the device online.

### Responses

Response 1:

To delete real device control block 300 from your system, enter the following:

```
delete rdevice 300  
RDEV 300 deleted  
Ready;
```

## Messages

- HCP6704E Missing token at end of line
- HCP6706E Invalid string - *string*
- HCP6790I *rdev1* processing halted. The next device that would have been processed is *rdev2*.
- HCP6833E Device *rdev* is not subchannel offline
- HCP6862E Device *rdev* cannot be changed or deleted because it is a base Parallel Access Volume for which an alias exists.

## DELETE RESPOOL

```
►► DELeTe — RESPool — poolname ►◄  
      └── CPUPOOL ─┘
```

### Authorization

Privilege Class: A

### Purpose

Use DELETE RESPOOL to delete a resource pool that is already defined. For compatibility with prior releases, CPUPOOL is accepted as a synonym for RESPOOL.

### Operands

#### *poolname*

is the name of the resource pool to be deleted.

### Usage Notes

1. The DELETE RESPOOL command can be issued only for a resource pool that has already been created with the DEFINE RESPOOL command.
2. The resource pool can be deleted only if there are no users assigned to the pool. Use the SCHEDULE command to remove users from the resource pool.

### Responses

Response 1:

```
Resource pool poolname is deleted
```

confirms that the resource pool has been deleted.

### Messages

- HCP002E Invalid operand — *operand*
- HCP003E Invalid option — command contains extra option(s) starting with *option*
- HCP1001E An operand is missing for RESPOOL
- HCP3151E Resource pool *poolname* does not exist
- HCP3152E Resource pool *poolname* cannot be deleted because users are still assigned to it

## DESTAGE

### Authorization

Privilege Class: B

### Purpose

Use DESTAGE to force the transfer of modified data in a direct access subsystem cache or nonvolatile storage (NVS) to the backing storage device. This command is valid for cache storage subsystems that support the cache fast write or DASD fast write functions.

The DESTAGE command can be used as part of a shutdown process.

### Operands

#### SUBSYSstem

specifies that data for the entire storage subsystem is to be destaged, regardless of which device within the subsystem receives the destage order. This is the default (and only) value.

#### rdev

#### rdev1-rdev2

is the real device number, a list of real device numbers, or a range of real device numbers, of devices to which the destage order is to be sent.

### Usage Notes

1. This command may produce delayed responses. For more information, see [“Delayed Responses to CP Commands”](#) on page 7.
2. The DESTAGE command is only valid for cache storage subsystems that support cache fastwrite or DASD fastwrite functions. An error message is generated if the subsystem containing the specified device does not support any of these functions.

### Responses

Response 1:

*Immediate Response:* If the transfer of subsystem data occurs immediately, the following response is issued to the originator of the command. This response is repeated for each *unique subsystem* identified by the devices specified on the command line.

```
rdev Subsystem data has been destaged.
```

#### rdev

is the real device number of one of the specified devices in a subsystem being destaged.

Response 2:

*Delayed Response:* If the transfer of subsystem data does not occur immediately, the following response is issued:

```
Command started: DESTAGE rdev.
```

## DESTAGE

When the transfer of subsystem data completes, the following responses are issued:

```
rdev Subsystem data has been destaged.
```

Under certain circumstances, it is possible that a cache storage subsystem will not notify CP when it has completed the transfer of the subsystem data. When this occurs, the appropriate command response cannot be generated. Under these circumstances, command processing is ended after generating the following response:

```
Command results lost: DESTAGE rdev.
```

If errors occur during the asynchronous processing of the command that prevent the successful completion of the command, the following response is displayed:

```
Command failed: DESTAGE rdev.
```

### ***rdev***

is the real device number of one of the specified devices in a subsystem being destaged.

Response 3:

*Response to System Operator:* If the originator of the command is not the system operator, the following response is issued to the system operator when the transfer of subsystem data completes. This response is also repeated for each *unique subsystem* identified by the devices specified on the command line.

```
rdev Subsystem data was destaged by userid.
```

### ***rdev***

is the real device number of one of the specified devices in a subsystem being destaged.

### ***userid***

is the ID of the user who issued the command.

## Messages

- HCP006E Invalid device type - {*rdev/vdev/ldev*}
- HCP009E Invalid range - *range*
- HCP021E A real device number was not supplied or it is invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP046E *type rdev* offline
- HCP319E Error processing subsystem command - *cmd* for DASD *rdev*
- HCP332E Invalid control unit type - *rdev*
- HCP1109E The *command* command cannot be processed for device *rdev* because the device is the secondary in a duplex pair.

## DETACH

---

### Purpose

Use the DETACH commands to detach the following:

- Virtual processors from your virtual machine
- Real devices from the host system
- Logical devices from the host system
- Real devices from your virtual machine
- Logical devices from your virtual machine
- Virtual devices from your virtual machine
- Virtual message processor and message devices from your virtual machine
- A guest LAN from the host system.

### Usage Notes

(General for DETACH)

1. SET IMSG OFF will suppress the informational messages for DETACH CPU, DETACH MSGPROC, and DETACH VDEV. DETACH RDEV is not affected by the IMSG setting.
2. You cannot be certain that the device has been detached until you receive the appropriate response from the system. If after a reasonable amount of time you haven't received the expected response, enter the QUERY command to determine the status of the device. Detachment may be pending or may have been unsuccessful.
3. If you detach a minidisk with this command without releasing it, CMS implicitly releases the minidisk. QUERY DISK will not display that minidisk.
4. You can designate a virtual CTCA by device address. If a virtual CTCA is detached while coupled with another virtual CTCA, the remote device is left in an uncoupled state, similar to its original condition after the DEFINE command.
5. In an SSI cluster, MDC will be turned on and off automatically when RDEV SHARED NO is in effect.
6. The DETACH command will not affect the various draining status indicators, so you can set the desired draining status before you attach a DASD to the system.

### Messages

- HCP6000E The range of device numbers cannot exceed 256.
- HCP6005E Option *option* is not supported by z/VM.
- HCP6324I An unexpected condition occurred writing to the subchannel for device *rdev*, code = *code*.
- HCP6866E Device *rdev* cannot be detached from the system because it is a base Parallel Access Volume for which one or more alias volumes are attached to the system.
- HCP6866E Device *vdev* cannot be detached from the user because it is a base Parallel Access Volume for which one or more alias volumes are associated.

- HCP6866E Device *rdev* cannot be detached from the user because it is a base Parallel Access Volume for which one or more alias volumes are attached.

## DETACH CFLINK

### Authorization

Privilege Class: B, G

### Purpose

Use the DETACH CFLINK command to detach links between coupling facilities.

### Operands

#### *msgprocid1*

is the user ID of the sending coupling facility virtual machine.

#### *msgprocid2*

is the user ID of the receiving coupling facility virtual machine.

#### **ALL**

specifies that all links, where *msgprocid1* is the sender and *msgprocid2* is the receiver, should be deleted.

#### **CHPID** *chpid*

specifies that only the link from *msgprocid1* to *msgprocid2* that is known to *msgprocid2* (the receiver) through channel path ID *chpid* should be deleted.

### Usage Notes

1. A class G only user must be coupled to both the sending and receiving coupling facilities.
2. If you detach a coupling facility link, all message devices that were created in the sender when that link was created are also deleted.

### Examples

CFVM1 and CFVM2 are connected as follows:

- In CFVM1, channel path ID E0 (devices 400 and 401) leads to channel path ID F0 in CFVM2.
- In CFVM1, channel path ID A0 (devices 800 and 801) leads to channel path ID B0 in CFVM2.

To detach all links, enter the following:

```
detach cflink cfvm1 cfvm2
```

To detach just the first link, enter the following:

```
detach cflink cfvm1 cfvm2 chpid f0
```

(This also results in devices 400 and 401 being deleted in CFVM1.)

To detach just the second link, enter the following:

```
detach cflink cfvm1 cfvm2 chpid b0
```

(This also results in devices 800 and 801 being deleted in CFVM1.)

## Messages

- HCP020E Userid missing or invalid
- HCP045E *userid* not logged on
- HCP047E CFLINK with this CHPID does not exist
- HCP047E CFLINK in *coupling\_facility\_id* does not exist
- HCP260E Command processing cannot complete due to errors.
- HCP846E Invalid channel path identifier.
- HCP2800E *msgprocid* is not a CF Service Machine.
- HCP2805E One or more message processors does not exist in your I/O configuration.
- HCP2806E You are not allowed to control message processors.

## DETACH CPU

### Authorization

Privilege Class: G

### Purpose

Use DETACH CPU to remove processors from your virtual machine configuration.

### Operands

#### ALL

specifies all virtual processors currently defined.

#### *cpuaddr*

is the processor address of the processor that you want to detach from your virtual machine configuration.

#### *cpuaddr cpuaddr*

is a list of addresses and/or ranges delimited by spaces.

#### *cpuaddr1-cpuaddr2*

specifies a nonwrapping pair of addresses separated by a hyphen (-) and not separated by any blanks.

### Usage Notes

1. You can detach any virtual processor from your virtual machine configuration except the base processor. You cannot detach the base processor from your virtual machine system.
2. Whenever you detach a virtual processor, your virtual machine is reset as if a CP SYSTEM CLEAR command had been processed. The effects of this system-reset-clear function are described in detail in the description for the SYSTEM CLEAR command. The system-reset-clear function sets all of your virtual machine's storage to binary zeros. Therefore, you must repeat your IPL procedure to proceed.
3. SET IMSG OFF suppresses informational messages for this command.
4. For more information, see [“Usage Notes” on page 279](#).

### Responses

```

CPU nn DETACHED
  
```

indicates that the command has been successfully processed.

This response is followed by:

```

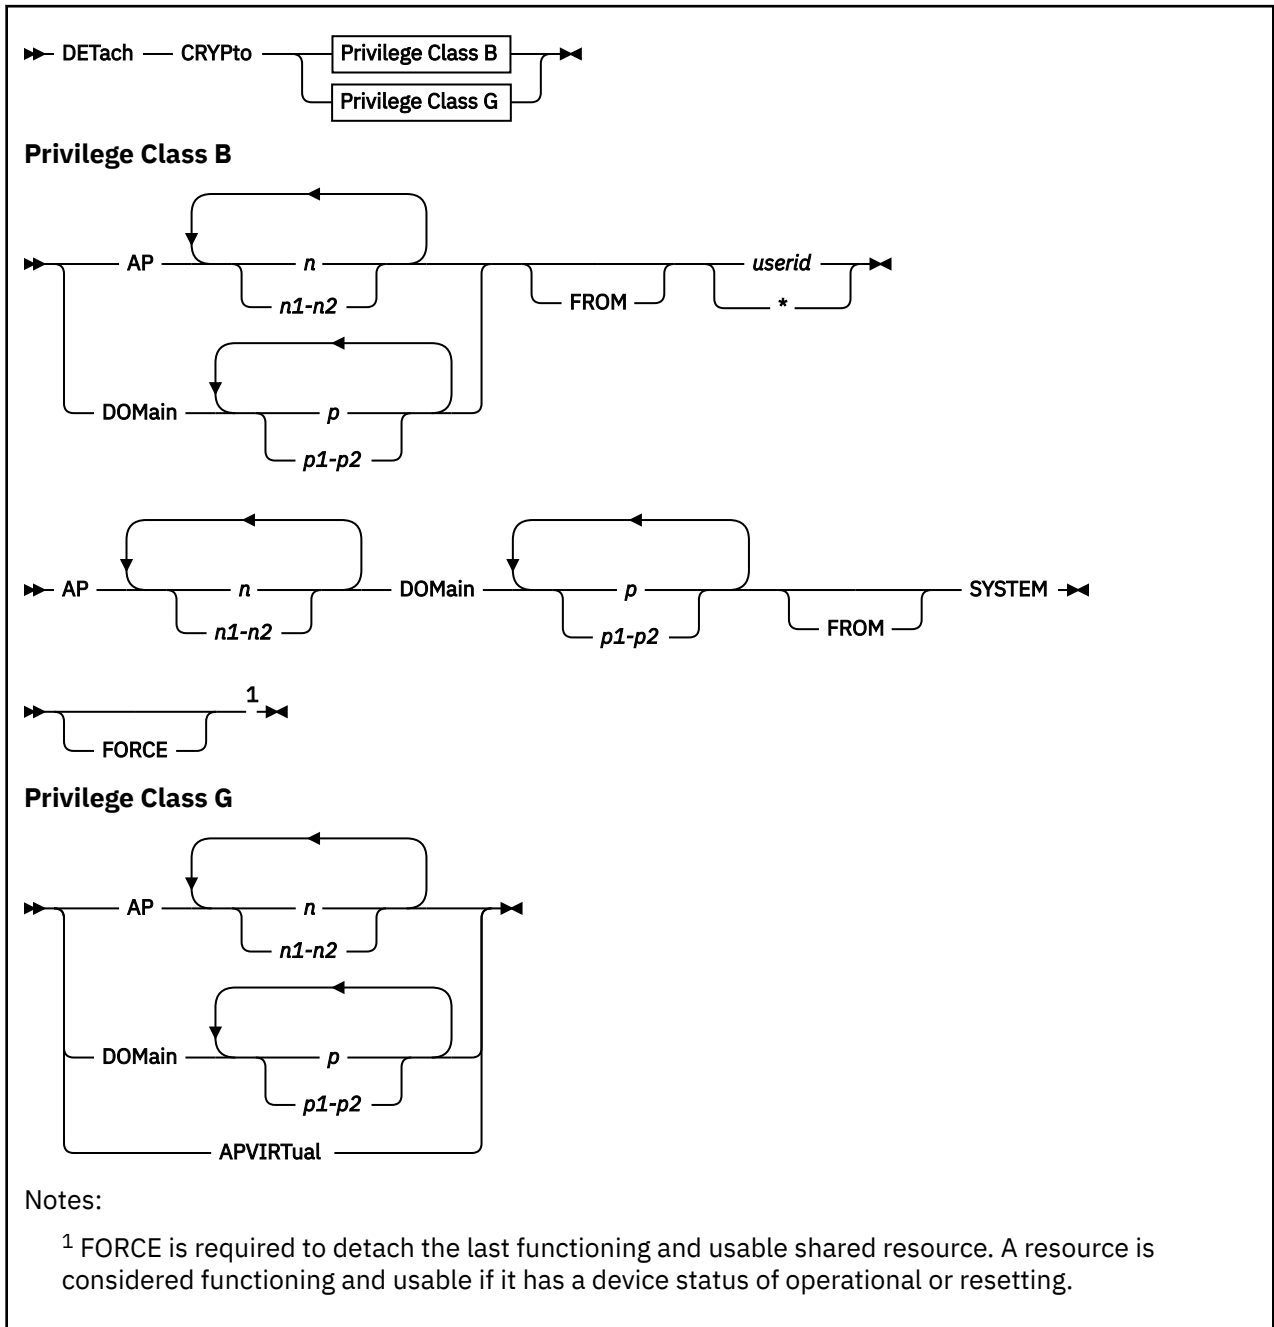

STORAGE CLEARED - SYSTEM RESET
  
```

indicating that all of your virtual machine's storage has been cleared to binary zeros, and your processors and I/O configuration have been reset.

***nn***

identifies the number of the CPU currently defined.

## DETACH CRYPTO

### Authorization

Privilege Class: B, G

### Purpose

Use DETACH CRYPTO to:

- Remove dedicated crypto resources from a virtual machine.
- Remove shared crypto resources from the system.
- Remove a virtual machine's access to the system's shared crypto resources.

## Operands

***n***

***n1-n2***

specifies the adapter number, a list of adapter numbers, a range of adapter numbers or a combination of these, to be detached. When detaching from a userid, crypto resources on all domains on the specified adapters will be detached. If you are specifying a list of adapter numbers, insert at least one blank between the numbers you specify. If you are specifying a range of adapter numbers, insert a hyphen (-) between the numbers you specify. The adapter number is a decimal number between 0 and 255.

***p***

***p1-p2***

specifies the domain number, a list of domain numbers, a range of domain numbers or a combination of these, to be detached. When detaching from a userid, crypto resources on all adapters on the specified domain(s) will be detached. If you are specifying a list of domain numbers, insert at least one blank between the numbers you specify. If you are specifying a range of domain numbers, insert a hyphen (-) between the numbers you specify. The crypto domain number is a decimal number between 0 and 255.

***userid***

**\***

is the virtual machine that the crypto resources are being detached from. When you are detaching from your own virtual machine, you can specify your user ID as an asterisk (\*).

### SYSTEM

indicates that the crypto resources are to be detached from the system.

### FORCE

this option is required when detaching the last remaining operational shared crypto resource from the system.

### APVIRTual

removes a virtual machine's access to the system's shared crypto resources.

## Usage Notes

1. When detaching dedicated crypto resources from a virtual machine configuration, the DETACH command must specify only adapter(s), or only domain(s). The DETACH command will be rejected if both adapters and domains are specified.
2. The crypto resources being detached are processed individually. A message indicating success or failure is given for each resource processed by the DETACH CRYPTO command. If the FORCE option is not specified, all of the resources specified which do not require the FORCE option will be detached. The detach will fail for any resource that requires the FORCE option.
3. For information on planning and managing crypto resources on a z/VM system, see [Crypto Planning and Management in z/VM: CP Planning and Administration](#).

## Examples

To detach adapter 7 domains 3 and 4 from the shared pool, enter:

```
DETACH CRYPTO AP 7 DOMAIN 3-4 FROM SYSTEM
```

To detach all dedicated domains on adapter 1 from the virtual machine, enter:

```
DETACH CRYPTO AP 1 FROM userid
```

To detach your access to the shared crypto resources, enter:

```
DETACH CRYPTO APVIRTUAL
```

## Responses

Response 1:

This response is sent to the command issuer when the command issuer is Class G.

```
Crypto AP apnum Domain domnum detached
Crypto APVIRTUAL detached
```

Response 2:

This response is sent to the command issuer when the command issuer is Class B.

```
Crypto AP apnum Domain domnum detached from target
Crypto AP apnum Domain domnum detached from SYSTEM
Crypto AP apnum Domain domnum detached from SYSTEM with FORCE
```

Response 3:

This response is sent to the primary system operator when the primary system operator is not the command issuer.

```
Crypto AP apnum Domain domnum detached from target by originator
Crypto AP apnum Domain domnum detached from SYSTEM by originator
Crypto AP apnum Domain domnum detached from SYSTEM with FORCE by originator
```

Response 4:

This response is sent to the target when the target is not the command issuer or the primary system operator.

```
Crypto AP apnum Domain domnum detached by originator
```

### ***apnum***

is the adapter number of the crypto resource.

### ***domnum***

is the domain number of the crypto resource.

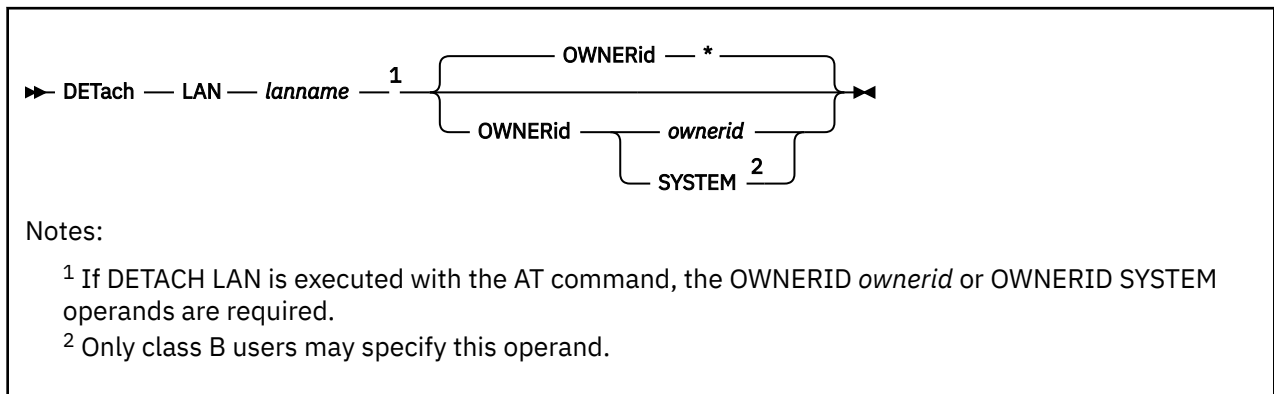

## Messages

- HCP6706E Invalid user ID
- HCP6706E Invalid Crypto Domain number
- HCP6706E Invalid Crypto AP number

## DETACH LAN

### Authorization

Privilege Class: B, G

### Purpose

Use DETACH LAN to eliminate a guest LAN from the CP system. This operation removes the designated LAN from the System LAN Table, disconnects any virtual adapters using the LAN, and releases system resources associated with the LAN. In general, this command must be issued by the owner of the LAN.

The Class B form of the command allows the invoker to remove a LAN owned by another user. Only a Class B user can specify OWNERID SYSTEM (removing a SYSTEM LAN).

### Operands

#### *lanname*

is the name of the guest LAN to be eliminated. Both *lanname* and *ownerid* must be known to fully qualify a LAN.

#### OWNERid \*

#### OWNERid *ownerid*

#### OWNERid SYSTEM

specifies the owner of the LAN. When OWNERID \* is specified, it indicates the invoker is the owner of the LAN. This is the default when OWNERID is omitted.

The Class G form of the command only accepts \* or the user ID of the invoker.

The Class B form of the command accepts another user ID (like OWNERID SYSTEM).

### Usage Notes

1. Only the current owner of the LAN, or a Class B user, can DETACH the LAN.
2. Any virtual network adapter that is connected to the LAN when it is detached is automatically uncoupled.

### Examples

1. DETACH LAN - Class G:

To remove the user LAN named QDIO0 from the system, enter:

```
cp detach lan qdio0
LAN VMUSERX QDIO0 is destroyed
```

2. DETACH LAN - Class B:

To remove the SYSTEM LAN named INEWS from the system, enter:

```
cp detach lan inews ownerid system  
LAN SYSTEM INEWS is destroyed
```

## Responses

Response 1:

```
LAN ownerid lanname is destroyed
```

is the normal response for this command.

Response 2:

```
NIC vdev is disconnected from LAN ownerid lanname
```

is the response for this command when a virtual network adapter connected to a LAN is detached.

## DETACH MSGPROC

►► DETach — MSGProc — *msgprocid* ◄◄

### Authorization

Privilege Class: G

### Purpose

Use the DETACH MSGPROC command to detach the specified message processor and message devices from the issuer's I/O configuration.

### Operands

#### *msgprocid*

specifies the user ID of the CF Service Virtual Machine to be deleted. CP will break the Coupling Facility connections between the user ID that issues this command and the user ID specified by *msgprocid*.

### Usage Notes

1. To define a virtual message processor and associated virtual message devices, use the DEFINE MSGPROC command.
2. To display information about virtual message processors in your I/O configuration, use the QUERY VIRTUAL MSGPROC command.
3. To display information about the virtual message devices within your I/O configuration, use the QUERY VIRTUAL MSGDEVICES command.
4. To restart a virtual message processor that is within your I/O configuration, use the RESTART MSGPROC command.
5. To remove all message facility capability from your virtual machine, use the SET MSGFACIL OFF command.
6. SET IMSG OFF suppresses informational messages for this command.
7. For more information, see DETACH (general) Usage Notes.

### Responses

Response 1:

To detach the CFCC1 message processor and associated message devices from your I/O configuration, enter the following:

```
detach msgp cfcc1
MSGPROC CFCC1 DETACHED
Ready;
```

## DETACH NIC

---

```
▶▶ DETach — NIC — vdev ▶◀
```

### Authorization

Privilege Class: G

### Purpose

Use DETACH NIC to remove a virtual network adapter (network interface card) from your virtual machine configuration. This command disconnects the virtual adapter from the guest LAN (if necessary), and removes each virtual device that was created by the DEFINE NIC command for this adapter.

### Operands

#### *vdev*

specifies the virtual device number (hex) of the adapter to be detached. You may specify the virtual device number of any virtual device that is attached to the adapter. However, CP responses will refer to each virtual adapter by its *base* device address; this is the first device in the range.

### Responses

Response 1:

```
NIC vdev is destroyed; devices vdev-lastvdev detached
```

#### *vdev*

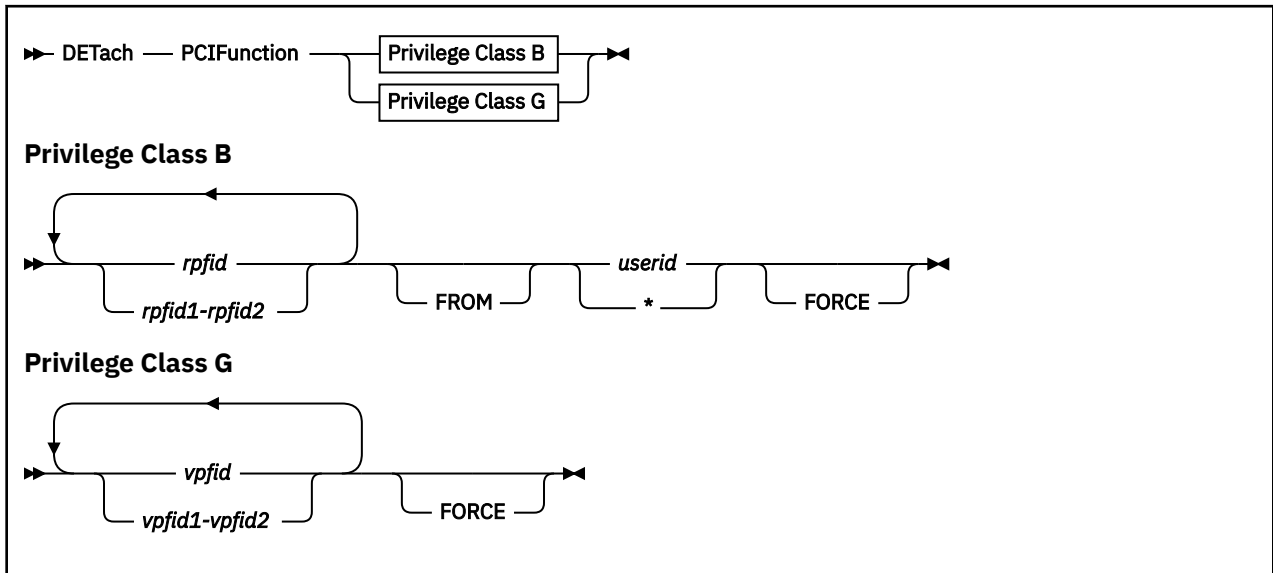

specifies the base device address

#### *lastvdev*

specifies the last device that is defined as part of this adapter

is the normal response for this command.

## DETACH PCIFUNCTION

### Purpose

Use DETACH to detach PCI function(s) from a virtual machine. Ordinarily, the guest is signaled to quiesce its use of the function. The function is detached and the command completes only when the guest relinquishes the function or a grace period expires.

### Operands

#### *rpfid*

#### *rpfid1-rpfid2*

specifies a real PCI function ID or a range of PCI function IDs to be detached from the specified user. Specify a PCI function ID as 8 hexadecimal digits. You may omit leading zeros. The total number of PCI functions specified cannot exceed 256.

#### *vpfid*

#### *vpfid1-vpfid2*

specifies a virtual PCI function ID or a range of PCI function IDs to be detached from the specified user. Specify a PCI function ID as 8 hexadecimal digits. You may omit leading zeros. The total number of PCI functions specified cannot exceed 256.

#### **FROM** *userid*

identifies the virtual machine to which the function or functions are currently attached. The specified user must currently be logged onto the system and not in the process of logging on. If you are detaching a function from your own virtual machine, you may specify your userid as an asterisk (\*). If you are a class G user you may only detach PCI functions from your own userid.

#### **FORCE**

indicates the function will be detached from the guest with no signal to the guest that the function is being detached and no time given to the guest to gracefully complete use of the function.

### Usage Notes

1. If the FORCE operand is not specified, the guest must be running in order to gracefully complete use of the function. For example, if the guest is stopped with CP SET RUN OFF, the guest will not be able to complete its use of the function.

## Responses

The receiver of the PCI function detached, the user who issued the DETACH command, and the primary system operator all receive messages indicating the DETACH was successful.

Response 1:

The following response goes to the originator of the DETACH command:

```
PCI FUNCTION rpfid DETACHED userid vpfid
```

Response 2:

The following response goes to the detachee of the PCI function:

```
PCI FUNCTION vpfid DETACHED BY originator
```

Response 3:

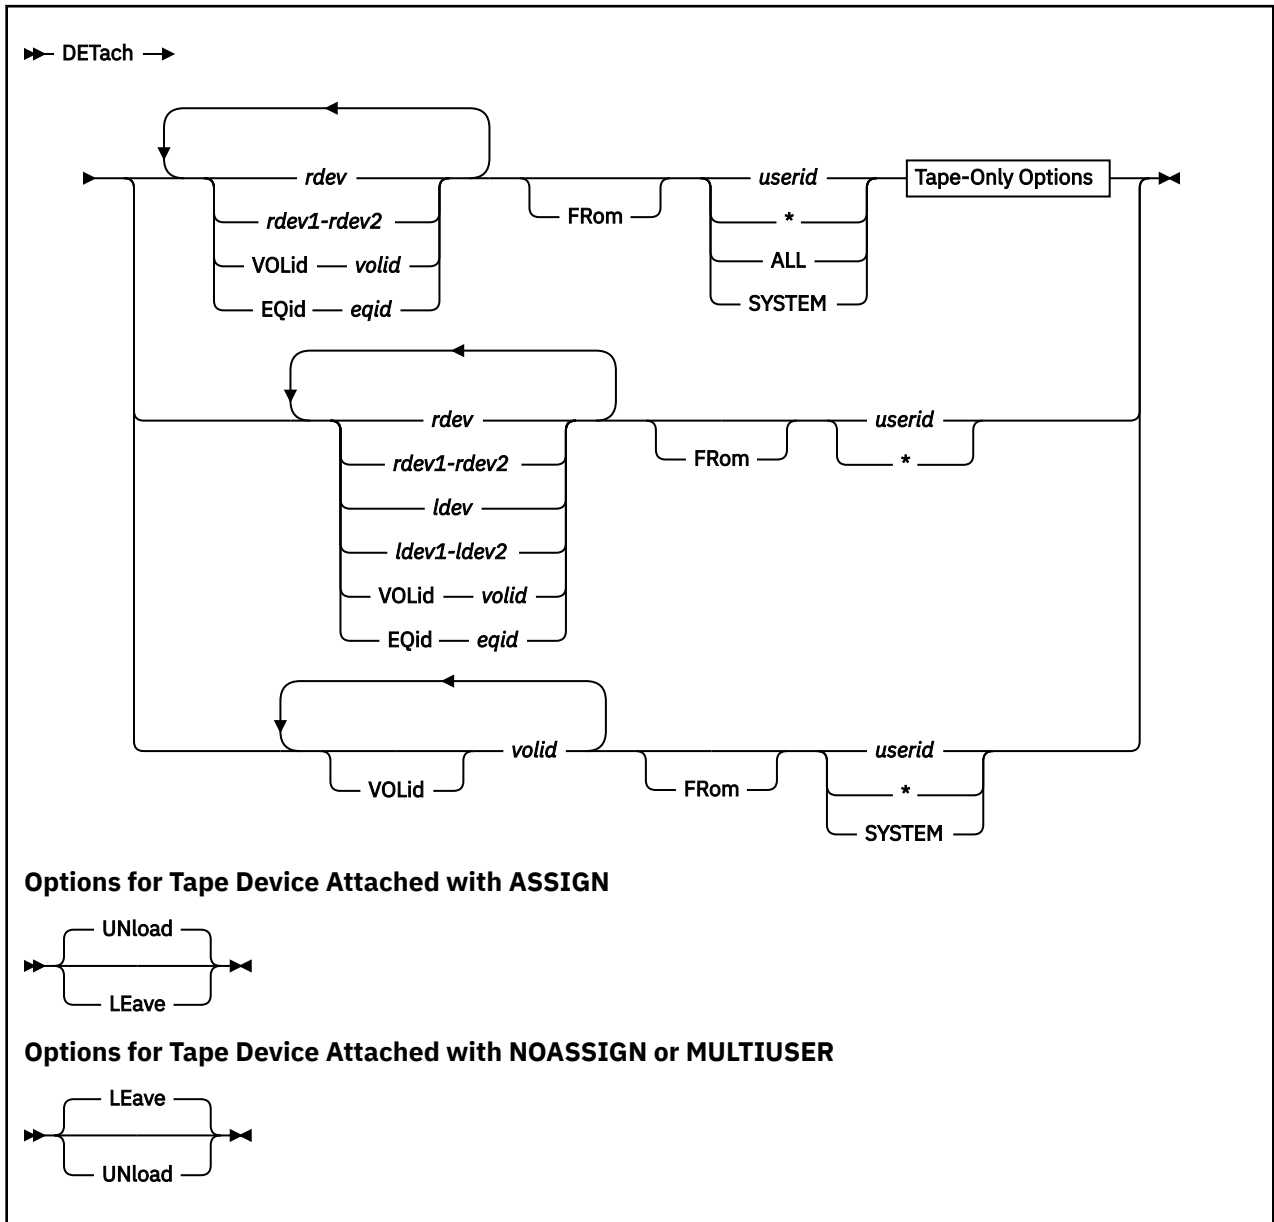

The following responses goes to the system operator:

```
PCI FUNCTION rpfid DETACHED FROM userid vpfid BY originator
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP009E Invalid range - *range*
- HCP020E Userid missing or invalid
- HCP021E A real PCI function ID was not supplied or it is invalid.
- HCP022E A virtual PCI function ID was not supplied or it was invalid.
- HCP040E PCI function *vpfid* does not exist
- HCP040E PCI function *rpfid* does not exist
- HCP121E PCI function *rpfid* not attached to *userid*
- HCP6000E The range of PCI function IDs cannot exceed 256.

## DETACH (Real Device)

### Authorization

Privilege Class: B

### Purpose

Use DETACH (real device) to detach the following:

- Local or remote real devices from one or more virtual machines
- Local real devices from the host system

**Note:** When detaching a remote device, specify its logical device address.

## Operands

### *rdev*

#### *rdev1-rdef2*

is a real device number, a list of real device numbers, or a range of real device numbers to be detached from the indicated user, from all users, or from the system. On a single command line, you may combine device numbers, lists of device numbers, and ranges of device numbers. Specify a real device number as one to four hexadecimal digits.

### *ldev*

#### *ldev1-ldev2*

is a logical device number, a list of logical device numbers, or a range of logical device numbers to be detached from the indicated user. On a single command line, you may combine device numbers, lists of device numbers, and ranges of device numbers. Specify a logical device number as an L followed by one to four hexadecimal digits.

### **VOLid**

indicates that a volume serial number, which must follow this keyword, is used to identify the real device. If the volume serial number is valid as an operand of the command (e.g., is a valid device number), specify VOLid to indicate that the operand is a volume serial.

### *valid*

specifies the 1- through 6-character volume serial number of a real DASD.

### **EQid**

indicates that a device equivalency ID, which must follow this keyword, is used to identify the real device. If the EQID is valid, and only one device with the specified EQID is attached to the target, the detach will be performed. If more than one device with the specified EQID is attached to the target, no detach will be performed.

### *eqid*

specifies a string of 1–8 alphanumeric characters for a user-specified EQID or a string of 50 alphanumeric characters plus a dash ("-") for a system-generated EQID.

### *userid*

\*

identifies the virtual machine to which the device is currently attached. The specified user must be logged on, not in the process of logging on. If you are detaching a device from your own virtual machine, you may specify *userid* as an asterisk (\*).

### **ALL**

detaches a real device from all virtual machines without having to specify the user IDs. This operand can be used to detach devices attached with the MULTIUSER option. The ALL operand is not valid for devices attached to SYSTEM.

### **SYSTEM**

detaches a DASD currently being used by CP for allocation and control.

### **UNload**

detaches the tape device and automatically rewinds and unloads it. UNLOAD is the default if the tape was attached with the ASSIGN option.

### **LEave**

detaches the tape device without rewinding and unloading it. The tape remains positioned as it was before issuing DETACH. LEAVE is the default if the tape was attached with the NOASSIGN or MULTIUSER option.

## Usage Notes

1. SET IMSG OFF will not suppress informational messages for this command.
2. A previously attached device can be detached from a user, even if the device is still in use.
3. When a device is detached from a user, all Concurrent Copy (CONCOPY) sessions associated with that device for that user are terminated in the storage control.

## DETACH (Real Device)

4. When a device is detached, all data blocks associated with the device are removed from the minidisk cache.
5. If you specify multiple device numbers or a range of device numbers on the DETACH (real device) command line, you receive an affirmative response for each device that is successfully detached and an error message for each device that cannot be detached.
6. If you attempt to detach an active shared device from SYSTEM, you receive an error message indicating that the device is being shared by multiple users. In order to detach the device, each of the affected users must detach the device from their virtual systems.
7. You cannot detach volumes in the CP-owned list that are in use by the system, shared by another system in an SSI cluster, or devices containing minidisks to which users are linked.
8. If a tape device being detached was transferred to a user with the GIVE (Real Device) command, the LEAVE or UNLOAD option specified on the DETACH command overrides any option that was set when the GIVE command was issued. If LEAVE or UNLOAD is not specifically requested on the DETACH command, the option specified when GIVE was issued is processed. If no option was specified on either GIVE or DETACH, the tape is rewound and unloaded.
9. If a device was attached using the CP ATTACH command and later detached, the system operator receives a response saying that the device was detached.
10. For more information, see [“Usage Notes” on page 279](#).
11. When the primary or the secondary volume of a duplex pair is detached from a virtual machine, the response generated will indicate that the volume was either the primary duplex volume or the secondary duplex volume of the duplex pair. When the primary of a duplex pair is detached from the system, the response generated will indicate that the volume was the primary duplex volume of the duplex pair.
12. A tape device attached with the SINGLEUSER option (the default) will automatically be unassigned by CP when the device is detached, unless the LEAVE option is specified on DETACH or the tape was attached with the NOASSIGN option.

A tape device attached with both the SINGLEUSER and NOASSIGN options will not be unassigned by CP when the device is detached, regardless of whether the tape is currently assigned by a guest. In other words, CP will not change the ASSIGNED or UNASSIGNED status of the drive. It is the responsibility of the guest to issue the ASSIGN CCW when it needs the tape drive and to issue the UNASSIGN CCW when it is finished using the drive.
13. A tape device attached with the MULTIUSER option will be unassigned by CP when the device is detached, even though MULTIUSER implies NOASSIGN. This prevents one user from unexpectedly locking out many other users from the drive.
14. When detaching Parallel Access Volume DASDs from a guest, all dedicated alias Parallel Access Volumes associated with a particular base Parallel Access Volume must be detached from that guest before that base Parallel Access Volume can be detached. When detaching Parallel Access Volume DASDs through VOLID, it is going to detach the base and alias associated with the base automatically.
15. When detaching Parallel Access Volume DASDs from the system, all system attached alias Parallel Access Volumes associated with a particular base Parallel Access Volume must be detached from the system before that base Parallel Access Volume can be detached. When detaching Parallel Access Volume DASDs through VOLID, it is going to detach the base and alias associated with the base automatically.
16. When detaching RDEVICES using an EQID, if more than one device exists with the specified EQID, no detach will be performed. To avoid accidental detaches, some other unique identifier (such as the RDEV number) must be used in this situation.
17. When a CP-owned DASD volume with SPOOL extents is detached from the owning system in an SSI cluster, an attempt will be made to automatically detach the volume from all other members in the SSI cluster.

## Responses

The user who currently owns the device (if different from the primary system operator), the user who issues the DETACH (real device) command (if different from the owner of the device), and the primary system operator (if different from the user who issued the command) each receive messages indicating that the DETACH (real device) is successful.

**Note:** The *type* variable in the following responses is omitted when a range of device numbers or multiple device numbers are being reflected in the response.

In the responses below, the term *type* is one of the following:

Type	Meaning
CTCA	Channel-to-channel adapter
CTRL	3745 Communications Controller
DASD	Direct access storage device
FCP	SCSI device adapter
GRAF	Display device
MSC	Mass Storage Controller
OSA	Open Systems Adapter
PRT	Printer
PUN	Card punch
RDR	Card reader
SWCH	Dynamic Switching device
TAPE	Magnetic tape
DEV	Any other device
LINE	Communication line

Response 1:

```
{type vdev} DETACHED BY originator [PRIMARY DUPLEX ]
{vdev...} [SECONDARY DUPLEX]
{vdev-vdev} [PAV BASE ]
[PAV ALIAS ]
[HYPERPAV BASE ]
[HYPERPAV ALIAS ]
```

is the response sent to the device owner (if the device owner is not the primary system operator). Note that the response refers only to the virtual device number (*vdev*) because this is the number by which the owner knows the device.

Response 2:

```
{type rdev} DETACHED {userid [vdev]} [PRIMARY DUPLEX ]
{rdev...} {SYSTEM } [SECONDARY DUPLEX]
{rdev-rdev} [PAV BASE ]
{type ldev} [PAV ALIAS ]
{ldev...} [HYPERPAV BASE ]
{ldev-ldev} [HYPERPAV ALIAS ]
```

is the response issued to the originator of the DETACH (real device) command if the originator is not the owner of the device or devices. When the response is for a single device (*rdev* or *ldev*), the virtual device number, and possibly the duplex state of the device, the PAV state of the device or the HyperPAV state of the device will appear in the responses following the *userid*. Because the secondary volume of a duplex pair cannot be attached to the system, SECONDARY DUPLEX will only be issued when detaching from another user ID.

## DETACH (Real Device)

Response 3:

```
{type rdev} DETACHED {userid [vdev]} BY originator [PRIMARY DUPLEX ]
{rdev...}      {SYSTEM}      {                } [SECONDARY DUPLEX]
{rdev-rdev}   [PAV BASE      ]
{type ldev}   [PAV ALIAS     ]
{ldev...}    [HYPERPAV BASE  ]
{ldev-ldev}  [HYPERPAV ALIAS ]
```

is the response sent to the primary system operator if another user (the originator) issued the DETACH (real device) command. When the response is for a single device (*rdev* or *ldev*), the virtual device number, and possibly the duplex state of the device, the PAV state of the device or the HyperPAV state of the device will appear in the responses following the *userid*. The secondary volume of a duplex pair cannot be attached to the system, therefore SECONDARY DUPLEX will only be issued when detaching from another user ID.

Response 4:

```
{TAPE rdev} DETACHED userid BY originator {, TAPE VOLUME(S) UNLOADED }
{rdev...}   {                } { TAPE VOLUME(S) NOT UNLOADED}
{rdev-rdev}
```

is the response issued to the system operator when one or more tape volumes are being detached.

Response 5:

```
TAPE vdev RETURNED
```

is the response the user receives when a tape drive given to another user through the GIVE command is returned.

Response 6:

```
TAPE rdev RETURNED TO userid vdev
```

is the response the primary system operator receives when a tape drive given to another user through the GIVE command is returned.

Response 7:

```
Detaching vdev has caused the termination of
CONCOPY session(s) on device(s): vdev1...
```

is the response the device owner receives if the process of detaching the device causes the termination of Concurrent Copy (CONCOPY) sessions, and the device owner is the originator of the DETACH command. The response lists the virtual devices that are part of the terminated CONCOPY sessions.

Response 8:

```
Detaching vdev by userid has caused the termination
of CONCOPY session(s) on device(s): vdev1...
```

is the response the device owner receives if the process of detaching the device causes the termination of Concurrent Copy (CONCOPY) sessions, and the device owner is *not* the originator of the DETACH command. The response identifies the originator of the DETACH command and lists the virtual devices that are part of the terminated CONCOPY sessions.

Response 9:

```
Detaching rdev has caused the termination of
CONCOPY session(s) for userid userid
```

is the response the originator of the DETACH command receives if the process of detaching the device causes the termination of Concurrent Copy (CONCOPY) sessions, and the originator of the command is *not* the owner of the device. The response identifies the user whose CONCOPY sessions have been terminated.

Response 10:

```
Detaching rdev by userid1 has caused the termination  
of CONCOPY session(s) for userid userid2
```

is the response the primary system operator receives if the process of detaching the device from user *userid2* causes the termination of Concurrent Copy (CONCOPY) sessions, and the system operator is *not* the originator of the DETACH command (*userid1*).

### Messages

- HCP048E No device with EQID *eqid* attached.
- HCP048E No device with EQID *eqid* exists.
- HCP135E Multiple devices with EQID *eqid* attached.
- HCP135E Multiple devices with EQID *eqid* exist.

## DETACH SYSASCII

### Notes:

- <sup>1</sup> Operands are valid only for class B users.
- <sup>2</sup> If DETACH SYSASCII is executed with the AT command, the *userid* operand is required.

## Authorization

Privilege Class: B, G

## Purpose

Use DETACH SYSASCII to remove the real ASCII console from a virtual machine configuration. If you are a class G user, you can remove the ASCII console from your own virtual machine. If you are a class B user, you can remove the ASCII console from any virtual machine.

## Operands

### *userid*

identifies the virtual machine to which the ASCII console is currently attached. The specified user must be logged on and cannot be in the process of logging on.

\*

detaches the ASCII console from the user who issues the command.

## Usage Notes

1. SET IMMSG OFF does not suppress informational messages for this command.
2. The ASCII console can be detached from a user even if it is still in use.
3. To avoid inadvertent transfer of data between virtual machines through the ASCII console, the screen is erased when the device is detached.
4. Whenever the ASCII console is detached, the system operator receives a message indicating that the facility is available.

## Responses

Receiving messages indicating that the DETACH SYSASCII was successful are:

- The user who currently owns the ASCII console
- The user who issued the DETACH SYSASCII command (if different from the owner of the ASCII console)
- The primary system operator (if different from the user who issued the command).

Response 1:

```
SYSASCII detached by originator
```

is the response sent to the owner of the ASCII console.

Response 2:

```
SYSASCII detached from userid
```

is the response issued to the originator of the DETACH SYSASCII command if the originator is not the owner of the ASCII console.

Response 3:

```
SYSASCII detached from userid by originator
```

is the response sent to the primary system operator when another user (identified by *originator*) issues DETACH SYSASCII.

## DETACH (Virtual Device)

### Authorization

Privilege Class: G

### Purpose

Use DETACH (virtual device) to remove devices from your virtual machine configuration.

### Operands

*vdev*

*vdev1-vdev2*

is a virtual device number, a list of virtual device numbers, or a range of virtual device numbers to be detached from your virtual machine. On a single command line, you may combine device numbers, lists of device numbers, and ranges of device numbers. If you are detaching a list of virtual devices, insert at least one blank between the device numbers you specify. If you are detaching a range of devices, insert a hyphen (-) between the device numbers you specify. The maximum number of devices allowed within a range is 256.

### Usage Notes

1. You can detach a virtual device even if it is currently in use.
2. When you detach a dedicated device, it becomes inaccessible to your virtual machine; it is released and becomes available to any virtual machine, another user, or the CP system. The system operator receives a response indicating that the device is free.
3. If the virtual device is part of a Concurrent Copy (CONCOPY) session for your virtual machine, the CONCOPY session is terminated in the storage control associated with the device.
4. Tape devices are automatically rewound and unloaded when you enter the DETACH command, unless the tape device was attached with the NOASSIGN or MULTIUSER option.
5. If you detach a dedicated device, and it was not obtained using a GIVE command with return specified, the system operator receives a message indicating that the device is free.
6. Command processing does not end if an error (other than a syntax error) is encountered when processing a range of device numbers or multiple device numbers. Instead, an error message is issued for each device that cannot be detached. Informational messages are issued to identify those devices that were successfully detached. These informational messages may appear several times in one command execution when you have specified on the command line a range of device numbers or multiple device numbers.
7. A tape device attached with the SINGLEUSER option (the default) will automatically be unassigned by CP when the device is detached, unless the device was attached with the NOASSIGN option.

A tape device attached with both the SINGLEUSER and NOASSIGN options will not be unassigned by CP when the device is detached, regardless of whether the tape is currently assigned by a guest. In other words, CP will not change the ASSIGNED or UNASSIGNED status of the drive. It is the responsibility of the guest to issue the ASSIGN CCW when it needs the tape drive and to issue the UNASSIGN CCW when it is finished using the drive.

8. A tape device attached with the MULTIUSER option will be unassigned by CP when the device is detached, even though MULTIUSER implies NOASSIGN. This prevents one user from unexpectedly locking out many other users from the drive.
9. Devices that are part of a virtual network adapter cannot be detached individually. Virtual network adapters are detached with the DETACH NIC command.
10. If you use DETACH to detach a virtual disk in storage, and you are the last user, the virtual disk in storage is destroyed.
11. SET IMSG OFF suppresses informational messages for this command.
12. When detaching Parallel Access Volume DASDs, all alias Parallel Access Volumes associated with a particular base Parallel Access Volume must be detached first before that base Parallel Access Volume can be detached.
13. This command will fail if issued for a VDISK or virtual disk in storage when VMRELOCATE is in progress.
14. For more information, see [“Usage Notes” on page 279](#).

## Responses

In Response 1, *type* is one of the following:

Type	Meaning
CONS	Console
CTCA	Channel-to-channel adapter
CTLR	3745 Communications Controller
DASD	Direct access storage device
DEV	Any other device
FCP	SCSI device adapter
GRAF	Display device
MSC	Mass Storage Controller
OSA	Open Systems Adapter
PRT	Printer
PUN	Card punch
RDR	Card reader
SWCH	Dynamic Switching device
TAPE	Magnetic tape

The *type* variable in the remaining responses is omitted when a range of device numbers or multiple device numbers are being reflected in the response.

Response 1:

```
{type vdev} DETACHED
{vdev ... }
{vdev-vdev}
```

is the response you receive for the device or devices that were successfully detached (if you are not the primary system operator).

Response 2:

```
CTCA vdev DROPPED FROM userid vdev
```

## DETACH (Virtual Device)

is the response if the device detached was a virtual CTCA connected using the COUPLE command.

### **CTCA *vdev***

is the virtual device number of the CTCA that you detached.

### ***userid vdev***

is the user identification and virtual device number of the CTCA that your CTCA had been coupled to.

This response is always followed by the response:

```
CTCA vdev DETACHED
```

to indicate that the command has been successfully processed. The response:

```
CTCA vdev DROPPED BY userid vdev
```

is sent to the user whose CTCA connection was dropped.

Response 3:

```
Tape vdev returned
```

is the response sent to a user who had issued the GIVE command with the RETURN option. The response is sent when the receiver of the tape detaches the tape.

### ***vdev***

is the virtual device number of the tape drive that was returned.

Response 4:

```
Tape rdev returned to userid vdev
```

is the response the primary system operator receives when a tape drive given to another user through the GIVE command is returned.

### ***rdev***

is the real device number of the tape drive.

### ***userid***

is the user ID the tape drive is being returned to.

### ***vdev***

is the virtual device number of the tape drive that was returned.

Response 5:

```
Detaching vdev has caused the termination of  
CONCOPY session(s) on device(s): vdev1...
```

indicates that one or more Concurrent Copy (CONCOPY) sessions have been terminated during the process of detaching the device.

### ***vdev***

is the virtual device number that you are detaching.

### ***vdev...***

is a list of the device numbers that are part of the terminated CONCOPY sessions.

## DETACH VSWITCH

```
▶▶ DETach VSWITCH — switchname ▶▶
```

### Authorization

Privilege Class: B

### Purpose

Use the DETACH VSWITCH command to remove the designated virtual switch from the CP system, uncouple any virtual adapters using the virtual switch, and release system resources associated with it.

### Operands

#### *switchname*

is the name of the virtual switch. The *switchname* is a single token of 1–8 alphanumeric characters.

### Usage Notes

1. Only a Class B user can DETACH a virtual switch.
2. Any virtual network adapter coupled to the virtual switch receives an indication that the LAN has stopped functioning.

### Examples

1. To detach virtual switch BIGANG from the system, enter the following:

```
detach vswitch bigang
```

### Responses

Response 1:

```
VSWITCH SYSTEM switchname is destroyed
```

This is the normal response for this command.

Response 2:

```
NIC vdev disconnected from VSWITCH SYSTEM switchname
```

This is the response when a virtual network adapter connected to a virtual switch is detached.

### Messages

- HCP3166E [ DETACH VSWITCH | SET VSWITCH DISCONNECT ] for IVL VSWITCH *ivlswitchnm* failed. Virtual switch *switchname* is defined on *systemnm* with the GLOBAL attribute.

## DIAL

### Authorization

Privilege Class: Any

### Purpose

Use DIAL to logically connect your terminal to a virtual machine.

### Operands

#### *userid*

identifies the virtual machine to which you want to connect. SYSTEM and asterisk (\*) are not valid user IDs for this command.

#### *vdev*

identifies the device number of the virtual terminal to which the connection is to be made.

### Usage Notes

1. The system accepts a DIAL command only at logon, and only as a substitute for a LOGON command.
2. Once the connection is made, your terminal operates entirely under the control of the virtual machine. The DIAL command matches your terminal to an equivalent type defined in the virtual machine. If no matching terminal type exists, the connection cannot be made, and an error message is issued.
3. The first-level operator of a virtual system can return the terminal to CP control by issuing either the RESET command or the DETACH command. A virtual system user can return the terminal by causing an unsolicited device end to be generated for the dialed terminal. To generate an unsolicited device end, use the TEST/NORMAL or POWER OFF/POWER ON functions.
4. A SNA/CCS terminal user cannot dial into the VTAM service machine controlling the terminal. A logical terminal user cannot dial into the virtual machine that created it.
5. The write-for-position operation is not supported for SNA/CCS terminals that are controlled by a level of VTAM service machine that is prior to ACF/VTAM version 3, release 1.1, for VM/SP (VM/VTAM). For this operation, a write CCW is chained to a read CCW; the write operation sets the 3270 buffer address from which the read operation is to begin. If a user attempts a write-for-position operation that is not supported by the controlling VTAM service machine, the virtual machine receives an operation exception on the read operation.
6. The DIAL command is not supported for SNA/CCS terminals controlled by a VCNA level of VTAM service machine. ACF/VTAM version 3 (VM/VTAM) VSMs, and later, support the DIAL command for SNA/CCS displays. The DIAL command is not supported for ASCII terminals attached through SNA/CCS.
7. If an external security manager is installed on your system, the DIAL command may be disabled. For additional information, contact your security administrator.

### Responses

Response 1:

```
DIALED TO userid vdev
```

is the response sent to the user indicating that a logical connection has been established.

**userid**

identifies the virtual machine in which the multiple-access operating system that you want to use is running.

**vdev**

identifies the virtual device number of the terminal to which the dialed connection has been made.

Response 2:

```
{type {rdev} } DIALED TO userid DIALED = nnnnn [FROM ipadr]
{
  {ldev}
}
{luname }
```

is the response sent to the primary system operator. It indicates a successful connection to the virtual machine (*userid*) and the total number of terminals (*nnnnn*) currently connected to other virtual machines.

**type**

identifies the user's terminal device type.

**rdev**

**ldev**

identifies the real or logical device number of your console.

**luname**

identifies a SNA/CCS terminal controlled by a VTAM service machine. It is the name from the VTAM definition of the terminal as an SNA logical unit.

**FROM ipadr**

identifies the IP address.

An IPv4 address is displayed in dotted-decimal format.

**Example:** 9 . 130 . 44 . 144

An IPv6 address is displayed in compressed format ("::" designates multiple 16-bit groups of zeros).

**Example:** The following is an IPv6 address:

```
F802:0000:0000:0000:0000:0000:0A00:0001
```

This address is displayed in compressed format as:

```
F802::A00:1
```

Response 3:

```
DROP FROM userid vdev
```

is the message sent to the user when the display is reset.

The system additionally responds with one of the following, depending on the type of terminal being used:

Type of Terminal	Message
3270 family	Press the ENTER or CLEAR key to continue
SNA/CCS 3270	Press the ENTER key to continue

Pressing the appropriate key on your terminal causes the logo to appear on the terminal, which readies the terminal for the next session. For terminals not listed above, control automatically returns to CP, and the "online" message is printed.

Response 4:

```
{type {rdev} } DROP FROM userid DIALED = nnnnn
{
  {ldev}
}
{luname }
```

## DIAL

is the message sent to the primary system operator when the display is reset.

### Messages

- HCP011E Invalid device type - *userid vdev*
- HCP020E Userid missing or invalid

- HCP206E Cannot connect to host virtual machine
- HCP743I DIAL function not available

## DISABLE (Device)

### Authorization

Privilege Class: A, B, F

### Purpose

Use DISABLE (device) to prevent the following devices from accessing the host system:

- Display devices
- EP (Emulator Program) controlled lines in the 3745
- SNA/CCS terminals.

### Operands

#### ALL

disables all real 3270 displays, including the operator's display, all real 328x printers, EP (Emulator Program) controlled lines in the 3745, and all SNA/CCS terminals.

**Note:** The logical 328x printers are not disabled.

#### SNA *userid*

disables communication with the SNA/CCS terminals owned by the VTAM service machine whose user ID is specified. If *userid* is omitted, communication with all SNA/CCS terminals for all VTAM service machines is disabled.

#### *rdev*

#### *rdev1-rdev2*

is a real device number, a list of real device numbers, or a range of real device numbers of display stations or lines that you want to disable. Specify each real device number as 1- to 4-hexadecimal digits. If you specify more than one device number, each must be separated from the others by at least one blank.

#### *ldev*

#### *ldev1-ldev2*

is a logical device number, a list of logical device numbers, or a range of logical device numbers of 328x display printers that you want to disable. Only 328x display printers are valid for this operand. Specify a logical device number as an L followed by 4 hexadecimal digits. If you specify more than one device number, each must be separated from the others by at least one blank.

### Usage Notes

1. On a single command line you may combine device numbers, lists of device numbers, and ranges of device numbers. The beginning and ending device numbers of a range must both be either real device numbers or both logical display printer numbers.
2. If the devices you specify on the DISABLE (device) command are not active, they are disabled immediately. If the devices are active, they are disabled when the user issues the LOGOFF or DISCONNECT command. A device is active if a user is logged onto it, or if a user is dialed from it.
3. If you enter the ENABLE (device) command to a device before it is physically disabled, you reinstate the device's enabled status and negate previously issued DISABLE commands directed to the device.
4. The DISABLE (device) command is an ASYNCHRONOUS command. This means the virtual machine is free to issue other commands before CP finishes disabling the specified devices. CP issues the "Command complete" response when it has finished processing the DISABLE (device) command, not when it has finished disabling all of the specified devices. Thus, one or more devices may not be completely disabled when you receive the "Command complete" response.

To display whether the specified real devices (*rdev*) are disabled, use the QUERY (Real Device) STATUS command (see [“QUERY \(Real Device\)”](#) on page 1114). To display whether the specified logical devices (*ldev*) are disabled, use the QUERY LDEVS command (see [“QUERY LDEVS”](#) on page 973).

### Responses

```
Command complete
```

is issued when the command completes successfully.

### Messages

## DISABLE COMMAND / CMD

### Authorization

Privilege Class: A

### Purpose

Use DISABLE COMMAND or CMD to prevent CP from processing requests for the specified CP command.

You can also prevent processing of CP commands during initialization using the DISABLE COMMAND or CMD configuration file statements. For more information, see [DISABLE COMMAND / CMD Statement in z/VM: CP Planning and Administration](#).

### Operands

#### **command**

is the name of the command that you are disabling. The variable *command* is a 1-character to 12-character alphanumeric string.

#### **Query SUBCmd subcommand**

tells CP the name of the CP QUERY subcommand that you are disabling. The variable *subcommand* is a 1-character to 12-character alphanumeric string.

#### **Query Virtual SUBCmd subcommand**

tells CP the name of the CP QUERY VIRTUAL subcommand that you are disabling. The variable *subcommand* is a 1-character to 12-character alphanumeric string.

#### **Set SUBCmd subcommand**

tells CP the name of the CP SET subcommand that you are disabling. The variable *subcommand* is a 1-character to 12-character alphanumeric string.

#### **IBMclass \***

tells CP to disable all versions of the specified command or subcommand. If omitted, IBMCLASS \* is the default.

#### **IBMclass c**

tells CP to disable a specific version of the specified command or subcommand. The variable *c* can be any one of the following:

##### **A**

this is a system-control command to be used by the primary system operator.

##### **B**

this is a command for operational control of real devices.

##### **C**

this is a command to alter system storage.

### D

this is a command for system-wide control of spool files.

### E

this is a command to examine system storage.

### F

this is a command for service control of real devices.

### G

this is a general-use command used to control the functions of a virtual machine.

### O

(zero) this command has no specific IBM class assigned.

## Usage Notes

1. To remove the command processing code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD” on page 117](#)).
2. To load the command processing code into the system execution space, use the CPXLOAD command (see [“CPXLOAD” on page 111](#)).
3. To deactivate a CP command while defining it, use the DISABLE operand of the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD” on page 143](#)).

If you disable a command that has an alias defined, then the alias will be treated as if it were also disabled.

4. To activate a CP command:
  - While defining it, use the ENABLE operand of the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD” on page 143](#)).
  - After defining it, use the ENABLE COMMAND or CMD command (see [“ENABLE COMMAND / CMD” on page 460](#)).
5. To change the definition of an existing CP command, use the MODIFY COMMAND or CMD command (see [“MODIFY COMMAND / CMD” on page 683](#)).
6. Once defined, commands, subcommands, and aliases cannot be deleted. They may be altered in various appropriate ways, but they remain in existence until a SHUTDOWN or RESTART IPL is done.
7. To obtain information such as the enable/disable status and the name of the base command for a command or alias that is defined, use the QUERY CPCMDS command (see [“QUERY CPCMDS” on page 817](#)).
8. To display the address of the CP command table entry block, the current IBM class, and the current privilege class for a specified CP command, use the LOCATE CMDBK command (see [“LOCATE CMDBK” on page 603](#)).
9. For more information about enabling and disabling commands, see [z/VM: CP Exit Customization](#).

## Responses

### Response 1:

To disable the class D version of the CP PURGE command, but not the class G version of the CP PURGE command, enter the following:

```
disable command purge ibmclass d
Ready;
```

### Response 2:

To disable the CP SHUTDOWN command, enter the following:

```
disable command shutdown  
Ready;
```

## Messages

- HCP002E Invalid operand - *operand*

- HCP9300E A system soft abend *code* has occurred on CPU *nnnn* for user *userid*.

## DISABLE DIAGNOSE

### Authorization

Privilege Class: A

### Purpose

Use `DISABLE DIAGNOSE` to prevent CP from processing requests for one or more locally-developed `DIAGNOSE` codes.

You can also prevent processing of locally-developed `DIAGNOSE` codes during initialization using the `DISABLE DIAGNOSE` configuration file statement. For more information, see [DISABLE DIAGNOSE Statement](#) in *z/VM: CP Planning and Administration*.

### Operands

#### ALL

tells CP to disable all existing `DIAGNOSE` codes.

**Note:** This operand disables all `DIAGNOSE` codes: the locally-defined ones, the IBM-supplied ones, and any supplied by third-party software vendors.

#### *diag*

#### *diag1-diag2*

is the number of the `DIAGNOSE` code that you are disabling. Each *diag* must be a hexadecimal number between X'0000' and X'03FC' and must be a multiple of 4. You can specify a single `DIAGNOSE` code, a range of `DIAGNOSE` codes, or any combination thereof.

### Usage Notes

1. If a `DIAGNOSE` code that you are disabling is currently processing a `DIAGNOSE` request, CP waits until the current request has finished before disabling the `DIAGNOSE` code. If there are `DIAGNOSE` requests waiting to execute after the current request, CP waits until the current request has finished, disables the `DIAGNOSE` code, and rejects any `DIAGNOSE` requests still waiting to be processed.
2. CP treats disabled `DIAGNOSE` codes as if they were never defined. If you try to use a disabled `DIAGNOSE` code in a program, CP will give you a program check specification exception.
3. To load the `DIAGNOSE` processing code into the system execution space, use the `CPXLOAD` command (see “[CPXLOAD](#)” on page 111).
4. To define a new `DIAGNOSE` code, use the `DEFINE DIAGNOSE` command (see “[DEFINE DIAGNOSE](#)” on page 172).

**Note:** Unless you specify the `ENABLE` operand of the `DEFINE DIAGNOSE` command, the new `DIAGNOSE` code is initially in a disabled state after being defined.

5. To activate a new `DIAGNOSE` code after defining it, use the `ENABLE DIAGNOSE` command (see “[ENABLE DIAGNOSE](#)” on page 463).

6. To change the definition of an existing DIAGNOSE code after initialization, use the MODIFY DIAGNOSE command (see [“MODIFY DIAGNOSE”](#) on page 697).
7. Once defined, a DIAGNOSE code cannot be deleted. It may be altered in various appropriate ways, but it remains in existence until a SHUTDOWN or RESTART IPL is done.
8. To display information about a DIAGNOSE code (status, entry point name, and privilege class), use the QUERY DIAGNOSE command (see [“QUERY DIAGNOSE”](#) on page 885).
9. To display the address of the CP DIAGNOSE code table block for a DIAGNOSE code, use the LOCATE DGNBK command (see [“LOCATE DGNBK”](#) on page 608).
10. To remove the DIAGNOSE processing code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD”](#) on page 117).
11. Many external security managers (ESMs) do not support DIAGNOSE codes above X'03FC'. For this reason, CP does not support DIAGNOSE codes above X'03FC'. The DIAGNOSE codes between X'0000' and X'03FC' are divided as follows:
  - X'0000' to X'00FC'**  
Reserved for IBM use
  - X'0100' to X'01FC'**  
Reserved for customer use
  - X'0200' to X'03FC'**  
Reserved for IBM use.
12. For more information about user-defined DIAGNOSE codes, see [Defining and Modifying Commands and Diagnose Codes in z/VM: CP Exit Customization](#).

## Responses

Response 1 (Disable One):

To disable DIAGNOSE code X'100', enter the following:

```
disable diagnose 100
Ready;
```

After CP finishes processing this command, any virtual machine that issues DIAGNOSE code X'100' receives a program specification exception in that virtual machine.

Response 2 (Disable All):

To disable all DIAGNOSE codes on your system, enter the following:

```
disable diagnose all
Ready;
```

Response 3 (Disable All Local):

To disable all locally-defined DIAGNOSE codes, enter the following:

```
disable diagnose 100-1fc
Ready;
```

Response 4 (Disable Almost All Local):

To disable all locally-defined DIAGNOSE codes except DIAGNOSE code X'01F0', enter the following:

```
disable diagnose 100-iec if4-1fc
Ready;
```

## Messages

- HCP002E Invalid operand - *operand*

## DISABLE DIAGNOSE

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP2751E Diagnose code *diag* does not exist
- HCP2751E Diagnose codes *diag1-dia2* do not exist

- HCP6706E Invalid Diagnose code - *diag*

## DISABLE EXITS

### Authorization

Privilege Class: A

### Purpose

Use `DISABLE EXITS` to prevent CP from calling all entry points and external symbols associated with one or more exit points.

You can also prevent CP from calling one or more exit points during initialization using the `DISABLE EXITS` configuration file statement. For more information, see [DISABLE EXITS Statement](#) in *z/VM: CP Planning and Administration*.

### Operands

#### ALL

tells CP to disable all existing CP exit points.

#### exit

#### exit1-exit2

is the number of the exit point (or exit points) that you no longer want CP to use. Each *exit* must be a hexadecimal number between X'0000' and X'FFFF'. You can specify a single exit point number, a range of exit point numbers, or any combination thereof.

### Usage Notes

1. If the exit point is currently processing an exit request, CP waits until that exit request is completed and then disables the exit point. If there are more exit requests waiting to be processed, CP places your `DISABLE EXIT` command in the exit request queue behind all the known exit requests. After processing all the known exit requests, CP disables the specified exit point and rejects any exit requests that arrived after it placed your `DISABLE EXITS` command in the exit request queue.
2. To load the exit point code into the system execution space, use the `CPXLOAD` command (see [“CPXLOAD”](#) on page 111).
3. To add to, change, or replace the list of entry points and external symbols associated with an exit point and to enable or disable that exit point, use the `ASSOCIATE EXITS` command (see [“ASSOCIATE EXIT”](#) on page 20).
4. To activate an exit point after associating it, use the `ENABLE EXITS` command (see [“ENABLE EXITS”](#) on page 465).
5. To display status and usage statistics information about a specific exit point, use the `QUERY EXITS` command (see [“QUERY EXITS”](#) on page 907).
6. To display the address of the CP exit block for a specific exit point, use the `LOCATE XITBK` command (see [“LOCATE XITBK”](#) on page 649).
7. To display the address of the CP indirect call locator block for a specific exit point, use the `LOCATE ICLBK` command (see [“LOCATE ICLBK”](#) on page 614).

## DISABLE EXITS

8. To change the definition of an existing dynamic exit point, or to remove the exit point from the system, use the MODIFY EXIT command (see [“MODIFY EXIT” on page 700](#)).
9. To remove the exit point code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD” on page 117](#)).
10. After processing a DISABLE EXITS command (or statement), CP updates the status of the exit point in its CP exit block, but does not erase the CP exit block. CP will not erase any CP exit blocks until the next IPL.
11. For more information about user-defined exit points, see [z/VM: CP Exit Customization](#).

## Responses

Response 1:

To stop CP from calling the entry points and external symbols associated with CP Exits 1, 2, 3, 4, and 6, enter the following:

```
disable exits 1-4 6
Ready;
```

Response 2:

To stop CP from calling the entry points and external symbols associated with all CP exit points, enter the following:

```
disable exits all
Ready;
```

## Messages

- HCP2752E Exit numbers do not exist
- HCP2752E Exit numbers *exit1-exit2* do not exist
- HCP6704E Missing token at end of line
- HCP6706E Invalid CP Exit number - *exit*

## DISABLE HCD

### Authorization

Privilege Class: B

### Purpose

Use the DISAbLe HCD command to disable the I/O-configuration capabilities of HCM and HCD for the rest of the current IML of your machine, transferring I/O configuration control to the applicable CP operator commands.

With HCM and HCD disabled, the hardware I/O configuration can be changed with the CP dynamic-I/O-configuration commands SET DYNAmic\_i/o, SET CONFIGmode, DEFine CHPID, DEFine CNTLUNIT, DEFine DEVEice, MODify CHPID, MODify CNTLUNIT, MODify DEVEice, DELete CHPID, DELete CNTLUNIT, DELete DEVEice, Set IOCDs\_active, and Set TOKen.

Additionally, with HCM and HCD disabled, the VM software I/O configuration can be changed with the CP operator commands Set RDEVEice, DELete RDEVEice, Set EDEVEice, DELete EDEVEice, Set DEVEices, and Set HOTIO.

### Operands

#### NOFORCE

can be specified to cause the command to be rejected if, as part of disabling HCM and HCD and enabling the CP dynamic-I/O-configuration commands, a VM configuration token cannot be established. The inability to establish a VM configuration token in the machine means that the CP dynamic-I/O-configuration commands cannot be used. Therefore the NOFORCE operand leaves the HCM and HCD capability intact if the CP dynamic-I/O-configuration commands cannot be made effective.

#### FORCE

can be specified to force execution of the command even though a VM configuration token cannot be established. In this case HCM and HCD are disabled from making I/O-configuration changes, and in addition the VM dynamic-I/O-configuration commands remain disabled. No hardware I/O-configuration changes are possible without a re-IML of your machine (thereby taking down all logical partitions if the machine is logically partitioned). Software I/O-configuration changes can still be made, however, using the applicable CP operator commands.

### Usage Notes

1. Once your machine is IMLed with HCM and HCD in control of the I/O configuration, the DISAbLe HCD command is a one-way escape mechanism to take control away from HCM and HCD and attempt to give it to the CP operator commands.

Note that once HCM and HCD are disabled, there is no way to re-enable them without re-IMLing your machine (thereby taking down all logical partitions if the machine is logically partitioned).

2. If HCM and HCD are currently disabled for hardware dynamic-I/O-configuration, this command does not attempt to establish a VM configuration token in the machine. No attempt is made to change the token (which would allow the use of the CP-dynamic-I/O-configuration commands) because “ownership” of the existing configuration token is uncertain and it is not known whether HCM and

## DISABLE HCD

HCD were ever used to dynamically change the machine configuration. In this case, whether *FORCE* or *NOFORCE* is specified, the command is executed and HCM and HCD are disabled. Even though the machine I/O configuration cannot be changed by any means in this case without a re-IML of your machine,, there is still the capability to dynamically change the software I/O configuration using CP operator commands.

3. If HCM and HCD are currently enabled for hardware dynamic-I/O-configuration when this command is issued and the configuration token is successfully changed to a VM configuration token, the SET DYNamic\_i/o ON command can be issued to enable the use of the CP dynamic-I/O-configuration commands.

### Responses

#### Response 1:

When the DISAbLe HCD command is issued and the VM/HCD service virtual machine does not exist or is not being used to control the I/O configuration, the following response will be issued:

```
disable hcd
HCD is not active
Ready;
```

#### Response 2:

When the DISAbLe HCD command is issued and the VM/HCD service virtual machine is enabled for hardware I/O-configuration changes, the following response is issued when the configuration token is successfully changed to a VM token in the machine:

```
disable hcd force
HCD was successfully disabled
Ready;
```

#### Response 3:

When the DISAbLe HCD command is issued and the VM/HCD service virtual machine is not enabled for hardware I/O-configuration changes, the following informational-message and command-response combination is issued:

```
disable hcd
HCPCCY654302I HCD is now disabled, but a VM configuration token
HCPCCY654302I was not established because HCD was not enabled for
HCPCCY654302I dynamic hardware changes.
Command complete.
Ready;
```

#### Response 4:

When the DISAbLe HCD FORCE command is issued and the VM/HCD service virtual machine is enabled for hardware I/O-configuration changes, the following informational-message and command-response combination is issued if the machine will not enter configuration mode to change the current configuration token to a VM configuration token:

```
disable hcd force
HCPCCY654301I HCD is now disabled, but the machine would not enter
HCPCCY654301I configuration mode to allow a VM configuration token
HCPCCY654301I to be established.
Command complete.
Ready;
```

#### Response 5:

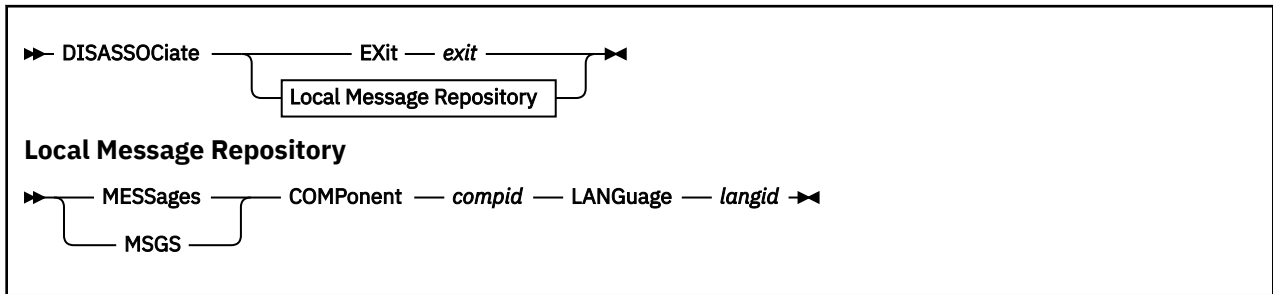

When the DISAbLe HCD command is issued and CP is in the process of updating the I/O configuration for the VM/HCD service virtual machine, the following response will be issued:

```
disable hcd
HCD is currently updating the I/O configuration and cannot be disabled.
Ready;
```

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP6544E Disable HCD command failed. The machine would not enter configuration mode to allow a VM configuration token to be established.

## DISASSOCIATE

### Authorization

Privilege Class: A

### Purpose

Use DISASSOCIATE to revoke all entry point and external symbol assignments associated with an exit point or local message repository using ASSOCIATE EXIT, MESSAGES, or MSGS commands or configuration file statements.

### Operands

#### EXIT *exit*

tells CP that you want to disassociate all entry points and external symbols from the specified exit point. The variable *exit* must be a hexadecimal number between X'0000' and X'FFFF'.

#### MESSAGES COMPONENT *compid* LANGUAGE *langid*

#### MSGS COMPONENT *compid* LANGUAGE *langid*

tells CP that you want to disassociate all entry points and external symbols from the specified local message repository.

The variable *compid* is a 1- to 3-character alphanumeric string. For example, the component ID for the system message repository (z/VM) is HCP.

The variable *langid* is a 1- to 5-character alphanumeric string. AMENG (American English) and UCENG (Uppercase English) are examples of two very common language IDs.

You can use generic language names to request a specific subset of languages. A generic language name is a 1- to 5-character string with asterisks (\*) in place of 1 or more characters and percent signs (%) in place of exactly 1 character. For example:

```
... language %%en*
```

disassociates all languages that have EN as their third and fourth characters.

### Usage Notes

1. When you use the DISASSOCIATE command for an exit point, CP does not change the status (enabled or disabled) of the exit point. If the exit point is enabled, it will remain enabled after your DISASSOCIATE command completes. If the exit point is disabled, it will remain disabled after your DISASSOCIATE command completes. Only the ASSOCIATE EXIT, DISABLE EXITS, and ENABLE EXITS commands (or configuration file statements) can change the status of the exit point.

To avoid unnecessary system processing, you should disable the exit point either before or after you issue the DISASSOCIATE command. If you do not disable the exit point, the effect is the same as having a single entry point name that did nothing except send back a return code of 0 (zero) to the mainline code.

2. After you revoke all entry point and external symbol assignments using the DISASSOCIATE command, you need to unload the customer-written CP routines using the CPXUNLOAD command (see [“CPXUNLOAD” on page 117](#)).
3. To assign entry points and external symbols to an exit point and to enable or disable that exit point, use the ASSOCIATE EXIT command (see [“ASSOCIATE EXIT” on page 20](#)).
4. To assign an external symbol to a local message repository, use the ASSOCIATE MESSAGES or MSGS command (see [“ASSOCIATE MESSAGES / MSGS” on page 24](#)).
5. After issuing DISASSOCIATE EXIT, CP erases the entry point names and external symbols from the CP exit block for that exit point, but CP does not erase the CP exit block itself. CP will not erase any CP exit blocks until the next IPL.
6. For more information about associating and disassociating entry points and external symbols, see [z/VM: CP Exit Customization](#).

## Responses

### Response 1:

To empty the list of entry point names and external symbols for exit point X'7DF', enter the following series of commands:

```
query exit 7df
Exit Status      Calls      Returns Seconds
07DF Enabled      8          8 10.008833
      EPName      Attempts   Calls Seconds
      HCPsrc00    8          8 0.002598
      HCPsrcZZ    8          0 0.000000
      HCPsrc08    8          4 0.002833
      HCPsrc99    6          6 10.002668
Ready;

disassociate exit 7df
Ready;

query exit 7df
Ready;
Exit Status      Calls      Returns Seconds
07DF Enabled      8          8 10.008833
```

### Response 2:

To empty the list of entry point names for the uppercase messages belonging to component AC\$, enter the following series of commands:

```
query cplanglist associated
Language: AMENG Component: AC$ EPName: AC$CSCT1
Language: UCENG Component: AC$ EPName: AC$CSCT2
Ready;

disassociate msgs component ac$ language uceng
Ready;

query cplanglist associated
Language: AMENG Component: AC$ EPName: AC$CSCT1
Ready;
```

### Response 3:

To empty the list of entry point names for all the messages belonging to component AC\$, enter the following series of commands:

```
query cplanglist associated
Language: AMENG Component: AC$ EPName: AC$CSCT1
Language: UCENG Component: AC$ EPName: AC$CSCT2
Ready;

disassociate msgs component ac$ language *eng
Ready;

query cplanglist associated
```

There are no associated message repositories  
Ready;

## DISCARD PINNED

### Authorization

Privilege Class: B

### Purpose

Use DISCARD PINNED to discard pinned data that is stored in a subsystem cache or nonvolatile storage (NVS). This command is valid for cache storage subsystems that support the cache fast write or DASD fast write functions.

### Operands

#### ALL

indicates that all pinned data for the specified devices is to be discarded.

#### CACHEFW

indicates that only pinned cache fast write data for the specified devices is to be discarded.

**Note:** For IBM DASD subsystems, this operand is being allowed for compatibility. Using the CACHEFW operand will have the same effect as the ALL operand. All pinned data will be discarded.

#### *rdev*

#### *rdev1-rdev2*

is the real device number, a list of real device numbers, or a range of real device numbers of devices for which data is to be discarded.

### Usage Notes

1. The DISCARD PINNED command is only valid for cache storage subsystems that support the cache fast write or DASD fast write functions. An error message is generated if the specified subsystem does not support any of these functions.
2. This command is used as a recovery tool to remove pinned data from cache and nonvolatile storage (NVS).
3.  **Attention:** This command results in a loss of data. Incorrect use of this command can result in unintended loss of data.
4. This command may be issued to offline devices.

### Responses

Response 1:

The following response is displayed for each specified device when you enter DISCARD PINNED ALL:

```
rdev Pinned data has been discarded.
```

If the originator of the command is not the system operator, the following response is issued to the system operator. This response is also repeated for each specified device.

## DISCARD PINNED

```
rdev Pinned data was discarded by userid.
```

### **rdev**

is the real device number of a device for which pinned data has been discarded.

### **userid**

is the ID of the user who issued the command.

Response 2:

The following response is displayed for each specified device when you enter DISCARD PINNED CACHEFW:

```
rdev Pinned cache fast write data has been discarded.
```

If the originator of the command is not the system operator, the following response is issued to the system operator. This response is also repeated for each specified device.

```
rdev Pinned cache fast write data was discarded by userid.
```

### **rdev**

is the real device number of a device for which pinned cache fast write data has been discarded.

### **userid**

is the ID of the user who issued the command.

## Messages

- HCP006E Invalid device type - {rdev/vdev/ldev}
- HCP009E Invalid range - range
- HCP021E A real device number was not supplied or it is invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {rdev/vdev/ldev} does not exist
- HCP046E type rdev offline
- HCP319E Error processing subsystem command - cmd for DASD rdev
- HCP332E Invalid control unit type - rdev
- HCP1109E The command command cannot be processed for device rdev because the device is the secondary in a duplex pair.

## DISCONNECT

### Authorization

Privilege Class: Any

### Purpose

Use DISCONNECT to disconnect your display from the host system without stopping operations in your virtual machine.

### Operands

#### HOLD

causes the non-SNA TTY display terminal telecommunication connection to remain in effect after your session is disconnected. If you specify the HOLD option from a logical device, you disconnect from the logical device without losing the connection between the logical device and the system.

### Usage Notes

1. Once you have issued DISCONNECT, you remain disconnected until you enter the LOGON command. If you have a functional secondary user, that user receives your messages and can enter commands and responses for you. If your virtual machine goes into a disabled wait state, or if a read is posted from the virtual machine or from CP, and you do not have a functional secondary user, you have an installation-defined grace period (usually 15 minutes) in which to log on, or your virtual machine is automatically logged off. If you do not have a functional secondary user, and your virtual machine is in disconnect mode, all “writes” or output messages sent to your virtual console are ignored unless you have issued the CP command SPOOL CONSOLE START.
2. If your connection is broken because of console errors, and you do not have a functional secondary user, CP places your virtual machine in disconnect mode for a grace period defined by the DISCONNECT\_TIMEOUT setting in the SYSTEM CONFIG file. Your virtual machine does not continue to run and you must log on within the grace period if you want to continue operations on your virtual machine and prevent the virtual machine from being FORCED.
3. An error message, without a message ID, is issued when the system disconnects a terminal because of an I/O error.

For example:

```
11:19:20 GRAF 0AB3 DISCONNECT ETC18566 USERS = 59 FORCED BY SYSTEM
```

4. When your virtual machine is reconnected using the usual logon procedure, it is placed in CP console function mode. To resume execution on your virtual machine, enter the BEGIN command.
5. If you specify the HOLD option on an SNA/CCS terminal, the command is not valid and an error message is issued. If you specify the HOLD option on a non-SNA TTY terminal, or a logical terminal, it is accepted and processed. The HOLD option is accepted but ignored on all other terminals.
6. If your installation has coded the E3270HLD feature in the system real I/O configuration file for a TTY display terminal connected to your DACU control unit 7171, the telecommunication connection always remains, regardless of the HOLD option.
7. This command, regardless of the SET RUN setting, causes your virtual machine to run as though BEGIN were entered immediately after DISCONNECT was entered.

## Responses

Response 1:

```
DISCONNECT AT hh:mm:ss zone weekday mm/dd/yy
```

is returned to the user who issued the command.

### hh:mm:ss

identifies the current time.

### zone

identifies the time zone.

### weekday

identifies the current day of the week.

### mm/dd/yy

identifies the current date in month/day-of-month/year format.

The system additionally responds with one of the following, depending on the type of terminal being used:

Type of Terminal	Message
3270 family	Press the ENTER or CLEAR key to continue
SNA/CCS terminal	Press the ENTER key to continue

Pressing the appropriate key on your terminal causes the logo to appear on the terminal, which readies the terminal for the next session. For terminals not listed above, control automatically returns to CP, and the logo is redisplayed.

Response 2:

```
{type {rdev}} DISCONNECT userid USERS = nnnn
{
  {ldev}
  {luname}
  {SYSC}
}
```

is returned to the primary system operator.

### type

identifies the user's display type.

### rdev

### ldev

identifies the real or logical device number associated with the display.

### luname

identifies an SNA/CCS terminal controlled by a VTAM service machine. It is the name from the VTAM definition of the terminal as an SNA logical unit.

### SYSC

identifies the system console.

### userid

identifies the user who has disconnected from the system.

### USERS = nnnnn

identifies the total number of users remaining on the system.

# DISPLAY

---

## Purpose

Use the DISPLAY commands to see data from the following machine components, both real and virtual:

- The contents of first-level (host) storage
- The contents of second-level storage (the storage that appears real to the operating system running in your virtual machine)
- The contents of third-level storage (the storage that appears virtual to the operating system running in your virtual machine)
- The old and new PSWs, and interrupt information for the following interrupts:
  - SVC
  - I/O
  - PROGRAM
  - EXTERNAL
  - MACHINE CHECK
- Storage keys
- Linkage stack
- The contents of these registers:
  - Access
  - Control
  - Floating-point
  - Floating-point control
  - General purpose
  - Prefix
- Subchannel information blocks (SCHIBS)
- The current program status word (PSW)

## Usage Notes

(General for DISPLAY)

1. Using a single command, you can display the contents of multiple storage locations, registers, and control words.

Follow these rules to execute the command properly:

- a. Do not put blanks between operands that relate to a single DISPLAY request, except for PSW and SCHIB, which require at least one blank between the first and second operands. For example, if you want to display hexadecimal location 40, enter **display H40**.
  - b. Separate each set of display requests from others by at least one blank. For example, if you want to display hexadecimal location 40 and the contents of register 5, enter **display H40 G5**.
2. The defaults for the following DISPLAY operands are:

Operand	Default Before Rounding
G	0-end
G-	0-end

## DISPLAY

Operand	Default Before Rounding
G-5	0-G5
G5-	G5-end
G5	G5
T	T0
T-	T0-end
T-1000	T0-1000
T1000-	T1000-end
T1000	T1000
PSW	Current

3. When displaying a range of addresses or subchannels, the command operand must be followed by an address, a range, or by a hyphen (-), colon (:), or period (.). When displaying registers, the command operand can stand alone.
4. If you enter a command line that contains an operand that is not valid, the DISPLAY command terminates when it encounters that operand. Any previous valid operands are processed before termination occurs.
5. The DISPLAY command lets you display storage in the following formats:
  - Hexadecimal string/word segments
  - EBCDIC or ASCII translation
  - Hexadecimal word segments with EBCDIC translation
  - Instruction
  - Storage key

**Note:** The EBCDIC translation is displayed only when the storage location contains the hexadecimal representation contained in a system translation table. This table is tailorable by the system programmer via the system configuration file. The IBM supplied table supports translations for the hexadecimal representation of the digits 0 through 9, the uppercase and lowercase letters A through Z, and a number of special characters. In all other cases, a period (.) is displayed.

If you enter multiple operands on a single command line to display storage and do not specify the format that you want the DISPLAY command processor to use, the last format type you explicitly enter on the command line defines the type of display you receive. That is, whenever you explicitly enter a display type, you implicitly define the default for subsequent operands of the current display function. If you do not enter any display format type on the command line, the system defaults are employed.

For example, the command **display 10 20 T40 80 G12 5 L60-100** displays the following, respectively:

- Hexadecimal location 10 without EBCDIC translation
  - Hexadecimal location 20 without EBCDIC translation
  - Hexadecimal location 40 with EBCDIC translation
  - Hexadecimal location 80 with EBCDIC translation
  - The contents of general register 12
  - The contents of general register 5
  - Hexadecimal locations 60 through 100 without EBCDIC translation.
6. Use the DISPLAY command to display the contents of various storage locations, registers, and control words. You can examine this information during program execution, and may be able to determine the cause of program errors.

To do this, you would typically define a TRACE trap, using the TRACE command, that will stop program execution at a specified point. Once program execution suspends, your virtual machine enters the CP

environment, and you can enter the DISPLAY command. Alternatively, you can process the DISPLAY command directly from TRACE using the TRACE command CMD option. For more information, see “TRACE: Options” on page 1949.

- The DISPLAY storage command supports indirect addressing. Indirect addressing tells the command to use the **contents** of an address you specified instead of the address itself. This can help reduce the number of displays you issue and the tedious tracking of address pointers. You specify indirect addressing with an **&** (for 64-bit) or a **%** (for 31-bit).

The following is an example of double indirection using the % for 31-bit addressing. First, the storage is shown using the usual DISPLAY without indirect addressing. Following that is the same storage displayed using indirect addressing with only one DISPLAY command (and without having to know that the information you want is at address 3F1AB40). The information displayed is a LNGBK control block for the system default language using a pointer from the CP nucleus SYSCM area.

```

- If the DISPLAY command processor is suppressing identical lines, it issues a response every time a segment boundary is crossed, rather than waiting for a nonidentical line.
- If you issue DISPLAY with the ASIT operand and specify the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the DISPLAY is rejected and error message HCPCDL6156E is issued. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value by using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:
  - SYSTEM CLEAR
  - IPL by NSS name
  - IPL by device with the CLeAr option
  - SET MACHine (to a different machine architecture)

# DISPLAY ACCESS LIST

►► Display — ACCList ◄◄

## Authorization

Privilege Class: G

## Purpose

Use the DISPLAY ACCESS LIST command to display entries in your virtual machine's host access list.

## Usage Notes

1. If you write a program or EXEC that parses the output of this command, you should avoid a dependency on the ordering of the columns in the output. Your program or EXEC should use the heading line to determine which column contains a particular piece of information.

## Responses

Response 1:

```

ALET      ACC  FAULTS  ASIT      SPACE IDENTIFICATION
ttttttt  {R/O} {ASYNCH} {aaaaaaaaaaaaaaaa} sssssssssssssssssssssssssssssss
          {R/W} {SYNCH } {**REVOKED** }
nnnn TOTAL ENTRIES:  vvvv VALID, rrrr REVOKED, uuuu UNUSED

```

### **ttttttt**

is the access list entry token (ALET) corresponding to the access list entry (8 hexadecimal digits).

### **R/O**

indicates that the access list entry can only be used for read references to the address space.

### **R/W**

indicates that the access list entry can be used for read and write references to the address space.

### **ASYNCH**

indicates that page-fault handshaking applies to the access list entry.

### **SYNCH**

indicates that page-fault handshaking does not apply to the access list entry.

### **aaa...aaa**

is the address space identification token (ASIT) for the address space designated by the access list entry (16 hexadecimal digits).

### **\*\*REVOKED\*\***

indicates that the access list entry previously designated an address space, but access to that address space has been revoked (the access list entry is in the revoked state). The SPACE IDENTIFICATION field is left empty for revoked access list entries.

### **sss...sss**

is the space ID for the address space designated by the access list entry (3 to 33 characters).

### **nnnn TOTAL ENTRIES**

is the total number of entries in the host access list.

### **vvvv VALID**

is the number of entries in the host access list that designate address spaces, and can be used to address data in those address spaces (access list entries that are in the valid state).

## DISPLAY ACCESS LIST

### ***rrrr* REVOKED**

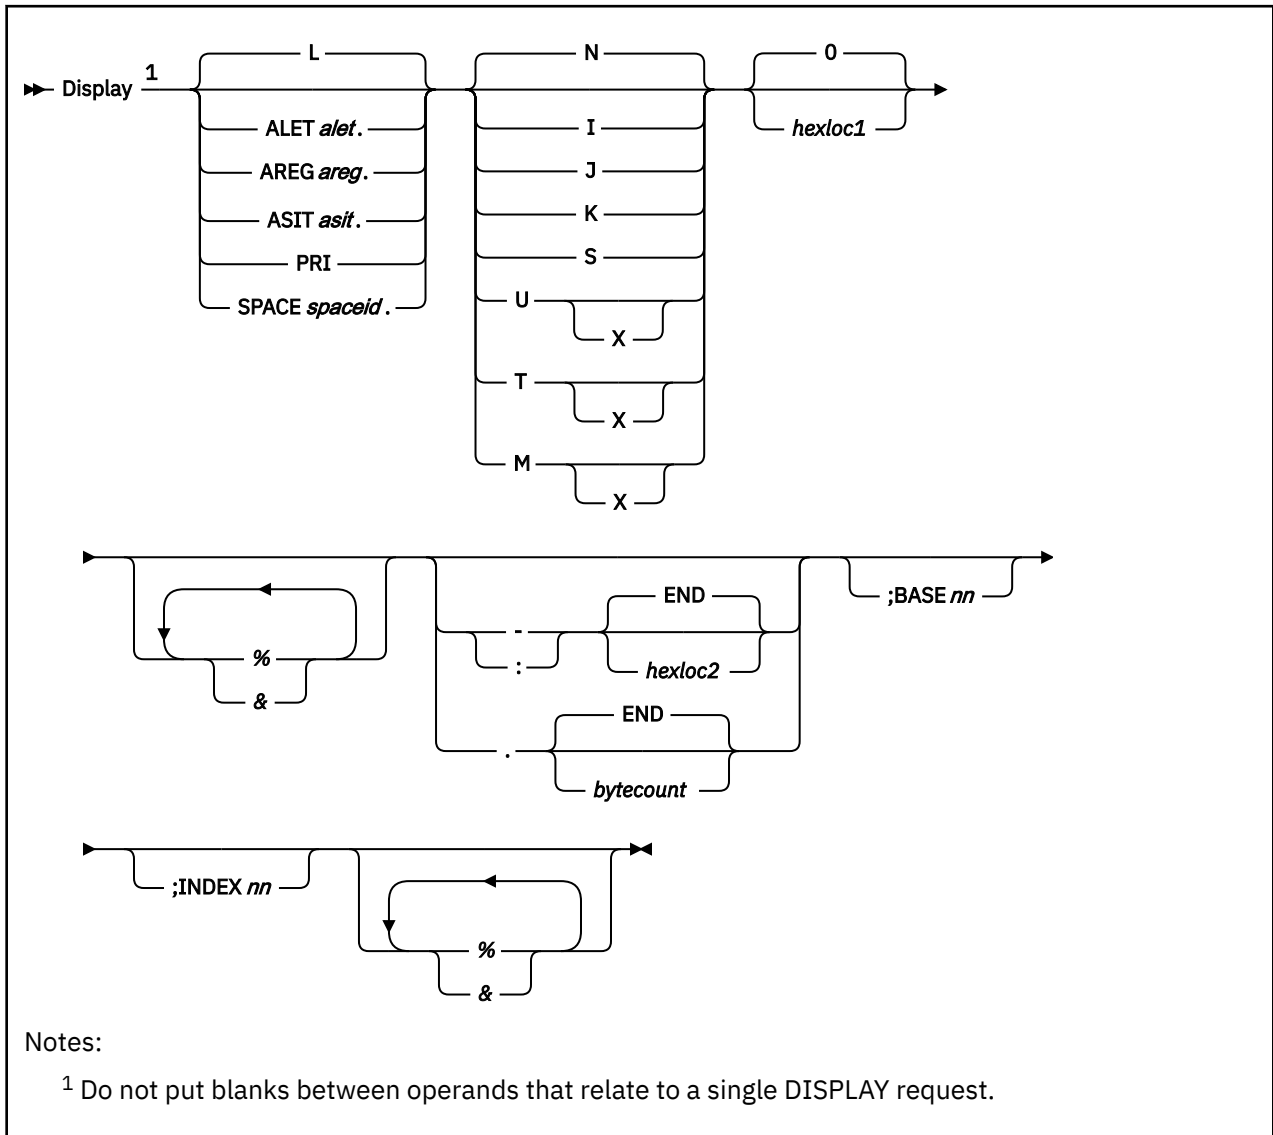

is the number of entries in the host access list that previously designated address spaces, but which can no longer be used to address data because the program's privileges to do so have been withdrawn (access list entries that are in the revoked state).

### ***uuuu* UNUSED**

is the number of entries in the host access list that remain available for use (access list entries that are in the unused state).

## DISPLAY (Guest Storage - ESA/XC, z/XC)

### Authorization

Privilege Class: G

### Purpose

Use DISPLAY (Guest Storage - ESA/XC, z/XC) to display the storage contents of an ESA/XC or z/XC virtual machine.

### Operands

**L**

displays the contents of storage based on the setting of the address-space-control field in the guest PSW. This is the default.

If the virtual CPU is in the primary-space mode, the contents of real storage in the host-primary address space are displayed. If the virtual CPU is in the access register mode and a nonzero BASEnn

operand is also specified, the contents of real storage in an access-register-specified address space are displayed.

If the virtual CPU is in the access register mode, but either the *BASEnn* operand is not specified or is specified as 'BASE0', the contents of real storage in the host-primary address space are displayed.

**ALETalet.**

displays the contents of real storage in an access list entry token (ALET) specified address space. The *alet* may be 1 to 8 hexadecimal digits; leading zeros are optional. The ALET is used in conjunction with the virtual machine's host access list to determine the address space to display.

**AREGareg.**

displays the contents of real storage in an access register specified address space. The *areg* may be specified as 1 hexadecimal or 2 decimal digits. The ALET within the access register is used in conjunction with the virtual machine's host access list to determine the address space to display.

**ASITasit.**

displays the contents of absolute storage in the address space identified by the specified address space identification token (ASIT). The *asit* may be 1 to 16 hexadecimal digits; leading zeros are optional.

**PRI**

displays the contents of real storage in the host-primary address space. This is the address space from which the virtual CPU is fetching instructions at the time the command is processed.

**SPACEspaceid.**

displays the contents of absolute storage in the address space identified by *spaceid*. The *spaceid* is a 1-character to 33-character string of the form:

where *owner* is an optional 1-character to 8-character user ID of the virtual machine that owns the address space, and *spacename* is the 1-character to 24-character address space name assigned to the address space.

If *owner* is not specified, your virtual machine is assumed to be the owner of the address space. The *spacename* 'BASE' is preassigned by CP to be the name of your virtual machine's host-primary address space.

**N**

displays the contents of storage in hexadecimal without character translation. This is the default. Storage is displayed in word segments. An address range is displayed starting at the fullword in which the specified address resides. Storage is displayed in fullword increments.

The storage key is displayed on the first line, as well as at every page boundary.

**I**

displays the contents of storage in instruction format. The specified address is rounded down to the nearest halfword boundary.

The storage key is displayed on the first line, as well as at every page boundary.

**J**

stores unformatted storage contents in a response buffer. An address range is stored starting at the byte location specified. If no length or end address is specified, four bytes are stored in the response buffer by default.

When the response buffer is smaller than the response length, a zero-length response is returned, with condition code one to indicate insufficient buffer length.

The operand is accepted only when the DISPLAY command is invoked via DIAGNOSE X'08' with the response-to-buffer option specified. Unlike other invocations of DIAGNOSE X'08', this form of the command does not store a trailing line-end (x'15') character. See usage note ["13"](#) on page 342

for an example of this invocation. See *z/VM: CP Programming Services* for more information about DIAGNOSE X'08'.

**K**

displays the storage keys in hexadecimal, the block-usage state, and the block-content state for all page frames or partial page frames included in the specified address range.

**S**

displays the contents of storage in hexadecimal translation. Storage is displayed as a string starting at the location specified. The specified address range is not boundary-aligned.

The storage key is displayed on the first line, as well as at every page boundary.

**T**

displays the contents of storage in hexadecimal and character form. Storage is displayed in word segments. An address range is displayed starting at the X'10'-byte boundary in which the specified address resides. X'10' bytes of storage are displayed per line. The default display is in EBCDIC; the display is in ASCII if the X option is specified.

The storage key is displayed on the first line, as well as at every page boundary.

**U**

displays the contents of storage in character form. Storage is displayed starting at the address specified as an EBCDIC string, or as an ASCII string if the X option is specified. The specified address range is not boundary-aligned.

The storage key is displayed on the first line, as well as at every page boundary.

**M**

displays the contents of storage in hexadecimal and character form. A header is displayed as the first line, and at every page boundary and contains the high-order 32 bits of the 64-bit address along with the storage key. Storage is displayed in word segments. An address range is displayed starting at the X'10' byte boundary in which the specified address resides. X'10' bytes of storage are displayed per line. The hexadecimal display is followed by the storage as an EBCDIC string, or as an ASCII string if the X option is specified.

**O**

***hexloc1***

specifies the starting storage location that is to be displayed. The value *hexloc1* may be 1 to 16 hexadecimal digits; leading zeros are optional. The default is zero.

If neither the BASE or INDEX operand is used, *hexloc1* is the address of the first location to be displayed. This address is treated as a 64-bit address, regardless of the addressing mode of the virtual CPU.

If either the BASE or the INDEX operand is used, *hexloc1* is a displacement rather than an address. The first location to be displayed is specified by the sum of *hexloc1* and the contents of the registers specified with the BASE operand or the INDEX operand or both. If general register 0 is specified in the BASE or INDEX operand, it is always treated as containing zero when this sum is being formed. The sum is treated as a 24-bit, 31-bit, or 64-bit address according to the addressing mode of the virtual CPU.

Storage locations and the minimum amount displayed are rounded according to the following conventions (in hexadecimal):

Option	Start	Minimum Length
T	10	10
M	10	10
K	800	800
S	1	1
I	2	2 - 6 depending on the instruction

Option	Start	Minimum Length
J	1	1 (default length is 4)
N	4	4
U	1	1

**%**

indicates 31-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 31 bits at the specified address (the high-order bit is turned off) are used as the new address for the DISPLAY command.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**&**

indicates 64-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 64 bits at the specified address are used as the new address for the DISPLAY command. A maximum of 16 indirection characters can be specified.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**-hexloc2**

**:hexloc2**

**-END**

**:END**

is the last of a range of hexadecimal storage locations whose contents are to be displayed. If specified, *hexloc2* must be equal to or greater than *hexloc1* and must be within the bounds of the address space to be displayed. The address *hexloc2* may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. A colon (:) means the same as a dash (-) when you are specifying a range of addresses.

If neither the BASE or INDEX operand is used, *hexloc2* is the address of the last location to be displayed. This address is treated as a 64-bit address, regardless of the addressing mode of the virtual CPU.

If either the BASE or the INDEX operand is used, *hexloc2* is a displacement rather than an address. The last location to be displayed is specified by the sum of *hexloc2* and the contents of the registers specified with the BASE and INDEX operands. If general register 0 is specified in the BASE or INDEX operand, it is always treated as containing zero when forming this sum. The sum is treated as a 24-bit, 31-bit, or 64-bit address according to the addressing mode of the virtual CPU.

Specify END if you want to display the remaining contents of storage. END is the default if you specify a dash (-) or a colon (:) without an address.

**.bytcoun**

**.END**

is a hexadecimal integer designating the number of bytes of storage (starting with the byte at *hexloc1*) to be displayed. If specified, *bytcoun* must have a value of at least 1 and may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional.

Specify END if you want to display the remaining contents of storage. END is the default if you specify period (.) without a byte count value.

**BASEnn**

displays the contents of guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified general register. The specified register may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F.

If the virtual CPU is in access register mode, and the L operand is specified (or defaulted), *nn* designates an access register/general register pair. Access register *nn* is implicitly used, in the same manner as if the AREG operand had been specified, in conjunction with the virtual machine's host

access list to determine the address space to display. If the virtual CPU is not in the access register mode, or if one of the other space-designation operands (PRI, AREG, ALET, SPACE, ASIT) is specified, access register *nn* is not implicitly used.

### INDEX $nn$

displays the contents of guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified register. The specified register may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F.

### Usage Notes

- Special authorization is required to use this command to view any address space other the host-primary address space of the virtual CPU. In order to use this command to display storage in an address space, one of the following conditions must be satisfied:
  - Your virtual machine must be the owner of the address space. Your virtual machine is the owner of its host-primary address space and of any address space that it creates using the CREATE function of the ADRSPACE macro.
  - If the address space is owned by another virtual machine, your virtual machine must have read-only or read-write authorization to the address space. The owner of the address space can grant authorization to your virtual machine using the PERMIT function of the ADRSPACE macro.

Authorization is granted on a space-by-space basis, so that you may be authorized to view one address space of a virtual machine, but may not be authorized to view a different space.
- When running with a saved segment, you can display storage locations outside the range of your virtual machine size if they are within the saved segment. If locations exist between the upper limit of your virtual machine and the address at which the saved segment was saved, any attempt to display those locations (or associated keys) causes the non-addressable storage response to be displayed.
- The operands L, PRI, AREG, and ALET specify the host-access-register translation (ART) process. The ART process performs special-case translation processes for certain ALET values and access registers:
  - The ALET X'00000000' always indicates the host-primary address space.
  - Access register 0 is always treated as containing ALET X'00000000'. The contents of access register 0 are not used during host-access-register translation processing.
- General register 0 is always treated as containing the value 0 when used as the base or index register with the BASE or INDEX operands. The contents of general register 0 are never used.
- In the XC environment, special rules govern the conversion of real addresses into absolute addresses. In some cases, prefixing is performed as usual to convert a real address to an absolute address, while in other cases prefixing is not performed and real addresses are treated unchanged as absolute addresses.

These rules have an effect on the interpretation of the addresses that specify the range of storage locations to be displayed:

- When storage is specified using the ALET or AREG operand and the ALET value used is not X'00000000', prefixing is not performed on the addresses that specify the range of storage in the target address space.
  - When storage in the host-primary address space is specified by using the PRI operand, or by using the ALET or AREG operand when the ALET value used is X'00000000', prefixing is performed as usual on the addresses that specify the range of storage in the host-primary address space.
- Although the R operand is not shown in the syntax for this command, it is accepted for compatibility with the DISPLAY (Guest Storage) command used for XA and ESA virtual machines. The R operand perform the same function as the L operand and displays storage from the host-primary address space.
  - The BASE operand is intended to be used in conjunction with the L operand. It lets you display the storage used by the virtual machine in one less step than would otherwise be possible. Without the BASE operand, you may need to display the contents of a general register, add the displacement,

and enter the DISPLAY command to examine storage the program is using. With the use of access registers, the BASE option additionally lets you examine storage without needing to know whether the program is currently in access register mode. This is done automatically for you by CP.

8. When multiple DISPLAY requests are entered on a single line, the BASE and INDEX operands are not applied to subsequent DISPLAY requests on the command line. They must be explicitly entered for each DISPLAY request.
9. During DISPLAY command processing, key-controlled protection is not used. However, all of the host-related protection mechanisms, such as those applied during host-access-register translation, are used as normal.
10. If the AREG or ALET operand is specified, the DISPLAY command uses the host-access-register translation (ART) process to determine the address space to display. This translation process may fail because of one of several program exception conditions. If the translation does not succeed, the current request is rejected and processing of the command line is terminated. The rejected operands are displayed along with a message indicating the nature of the exception condition.
11. When the ASIT or SPACE operand is specified, the DISPLAY request fails if the specified address space does not exist, or if you are not authorized to access the address space. The current request is rejected and processing of the command line is terminated. The rejected operands are displayed along with a message indicating the nature of the error.
12. If you use an underscore, it must be followed by 8 hexadecimal digits.
13. The J operand is useful in an adjunct context to retrieve memory from the principal configuration. For example, the following line

```
pgmold=Diag(8,'CPU * DISPLAY RJ28.8')
```

can be included in a REXX exec to capture the z/Architecture program old PSW.

14. For more information, see [“Usage Notes” on page 331](#).

## Responses

### Notes:

1. The value *hexloc* is a hexadecimal storage address.
2. The character displayed for the variable *t* in the string *thexloc* indicates the type of storage:
  - R indicates real storage (second-level storage).
  - V indicates virtual storage (third-level storage).

Response 1:

```
Rhexloc word1 word2 word3 word4 [key] [*TRANSLATION*]
```

is the response you receive for the T or N option. The translation is displayed only if you have also entered the T option and is in either EBCDIC or (if the TX option is specified) ASCII. The storage key is displayed on the first line of a request, and at every page boundary.

Response 2:

```
Rhexlochi_ Storage Key - [key]  
hexlocl_ word1 word2 word3 word4 [*TRANSLATION*]
```

is the response you receive for the M option. The translation is displayed in either EBCDIC or (if the MX option is specified) ASCII. The storage key is displayed on the first line, and at every page boundary.

Response 3:

```
Rhexloc *TRANSLATION* [key]
```

is the response you receive for the U option. The value *hexloc* is the location of the first data byte to be displayed. A minimum of 1 character and a maximum of 32 characters are displayed on each line. The contents of storage are displayed in translated form and are in either EBCDIC or (if the UX option is specified) ASCII. Periods in your display represent unprintable characters. The storage key is displayed on the first line of a request and at every page boundary.

Response 4:

```
Rhexloc mnemonic x-x mnemonic x-x mnemonic x-x [key]
```

is the response you receive for the I option. The value *hexloc* is the location of the first instruction to be displayed. The value *mnemonic* is a character representation of the instruction code; this is a 7-character field in which the mnemonic is left-justified. The expression *x-x* is the actual hexadecimal contents of storage and is 2, 4, or 6 bytes as determined by the instruction length code. Unrecognizable instruction codes are indicated by a series of asterisks. A minimum of 1 instruction and a maximum of 3 instructions are displayed on each line. The storage key is displayed on the first line of a request and at every page boundary.

Response 5:

```
Rhexloc stringhexadecimaldata [key]
```

is the response you receive for the S option. The storage key is displayed on the first line of a request and at every page boundary.

Response 6:

```
thexloc1 TO hexloc2 KEY = key STATE = uc
```

is the response you receive for the K option. The values *hexloc1* and *hexloc2* are storage locations, *key* is the associated storage key for *hexloc1*, and *uc* is a two-letter code describing the block-usage and block-content state:

**u**

is a code for the block-usage state:

**Code**

**Meaning**

**S**

Stable

**U**

Unused

**V**

Volatile

**P**

Potentially volatile

**c**

is a code for the block-content state:

**Code**

**Meaning**

**R**

Resident

**P**

Preserved

**Z**

Logically zero

For more information about block-usage and block-content states, see [Collaborative memory management assist](#) in *z/VM: CP Programming Services*.

## DISPLAY (Guest Storage - ESA/XC)

A response is sent for every contiguous address range that has unique storage keys and whenever a segment boundary is crossed.

Response 7:

The PSW is used to resolve a logical address. An invalid PSW causes the current request to be rejected and processing to continue with the next request (if any) on the command line. In all cases, a reset PSW (all-zeros) is accepted. The rejected operands are displayed along with a response indicating the PSW is invalid. The response is:

```
addr is not addressable because of an invalid PSW.
```

where *addr* is the rejected operand or operands; it specifies an address space and a storage location within that address space.

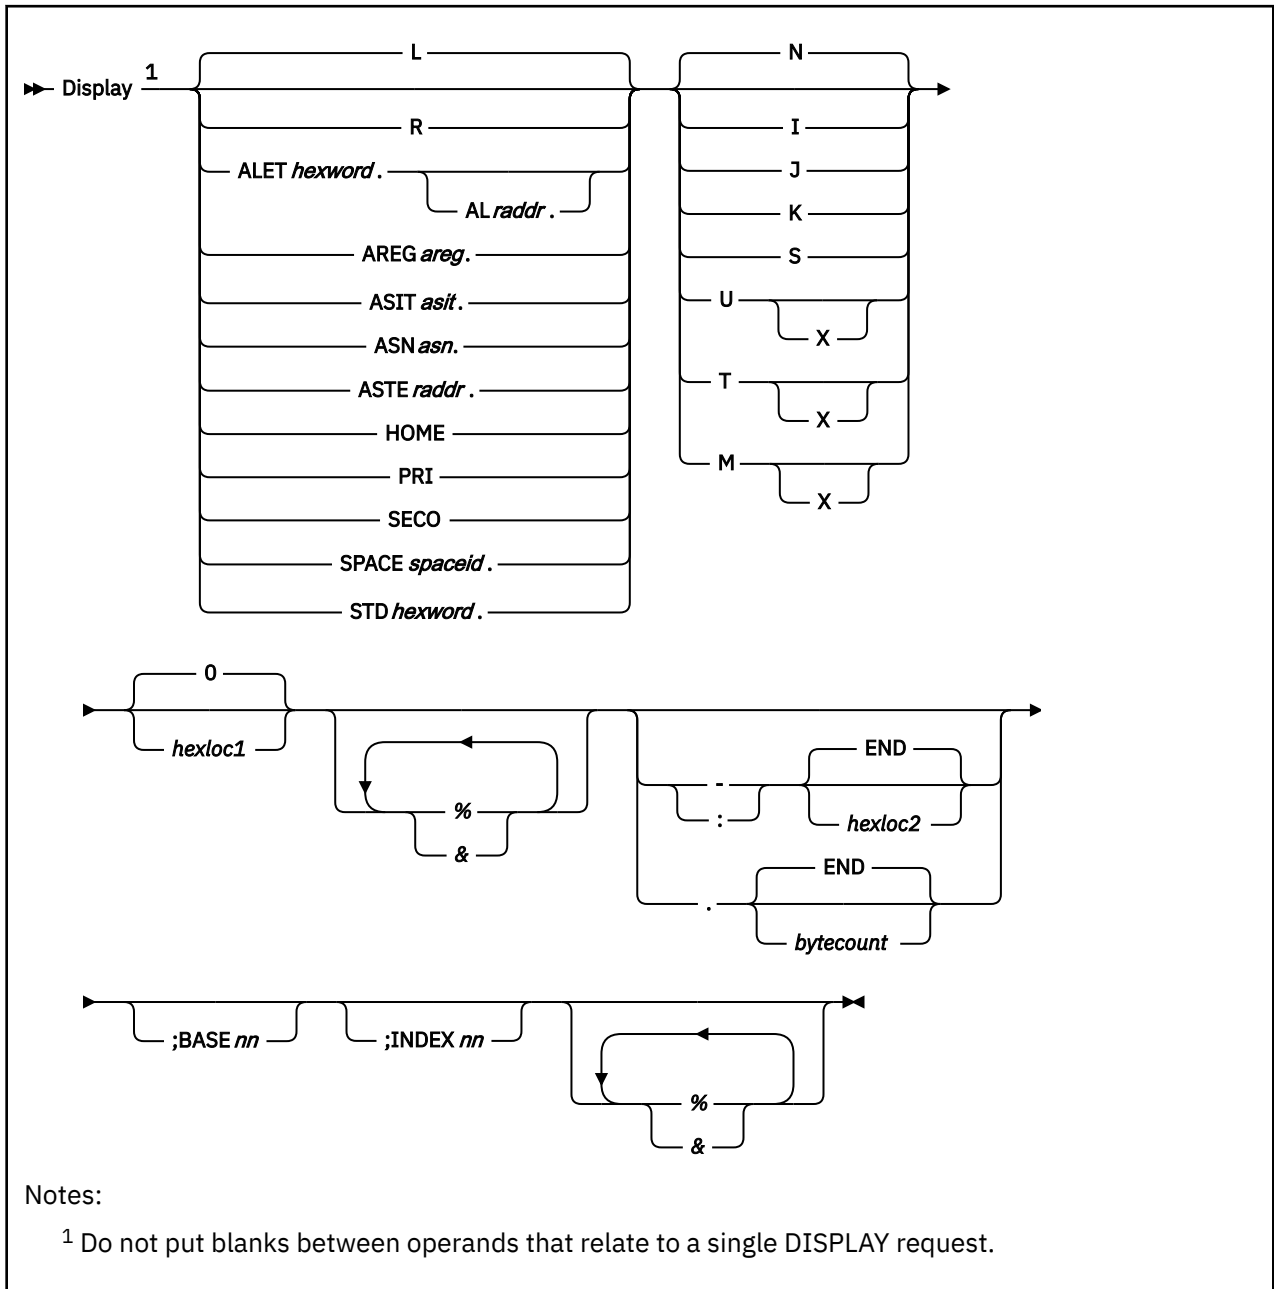

Response 8:

If your display request includes a request to display identical lines, you receive the following response:

```
Rhexloc1 TO hexloc2 SUPPRESSED LINE(S) SAME AS ABOVE ...
```

## DISPLAY (Guest Storage - ESA/390)

### Authorization

Privilege Class: G

### Purpose

Use DISPLAY (Guest Storage - ESA/390) to display the storage contents of an ESA/390 virtual machine.

## Operands

### L

displays the contents of second-level storage (storage that appears real to your virtual machine) if the virtual machine is operating in DAT OFF mode, or displays the contents of third-level storage (storage that appears virtual to your virtual machine) if the virtual machine is operating in DAT ON mode. This is the default.

The address space selected for display of third-level storage corresponds with the setting of the address space control field in the guest PSW and is the primary, secondary, or (if the virtual machine is an ESA virtual machine) home space. When the PSW indicates access register mode, the primary space is selected for display unless a nonzero BASExx operand is also specified and the virtual machine is an ESA virtual machine, in which case an access register specified address space is displayed.

### R

displays the contents of second-level storage (storage that appears real to your virtual machine).

#### **ALE***hexword*.

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using the specified access list entry token (ALET). The ALET is used in conjunction with guest access register translation tables to locate the guest address space to display.

#### **AL***raddr*.

specifies an access list (AL) to be used in conjunction with the ALET to locate the guest address space. The guest real address of the access list may be 1 to 8 hexadecimal digits.

#### **AREG***areg*.

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using the contents of the specified access register. The *areg* may be specified as 1 hexadecimal or 2 decimal digits. The ALET within the access register is used in conjunction with guest access register translation tables to locate the guest address space to display.

#### **ASIT***asit*.

displays the contents of absolute storage in the CP-created address space identified by the specified address space identification token (ASIT). The *asit* may be 1 to 16 hexadecimal digits; leading zeros are optional.

#### **ASN***asn*.

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using the specified address space number (ASN). The *asn* may be 1 to 4 hexadecimal digits. It is used in conjunction with guest ASN-translation tables to locate a guest address space to display.

#### **ASTE***raddr*.

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using the segment table designation contained within the specified ASN second table entry (ASTE) located at guest real address *raddr*.

#### **HOME**

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using guest control register 13.

#### **PRI**

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using guest control register 1.

#### **SECO**

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using guest control register 7.

#### **SPACE***spaceid*.

displays the contents of absolute storage in the CP-created address space identified by *spaceid*. The *spaceid* is a 1-character to 33-character string of the form:

where *owner* is an optional 1-character to 8-character user ID of the virtual machine that owns the CP-created address space, and *spacename* is the 1-character to 24-character address space name assigned to the address space.

If *owner* is not specified, your virtual machine is assumed to be the owner of the address space. The *spacename* 'BASE' is preassigned by CP to be the name of your virtual machine's host-primary address space.

**STDhexword.**

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using the specified guest segment table designation (STD).

**N**

displays the contents of storage in hexadecimal without EBCDIC translation. This is the default. Storage is displayed in word segments. An address range is displayed starting at the fullword in which the specified address resides. Storage is displayed in fullword increments.

The storage key is displayed on the first line, as well as at every page boundary.

**I**

displays the contents of storage in instruction format. The specified address is rounded down to the nearest halfword boundary.

The storage key is displayed on the first line, as well as at every page boundary.

**J**

stores unformatted storage contents in a response buffer. An address range is stored starting at the byte location specified. If no length or end address is specified, four bytes are stored in the response buffer by default.

When the response buffer is smaller than the response length, a zero-length response is returned, with condition code one to indicate insufficient buffer length.

The operand is accepted only when the DISPLAY command is invoked via DIAGNOSE X'08' with the response-to-buffer option specified. Unlike other invocations of DIAGNOSE X'08', this form of the command does not store a trailing line-end (x'15') character. See usage note "15" on page 350 for an example of this invocation. See [z/VM: CP Programming Services](#) for more information about DIAGNOSE X'08'.

**K**

displays the storage keys in hexadecimal, the block-usage state, and the block-content state for all page frames or partial page frames included in the specified address range.

**S**

displays the contents of storage in hexadecimal translation. Storage is displayed as a string starting at the location specified. The specified address range is not boundary-aligned.

The storage key is displayed on the first line, as well as at every page boundary.

**U**

displays the contents of storage in character form. Storage is displayed starting at the address specified as an EBCDIC string or as an ASCII string if the X option is specified. The specified address range is not boundary-aligned.

The storage key is displayed on the first line, as well as at every page boundary.

**T**

displays the contents of storage in hexadecimal and character form. Storage is displayed in word segments. An address range is displayed starting at the X'10'-byte boundary in which the specified address resides. X'10' bytes of storage are displayed per line. The default display is in EBCDIC; the display is in ASCII if the X option is specified.

The storage key is displayed on the first line, as well as at every page boundary.

**M**

displays the contents of storage in hexadecimal and character form. A header is displayed as the first line, and at every page boundary, which contains the high-order 32 bits of the 64-bit address along with the storage key. Storage is displayed in word segments. An address range is displayed starting at the X'10' byte boundary in which the specified address resides. X'10' bytes of storage are displayed per line. The hexadecimal display is followed by the storage as an EBCDIC string or as an ASCII string if the X option is specified.

**0**

**hexloc1**

is the starting storage location that is to be displayed. The address *hexloc1* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability, leading zeros are optional. The default is zero.

Storage locations and the minimum amount displayed are rounded according to the following conventions (in hexadecimal):

Option	Start	Minimum Length
T	10	10
M	10	10
K	800	800
S	1	1
I	2	2 - 6 depending on the instruction
J	1	1 (default length is 4)
N	4	4
U	1	1

**%**

indicates 31-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 31 bits at the specified address (the high-order bit is turned off) are used as the new address for the DISPLAY command.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**&**

indicates 64-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 64 bits at the specified address are used as the new address for the DISPLAY command. A maximum of 16 indirection characters can be specified.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**-hexloc2**

**:hexloc2**

**-END**

**:END**

is the last of a range of hexadecimal storage locations whose contents are to be displayed. If specified, *hexloc2* must be equal to or greater than *hexloc1* and must be within the virtual machine storage size. The address *hexloc2* may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. A colon (:) means the same as a dash (-) when you are specifying a range of addresses.

Specify END if you want to display the remaining contents of storage. END is the default if you specify a dash (-) or a colon (:) without an address.

**.bytecount****.END**

is a hexadecimal integer designating the number of bytes of storage (starting with the byte at *hexloc1*) to be displayed. If specified, the *bytecount* must have a value of at least 1 and may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional.

Specify END if you want to display the remaining contents of storage. END is the default if you specify a period (.) without a byte count value.

**BASEnn**

displays the contents of guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified general register (*nn*). The general register may be specified as a decimal number from 0 to 15 or as a hexadecimal number from 0 to F. *nn* specifies an AR/GR pair if all of the following are true:

- The L operand is specified.
- The virtual machine is an ESA virtual machine in ESA/390 mode (the default mode).
- The virtual CPU is in access register mode.

The specified access register is used, in the same manner as if the *AREGareg.* operand had been specified, in conjunction with guest access-register-translation tables to locate the guest address space to display.

**INDEXnn**

displays the contents of guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified register (*nn*). This register may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F.

**Usage Notes**

1. When running with a saved segment, you can display storage locations outside the range of your virtual machine size if they are within the saved segment. If locations exist between the upper limit of your virtual machine and the address at which the saved segment was saved, any attempt to display those locations (or associated keys) causes the non-addressable storage response to be displayed.

Refer to [“Usage Notes” on page 331](#).

2. The operands HOME, *AREGareg.*, *ALETheyword.*, and *ALETheyword.ALraddr.* are valid only if the virtual machine is an XA or ESA virtual machine.
3. When you use the operand *ALETheyword.ALraddr.*, the primary list bit in the ALET is ignored.
4. When the operands L, PRI, SECO, HOME, *ASTERaddr.*, *STDhexword.*, *ASNasn.*, *AREGareg.*, *ALETheyword.*, and *ALETheyword.ALraddr.* are specified, the access-register-translation (ART), the ASN translation, and the dynamic-address-translation (DAT) processes may be used. These contain special-case translation processes, including:
  - ALET 0 always indicates the current primary address space designated by the STD in guest control register 1, regardless of the current contents of the dispatchable-unit access list.
  - ALET 1 always indicates the current secondary address space designated by the STD in guest control register 7, regardless of the current contents of the dispatchable-unit access list.
  - Access register 0 is always treated as containing ALET 0. The contents of access register 0 are not used during access-register-translation processing.
  - General register 0 is always treated as containing the value 0 when used as the base or index register. The contents of general register 0 are never used.
5. The BASE operand is primarily intended to be used in conjunction with the L operand. It lets you display the storage used by the virtual machine in one less step than would otherwise be possible. Without the BASE operand, you may need to display the contents of a general register, add the displacement, and then enter the DISPLAY command to examine storage the program is using. With the use of access registers, the BASE option also lets you examine storage without needing to know whether the program is currently in access register mode. This is done automatically for you by CP.

6. If the *BASEnn* and *INDEXnn* operands are used together, the specified starting address for display is used as a displacement from the address formed from the sum of the contents of the two specified registers.

The values in the registers specified by the *BASEnn* and *INDEXnn* operands are treated as 24-bit or 31-bit real addresses according to the addressing mode (A) bit in the virtual machine's PSW. That is, if the A bit is 1, the value is a 31-bit address; if the A bit is 0, the value is a 24-bit address.

7. During DISPLAY command processing, the authorization mechanisms used during normal address translation are not used.
8. Special authorization is required to use the SPACE or ASIT operand of this command to view any address space other the host-primary address space of the virtual CPU. In order to use this command to display storage in an address space, one of the following conditions must be satisfied:
  - Your virtual machine must be the owner of the address space. Your virtual machine is the owner of its host-primary address space and of any address space that it creates using the CREATE function of the ADRSPACE macro.
  - If the address space is owned by another virtual machine, your virtual machine must have read-only or read-write authorization to the address space. The owner of the address space can grant authorization to your virtual machine using the PERMIT function of the ADRSPACE macro.

Authorization is granted on a space-by-space basis, so that you may be authorized to view one address space of a virtual machine, but not to view a different space.

9. The operands V and W used in displaying third-level storage from guest primary and secondary are supported for compatibility. The PRI and SECO operands replace the V and W operands.
10. When multiple DISPLAY requests are entered on a single line, the *BASEnn* and *INDEXnn* operands are not applied to subsequent DISPLAY requests on the command line. They must be explicitly entered for each DISPLAY request.
11. When the ASIT or SPACE operand is specified, the DISPLAY request will fail if the specified address space does not exist, or if you are not authorized to access the address space. The current request is rejected and processing of the command line is terminated. The rejected operands are displayed along with a message indicating the nature of the error.
12. The DISPLAY command requires a segment table designation (STD) to display third-level storage (storage that appears virtual to your virtual machine). It may receive the STD as an operand, find it in a control register, or use the access-register translation (ART) process or the address space number (ASN) translation process to obtain the STD. The access-register translation and ASN translation processes may fail because of one of several program exception conditions. If the translation does not succeed, the current request is rejected, and processing of the command line is terminated. The rejected operands are displayed along with a response indicating the nature of the exception condition.
13. If you use an underscore, it must be followed by 8 hexadecimal digits.
14. If you issue DISPLAY with the ASIT operand and specify the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the DISPLAY command is rejected and error message HCPCDL6156E is issued. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value by using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:
  - SYSTEM CLEAR
  - IPL by NSS name
  - IPL by device with the CLear option
  - SET MACHine (to a different machine architecture)
15. The J operand is useful in an adjunct context to retrieve memory from the principal configuration. For example, the following line

```
pgmold=Diag(8,'CPU * DISPLAY RJ28.8')
```

can be included in a REXX exec to capture the z/Architecture program old PSW.

16. For more information, see [“Usage Notes” on page 331](#).

## Responses

### Notes:

1. The value *hexloc* is a hexadecimal storage address.
2. The character displayed for the variable *t* in the string *thexloc* indicates the type of storage:
  - R indicates real storage (second-level storage).
  - V indicates virtual storage (third-level storage).
3. In responses that include third-level storage, an *Rhexloc* trailer shows the second-level address that corresponds to the third-level address. The trailer is displayed on the first line of a range and at every page boundary.

Response 1:

```
thexloc word1 word2 word3 word4 [key] [*TRANSLATION*] [Rhexloc]
```

is the response you receive for the T or N option. The translation is given only for the T option and is in either EBCDIC or (if the TX option is specified) ASCII. The storage key is displayed on the first line of a request, and at every page boundary.

Response 2:

```
thexlochi Storage Key - [key]  
hexloclo word1 word2 word3 word4 [*TRANSLATION*] [Rhexloc]
```

is the response you receive for the M option. The translation is displayed in either EBCDIC or (if the MX option is specified) ASCII. The storage key is displayed on the first line, and at every page boundary.

Response 3:

```
thexloc *TRANSLATION* [key] [Rhexloc]
```

is the response you receive for the U option. The value *hexloc* is the location of the first data byte to be displayed. A minimum of 1 character and a maximum of 32 characters are displayed on each line. The contents of storage are displayed only in translated form and are in either EBCDIC or (if the UX option is specified) ASCII. Periods in the display represent unprintable characters. The storage key is displayed on the first line of a request and at every page boundary.

Response 4:

```
thexloc mnemonic x-x mnemonic x-x mnemonic x-x [key] [Rhexloc]
```

is the response you receive for the I option. The value *hexloc* is the location of the first instruction to be displayed. The value *mnemonic* is a character representation of the instruction code; this is a 7-character field in which the mnemonic is left-justified. The expression *x-x* is the actual hexadecimal contents of storage and is 2, 4, or 6 bytes as determined by the instruction length code. Unrecognizable instruction codes are indicated by a series of asterisks. A minimum of 1 instruction and a maximum of 3 instructions are displayed on each line. The storage key is displayed on the first line of a request and at every page boundary.

Response 5:

```
thexloc stringhexadecimaldata [key] [Rhexloc]
```

is the response you receive for the S option. The storage key is displayed on the first line of a request and at every page boundary.

Response 6:

```
thexloc1 TO hexloc2 KEY = key STATE = uc
```

is the response you receive for the K option. The values *hexloc1* and *hexloc2* are storage locations, *key* is the associated storage key for *hexloc1*, and *uc* is a two-letter code describing the block-usage and block-content state:

**u**

is a code for the block-usage state:

**Code**

**Meaning**

**S**

Stable

**U**

Unused

**V**

Volatile

**P**

Potentially volatile

**c**

is a code for the block-content state:

**Code**

**Meaning**

**R**

Resident

**P**

Preserved

**Z**

Logically zero

For more information about block-usage and block-content states, see [Collaborative memory management assist](#) in *z/VM: CP Programming Services*.

A response is sent for every contiguous address range that has unique storage keys and whenever a segment boundary is crossed.

Response 7:

The PSW is used to resolve a logical address. A PSW that is not valid causes the current request to be rejected and processing to continue with the next request (if any) on the command line. In all cases, a reset PSW (all-zero) is accepted. The rejected operands are displayed along with a response indicating that the PSW is not valid. The response is:

```
addr is not addressable because of a invalid PSW.
```

where *addr* is the rejected operand or operands; it specifies an address space and a storage location within that address space.

Response 8:

The dynamic-address translation (DAT) process uses the segment table designator (STD) to convert a third-level address to a second-level address (storage that appears real to your virtual machine). The translation process may generate one of several exceptions, identifying why one or more pages of storage are not addressable. A range of rejected storage addresses is displayed along with a response indicating the nature of the exception condition. The responses are:

```
thexloc1 to hexloc2 non-addressable storage
thexloc1 to hexloc2 non-addressable storage
- protection exception
thexloc1 to hexloc2 non-addressable storage
- addressing exception
```

```
hexloc1 to hexloc2 non-addressable storage  
- segment translation exception  
hexloc1 to hexloc2 non-addressable storage  
- page translation exception  
hexloc1 to hexloc2 non-addressable storage  
- translation specification exception
```

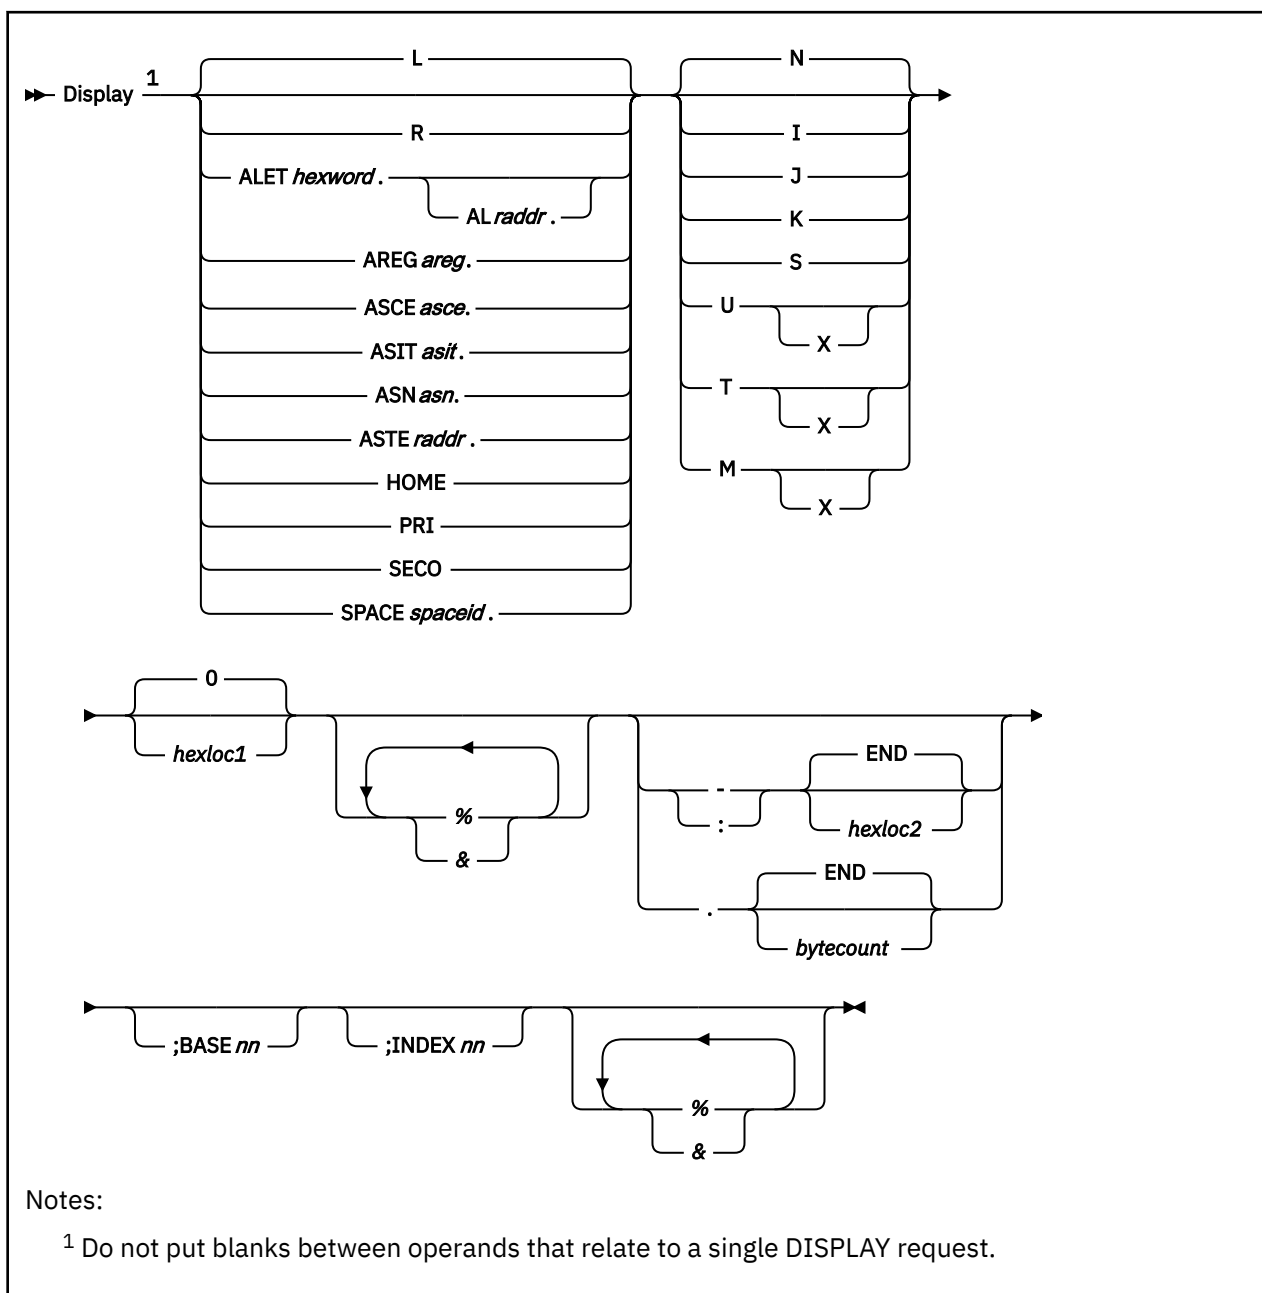

where *hexloc1* is the starting address and *hexloc2* the ending address of the non-addressable storage. The addresses take into account basing, indexing, and wrapping and are padded to 8 digits.

Response 9:

If your display request includes a request to display identical lines, you receive the following response:

```
hexloc1 TO hexloc2 SUPPRESSED LINE(S) SAME AS ABOVE ...
```

## DISPLAY (Guest Storage - z/Architecture)

### Authorization

Privilege Class: G

### Purpose

Use DISPLAY (Guest Storage - z/Architecture) to display the storage contents of a virtual machine in z/Architecture mode.

## Operands

### L

displays the contents of second-level storage (storage that appears real to your virtual machine) if the virtual machine is operating in DAT OFF mode, or displays the contents of third-level storage (storage that appears virtual to your virtual machine) if the virtual machine is operating in DAT ON mode. This is the default.

The address space selected for display of third-level storage corresponds with the setting of the address space control field in the guest PSW and is the primary, secondary, or (if the virtual machine is an ESA virtual machine) home space. When the PSW indicates access register mode, the primary space is selected for display unless a nonzero *BASEnn* operand is also specified and the virtual machine is an ESA virtual machine, in which case an access register specified address space is displayed.

### R

displays the contents of second-level storage (storage that appears real to your virtual machine).

#### **ALET***hexword*.

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using the specified access list entry token (ALET). The ALET is used in conjunction with guest access register translation tables to locate the guest address space to display.

#### **AL***raddr*.

specifies an access list (AL) to be used in conjunction with the ALET to locate the guest address space. The guest real address of the access list may be 1 to 8 hexadecimal digits.

#### **AREG***areg*.

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using the contents of the specified access register. The *areg* may be specified as 1 hexadecimal or 2 decimal digits. The ALET within the access register is used in conjunction with guest access register translation tables to locate the guest address space to display.

#### **ASCE***asce*.

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using the specified address-space-control element (ASCE). The *asce* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional.

#### **ASIT***asit*.

displays the contents of absolute storage in the CP-created address space identified by the specified address space identification token (ASIT). The *asit* may be 1 to 16 hexadecimal digits; leading zeros are optional.

#### **ASN***asn*.

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using the specified address space number (ASN). The *asn* may be 1 to 4 hexadecimal digits. It is used in conjunction with guest ASN-translation tables to locate a guest address space to display.

#### **ASTE***raddr*.

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using the segment table designation contained within the specified ASN second table entry (ASTE) located at guest real address *raddr*.

### HOME

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using guest control register 13.

### PRI

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using guest control register 1.

### SECO

displays the contents of third-level storage (storage that appears virtual to your virtual machine) using guest control register 7.

**SPACEspaceid.**

displays the contents of absolute storage in the CP-created address space identified by *spaceid*. The *spaceid* is a 1-character to 33-character string of the form:

where *owner* is an optional 1-character to 8-character user ID of the virtual machine that owns the CP-created address space, and *spacename* is the 1-character to 24-character address space name assigned to the address space.

If *owner* is not specified, your virtual machine is assumed to be the owner of the address space. The *spacename* 'BASE' is preassigned by CP to be the name of your virtual machine's host-primary address space.

**N**

displays the contents of storage in hexadecimal without character translation. This is the default. Storage is displayed in word segments. An address range is displayed starting at the fullword in which the specified address resides. Storage is displayed in fullword increments.

The storage key is displayed on the first line, as well as at every page boundary.

**I**

displays the contents of storage in instruction format. The specified address is rounded down to the nearest halfword boundary.

The storage key is displayed on the first line, as well as at every page boundary.

**J**

stores unformatted storage contents in a response buffer. An address range is stored starting at the byte location specified. If no length or end address is specified, four bytes are stored in the response buffer by default.

When the response buffer is smaller than the response length, a zero-length response is returned, with condition code one to indicate insufficient buffer length.

The operand is accepted only when the DISPLAY command is invoked via DIAGNOSE X'08' with the response-to-buffer option specified. Unlike other invocations of DIAGNOSE X'08', this form of the command does not store a trailing line-end (x'15') character. See usage note "14" on page 360 for an example of this invocation. See [z/VM: CP Programming Services](#) for more information about DIAGNOSE X'08'.

**K**

displays the storage keys in hexadecimal, the block-usage state, and the block-content state for all page frames or partial page frames included in the specified address range.

**S**

displays the contents of storage in hexadecimal translation. Storage is displayed as a string starting at the location specified. The specified address range is not boundary-aligned.

The storage key is displayed on the first line, as well as at every page boundary.

**U**

displays the contents of storage in character form. Storage is displayed starting at the address specified as an EBCDIC string or as an ASCII string if the X option is specified. The specified address range is not boundary-aligned.

The storage key is displayed on the first line, as well as at every page boundary.

**T**

displays the contents of storage in hexadecimal and character form. Storage is displayed in word segments. An address range is displayed starting at the X'10'-byte boundary in which the specified address resides. X'10' bytes of storage are displayed per line. The default display is in EBCDIC; the display is in ASCII if the X option is specified.

The storage key is displayed on the first line, as well as at every page boundary.

**M**

displays the contents of storage in hexadecimal and character form. A header is displayed as the first line, and at every page boundary, which contains the high-order 32 bits of the 64-bit address along with the storage key. Storage is displayed in word segments. An address range is displayed starting at the X'10' byte boundary in which the specified address resides. X'10' bytes of storage are displayed per line. The hexadecimal display is followed by the storage as an EBCDIC string or as an ASCII string if the X option is specified.

**O**

**hexloc1**

is the starting storage location that is to be displayed. The address *hexloc1* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability, leading zeros are optional. The default is zero.

Storage locations and the minimum amount displayed are rounded according to the following conventions (in hexadecimal):

Option	Start	Minimum Length
T	10	10
M	10	10
K	800	800
S	1	1
I	2	2 - 6 depending on the instruction
J	1	1 (default length is 4)
N	4	4
U	1	1

**%**

indicates 31-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 31 bits at the specified address (the high-order bit is turned off) are used as the new address for the DISPLAY command.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**&**

indicates 64-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 64 bits at the specified address are used as the new address for the DISPLAY command. A maximum of 16 indirection characters can be specified.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**-hexloc2**

**:hexloc2**

**-END**

**:END**

is the last of a range of hexadecimal storage locations whose contents are to be displayed. If specified, *hexloc2* must be equal to or greater than *hexloc1* and must be within the virtual machine storage size. The address *hexloc2* may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. A colon (:) means the same as a dash (-) when you are specifying a range of addresses.

Specify END if you want to display the remaining contents of storage. END is the default if you specify a dash (-) or a colon (:) without an address.

### **.bytecount**

#### **.END**

is a hexadecimal integer designating the number of bytes of storage (starting with the byte at *hexloc1*) to be displayed. If specified, the *bytecount* must have a value of at least 1 and may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional.

Specify END if you want to display the remaining contents of storage. END is the default if you specify a period (.) without a byte count value.

### **BASEnn**

displays the contents of guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified general register (*nn*). The general register may be specified as a decimal number from 0 to 15 or as a hexadecimal number from 0 to F. *nn* specifies an AR/GR pair if all of the following are true:

- The L operand is specified.
- The virtual machine is an ESA virtual machine in z/Architecture mode.

**Note:** An ESA virtual machine simulates ESA/390 architecture when initially defined. However, a guest may have the capability to switch the virtual machine from ESA/390 mode to z/Architecture mode.

- The virtual CPU is in access register mode.

The specified access register is used, in the same manner as if the *AREGareg.* operand had been specified, in conjunction with guest access-register-translation tables to locate the guest address space to display.

### **INDEXnn**

displays the contents of guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified register (*nn*). This register may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F.

## **Usage Notes**

1. When running with a saved segment, you can display storage locations outside the range of your virtual machine size if they are within the saved segment. If locations exist between the upper limit of your virtual machine and the address at which the saved segment was saved, any attempt to display those locations (or associated keys) causes the non-addressable storage response to be displayed.

Refer to [“Usage Notes” on page 331](#).

2. When you use the operand *ALETheyword.ALraddr.*, the primary list bit in the ALET is ignored.
3. When the operands L, PRI, SECO, HOME, *ASTERaddr.*, *ASCEhexword.*, *ASNasn.*, *AREGareg.*, *ALETheyword.*, and *ALETheyword.ALraddr.* are specified, the access-register-translation (ART), the ASN translation and the dynamic-address-translation (DAT) processes may be used. These contain special-case translation processes, including:
  - ALET 0 always indicates the current primary address space designated by the ASCE in guest control register 1, regardless of the current contents of the dispatchable-unit access list.
  - ALET 1 always indicates the current secondary address space designated by the ASCE in guest control register 7, regardless of the current contents of the dispatchable-unit access list.
  - Access register 0 is always treated as containing ALET 0. The contents of access register 0 are not used during access-register-translation processing.
  - General register 0 is always treated as containing the value 0 when used as the base or index register. The contents of general register 0 are never used.
4. The BASE operand is primarily intended to be used in conjunction with the L operand. It lets you display the storage used by the virtual machine in one less step than would otherwise be possible. Without the BASE operand, you may need to display the contents of a general register, add the displacement, and then enter the DISPLAY command to examine storage the program is using. With

the use of access registers, the BASE option also lets you examine storage without needing to know whether the program is currently in access register mode. This is done automatically for you by CP.

5. If the BASE $nn$  and INDEX $nn$  operands are used together, the specified starting address for display is used as a displacement from the address formed from the sum of the contents of the two specified registers.

The values in the registers specified by the BASE $nn$  and INDEX $nn$  operands are treated as 24-bit, 31-bit, or 64-bit real addresses according to the addressing mode bits (EA and BA - bits 31 and 32) in the virtual machine's PSW. The addressing mode is determined as follows:

Bit 31	Bit 32	Addressing Mode
0	0	24-bit
0	1	31-bit
1	1	64-bit

6. During DISPLAY command processing, the authorization mechanisms used during normal address translation are not used.
7. Special authorization is required to use the SPACE or ASIT operand of this command to view any address space other than the host-primary address space of the virtual CPU. In order to use this command to display storage in an address space, one of the following conditions must be satisfied:
  - Your virtual machine must be the owner of the address space. Your virtual machine is the owner of its host-primary address space and of any address space that it creates using the CREATE function of the ADRSPACE macro.
  - If the address space is owned by another virtual machine, your virtual machine must have read-only or read-write authorization to the address space. The owner of the address space can grant authorization to your virtual machine using the PERMIT function of the ADRSPACE macro.

Authorization is granted on a space-by-space basis, so that you may be authorized to view one address space of a virtual machine, but not to view a different space.
8. The operands V and W used in displaying third-level storage from guest primary and secondary are supported for compatibility. The PRI and SECO operands replace the V and W operands.
9. When multiple DISPLAY requests are entered on a single line, the BASE $nn$  and INDEX $nn$  operands are not applied to subsequent DISPLAY requests on the command line. They must be explicitly entered for each DISPLAY request.
10. When the ASIT or SPACE operand is specified, the DISPLAY request will fail if the specified address space does not exist, or if you are not authorized to access the address space. The current request is rejected and processing of the command line is terminated. The rejected operands are displayed along with a message indicating the nature of the error.
11. The DISPLAY command requires an address-space-control element (ASCE) to display third-level storage (storage that appears virtual to your virtual machine). It may receive the ASCE as an operand, find it in a control register, or use the access-register translation (ART) process or the address space number (ASN) translation process to obtain the ASCE. The access-register translation and ASN translation processes may fail because of one of several program exception conditions. If the translation does not succeed, the current request is rejected, and processing of the command line is terminated. The rejected operands are displayed along with a response indicating the nature of the exception condition.
12. If you use an underscore, it must be followed by 8 hexadecimal digits.
13. If you issue DISPLAY with the ASIT operand and specify the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the DISPLAY command is rejected and error message HCPCDL6156E is issued. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value by using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:

## DISPLAY (Guest Storage - z/Architecture)

- SYSTEM CLEAR
  - IPL by NSS name
  - IPL by device with the CLeAr option
  - SET MACHine (to a different machine architecture)
14. The J operand is useful in an adjunct context to retrieve memory from the principal configuration. For example, the following line

```
pgmold=Diag(8,'CPU * DISPLAY RJ140.10')
```

can be included in a REXX exec to capture the z/Architecture program old PSW.

15. For more information, see [“Usage Notes” on page 331](#).

## Responses

### Notes:

1. The value *hexloc* is a hexadecimal storage address.
2. The character displayed for the variable *t* in the string *thexloc* indicates the type of storage:
  - R indicates real storage (second-level storage).
  - V indicates virtual storage (third-level storage).
3. In responses that include third-level storage, an *Rhexloc* trailer shows the second-level address that corresponds to the third-level address. The trailer is displayed on the first line of a range and at every page boundary.

Response 1:

```
thexloc word1 word2 word3 word4 [key] [*TRANSLATION*] [Rhexloc]
```

is the response you receive for the T or N option. The translation is given only for the T option and is in either EBCDIC or (if the TX option is specified) ASCII. The storage key is displayed on the first line of a request, and at every page boundary. If the high-order 32 bits of *hexloc* are not zero, *hexloc* will be displayed as a 64-bit address, in which case the output could wrap to the next line. To make the display more readable, use the M option described in Response 2.

Response 2:

```
thexlochi_ Storage Key - [key]  
hexloclo word1 word2 word3 word4 [*TRANSLATION*] [Rhexloc]
```

is the response you receive for the M option. The translation is displayed in either EBCDIC or (if the MX option is specified) ASCII. The storage key is displayed on the first line, and at every page boundary.

Response 3:

```
thexloc *TRANSLATION* [key] [Rhexloc]
```

is the response you receive for the U option. The value *hexloc* is the location of the first data byte to be displayed. A minimum of 1 character and a maximum of 32 characters are displayed on each line. The contents of storage are displayed only in translated form and are in either EBCDIC or (if the UX option is specified) ASCII. Periods in your display represent unprintable characters. The storage key is displayed on the first line of a request and at every page boundary.

Response 4:

```
thexloc mnemonic x-x mnemonic x-x mnemonic x-x [key] [Rhexloc]
```

is the response you receive for the I option. The value *hexloc* is the location of the first instruction to be displayed. The value *mnemonic* is a character representation of the instruction code; this is a 7-character field in which the mnemonic is left-justified. The expression *x-x* is the actual hexadecimal contents of

storage and is 2, 4, or 6 bytes as determined by the instruction length code. Unrecognizable instruction codes are indicated by a series of asterisks. A minimum of 1 instruction and a maximum of 3 instructions are displayed on each line. The storage key is displayed on the first line of a request and at every page boundary.

Response 5:

```
thexloc stringhexadecimaldata [key] [Rhexloc]
```

is the response you receive for the S option. The storage key is displayed on the first line of a request and at every page boundary.

Response 6:

```
thexloc1 TO hexloc2 KEY = key STATE = uc
```

is the response you receive for the K option. The values *hexloc1* and *hexloc2* are storage locations, *key* is the associated storage key for *hexloc1*, and *uc* is a two-letter code describing the block-usage and block-content state:

**u**

is a code for the block-usage state:

**Code**

**Meaning**

**S**

Stable

**U**

Unused

**V**

Volatile

**P**

Potentially volatile

**c**

is a code for the block-content state:

**Code**

**Meaning**

**R**

Resident

**P**

Preserved

**Z**

Logically zero

For more information about block-usage and block-content states, see [Collaborative memory management assist in z/VM: CP Programming Services](#).

A response is sent for every contiguous address range that has unique storage keys and whenever a segment boundary is crossed.

Response 7:

The PSW is used to resolve a logical address. A PSW that is not valid causes the current request to be rejected and processing to continue with the next request (if any) on the command line. In all cases, a reset PSW (all-zero) is accepted. The rejected operands are displayed along with a response indicating that the PSW is not valid. The response is:

```
addr is not addressable because of an invalid PSW.
```

## DISPLAY (Guest Storage - z/Architecture)

where *addr* is the rejected operand or operands; it specifies an address space and a storage location within that address space.

Response 8:

The dynamic-address translation (DAT) process uses the segment table designator (ASCE) to convert a third-level address to a second-level address (storage that appears real to your virtual machine). The translation process may generate one of several exceptions, identifying why one or more pages of storage are not addressable. A range of rejected storage addresses is displayed along with a response indicating the nature of the exception condition. The responses are:

```
thexloc1 to hexloc2 non-addressable storage  
thexloc1 to hexloc2 non-addressable storage  
- protection exception  
thexloc1 to hexloc2 non-addressable storage  
- addressing exception  
thexloc1 to hexloc2 non-addressable storage  
- segment translation exception  
thexloc1 to hexloc2 non-addressable storage  
- page translation exception  
thexloc1 to hexloc2 non-addressable storage  
- translation specification exception  
thexloc1 to hexloc2 non-addressable storage  
- ASCE type exception  
thexloc1 to hexloc2 non-addressable storage  
- region-first-translation exception  
thexloc1 to hexloc2 non-addressable storage  
- region-second-translation exception  
thexloc1 to hexloc2 non-addressable storage  
- region-third-translation exception  
thexloc1 to hexloc2 non-addressable storage  
- block volatility exception
```

where *hexloc1* is the starting address and *hexloc2* the ending address of the non-addressable storage. The addresses take into account basing, indexing, and wrapping and are padded to 8 digits.

Response 9:

If your display request includes a request to display identical lines, you receive the following response:

```
thexloc1 TO hexloc2 SUPPRESSED LINE(S) SAME AS ABOVE ...
```

## DISPLAY (Host Storage)

### Authorization

Privilege Class: C, E

### Purpose

Use DISPLAY (Host Storage) to see the contents of host (first-level) storage.

### Operands

**L**

specifies that host logical storage addresses are to be displayed. Host logical storage consists of 4 KB pages where each page boundary has an address that ends in X'000'. This is the default.

**R**

specifies that host real storage addresses are to be displayed. Host real storage consists of 4 KB frames where each frame boundary has an address that ends in X'000'.

**N**

displays the contents of storage in hexadecimal without character translation. This is the default. Storage is displayed in word segments. An address range is displayed starting at the fullword in which the specified address resides. Storage is displayed in fullword increments.

The storage key is included on the first line and at every page or frame boundary.

## DISPLAY (Host Storage)

### I

displays the contents of storage in instruction format. The specified address is rounded down to the nearest halfword boundary.

The storage key is included on the first line and at every page or frame boundary.

### K

displays in hexadecimal the storage keys for all frames or partial frames included in the specified address range. If you are displaying host logical storage addresses, these are storage keys for the backing frames in host real storage.

### S

displays the contents of storage in hexadecimal translation. Storage is displayed as a string starting at the location specified. The specified address range is not boundary-aligned.

The storage key is included on the first line and at every page or frame boundary.

### T

displays the contents of storage in hexadecimal and character form. Storage is displayed in word segments. An address range is displayed starting at the X'10'-byte boundary in which the specified address resides. X'10' bytes of storage are displayed per line. The default display is in EBCDIC; the display is in ASCII if the X option is specified.

The storage key is included on the first line and at every page or frame boundary.

### U

displays the contents of storage in character form. Storage is displayed starting at the address specified as an EBCDIC string or as an ASCII string if the X option is specified. The specified address range is not boundary-aligned.

The storage key is included on the first line and at every page or frame boundary.

### M

displays the contents of storage in hexadecimal and character form. A header is included as the first line and at every page or frame boundary. It contains the high-order 32 bits of the 64-bit address along with the storage key. Storage is displayed in word segments. An address range is displayed starting at the X'10' byte boundary in which the specified address resides. X'10' bytes of storage are displayed per line. The hexadecimal display is followed by the storage as an EBCDIC string, or as an ASCII string if the X option is specified.

### O

#### ***hexloc1***

is the starting storage location that is to be displayed. The address *hexloc1* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. The default is zero.

Storage locations and the minimum amount displayed are rounded according to the following conventions (in hexadecimal):

Option	Start	Minimum Length
T	10	10
M	10	10
K	800	800
S	1	1
I	2	2 - 6 depending on the instruction
N	4	4
U	1	1

%

indicates 31-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 31 bits at the specified address (the high-order bit is turned off) are used as the new address for the DISPLAY command.

&amp;

indicates 64-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 64 bits at the specified address are used as the new address for the DISPLAY command.

**-hexloc2****:hexloc2****-END****:END**

is the last of the range of hexadecimal storage locations whose contents are to be displayed. If specified, *hexloc2* must be equal to or greater than *hexloc1* and must be within the bounds of addressable storage (see usage note “3” on page 365). The address *hexloc2* may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. A colon (:) means the same as a dash (-) when you are specifying a range of addresses.

Specify END if you want to display the remaining contents of storage. END is the default if you specify a dash (-) or a colon (:) without an address.

**.bytecount****.END**

is a hexadecimal integer designating the number of bytes of storage (starting with the byte at *hexloc1*) to be displayed. If specified, the *bytecount* must have a value of at least 1 and may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. The sum of *hexloc1* and *bytecount* must be an address within the bounds of addressable storage (see usage note “3” on page 365).

Specify END if you want to display the remaining contents of storage. END is the default if you specify a period (.) without a byte count value.

## Usage Notes

1. While host storage is being displayed, the running of a virtual machine or someone else using the STORE (Host Storage) command could cause data to be changed. This could create an inconsistency in the data that is viewed.
2. In a multiprocessor environment, each processor has a prefix register that it uses to relocate addresses between 0 and X'1FFF' (an 8 KB area known as the prefix area) to two other contiguous frames in real storage. The prefix register enables each processor to use a different prefix area to avoid conflict with other processors for such activity as interrupt code recording. Thus, the range 0 through X'1FFF' refers to different areas of storage, depending on which processor generates the address. All references to first-level storage are handled as if they were made on the IPL processor. Because those locations in the system execution space are identity-mapped, addresses in the range 0 through X'1FFF' have the same content in DISPLAY HL output and DISPLAY HR output.
3. For host logical storage (the system execution space), addressable storage includes the system execution area, which resides below 2 GB, plus the system frame table and the system execution space page management table, which reside above 2 GB. To display the storage address ranges used for the system execution space, issue the QUERY SXSSTORAGE command. The address range that you specify on the DISPLAY command must start and end in the same address range of the system execution space. If the END operand is specified (or allowed to default), it refers to the end of the range in which the starting address is located.

For host real storage, addressable storage is the lesser of CP's configured storage size (if specified at system generation) and the real machine storage size. To display the size of host real storage, issue the QUERY STORAGE command.

4. When displaying host logical storage, if you specify an address that is not backed with a real storage frame, error message HCP6151E is issued, even if the address is included in the ranges of in-use and usable addresses displayed by the QUERY SXSSTORAGE command.
5. If you use an underscore, it must be followed by 8 hexadecimal digits.
6. For more information, see [“Usage Notes” on page 331](#).

## Responses

### Notes:

1. The variable *hexloc* represents a hexadecimal storage address. The variables *hexlochi* and *hexloclo* represent the high-order 32 bits and low-order 32 bits of a 64-bit hexadecimal storage address.
2. The character displayed for the variable *t* in the string *Hthexloc* indicates the type of storage:
  - L indicates host logical storage.
  - R indicates host real storage.
3. In responses that include host logical storage, an *Rhexloc* trailer shows the host real storage address that corresponds to the host logical storage address. The trailer is displayed on the first line of a range and at every page boundary.

### Response 1:

```
Hthexloc word1 word2 word3 word4 [key] [*TRANSLATION*] [Rhexloc]
```

is the response you receive for the T or N option. The translation is displayed only if you have also entered the T option and is in either EBCDIC or (if the TX option is specified) ASCII. The storage key is displayed on the first line, and at every page or frame boundary.

### Response 2:

```
Hthexlochi_ Storage Key - [key]  

hexloclo word1 word2 word3 word4 [*TRANSLATION*] [Rhexloc]
```

is the response you receive for the M option. The translation is displayed in either EBCDIC or (if the MX option is specified) ASCII. The storage key is displayed on the first line, and at every page or frame boundary.

### Response 3:

```
Hthexloc *TRANSLATION* [key] [Rhexloc]
```

is the response you receive for the U option. The value *hexloc* is the location of the first data byte to be displayed. A minimum of 1 character and a maximum of 32 characters is displayed on each line. The contents of storage are displayed in translated form and are in either EBCDIC or (if the UX option is specified) ASCII. Periods in the display data represent unprintable characters. The storage key is displayed on the first line, and at every page or frame boundary.

### Response 4:

```
Hthexloc mnemonic x-x mnemonic x-x mnemonic x-x [key] [Rhexloc]
```

is the response you receive for the I option. The value *hexloc* is the location of the first instruction to be displayed. The value *mnemonic* is a character representation of the instruction code; this is a 7-character field in which the mnemonic is left-justified. The expression *x-x* is the actual hexadecimal contents of storage and is 2, 4, or 6 bytes as determined by the instruction length code. Unrecognizable instruction codes are indicated by a series of asterisks. A minimum of 1 instruction and a maximum of 3 instructions are displayed on each line. The storage key is displayed on the first line and at every page or frame boundary.

### Response 5:

```
Hthexloc stringhexadecimaldata [key] [Rhexloc]
```

is the response you receive for the S option. The storage key is displayed on the first line of a range, and at every page or frame boundary.

Response 6:

```
Hthexloc1 TO hexloc2 KEY = key
```

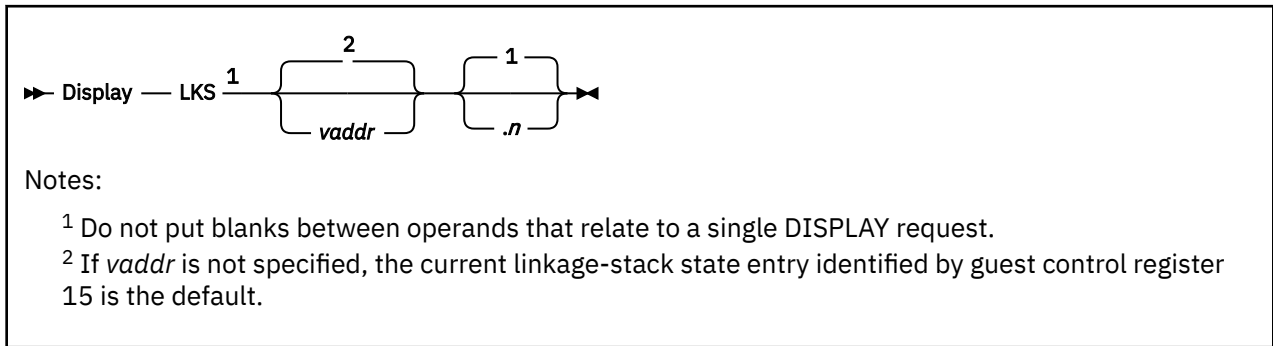

is the response you receive for the K option. The values *hexloc1* and *hexloc2* are storage locations, and *key* is the associated storage key for *hexloc1*. You receive this response for every contiguous address range that has unique storage keys, and whenever a segment boundary is crossed.

Response 7:

If your display request includes a request to display one or more lines identical with the previous line, you receive the following response:

```
Hthexloc1 TO hexloc2 SUPPRESSED LINE(S) SAME AS ABOVE ...
```

## DISPLAY LKS

### Authorization

Privilege Class: G

### Purpose

Use DISPLAY LKS to see the state entries of a guest linkage stack.

### Operands

#### *vaddr*

displays the branch or program-call linkage-stack state entry that contains the specified guest virtual address (*vaddr*) within the current home address space designated by guest control register 13. The default is the current linkage-stack state entry identified by guest control register 15.

**1**

***n***

*n* is a decimal number, up to eight digits, specifying the number of branch and program-call linkage-stack state entries to be displayed. The display starts with the specified/current entry and moves back toward the first entry on the linkage stack. 1 is the default, and 0 is treated as 1.

### Usage Notes

1. This command is valid only for an ESA virtual machine.
2. The *first* linkage-stack state entry is the oldest state entry (the first one put on the stack). The *last* linkage-stack state entry is the current state entry (the most recent one put on the stack).
3. Unlike other DISPLAY command operands, Linkage Stack does not define the default for subsequent operands of the current DISPLAY function.
4. The virtual address specified in *vaddr* must fall within the branch or program-call linkage-stack state entry, including the first and last bytes of the linkage-stack state entry.
5. A linkage stack state entry is an entry on the linkage stack that describes the environment in an address space (such as access registers, general-purpose registers, and PSWs).
6. For more information, see [“Usage Notes” on page 331](#).

### Responses

Heading	Description
ED-ADDR	The linkage-stack-entry description address, a guest home virtual address consisting of eight hexadecimal digits (16 hexadecimal digits for a z/Architecture guest).

Heading	Description
U	The unstack-suppression bit, either 0 or 1.
ET	The entry type, either BRN for a branch state entry or PRC for a program-call state entry.
SI	The section identification, represented as two hexadecimal digits.
RFS	The remaining free space, represented as four hexadecimal digits.
NES	The next-entry size, represented as four hexadecimal digits.
PKM	The PSW-key mask, represented as four hexadecimal digits.
SASN	The secondary ASN, represented as four hexadecimal digits.
EAX	The extended authorization index, represented as four hexadecimal digits.
PASN	The primary ASN, represented as four hexadecimal digits.
PSW	The program-status word, represented as 16 hexadecimal digits (32 hexadecimal digits for a z/Architecture guest).
A	The addressing mode, which may be either a 0 or 1 for an ESA/390 guest and either 24, 31 or 64 for a z/Architecture guest.
B-ADDR	The branch address, represented as eight hexadecimal digits (16 hexadecimal digits for a z/Architecture guest).
MOD-AREA	The modifiable area, represented as 16 hexadecimal digits.
PC-NUM	The program call number, represented as eight hexadecimal digits.
CSID	The called-space identification, if any, represented as eight hexadecimal digits.
SINST	Secondary ASTE instance number, if any, represented as eight hexadecimal digits.
PINST	Primary ASTE instance number, if any, represented as eight hexadecimal digits.
GPR	General purpose register, represented as eight hexadecimal digits.
GRG	General purpose register for z/Architecture guests, represented as 16 hexadecimal digits.
AR	Access register, represented as eight hexadecimal digits.

Response 1:

The linkage-stack entry for an ESA/390 branch state entry has the following format:

ED-ADDR	U	ET	SI	RFS	NES	PKM	SASN	EAX	PASN
nnnnnnnn	n	BRN	nn	nnnn	nnnn	nnnn	nnnn	nnnn	nnnn
PSW		A	B-ADDR	MOD-AREA					
nnnnnnnn	nnnnnnnn	n	nnnnnnnn	nnnnnnnnnnnnnnnnnn					
GPR	0 =	greg0	greg1	greg2	greg3				
GPR	4 =	greg4	greg5	greg6	greg7				
GPR	8 =	greg8	greg9	greg10	greg11				
GPR	12 =	greg12	greg13	greg14	greg15				
AR	0 =	areg0	areg1	areg2	areg3				
AR	4 =	areg4	areg5	areg6	areg7				
AR	8 =	areg8	areg9	areg10	areg11				
AR	12 =	areg12	areg13	areg14	areg15				

The headings in this response are described under [“Responses”](#) on page 368.

Response 2:

The linkage-stack entry for a z/Architecture branch state entry has the following format:

```

ED-ADDR      U ET  SI RFS  NES  PKM  SASN  EAX  PASN
nnnnnnnnnnn n BRN nn  nnnn  nnnn  nnnn  nnnn  nnnn  nnnn

                PSW                      A      B-ADDR
nnnnnnnnnnn  nnnnnnnnnn nnnnnnnnnn nnnnnnnnnn nn  nnnnnnnnnnnnnnnnnnn

        MOD-AREA      SINST      PINST

AR   8 = areg8  areg9  areg10 areg11
AR  12 = areg12 areg13 areg14 areg15
    
```

The headings in this response are described under [“Responses” on page 368](#).

ED-ADDR and B-ADDR can be either 32 or 64 bits.

Response 3:

The linkage-stack entry for an ESA/390 program call state entry has the following format:

```

ED-ADDR  U ET  SI RFS  NES  PKM  SASN  EAX  PASN
nnnnnnnn n PRC nn  nnnn  nnnn  nnnn  nnnn  nnnn  nnnn

                PSW      PC-NUM      MOD-AREA      CSID
nnnnnnnnnnn  nnnnnnnnnn nnnnnnnnnnnnnnnnnnn nnnnnnnnnn

GPR  0 = greg0  greg1  greg2  greg3
GPR  4 = greg4  greg5  greg6  greg7
GPR  8 = greg8  greg9  greg10 greg11
GPR 12 = greg12 greg13 greg14 greg15

AR   0 = areg0  areg1  areg2  areg3
AR   4 = areg4  areg5  areg6  areg7
AR   8 = areg8  areg9  areg10 areg11
AR  12 = areg12 areg13 areg14 areg15
    
```

The headings in this response are described under [“Responses” on page 368](#).

Response 4:

The linkage-stack entry for a z/Architecture program call state entry has the following format:

```

ED-ADDR      U ET  SI RFS  NES  PKM  SASN  EAX  PASN
nnnnnnnnnnn n PRC nn  nnnn  nnnn  nnnn  nnnn  nnnn  nnnn

                PSW                      PC-NUM
nnnnnnnnnnn  nnnnnnnnnn nnnnnnnnnn nnnnnnnnnn nnnnnnnnnn

        MOD-AREA      CSID      SINST      PINST
nnnnnnnnnnnnnnnnnnn nnnnnnnnnn nnnnnnnnnn nnnnnnnnnn

GRG  0 = greg0                greg1
GRG  2 = greg2                greg3
GRG  4 = greg4                greg5
GRG  6 = greg6                greg7
GRG  8 = greg8                greg9
GRG 10 = greg10               greg11
GRG 12 = greg12               greg13
GRG 14 = greg14               greg15

AR   0 = areg0  areg1  areg2  areg3
AR   4 = areg4  areg5  areg6  areg7
    
```

```
AR 8 = areg8 areg9 areg10 areg11
AR 12 = areg12 areg13 areg14 areg15
```

The headings in this response are described under [“Responses”](#) on page 368.

ED-ADDR can be either 32 or 64 bits.

Response 5:

If a guest virtual address from the home address space cannot be converted to a host address, the translation process generates one of several exceptions, identifying the first page that was not addressable. The responses are:

```
Vhexloc1 to hexloc2 nonaddressable storage
- protection exception
Vhexloc1 to hexloc2 nonaddressable storage
- addressing exception
Vhexloc1 to hexloc2 nonaddressable storage
- segment translation exception
Vhexloc1 to hexloc2 nonaddressable storage
- page translation exception
Vhexloc1 to hexloc2 nonaddressable storage
- translation specification exception
```

The operand *Vhexloc1* is the starting address, and *hexloc2* the ending address, of the nonaddressable storage.

Response 6:

If a state entry that is neither a branch nor a program call is reached, the following response is issued:

```
Vhexloc1 to hexloc2 are linkage stack
state entries that are not branch or program-call.
```

The operand *Vhexloc1* is the starting address, and *hexloc2* the ending address, of the block of contiguous state entries in a linkage stack section that are not a branch or a program call.

Response 7:

```
The linkage stack is empty.
```

is issued if the linkage stack is empty.

Response 8:

If the specified guest virtual address is not within a branch or program-call state entry, the following response is issued:

```
Virtual address hexloc is not within a linkage
stack branch state entry or a program-call state entry.
```

The operand *hexloc* is the guest virtual address specified on the command line. Header and trailer state entries are not displayed.

Response 9:

```
The first state entry in the linkage stack has been reached.
```

is issued if the bottom of the stack is reached during command processing.

## DISPLAY PREFIX

---

```
►► Display — PREFIX ◄◄
```

### Authorization

Privilege Class: G

### Purpose

Use DISPLAY PREFIX to display the contents of the prefix register. This shows you the absolute location of guest page 0.

### Usage Notes

1. For usage information, see [“Usage Notes” on page 331](#).

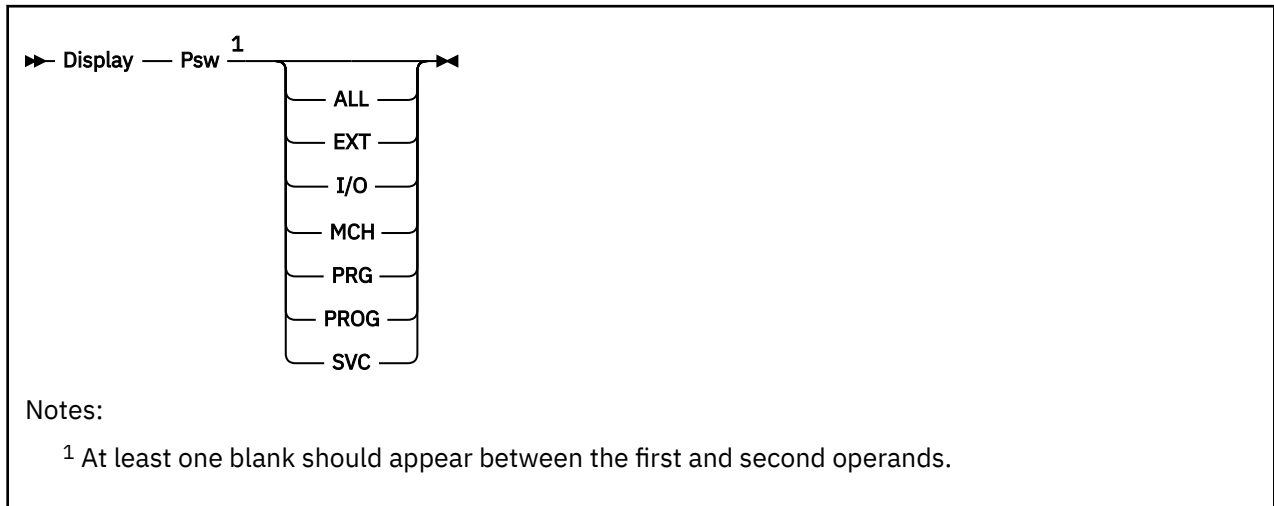

### Responses

Response 1:

```
PREFIX = xxxxxxxx
```

displays in hexadecimal the contents of the prefix register.

## DISPLAY PSW

### Authorization

Privilege Class: G

### Purpose

Use DISPLAY PSW to see the program status word of your virtual machine.

### Operands

#### ALL

displays the current values and interruption code information for the current PSW and all old and new interrupt PSWs (except RESTART).

#### EXT

#### I/O

#### MCH

#### PRG

#### PROG

#### SVC

displays the current values and appropriate interruption code information for both the new and old PSWs specified—that is, external, SVC, program check, machine check, and I/O.

### Usage Notes

1. The DISPLAY PSW command is valid for a z/Architecture or z/XC virtual machine only if SET PSWTRANS (with ALL or DISPLAY option) has been issued previously.
2. DISPLAY PSW ALL displays the PSW as a 128-bit PSW for z/Architecture and z/XC virtual machines.
3. For a z/Architecture or z/XC virtual machine, the PSW is 128 bits to accommodate 64-bit instruction addresses. An expanded PSW is labeled in the command output as "PSWG". The SET PSWTRANS command allows the PSWs from a z/Architecture or z/XC virtual machine to be shown and manipulated in the 64-bit ESA/390 format.

When the DISPLAY PSW command is issued from a z/Architecture or z/XC virtual machine (with a previous SET PSWTRANS ALL/DISPLAY issued), the 128-bit z/Architecture format PSW must be converted to a 64-bit ESA/390 format PSW. This conversion is done as follows:

## DISPLAY PSW

- bits 0-31 are set to bits 0-31 of the z/Architecture or z/XC PSW with bit 12 set to 1 and bit 31 set to 0.
- bits 33-63 of the PSW are set to bits 97-127 of the z/Architecture or z/XC PSW. If bits 64-95 of the z/Architecture or z/XC PSW are not 0, the PSW is flagged as non-translatable.
- bit 32 is set as follows:
  - if bits 31 and 32 of the z/Architecture or z/XC PSW are both 1, the PSW is flagged as non-translatable
  - if bits 31 and 32 of the z/Architecture or z/XC PSW are both 0, bit 32 of the ESA/390 PSW is set to 0
  - if bit 31 of the z/Architecture or z/XC PSW is 0 and bit 32 is 1, bit 32 of the ESA/390 PSW is set to 1.

## Responses

### Response 1:

The command DISPLAY PSW with no other options displays the current PSW. This is the response you receive on ESA/390 and ESA/XC virtual machines:

```
PSW = 03E40000 8003010C
```

### Response 2:

The command DISPLAY PSW with no other options displays the current PSW. This is the response you receive on z/Architecture and z/XC virtual machines:

```
PSW = 03EC0000 8003010C PSWG = 03E40000 80000000 00000000 0003010C
```

### Response 3:

The command DISPLAY PSW with no other options displays the current PSW. If the current PSW for a guest machine cannot be converted to a 64-bit PSW, then this is the response that you receive on z/Architecture and z/XC virtual machines:

```
PSW = NON TRANSLATABLE PSWG = 03E40000 80000000 00000000 0003010C
```

### Response 4:

The command DISPLAY PSW ALL displays the old and new PSWs and expands the interruption code into four hexadecimal digits in front of the old PSWs. *nnnn* represents the EC-mode interruption code. The numbers 18, 20, 28... are storage locations. Each *xxxxxxxx xxxxxxxx* represents the content of a PSW. This is the response you receive on ESA/390 and ESA/XC virtual machines:

```
PSW = xxxxxxxx xxxxxxxx  
EXT nnnn 18 OLD xxxxxxxx xxxxxxxx 58 NEW xxxxxxxx xxxxxxxx  
SVC nnnn 20 OLD xxxxxxxx xxxxxxxx 60 NEW xxxxxxxx xxxxxxxx  
PRG nnnn 28 OLD xxxxxxxx xxxxxxxx 68 NEW xxxxxxxx xxxxxxxx  
MCH nnnn 30 OLD xxxxxxxx xxxxxxxx 70 NEW xxxxxxxx xxxxxxxx  
I/O nnnn 38 OLD xxxxxxxx xxxxxxxx 78 NEW xxxxxxxx xxxxxxxx
```

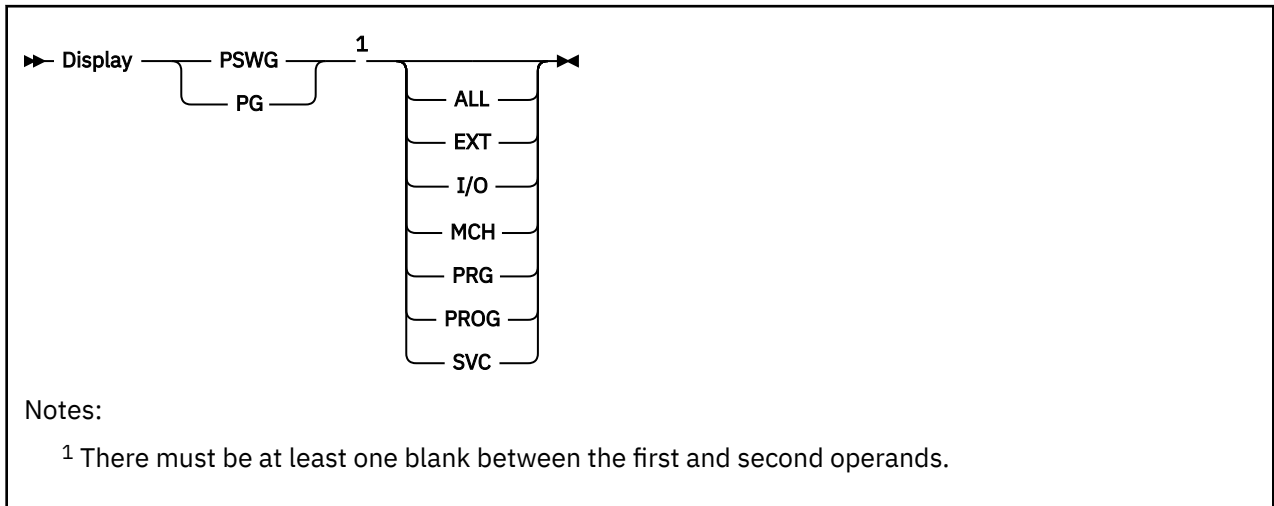

### Response 5:

The command DISPLAY PSW ALL displays the old and new PSWs and expands the interruption code into four hexadecimal digits in front of the old PSWs. *nnnn* represents the interruption code. The numbers 130, 140, 150, ... are storage locations. Each *xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx* represents the content of a PSW. This is the response that you receive on z/Architecture and z/XC virtual machines.

```
PSW = 03EC0000 8003010C PSWG = 03E40000 80000000 00000000 0003010C  
EXT nnnn 130 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx  
1B0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx  
SVC nnnn 140 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx  
1C0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx  
PRG nnnn 150 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
```

```
1D0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx  
MCH nnnn 160 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx  
1E0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx  
I/O nnnn 170 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx  
1F0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
```

## DISPLAY PSWG

### Authorization

Privilege Class: G

### Purpose

Use DISPLAY PSWG to see the program status word of your z/Architecture or z/XC virtual machine.

### Operands

#### ALL

displays the current values and interruption code information for the current PSW and all old and new interrupt PSWs (except RESTART).

#### EXT

#### I/O

#### MCH

#### PRG

#### PROG

#### SVC

displays the current values and appropriate interruption code information for both the new and old PSWs specified—that is, external, SVC, program check, machine check, and I/O.

### Usage Notes

- To display the PSW for an ESA/390 or ESA/XC virtual machine, use the DISPLAY PSW command.

### Responses

Response 1:

The command DISPLAY PSWG with no other options displays the current PSW.

```
PSW = 03E40000 80000000 00000000 0003010C
```

Response 2:

The command DISPLAY PSWG ALL displays the old and new PSWs and expands the interruption code into four hexadecimal digits in front of the old PSWs. *nnnn* represents the interruption code. The numbers 130,

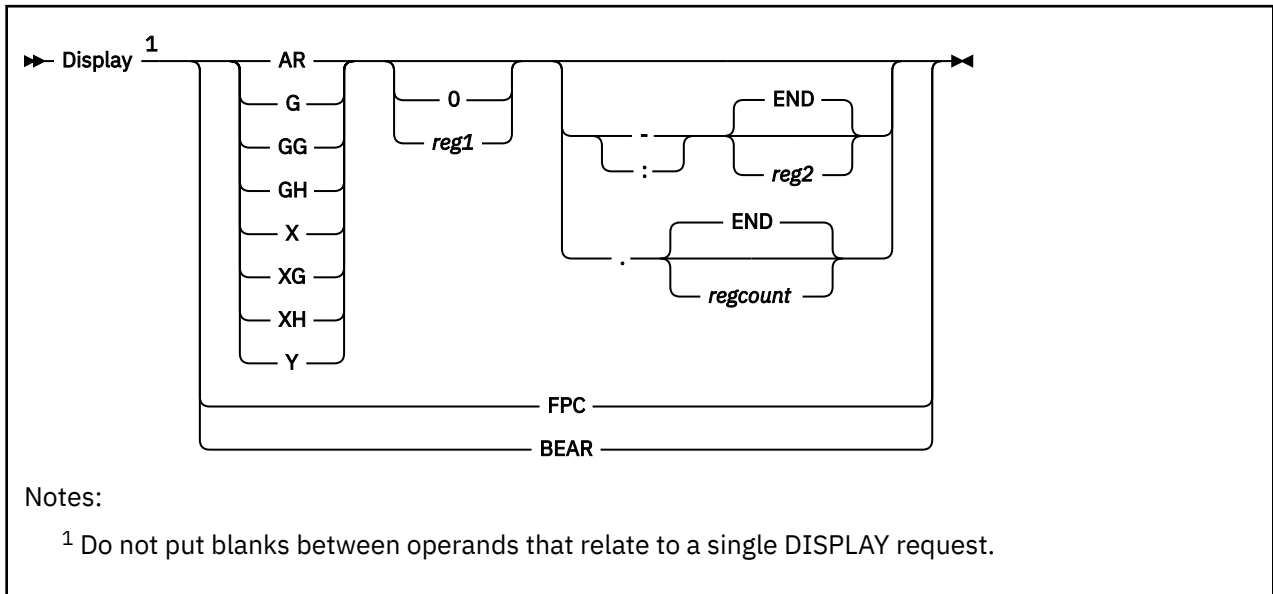

140, 150, ... are storage locations. Each xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx represents the content of a PSW.

```

PSW = 03E40000 80000000 00000000 0003010C
EXT nnnn 130 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
          1B0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx

```

## DISPLAY (Registers)

### Authorization

Privilege Class: G

### Purpose

Use DISPLAY (Registers) to see the following:

- Access registers
- General-purpose registers
- Control registers.
- Floating-point registers
- Floating-point control register
- Breaking-event-address register

### Operands

#### ARreg1

*reg1* is a decimal number from 0 to 15 or a hexadecimal number from 0 to F representing the first, or only, access register whose contents are to be displayed. If you specify AR without a register number, the contents of all access registers are displayed.

#### Greg1

G indicates a full register for an ESA/390 or ESA/XC guest or the low half of the register for a z/Architecture or z/XC guest. *reg1* is a decimal number from 0 to 15 or a hexadecimal integer from 0 to F representing the first, or only, general register whose contents are to be displayed. If you specify G without a register number, the appropriate contents of all of the general registers are displayed.

#### GGreg1

GG indicates a full register (32 bits for an ESA/390 or ESA/XC guest, 64 bits for a z/Architecture or z/XC guest). *reg1* is a decimal number from 0 to 15 or a hexadecimal integer from 0 to F representing the first, or only, general register whose contents are to be displayed. If you specify GG without a register number, the appropriate contents of all of the general registers are displayed.

**GHreg1**

GH indicates the upper half of a register for a z/Architecture or z/XC guest. This option is not valid for an ESA/390 or ESA/XC guest. *reg1* is a decimal number from 0 to 15 or a hexadecimal integer from 0 to F representing the first, or only, general register whose contents are to be displayed. If you specify GH without a register number, the high halves of all of the general registers are displayed.

**Xreg1**

X indicates a full control register for an ESA/390 or ESA/XC guest or the low half of the control register for a z/Architecture or z/XC guest. *reg1* is a decimal number from 0 to 15 or a hexadecimal number from 0 to F representing the first, or only, control register whose contents are to be displayed. If you specify X without a register number, the appropriate contents of all of the control registers are displayed.

**XGreg1**

XG indicates a full control register (32 bits for an ESA/390 or ESA/XC guest, 64 bits for a z/Architecture or z/XC guest). *reg1* is a decimal number from 0 to 15 or a hexadecimal integer from 0 to F representing the first, or only, control register whose contents are to be displayed. If you specify XG without a register number, the appropriate contents of all of the control registers are displayed.

**XHreg1**

XH indicates the upper half of a control register for a z/Architecture or z/XC guest. This option is not valid for an ESA/390 or ESA/XC guest. *reg1* is a decimal number from 0 to 15 or a hexadecimal integer from 0 to F representing the first, or only, control register whose contents are to be displayed. If you specify XH without a register number, the high halves of all of the control registers are displayed.

**Yreg1**

*reg1* is a decimal number from 0 to 15, or a hexadecimal number from 0 to F, representing the first, or only, floating-point register whose contents are to be displayed. If you specify Y without a register number, the contents of all the floating-point registers are displayed.

**FPC**

FPC displays the contents of the floating-point control register.

**BEAR**

BEAR displays the contents of the breaking-event-address register if the PER-3 Facility is available.

**: END****- reg2**

*reg2* is a number of the last register whose contents are to be displayed. You must specify the dash (-) or the colon (:) when you are requesting more than one register by register number. You must specify the range of registers in ascending order. Therefore, the value you specify for *reg2* must be equal to or greater than the value you specify for *reg1*.

The colon (:) means the same as a dash (-) when you are specifying a range of addresses.

If you specify AR, G, GG, GH, X, XG, XH, or Y, *reg2* may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F. The contents of *reg1* through *reg2* are displayed.

Specify END to display the contents of all remaining registers. END is the default.

**END****. regcount**

*regcount* is a decimal number from 1 to 16 or a hexadecimal number from 1 to F specifying the number of registers (starting with register 1) whose contents are to be displayed. If you specify AR, G, GG, GH, X, XG, XH, or Y, *regcount* can be a decimal number from 1 to 16 or a hexadecimal number from 1 to F.

The sum of *reg1* and *regcount* must be a number that does not exceed the maximum register number for the type of registers being displayed.

Specify END to display the contents of all remaining registers. END is the default.

## Usage Notes

1. The G and X operands are valid for an ESA/390, ESA/XC, z/Architecture, or z/XC guest. For an ESA/390 or ESA/XC guest, these operands refer to the full four-byte register. For a z/Architecture or /XC guest, these operands refer to the low-order four bytes of the full eight-byte register.
2. The GG and XG operands are valid for an ESA/390, ESA/XC, z/Architecture, or z/XC guest. For an ESA/390 or ESA/XC guest, these operands refer to the full four-byte register. For a z/Architecture or z/XC guest, these operands refer to the full eight-byte register.
3. The GH and XH operands are valid only for a z/Architecture or z/XC guest. These operands refer to the high-order four bytes of the full eight-byte register.
4. When a dash (-), colon (:), or period (.) is not preceded by a register number, the first register number defaults to 0. When a dash, colon, or period is not followed by a register number, the last register defaults to END.
5. For more information, see [“Usage Notes” on page 331](#).

## Responses

Response 1:

*Displaying General Registers:*

```
GPR nn = genreg0 genreg1 genreg2 genreg3
```

is the response you receive when you display general registers using *D G* or *D GG* from an ESA/390 or ESA/XC guest. *nn* indicates the first (or only) register whose contents are displayed.

The content of each register is displayed in hexadecimal. Up to four registers per line are displayed for each range you specify. If required, multiple lines are displayed to a maximum of four lines.

Response 2:

*Displaying General Registers:*

```
HCPCDE6150E An option has been specified that is not valid in
ESA/390 mode.
```

is the response you receive when you display general registers using *D GH* from an ESA/390 guest (an appropriate message will be issued from an ESA/XC guest).

Response 3:

*Displaying General Registers:*

```
GPR nn = genreg0l genreg1l genreg2l genreg3l
```

is the response you receive when you display general registers using *D G* from a z/Architecture or z/XC guest. *nn* indicates the first (or only) register whose contents are displayed.

The content of each register is displayed in hexadecimal and represents the low half of the full 64-bit register. Up to four registers per line are displayed for each range you specify. If required, multiple lines are displayed to a maximum of four lines.

Response 4:

*Displaying General Registers:*

```
GRG nn = genreg0hgenreg0l genreg1hgenreg1l
```

is the response you receive when you display general registers using *D GG* from a z/Architecture or z/XC guest. *nn* indicates the first (or only) register whose contents are displayed.

The content of each register is displayed in hexadecimal and represents the the full 64-bit register. Up to two registers per line are displayed for each range you specify. If required, multiple lines are displayed to a maximum of eight lines.

The high and low halves of each register may be separated by an optional underscore for readability. To have the underscore displayed, use the SET UNDERSCORE command.

Response 5:

*Displaying General Registers:*

```
GRH nn = genreg0h genreg1h genreg2h genreg3h
```

is the response you receive when you display general registers using *D GH* from a z/Architecture or z/XC guest. *nn* indicates the first (or only) register whose contents are displayed.

The content of each register is displayed in hexadecimal and represents the high half of the full 64-bit register. Up to four registers per line are displayed for each range you specify. If required, multiple lines are displayed to a maximum of four lines.

Response 6:

*Displaying Control Registers:*

```
ECR nn = ctlreg0 ctlreg1 ctlreg2 ctlreg3
```

is the response you receive when you display control registers using *D X* or *D XG* from an ESA/390 or ESA/XC guest. *nn* indicates the first (or only) register whose contents are displayed.

The content of each register is displayed in hexadecimal. Up to four registers per line are displayed for each range you specify. If required, multiple lines are displayed to a maximum of four lines.

Response 7:

*Displaying Control Registers:*

```
HCPCDE6150E An option has been specified that is not valid in
ESA/390 mode.
```

is the response you receive when you display control registers using *D XH* from an ESA/390 guest (an appropriate message will be issued from an ESA/XC guest).

Response 8:

*Displaying Control Registers:*

```
ECR nn = ctlreg0l ctlreg1l ctlreg2l ctlreg3l
```

is the response you receive when you display control registers using *D X* from a z/Architecture or z/XC guest. *nn* indicates the first (or only) register whose contents are displayed.

The content of each register is displayed in hexadecimal and represents the low half of the full 64-bit register. Up to four registers per line are displayed for each range you specify. If required, multiple lines are displayed to a maximum of four lines.

Response 9:

*Displaying Control Registers:*

```
CRG nn = ctlreg0hctlreg0l ctlreg1hctlreg1l
```

is the response you receive when you display control registers using *D XG* from a z/Architecture or z/XC guest. *nn* indicates the first (or only) register whose contents are displayed.

The content of each register is displayed in hexadecimal and represents the the full 64-bit register. Up to two registers per line are displayed for each range you specify. If required, multiple lines are displayed to a maximum of eight lines.

## DISPLAY (Registers)

The high and low halves of each register may be separated by an optional underscore for readability. To have the underscore displayed, use the SET UNDERSCORE command.

Response 10:

*Displaying Control Registers:*

```
CRH nn = ctlreg0h ctlreg1h ctlreg2h ctlreg3h
```

is the response you receive when you display control registers using *D XH* from a z/Architecture or z/XC guest. *nn* indicates the first (or only) register whose contents are displayed.

The content of each register is displayed in hexadecimal and represents the high half of the full 64-bit register. Up to four registers per line are displayed for each range you specify. If required, multiple lines are displayed to a maximum of four lines.

Response 11:

*Displaying Access Registers:*

```
AR nn = areg0 areg1 areg2 areg3
```

is the response you receive when you display access registers; *nn* is the first (or only) access register whose contents are displayed.

The contents of the requested access registers are displayed in hexadecimal. Up to four registers per line are displayed. If required, multiple response lines are displayed to a maximum of four lines.

Response 12:

*Displaying Floating Point Registers:*

```
FPR nn = xxxxxxxxxxxxxxxx ±.ddddddddddddddd E dd
```

is the response you receive when you display floating-point registers. The *nn* is the floating-point register whose contents are displayed on the line. The contents of the floating-point registers are displayed in both the internal hexadecimal format and the E-format; the first part of the response is the contents of the register in hexadecimal, and the second part of the response is the contents in exponential decimal format. Only one register is displayed per line. If you specified a range of registers, multiple response lines are displayed.

Response 13:

*Displaying Floating-Point Control Register:*

```
FPC = mmmmmmm
```

is the response you receive when you display the floating-point control register. The contents of the floating-point control register are displayed in hexadecimal format.

Response 14:

*Displaying Breaking-event-address Register:*

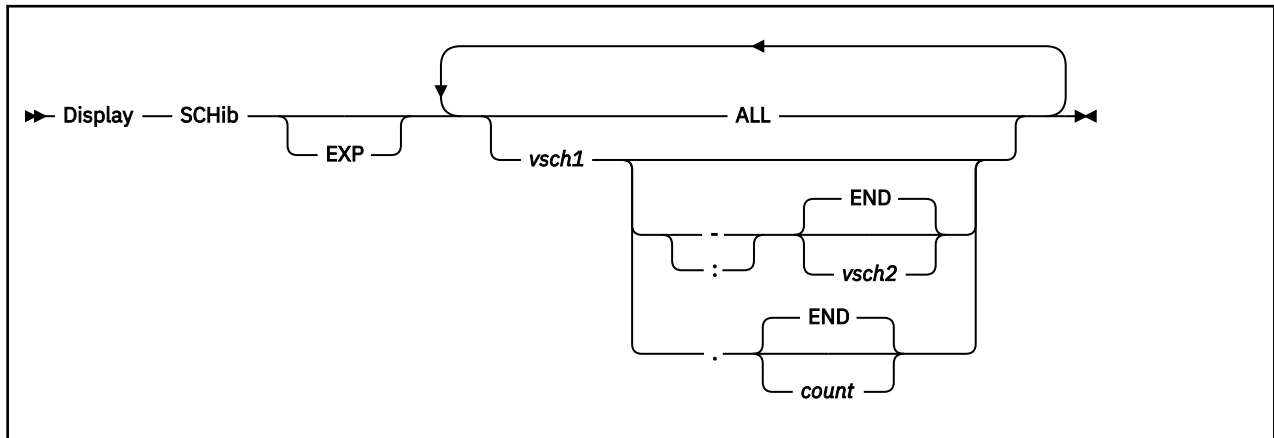

```
BEA = mmmmmmmmmmmmmmm
```

is the response you receive when you display the breaking-event-address register. The contents of the breaking-event-address register are displayed in hexadecimal format.

For ESA/390 and ESA/XC mode guests, the breaking-event-address is displayed with 4 bytes. In z/Architecture mode, the breaking-event-address is displayed with 8 bytes.

In z/Architecture mode the high and low half of the register may be separated by an optional underscore for readability. To have the underscore displayed, use the SET UNDERSCORE command.

## DISPLAY SCHIB

### Authorization

Privilege Class: G

### Purpose

Use DISPLAY SCHIB to see your subchannel information blocks (SCHIB).

### Operands

#### EXP

specifies that extended channel measurement information is to be displayed.

#### ALL

specifies that SCHIBs for all virtual devices are to be displayed.

#### *vsch1*

identifies the starting (or only) virtual subchannel whose SCHIB is to be displayed.

#### : END

#### - *vsch2*

*vsch2* specifies that all SCHIBs in the range *vsch1* to *vsch2* are to be displayed, or that all SCHIBs from *vsch1* to the highest number subchannel are to be displayed. END is the default if you specify a hyphen (-), or a colon (:). A colon (:) means the same as a hyphen (-) when specifying a range.

#### END

#### . *count*

*count* identifies the number of consecutive SCHIBs starting at *vsch1* that are to be displayed. Specify END to display all SCHIBs from *vsch1* to the highest number subchannel. END is the default if you specify a period (.).

### Usage Notes

1. If you specify a list of SCHIBS, and one is not found, the DISPLAY command terminates at the first SCHIB not found. For example, if you enter `display SCHIB 0022 0033 0055 0011`, and subchannel 0055 is not found, only SCHIB 0022 and 0033 will be displayed.

If you specify a range of SCHIBs, the DISPLAY command terminates if the first SCHIB in the range is not found. Otherwise, all those SCHIBs that were found are displayed.

2. You can use the QUERY VIRTUAL command to determine the subchannel number associated with a virtual device.

3. The response to this command is a header line followed by a line of information for each SCHIB that you specify. (The header line identifies, column by column, the SCHIB information below it. See “Responses” below.)
4. For more information, see [“Usage Notes” on page 331](#).

## Responses

### Response 1: When EXP is not specified

```
SCHIB DEV INT-PARM ISC FLG LP PNO (Con't)
nnnn nnnn nnnnnnnn n nn nn nn

LPU PI MBI PO PA CHPID0-3 CHPID4-7
nn nn nnnn nn nn nnnnnnnn nnnnnnnn
```

If an interrupt is pending for the virtual subchannel, the following line describes the pending interrupt:

```
KEY ECC FPI ZN SCTL CCW-ADDR DS SS CNT EXT-LOG
n n n n nnnn nnnnnnnn nn nn nnnn nnnnnnnn
```

### Response 2: When EXP is specified

```
SCHIB DEV INT-PARM ISC FLG MBI FLG2 MBA
nnnn nnnn nnnnnnnn n nn nnnn nn nnnnnnnnnnnnnnnnn
```

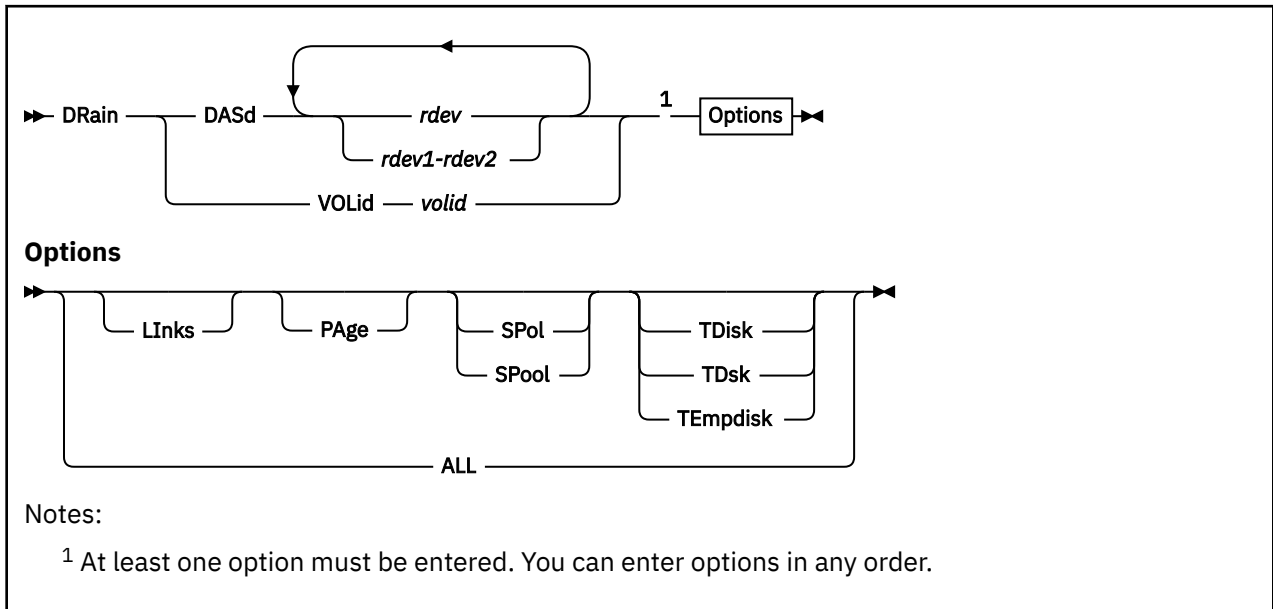

Response header lines contain headings from the list below. A brief description is included.

Heading	Description
INT-PARM	The interrupt parameter
ISC	The interrupt subclass
FLG	The flag field
LP	The logical-path mask
PNO	The path-not-operational mask
LPU	The last-path-used mask
PI	The path-installed mask
MBI	The measurement block index
	<b>Note:</b> This will be ----- when format-1 measurement blocks are being used.
PO	The path-operational mask
PA	The path-available mask
CHPID	The channel path identifiers
FLG2	The flag field (PMCW word 6, bits 24–31)
MBA	The measurement block address
KEY	The SCSW protect key
ECC	The logout condition code bits
FPI	The format, prefetch, and initial response bits
ZN	The initial status condition
SCTL	The function and activity control bytes
CCW-ADDR	The SCSW CCW address
DS	The SCSW device status bits

<b>Heading</b>	<b>Description</b>
SS	The subchannel status bits
CNT	The SCSW residual CCW data count
EXT-LOG	The extended status/time word

## DRAIN (Disk)

### Authorization

Privilege Class: B

### Purpose

Use DRAIN to prevent new allocations on specified real DASDs.

### Operands

#### DASd *rdev*

indicates that you want to drain one or more real DASD. You specify which ones by entering their real device numbers (*rdev*). Each *rdev* must be a hexadecimal device number between X'0000' and X'FFFF'.

#### VOLid *valid*

indicates that you want to drain a real DASD volume, specified by its real volume serial number (*valid*).

### Options

#### ALL

means all of the following:

#### LInks

tells CP not to allow LINK commands to minidisks on this device.

#### PAGe

tells CP not to write pages to this device during page-out operations.

#### SPol

#### SPOOL

tells CP not to allocate space on this device for new spool records.

The hard abend dump spool file or soft abend dump spool file may be open on the device that is being drained. These spool files must be closed for the device to drain completely. Refer to the SET ABEND command and the SET DUMP command for information about closing and reopening these spool files.

For more information about the SET ABEND command, see [“SET ABEND” on page 1413](#). For more information about the SET DUMP command, see [“SET DUMP” on page 1493](#).

**TDisk****TDsk****TEmpdisk**

tells CP not to allocate temporary disk requests to this device.

**Usage Notes**

1. A DASD that has been set to drain a particular usage will appear as if it were full. During allocation attempts, CP continues with the next normal step after encountering a full volume.
2. A DASD set for draining LINKS will not appear mounted when LINK commands are issued.
3. A DASD set for draining may still be attached to a virtual machine.
4. ATTACH and DETACH commands will not affect the various draining status indicators, so you can set the desired draining status before you attach a DASD to the system.
5. Use the QUERY DASD DRAINING command or the QUERY ALLOC command to see the draining status. For more information, see [“QUERY DASD” on page 867](#) and [“QUERY ALLOC” on page 773](#).
6. If you are authorized for some options of this command but not for others and you enter an unauthorized option, your command will be interpreted in the formats for which you are authorized. This may cause the command to run in an unexpected fashion, or reflect an unexpected message.
7. Use the START command to restart a device after it has been drained.

**Responses**

Response 1:

After you enter the DRAIN command, you see the following:

```
Command complete
```

- or -

```
nnnnnnnn device(s) specified; nnnnnnnn device(s)
successfully processed by DRAIN
```

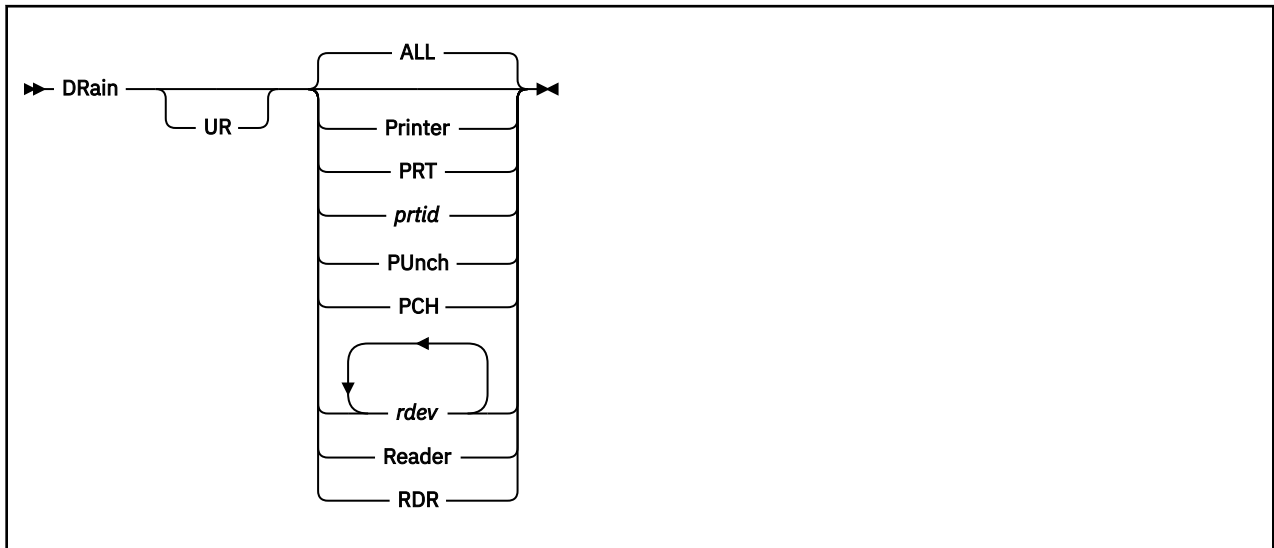

The following response may be sent to the system operator:

```
userid issued DRAIN command for volume volid
on device rdev for alloctype1 [alloctype2] [...]
```

**Messages**

- HCP002E Invalid operand - *operand*
- HCP021E A real device number was not specified or it is invalid.
- HCP023E VOLID missing or invalid
- HCP026E Operand missing or invalid
- HCP040E Device *rdev* does not exist
- HCP009E Invalid range - *range*
- HCP1004E *rdev* is not a DASD volume or is an invalid DASD type.

## DRAIN UR (Unit Record Device)

### Authorization

Privilege Class: D

### Purpose

Use DRAIN (unit record device) to stop spooling operations on specified real unit record devices.

**Note:** Spooling operations stop when the current file finishes processing.

### Operands

#### UR

tells CP you want to drain a real unit record device.

#### ALL

drains all spooled unit record devices in the system. ALL is the default.

#### Printer

#### PRT

#### PUnch

#### PCH

#### Reader

#### RDR

drains all printers, punches, or readers.

#### *rdev*

is a real device number or list of real device numbers of the real spooled devices that you want drained. Each *rdev* must be a hexadecimal device address between X'0000' and X'FFFF'.

#### *prtld*

indicates that the entire command is to be passed for processing to the print server virtual machine designated by *prtld*. The value of *prtld* is provided by the print server virtual machine that will enter the DRAIN command to an AFP. The value is one to eight alphanumeric characters long. If you specify a value of four or fewer characters, *prtld* cannot contain only hexadecimal characters because CP then interprets *prtld* as *rdev*.

## Usage Notes

1. Use the DRAIN command to bring the spooling system or a specified device to a controlled halt. You would normally drain all unit record devices before a system shutdown, and drain a printer before you change the contents of the UCS printer buffer.
2. A device is drained immediately if it is not active when the DRAIN command is issued; otherwise, it is drained when processing of the current file has completed. You can restart a drained device by issuing the START command. If you enter a START command to a device before draining has been completed, the device does not enter drained status, and it continues processing.
3. If you specify more than one real device number, execution of the DRAIN command terminates upon encountering an invalid real device number. None of the remaining devices are drained.
4. For a printer ID, the virtual machine associated with the printer ID processes the DRAIN command. Therefore, the options given on the DRAIN command must be valid for the virtual machine that is doing the processing.

When you enter the DRAIN, DRAIN PRINTER, DRAIN ALL, DRAIN UR, DRAIN UR PRINTER, or DRAIN UR ALL commands, all printers associated with all *prtids* are drained.

## Responses

The following section lists the printer, punch, and reader responses that occur when drained status has been attained. An explanation of the various options that appear in the responses follows the last response.

Inactive Printer Responses:

For every inactive printer that attains the drained status, the first line of the response is the same. The second line varies based upon printer type.

```
PRT rdev DRAINED userid CLASS c ...
PRT rdev FORM form {AUTO } {SEP } {NO3800 } [DEFFCB] LIMIT [NONE]
                  {MANUAL} {NOSEP} {BEG3800} [FILEFCB] [nnnnnnnnnn ]
                  {SETUP } {ANY3800}
```

For **3800 printers** the third line is:

```
PRT rdev FLASH name IMAGE imagelib CHARS name FCB {name} {HOLD } LPP nnn
                                                    {6 } {PURGE}
                                                    {8 }
                                                    {10}
                                                    {12}
```

For **impact printers** the third line is:

```
PRT rdev {NOFOLD} IMAGE imagelib CHARS chars [FCB name] [INDEX nn] LPP nnn
        {FOLD }
```

The fourth line of the response for **all printers** is:

```
PRT rdev DEST {dest1} DEST {dest2 } DEST {dest3 } DEST {dest4 }
              {OFF } { - NONE - } { - NONE - } { - NONE - }
```

The last line of the response for **3800 printers** is:

```
PRT rdev {AFP } {MARK }
        {NOAFP} {NOMARK}
```

The last line of the response for **impact printers** is:

```
PRT rdev {AFP }
        {NOAFP}
```

Inactive Punch Responses:

The following response occurs for each punch that attains the drained status:

```
PUN rdev DRAINED userid CLASS c ...
PUN rdev FORM form {AUTO } {SEP } LIMIT [NONE] (Con't)
                  {MANUAL} {NOSEP} [nnnnnnnnnn ]
                  {SETUP }
```

Continued:

```
PUN rdev DEST {dest1} DEST {dest2 } DEST {dest3 } DEST {dest4 }
              {OFF }      {- NONE -} {- NONE -} {- NONE -}
```

Inactive Reader Response:

```
RDR rdev DRAINED SYSTEM
```

Active Printer Responses:

For every active printer that attains the drained status, the first line of the response is the same. The second line varies according to printer type.

```
PRT rdev DRAINING userid CLASS c ...
PRT rdev FORM form {AUTO } {SEP } {N03800 } [DEFFCB] LIMIT [NONE]
                  {MANUAL} {NOSEP} {BEG3800} [FILEBCB] [nnnnnnnnnn ]
                  {SETUP } {ANY3800}
```

For **3800 printers** the third line is:

```
PRT rdev FLASH name IMAGE imagelib CHARS name FCB {name} {HOLD } LPP nnn
                                                    { }
                                                    6 {PURGE}
                                                    { }
                                                    8 { }
                                                    { }
                                                    10 { }
                                                    { }
                                                    12 { }
```

For **impact printers** the third line is:

```
PRT rdev {NOFOLD} IMAGE imagelib CHARS chars [FCB name] [INDEX nn] LPP nnn
        {FOLD }
```

The fourth line of the response for **all printers** is:

```
PRT rdev DEST {dest1} DEST {dest2 } DEST {dest3 } DEST {dest4 }
              {OFF }      {- NONE -} {- NONE -} {- NONE -}
```

The next line of the response for **3800 printers** is:

```
PRT rdev {AFP } {MARK }
        {NOAFP} {NOMARK}
```

The next line of the response for **impact printers** is:

```
PRT rdev {AFP }
        {NOAFP}
```

The last line of the response for **all printers** is:

```
PRT rdev PRINTING userid FILE spoolid RECS {nnnn} COPY [*]nnn SEQ sss
                                           {nnnK}
                                           {nnnM}
```

Continued:

```
CL c typ
```

You receive a message when the system begins processing a spool file that has been sent to the real device with the MSG attribute specified with the SPOOL command.

**Note:** CP itself does not provide a response for *prtids*. The virtual machine associated with *prtid* provides the response.

Active Punch Responses:

The following response occurs for each punch that attains the drained status:

```
PUN rdev DRAINING userid CLASS c ...
PUN rdev FORM form {AUTO } {SEP } LIMIT [NONE] (Con't)
                  {MANUAL} {NOSEP} [nnnnnnnnnn ]
                  {SETUP }
Continued:
PUN rdev DEST {dest1} DEST {dest2 } DEST {dest3 } DEST {dest4 } (Con't)
              {OFF }      {-NONE -} {- NONE -} {- NONE -}
Continued:
PUN rdev PUNCHING userid FILE spoolid RECS {nnnn} COPY [*]nnn SEQ sss
                                           {nnnK}
                                           {nnnM}
Continued:
CL c typ

Active Reader Response:

```
RDR rdev DRAINING SYSTEM
```

Explanation of Responses:

All the various options used in the preceding response section are detailed below.

#### **PRT**

#### **PUN**

#### **RDR**

*rdev* is the device that you drained or are draining.

#### **rdev**

*rdev* is the real device number of the drained or draining device.

#### **CLASS c**

*c* are those output classes that the drained or draining device was servicing. One to eight classes are displayed for each printer or punch device that was drained or is draining.

#### **FORM form**

*form* changes the form name of a spool file. *form* is one to eight characters long.

#### **AUTO**

**AUTO** indicates that the operator wants CP to schedule forms output. The currently active form is processed first. When all files with the current form have been printed or punched, CP automatically selects a new form for the device. The operator receives a message to change forms, and the output device is idle. The operator can then put in the new form and press the START button (or enter the START command) to print files with the new form.

#### **MANUAL**

**MANUAL** indicates that the operator schedules output forms. Only spool files with the form currently active on the device are processed. When the last spool file with the current form is printed or punched, the output device stops. The operator can then schedule a new form by issuing a START command with the FORM option.

#### **SETUP**

**SETUP** indicates that the operator wants CP to print a page so that forms alignment can be verified. (This option is valid only for impact printers.) The operator gets a message indicating that the form should be set up. When the form has been set up, the operator should press the STOP button, then the START button. An alignment page is then printed. It is the first page of the file, with letters replaced with Xs and the numbers replaced with 9s. Each time the operator presses the STOP or START buttons after

a full alignment page is printed, another alignment page is printed. When the forms are aligned, you should enter the START command for the device. The printer then returns to its previous mode (AUTO or MANUAL), and the file prints in its entirety.

If neither MANUAL, AUTO, nor SETUP is specified and the printer is currently in SETUP mode, it returns to the previous mode, AUTO or MANUAL. If no START command has been issued with the MANUAL, AUTO, or SETUP options since a system cold start, the default is MANUAL.

**SEP  
NOSEP**

indicates the current separator status.

**LIMIT NONE****LIMIT *nnnnnnnnnn***

indicates the current value for LIMIT, which was set by the CP START command or the system configuration file.

**NO3800****BEG3800****ANY3800**

specifies the restrictions on the 3800 load CCWs in effect after the device is started again.

**DEFFCB****FILEFCB**

specifies the FCB that is currently in use. DEFFCB means that the default that was loaded in the printer is used. FILEFCB means that file FCBs are sent to the real printer.

***rdev***

is the real 3800 printer or list of 3800 printer numbers that you want drained.

**FLASH *name***

signifies that a form overlay contained in the 3800 printer is to be superimposed (or flashed) onto the specified number of copies of the output. The name, to be one to four characters long, identifies the forms overlay to be used in the projection.

**IMAGE *imagelib***

specifies the name of the system image library file that contains the load images (character sets), FCBs, graphic character modifications, or copy modifications that are to be used for printing files and separators. *imagelib* may be from one to eight characters long, and must be an existing image library file.

**FCB *name***

is the name of the forms control buffer (FCB) module to be used by the printer in the vertical formatting of a page.

**Note:** This does not appear for 1403-type printers.

**CHARS *name***

specifies the name of the default character set used when spool files are being printed that do not specify a character set.

**HOLD**

prevents the printing of a file by placing it in a user hold status.

**PURGE**

closes and purges the spool file on the specified 3800 printer, regardless of the cont, keep, and hold setting for the device.

**LPP *nnn***

indicates the lines per page that the printer is using for the generation of separator pages. The LPP value is determined from the FCB loaded on the printer.

If no FCB has been loaded to the printer, the LPP will appear as zero. Since the FCB is actually loaded when a file is printed, it is possible that the LPP will appear as zero or the LPP value for the prior FCB after the START command with the FCB operand is issued.

**Note:** If the number of lines per page derived from the FCB data is less than 30 or greater than 255, the LPP for that printer will be set to a default value of 66 for impact printers, or 60 for 3800 printers.

**NOFOLD****FOLD**

indicates whether lowercase characters are being translated (folded) into uppercase for printing.

**CHARS *chars***

indicates the character set being used by the printer.

**INDEX *nn***

indicates the character position on the page at which to begin printing.

**PRT****PUN**

indicates the type of device on which the file is being processed.

***rdev***

is the real device number.

**DEST *dest***

is the destination value. *dest* is a one- to eight-character value. OFF is the default destination for the device for the first of four destination values. The designation - NONE - is shown for other destination values that have not been set.

**AFP****NOAFP**

specifies whether the printer is to process files with advanced function printer (AFP) characteristics.

**MARK****NOMARK**

indicates whether 3800 separator trailer pages are being marked with separator bars.

***userid***

is the name of the spool file owner.

**FILE *spoolid***

is the spool file number.

**RECS *nnnn*****RECS *nnnK*****RECS *nnnM***

is the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines rounded to the nearest 1000 records. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines rounded to the nearest million.

**COPY *nnn*****COPY \* *nnn***

specifies the number of file copies you want printed or punched when the file is produced.

When the optional asterisk (\*) is specified, the 3800 printer prints each page from the spooled output files *nnn* times before going on to the next page.

If a file is not spooled to the 3800 printer, the function performed by specifying the asterisk (\*) is ignored, and duplication occurs normally.

**SEQ *sss***

is the sequence number for the file on the printer or punch.

**CL *c***

is the spool file class.

***typ***

shows the device type that originally produced the spool file. The type can be RDR, PRT, PUN, CON, DMP, or SYS.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP007E Invalid userid - *userid*

- HCP2500E Image library *libname* could not be found [for printer *rdev*].
- HCP2501E A spool paging I/O error occurred while reading image [[library] *imagename* on printer *rdev*
- HCP6005E Option *option* is not supported by z/VM.
- HCP6525E Authorization request failed.

# DUMP

---

## Purpose

Use the DUMP commands to send data to your printer from the following machine components, both real and virtual:

- The contents of first-level storage (host real storage or host logical storage)
- The contents of second-level storage (the storage that appears real to the operating system running in your virtual machine)
- The contents of third-level storage (the storage that appears virtual to the operating system running in your virtual machine)
- Old and new PSWs and interrupt information for the following interrupts:
  - SVC
  - I/O
  - PROGRAM
  - EXTERNAL
  - MACHINE CHECK
- Storage keys
- Linkage stack
- Contents of registers:
  - Access
  - Control
  - Floating-point
  - Floating-point control
  - General purpose
  - Prefix
- Subchannel information blocks (SCHIBs)

## Usage Notes

1. The DUMP command prints the contents of various storage locations, registers, and control registers to your virtual printer. You may be able to detect the cause of program errors by examining this information.
2. Using a single command, you can dump multiple storage locations, registers, and control words.  
Follow these rules to execute the command properly:
  - a. Do not put blanks between operands that relate to a single DUMP request, except for PSW and SCHIB, which require at least one blank between the first and second operands. For example, if you want to dump hexadecimal location 40, enter `dump H40`.
  - b. Separate each set of dump requests from others by at least one blank.  
For example, if you want to dump the hexadecimal location 40 and the contents of register 5, enter `dump H40 G5`.
3. You can assign a *dumpid* to any dump that you create by means of the DUMP command. Note, however, that even though you can use a single DUMP command to make multiple DUMP requests, you can assign only one *dumpid* per command.

## DUMP

The dump identifier is an asterisk (\*) followed by a 1- to 97-character string (truncated to 80 characters for a z/Architecture mode guest) that is to be assigned to the dump. If specified, the dump identifier must be the last operand you enter on the command line. Blanks are permitted in the *dumpid*.

For example, `dump G *general registers` creates a dump of your general registers and assigns the dump the identifier "general registers".

4. As each request is processed, a message is sent to your display device. This permits you to stop DUMP processing by pressing the PA1 key. When the command terminates, you may enter another command.
5. The defaults for the following DUMP operands are:

<b>Operand</b>	<b>Default Before Rounding</b>
G	0-end
G-	0-end
G-5	0-G5
G5-	G5-end
G5	G5
T	T0
T-	T0-end
T-1000	T0-1000
T1000-	T1000-end
T1000	T1000
PSW	current

6. When dumping a range of addresses or subchannels, the command operand must be followed by an address, a range, or a colon (:), hyphen (-), or period (.) which forms a range. When dumping registers, the command operand can stand alone.
7. If you enter a command line that contains an operand that is not valid, the DUMP command terminates when it encounters that operand. Any previous valid operands are processed before termination occurs.
8. The DUMP command lets you dump information in the following formats:
  - Hexadecimal string / word segments
  - EBCDIC translation for uppercase letters and numbers 0 through 9
  - Hexadecimal word segments with EBCDIC and ASCII translation
  - Instruction
  - Storage key

**Note:** The EBCDIC translation is displayed only when the storage location contains the hexadecimal representation contained in a system translation table. This table is can be tailored by the system programmer via the system configuration file. The IBM-supplied table supports translation for the hexadecimal representation of the digits 0 through 9, the uppercase and lowercase letters A through Z, and a number of special characters. In all other cases, a period (.) is dumped.

If you enter multiple operands on a single command line for a storage or register dump, and do not specify the format that you want the DUMP command processor to use, the last format type that you explicitly entered on the command line defines the type of dump you receive. That is, whenever you explicitly enter a dump type, you implicitly define the default for subsequent operands of the current dump function. If you do not enter any dump format type on the command line, the system defaults are used.

For example, `dump 10 20 T40 80 G12 5 L60-100` dumps the following, respectively:

- Hexadecimal location 10 without EBCDIC translation
- Hexadecimal location 20 without EBCDIC translation
- Hexadecimal location 40 with EBCDIC translation
- Hexadecimal location 80 with EBCDIC translation
- The contents of general register 5
- The contents of general register 12
- Hexadecimal locations 60 through 100 without EBCDIC translation

The DUMP command suppresses identical lines and imbeds a response whenever a 64K boundary is crossed.

9. The DUMP storage command supports indirect addressing. Indirect addressing tells the command to use the **contents** of an address you specified instead of the address itself. This can help reduce the number of commands you issue and the tedious tracking of address pointers. You specify indirect addressing with an **&** (for 64-bit) or a **%** (for 31-bit).

The following is an example of double indirection using the % for 31-bit addressing. First, the storage is shown using the usual DUMP without indirect addressing. Following that is the same storage displayed using indirect addressing with only one DUMP command (and without having to know that the information you want is at address 3F1AB40). The information displayed is a LNGBK control block for the system default language using a pointer from the CP nucleus SYSCM area.

10. If you issue DISPLAY with the ASIT operand and specify the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the DISPLAY is rejected and error message HCPCLD6156E is issued. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value by using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:

- SYSTEM CLEAR
- IPL by NSS name
- IPL by device with the CClear option

- SET MACHine (to a different machine architecture)

## Messages

## DUMP ACCESS LIST

```

▶▶ DUmP — ACCList 1 —————▶▶
                    |
                    | *dumpid
                    |

```

Notes:

<sup>1</sup> Do not put blanks between operands that relate to a single DUMP request.

### Authorization

Privilege Class: G

### Purpose

Use DUMP ACCESS LIST to dump entries in your virtual machine's host access list.

### Operands

#### *\*dumpid*

is an asterisk followed by a 1- to 97-character identifier that is to be assigned to the dump. If specified, *dumpid* must be the last operand you enter on the command line.

### Usage Notes

1. If you write a program or EXEC that parses the output of this command, you should avoid a dependency on the ordering of the columns in the output. Your program or EXEC should use the heading line to determine which column contains a particular piece of information.
2. For more information, see [“Usage Notes” on page 395](#).

### Responses

Response 1:

```

ALET      ACC   FAULTS  ASIT      SPACE IDENTIFICATION  (Con't)
tttttttt {R/O} {ASYNCH} {aaaaaaaaaaaaaaaa}  sssssssssssssssssssssssssssssssssss
          {R/W} {SYNCH } {**REVOKED** }

```

Continued:

```

nnnn TOTAL ENTRIES:  vvvv VALID,  rrrr REVOKED,  uuuu UNUSED

```

#### *ttttttt*

is the access list entry token (ALET) corresponding to the host access-list entry (8 hexadecimal digits).

#### **R/O**

indicates that the host access-list entry can be used only for read references to the address space.

#### **R/W**

indicates that the host access-list entry can be used for read and write references to the address space.

#### **ASYNCH**

indicates that page-fault handshaking applies to the host access-list entry.

#### **SYNCH**

indicates that page-fault handshaking does not apply to the host access-list entry.

## DUMP ACCESS LIST

### **aaa...aaa**

is the address space identification token (ASIT) for the address space designated by the host access-list entry (16 hexadecimal digits).

### **\*\*REVOKED\*\***

indicates that the host access-list entry previously designated an address space, but access to that address space has been revoked (the host access-list entry is in the revoked state). The *spaceid* field is left empty for revoked host access-list entries.

### **sss...sss**

is the *spaceid* for the address space designated by the host access-list entry (3 to 33 characters).

### **nnnn TOTAL ENTRIES**

is the total number of entries in the host access list.

### **vvvv VALID**

is the number of entries in the host access list that designate address spaces, and can be used to address data in those address spaces (host access-list entries that are in the valid state).

### **rrrr REVOKED**

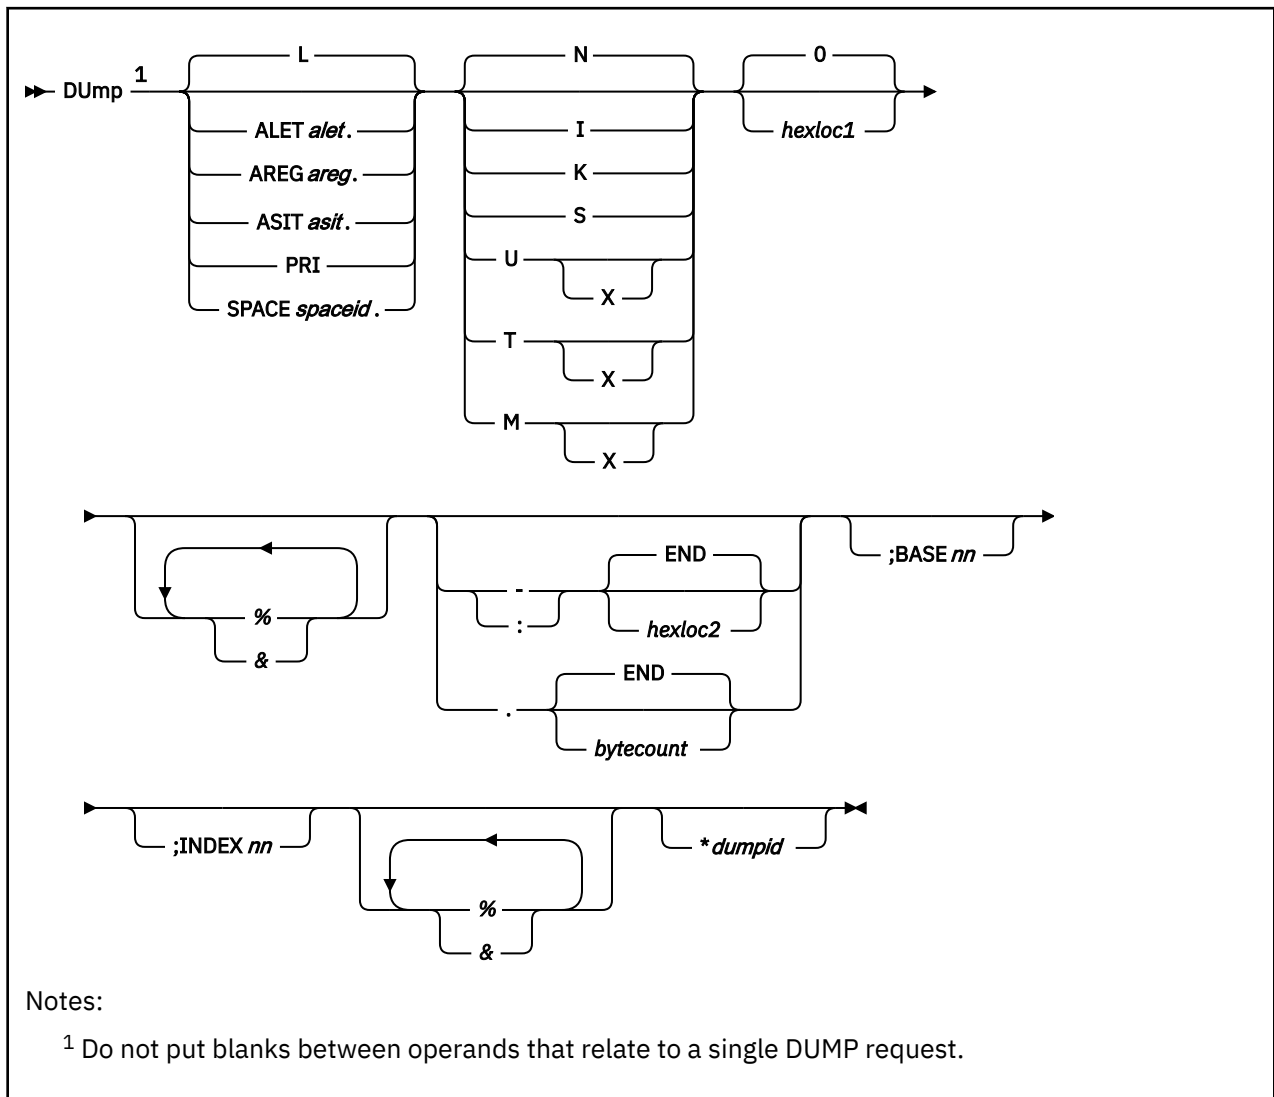

is the number of entries in the host access list that previously designated address spaces, but which can no longer be used to address data because the program's privileges to do so have been withdrawn.

### **uuuu UNUSED**

is the number of entries in the host access list that remain available for use (host access-list entries that are in the unused state).

## DUMP (Guest Storage - ESA/XC, z/XC)

### Authorization

Privilege Class: G

### Purpose

Use DUMP (Guest Storage - ESA/XC, z/XC) to dump the storage contents of an ESA/XC or z/XC virtual machine.

### Operands

**L**

dumps the contents of storage based on the setting of the address-space-control field in the guest PSW. This is the default.

If the virtual CPU is in the primary-space mode, the contents of real storage in the host-primary address space are dumped. If the virtual CPU is in the access-register mode and a nonzero BASE*nn* operand is also specified, the contents of real storage in an access register specified address space are dumped.

## DUMP (Guest Storage - ESA/XC)

If the virtual CPU is in the access-register mode, but either the *BASEnn* operand is not specified or is specified as 'BASE0', the contents of real storage in the host-primary address space are dumped.

### **ALE***alet.*

umps the contents of real storage in an access list entry token (ALET) specified address space. The *alet* may be 1 to 8 hexadecimal digits; leading zeros are optional. The ALET is used in conjunction with the virtual machine's host access list to determine the address space to dump.

### **AREG***areg.*

umps the contents of real storage in an access register specified address space. The *areg* may be specified as 1 hexadecimal or 2 decimal digits. The ALET within the access register is used in conjunction with the virtual machine's host access list to determine the address space to dump.

### **ASIT***asit.*

umps the contents of absolute storage in the address space identified by the address space identification token (ASIT). The *asit* may be 1 to 16 hexadecimal digits; leading zeros are optional.

### **PRI**

umps the contents of real storage in the host-primary address space. This is the address space from which the virtual CPU is fetching instructions at the time the command is run.

### **SPACE***spaceid.*

umps the contents of absolute storage in the address space identified by *spaceid*. The *spaceid* is a 1-character to 33-character string of the form:

where *owner* is an optional 1-character to 8-character user ID of the virtual machine that owns the address space, and *spacename* is the 1-character to 24-character address-space name assigned to the address space.

If *owner* is not specified, your virtual machine is assumed to be the owner of the address space. The *spacename* 'BASE' is preassigned by CP to be the name of your virtual machine's host-primary address space.

### **N**

umps the contents of storage in hexadecimal without character translation. This is the default. Storage is dumped in word segments. An address range is dumped starting at the fullword in which the specified address resides. Storage is dumped in fullword increments.

The storage key is dumped on the first line, as well as at every page boundary.

### **I**

umps the contents of storage in instruction format. The specified address is rounded down to the nearest halfword boundary.

The storage key is dumped on the first line, as well as at every page boundary.

### **K**

umps the storage keys in hexadecimal for all page frames or partial page frames included in the specified address range.

### **S**

umps the contents of storage in hexadecimal translation. Storage is dumped as a string starting at the location specified. The specified address range is not boundary-aligned.

The storage key is dumped on the first line and at every page boundary.

### **T**

umps the contents of storage in hexadecimal and character form. Storage is dumped in word segments. An address range is dumped starting at the X'10'-byte boundary in which the specified address resides. Storage is dumped in X'10' increments. The hexadecimal data is followed by the storage as an EBCDIC string, or as an ASCII string if the X option is specified.

The storage key is dumped on the first line and at every page boundary.

**U**

umps the contents of storage in character form. Storage is dumped starting at the specified address as an EBCDIC string, or as an ASCII string if the X option is specified. The specified address range is not boundary-aligned.

The storage key is dumped on the first line and at every page boundary.

**M**

umps the contents of storage in hexadecimal and character form. A header is dumped as the first line, and at every page boundary and contains the high-order 32 bits of the 64-bit address along with the storage key. Storage is dumped in word segments. An address range is dumped starting at the X'10' byte boundary in which the specified address resides. The hexadecimal output is followed by the storage as an EBCDIC string, or as an ASCII string if the X option is specified.

**0****hexloc1**

specifies the starting storage location that is to be dumped. The value *hexloc1* may be 1 to 16 hexadecimal digits, leading zeros are optional. The default is zero.

If neither the BASE or INDEX operand is used, *hexloc1* is the address of the first location to be dumped. This address is treated as a 64-bit address, regardless of the addressing mode of the virtual CPU.

If either the BASE or the INDEX operand is used, *hexloc1* is a displacement rather than an address. The first location to be dumped is specified by the sum of *hexloc1* and the contents of the registers specified with the BASE operand or the INDEX operand or both. If general register 0 is specified in the BASE or INDEX operand, it is always treated as containing zero when forming this sum. The sum is treated as a 24-bit, 31-bit, or 64-bit address according to the addressing mode of the virtual CPU.

Storage locations and the minimum amount dumped are rounded according to the following conventions (in hexadecimal):

Option	Start	Minimum Length
T	10	10
M	10	10
K	800	800
S	1	1
I	2	2 - 6 depending on the instruction
N	4	4
U	1	1

**%**

indicates 31-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 31 bits at the specified address (the high-order bit is turned off) are used as the new address for the DUMP command.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**&**

indicates 64-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 64 bits at the specified address are used as the new address for the DUMP command. A maximum of 16 indirection characters can be specified.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**-hexloc2**  
**:hexloc2**  
**-END**  
**:END**

is the last of a range of hexadecimal storage locations whose contents are to be dumped. If specified, *hexloc2* must be equal to or greater than *hexloc1* and must be within the bounds of the address space to be dumped. The address *hexloc2* may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. A colon (:) means the same as a dash (-) when you are specifying a range of addresses.

If neither the BASE or INDEX operand is used, *hexloc2* is the address of the last location to be dumped. This address is treated as a 64-bit address, regardless of the addressing mode of the virtual CPU.

If either the BASE or the INDEX operand is used, *hexloc2* is a displacement rather than an address. The last location to be dumped is specified by the sum of *hexloc2* and the contents of the registers specified with the BASE and INDEX operands. If general register 0 is specified in the BASE or INDEX operand, it is always treated as containing zero when this sum is being formed. The sum is treated as a 24-bit, 31-bit, or 64-bit address according to the addressing mode of the virtual CPU.

Specify END if you want to dump the remaining contents of storage. END is the default if you specify a dash (-) or a colon (:) without an address.

**.bytecount**  
**.END**

is a hexadecimal integer designating the number of bytes of storage (starting with the byte at *hexloc1*) to be dumped. If specified, the *bytecount* must have a value of at least 1 and may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional.

Specify END if you want to dump the remaining contents of storage. END is the default if you specify a period (.) without a byte count value.

**BASEnn**

.dumps the contents of guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified general register. The specified register (*nn*) may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F.

If the virtual CPU is in access-register mode, and the L operand is specified (or defaulted), *nn* designates an access register/general register pair. Access register *nn* is implicitly used, in the same manner as if the AREG operand had been specified, in conjunction with the virtual machine's host access list to determine the address space to dump. If the virtual CPU is not in the access-register mode, or if one of the other space-designation operands (PRI, AREG, ALET, SPACE, ASIT) is specified, access register *nn* is not implicitly used.

**INDEXnn**

.dumps the contents of guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified register. The specified register may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F.

**\*dumpid**

is an asterisk followed by a 1-character to 97-character identifier that is to be assigned to the dump. If specified, the *dumpid* must be the last operand you enter on the command line.

## Usage Notes

1. Special authorization is required to use this command to dump any address space other than the host-primary address space of the virtual CPU. In order to use this command to dump storage in an address space, one of the following conditions must be satisfied:
  - Your virtual machine must be the owner of the address space. Your virtual machine is the owner of its host-primary address space and of any address space that it creates using the CREATE function of the ADRSPACE macro.

- If the address space is owned by another virtual machine, your virtual machine must have read-only or read-write authorization to the address space. The owner of the address space can grant authorization to your virtual machine using the PERMIT function of the ADRSPACE macro.

Authorization is granted on a space-by-space basis, so that you may be authorized to dump one address space of a virtual machine but may not be authorized to dump a different space.

2. In addition to dumping the contents of the specified storage, the DUMP (Guest Storage) command dumps the program status words (PSWs), the contents of registers (general, access, floating-point, control, and prefix), and the subchannel information blocks (SCHIBs).
3. When running with a saved segment, you can dump storage locations outside the range of your virtual machine size if they are within the saved segment. If locations exist between the upper limit of your virtual machine and the address at which the saved segment was saved, any attempt to dump those locations (or associated keys) causes the non-addressable storage response to be dumped.
4. The operands L, PRI AREG, and ALET use the host-access-register translation (ART) process. The ART process performs special-case translation processes for certain ALET values and access registers:
  - The ALET X'00000000' always indicates the host-primary address space.
  - Access register 0 is always treated as containing ALET X'00000000'. The contents of access register 0 are not used during host-access-register translation processing.
5. General register 0 is always treated as containing the value 0 when used as the base or index register using the BASE or INDEX operands. The contents of general register 0 are never used.
6. In the XC environment, special rules govern the conversion of real addresses into absolute addresses. In some cases, prefixing is performed as usual to convert a real address to an absolute address, while in other cases prefixing is not performed and real addresses are treated unchanged as absolute addresses.

These rules have an effect on the interpretation of the addresses that specify the range of storage locations to be dumped:

- When storage is specified using the ALET or AREG operand and the ALET used is not X'00000000', prefixing is not performed on the addresses that specify the range of storage in the target address space.
  - When storage in the host-primary address space is specified by using the PRI operand, or by using the ALET or AREG operand when the ALET used is X'00000000', prefixing is performed as usual on the addresses that specify the range of storage in the host-primary address space.
7. Although the R operand is not shown in the syntax for this command, it is accepted for compatibility with the DUMP (Guest Storage) command used for XA and ESA virtual machines. The R operand perform the same function as the L operand and dumps storage from the host-primary address space.
  8. The BASE operand is intended to be used in conjunction with the L operand. It lets you dump the storage used by the virtual machine in one less step than would otherwise be possible. Without the BASE operand, you may need to dump the contents of a general register, then add the displacement, and then enter the DUMP command to examine storage the program is using. With the use of access registers, the BASE option additionally lets you examine storage without needing to know whether the program is currently in the access-register mode. This is done automatically for you by CP.
  9. When multiple DUMP requests are entered on a single line, the BASE and INDEX operands are not applied to subsequent DUMP requests on the command line. They must be explicitly entered for each DUMP request.
  10. During DUMP command processing, key-controlled protection is not used. However, all of the host-related protection mechanisms, such as those applied during host-access-register translation, are used as normal.
  11. If the AREG or ALET operand is specified, the DUMP command uses the host-access-register translation (ART) process to determine the address space to display. This translation process may fail, because of one of several program exception conditions. If the translation does not succeed, the current request is rejected and processing of the command line is terminated. The rejected operands are displayed along with a message indicating the nature of the exception condition.

12. When the ASIT or SPACE operand is specified, the DUMP request fails if the specified address space does not exist, or if you are not authorized to access the address space. The current request is rejected, and processing of the command line is terminated. The rejected operands are displayed along with a message indicating the nature of the error.
13. If you use an underscore, it must be followed by 8 hexadecimal digits.
14. For more information, see [“Usage Notes” on page 395](#).

## Responses

**Note:** The value *hexloc* is a hexadecimal storage address.

Response 1:

```
Rhexloc word1 word2 word3 word4 [key] [*TRANSLATION*]
```

is the response you receive for the T or N option. The EBCDIC translation is given only for the T option. The storage key is dumped on the first line of a request, and at every page boundary.

Response 2:

```
Rhexlochi_ Storage Key - [key]  
hexloclo word1 word2 word3 word4 [*TRANSLATION*]
```

is the response you receive for the M option. The translation is displayed in either EBCDIC or (if the MX option is specified) ASCII. The storage key is displayed on the first line, and at every page boundary.

Response 3:

```
Rhexloc *TRANSLATION* [key]
```

is the response you receive for the U option. The value *hexloc* is the location of the first data byte to be dumped. A minimum of 1 character and a maximum of 32 characters are dumped on each line. The contents of storage are dumped only in translated form and are either EBCDIC or (if the UX option is specified) ASCII. The contents of storage are dumped only in an EBCDIC translation. Periods in your dump represent unprintable characters. The storage key is dumped on the first line of a request and at every page boundary.

Response 4:

```
Rhexloc mnemonic1 x-x ... mnemonic5 x-x [key]
```

is the response you receive for the I option. The value *hexloc* is the location of the first instruction to be dumped. The value *mnemonic* is a character representation of the instruction code; this is a 7-character field in which the mnemonic is left-justified. The expression *x-x* is the actual hexadecimal contents of storage and is 2, 4, or 6 bytes as determined by the instruction length code. Unrecognizable instruction codes are indicated by a series of asterisks. A minimum of 1 instruction and a maximum of 5 instructions are dumped on each line. The storage key is dumped on the first line of a request and at every page boundary.

Response 5:

```
Rhexloc stringhexadecimaldata [key]
```

is the response you receive for the S option. The storage key is dumped on the first line of a request and at every page boundary.

Response 6:

```
Rhexloc1 TO hexloc2 KEY = key
```

is the response you receive for the K option. The values *hexloc1* and *hexloc2* are storage locations, and *key* is the associated storage key for *hexloc1*. A response is sent for every contiguous address range that has unique storage keys and whenever a segment boundary is crossed.

## Response 7:

The PSW is used to resolve a logical address. An invalid PSW causes the current request to be rejected and processing to continue with the next request (if any) on the command line. In all cases, a reset PSW (all-zero) is accepted. The rejected operands are displayed along with a response indicating the PSW is invalid. The response is:

```
addr is not addressable because of an invalid PSW.
```

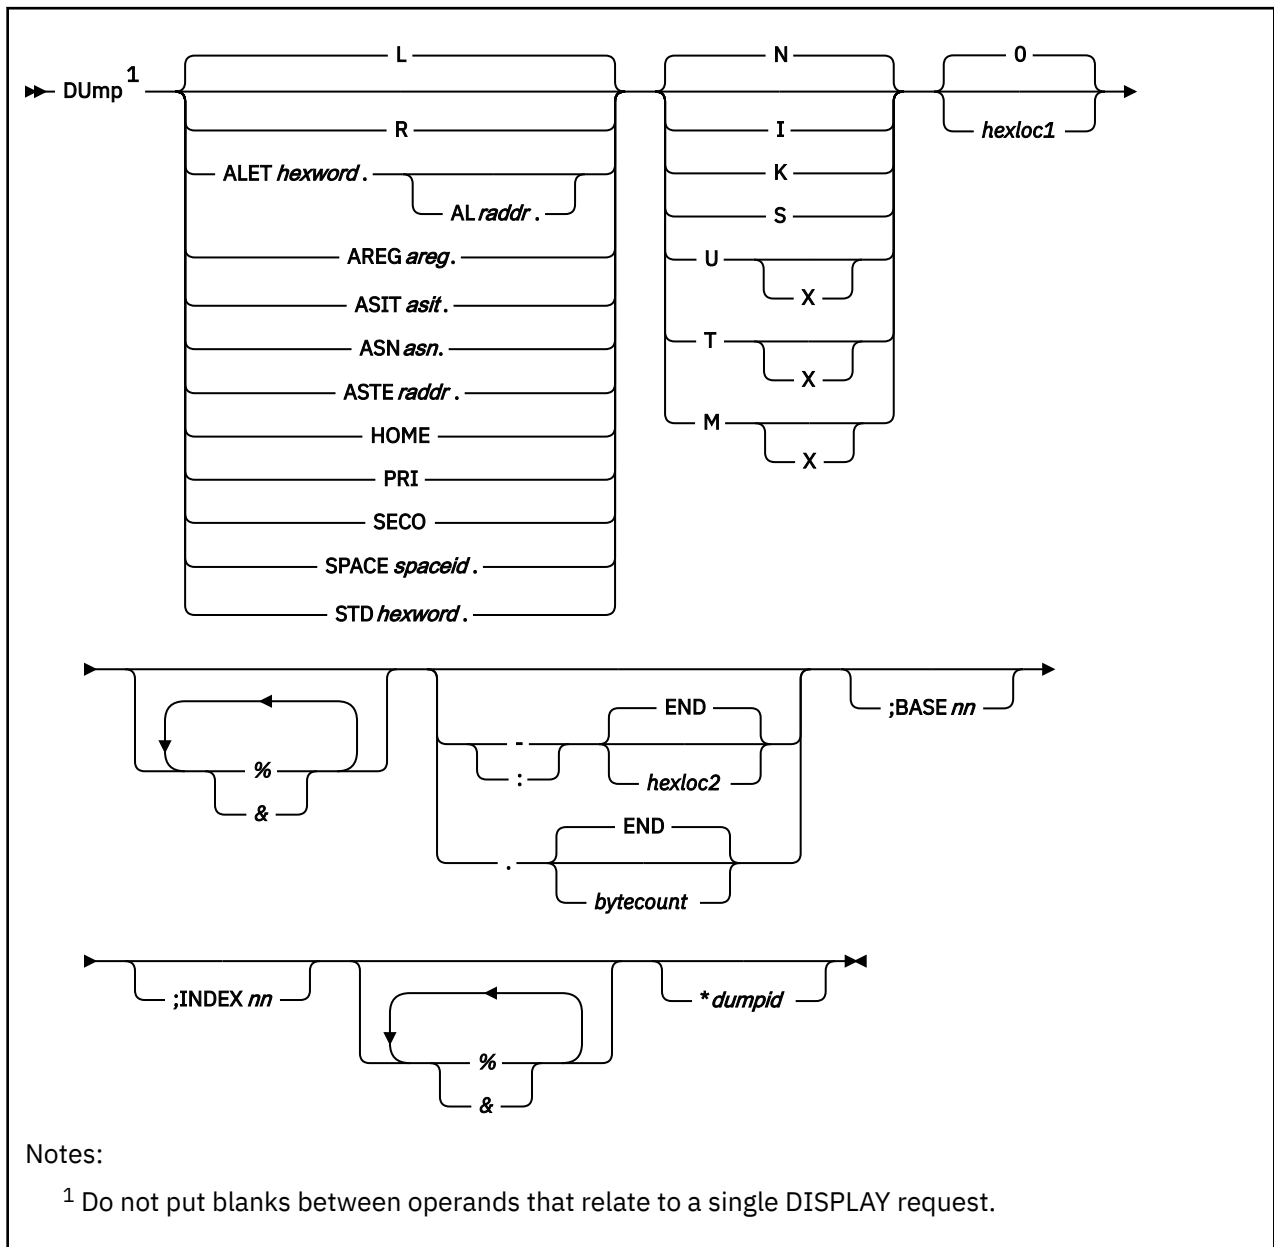

where *addr* is the rejected operand or operands; it specifies an address space and a storage location within that address space.

## Response 8:

If your dump request includes a request to dump identical lines, you receive the following response:

```
Rhexloc1 TO hexloc2 SUPPRESSED LINE(S) SAME AS ABOVE ....
```

## DUMP (Guest Storage - ESA/390)

### Authorization

Privilege Class: G

### Purpose

Use DUMP (Guest Storage - ESA/390) to dump the storage contents of an ESA/390 virtual machine.

### Operands

**L**

dumps the contents of second-level storage (storage that appears real to your virtual machine) if the virtual machine is operating in DAT OFF mode, or dumps the contents of third-level storage (storage

that appears virtual to your virtual machine) if the virtual machine is operating in DAT ON mode. This is the default.

The address space selected for dumping third-level storage corresponds with the setting of the address space control field in the guest PSW and is the primary, secondary, or (if the virtual machine is an ESA virtual machine) home space. When the PSW indicates access register mode, the primary space is selected for dumping unless a nonzero *BASEnn* operand is also specified and the virtual machine is an ESA virtual machine, in which case an access register specified address space is dumped.

## R

.dumps the contents of second-level storage (storage that appears real to your virtual machine).

### **ALE***Thexword*.

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using the specified access list entry token (ALET). The ALET is used in conjunction with guest access register translation tables to locate the guest address space.

### **AL***raddr*.

specifies an access list (AL) to be used in conjunction with the ALET to locate the guest address space. The guest real address of the access list may be specified as 1 to 8 hexadecimal digits.

### **AREG***areg*.

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using the contents of the specified access register. The *areg* may be specified as 1 hexadecimal or 2 decimal digits. The ALET within the access register is used in conjunction with guest access register translation tables to locate the guest address space.

### **ASIT***asit*.

dumps the contents of absolute storage in the CP-created address space identified by the specified address space identification token (ASIT). The *asit* may be 1 to 16 hexadecimal digits; leading zeros are optional.

### **ASN***asn*.

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using the specified address space number (ASN). The *asn* may be 1 to 4 hexadecimal digits. It is used in conjunction with guest ASN-translation tables to locate the guest address space to display.

### **ASTE***raddr*.

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using the segment table designation contained within the specified ASN second table entry (ASTE) located at guest real address *raddr*.

## HOME

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using guest control register 13.

## PRI

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using guest control register 1.

## SECO

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using guest control register 7.

### **SPACE***spaceid*.

dumps the contents of absolute storage in the CP-created address space identified by *spaceid*. The *spaceid* is a 1-character to 33-character string of the form:

where *owner* is an optional 1-character to 8-character user ID of the virtual machine that owns the CP-created address space, and *spacename* is the 1-character to 24-character address-space name assigned to the address space.

If *owner* is not specified, your virtual machine is assumed to be the owner of the address space. The *spacename* 'BASE' is preassigned by CP to be the name of your virtual machine's host-primary address space.

**STDhexword.**

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using the specified guest segment table designation.

**N**

dumps the contents of storage in hexadecimal without character translation. This is the default. Storage is dumped in word segments. An address range is dumped starting at the fullword in which the specified address resides. Storage is dumped in fullword increments.

The storage key is dumped on the first line and at every page boundary.

**I**

dumps the contents of storage in instruction format. The specified address is rounded down to the nearest halfword boundary.

The storage key is dumped on the first line and at every page boundary.

**K**

dumps the storage keys in hexadecimal for all page frames or partial page frames included in the specified address range.

**S**

dumps the contents of storage in hexadecimal translation. Storage is dumped as a string starting at the location specified. The specified address range is not boundary-aligned.

The storage key is dumped on the first line and at every page boundary.

**T**

dumps the contents of storage in hexadecimal and character form. Storage is dumped in word segments. An address range is dumped starting at the X'10'-byte boundary in which the specified address resides. Storage is dumped in X'10' increments. The hexadecimal output is followed by the storage as an EBCDIC string, or as an ASCII string if the X option is specified.

The storage key is dumped on the first line and at every page boundary.

**U**

dumps the contents of storage in character form. Storage is dumped starting at the specified address as an EBCDIC string or as an ASCII string if the X option is specified. The specified address range is not boundary-aligned.

The storage key is dumped on the first line and at every page boundary.

**M**

dumps the contents of storage in hexadecimal and character form. A header is dumped as the first line, and at every page boundary and contains the high-order 32 bits of the 64-bit address along with the storage key. Storage is dumped in word segments. An address range is dumped starting at the X'10' byte boundary in which the specified address resides. The hexadecimal output is followed by the storage as an EBCDIC string, or as an ASCII string if the X option is specified.

**O****hexloc1**

is the starting storage location that is to be dumped to your virtual printer. The address *hexloc1* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. The default is zero. The starting address will be translated to a X'10'-byte boundary.

Storage locations and the minimum amount dumped are rounded according to the following conventions in hexadecimal:

Option	Start	Minimum Length
T	10	10

Option	Start	Minimum Length
M	10	10
K	800	800
S	1	1
I	2	2 - 6 depending on the instruction
N	4	4
U	1	1

**%**

indicates 31-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 31 bits at the specified address (the high-order bit is turned off) are used as the new address for the DUMP command.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**&**

indicates 64-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 64 bits at the specified address are used as the new address for the DUMP command. A maximum of 16 indirection characters can be specified.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**-hexloc2****:hexloc2****-END****:END**

is the last of a range of hexadecimal storage locations whose contents are to be dumped to your virtual printer. If specified, *hexloc2* must be equal to or greater than *hexloc1* and must be within the virtual machine storage size. The address *hexloc2* may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. A colon (:) means the same as a dash (-) when you are specifying a range of addresses.

Specify END if you want to dump the remaining contents of storage. END is the default if you specify a dash (-) or a colon (:) without an address.

**.bytecount****.END**

is a hexadecimal number designating the number of bytes of storage (starting with the byte at *hexloc1*) to be dumped to your virtual printer. If specified, the *bytecount* must have a value of at least 1 and may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional.

Specify END if you want to dump the remaining contents of storage. END is the default if you specify a period (.) without a byte count value.

**BASEnn**

.dumps the contents of guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified general register (*nn*). The general register may be specified as a decimal number from 0 to 15 or as a hexadecimal number from 0 to F. *nn* specifies an AR/GR pair if all of the following are true:

- The L operand is specified.
- The virtual machine is an ESA virtual machine in ESA/390 mode (the default mode).
- The virtual CPU is in access register mode.

The specified access register is used, in the same manner as if the *AREGareg.* operand had been specified, in conjunction with guest access-register-translation tables to locate the guest address space.

**INDEXnn**

dumps the contents of guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified register. The specified register may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F.

**\*dumpid**

is an asterisk followed by a 1-character to 97-character identifier that is to be assigned to the dump. If specified, *dumpid* must be the last operand you enter on the command line.

**Usage Notes**

1. The DUMP (Guest Storage) command dumps the program status words (PSWs), and the contents of registers (general, floating-point, control, and prefix), along with the contents of the specified storage. If your virtual machine is an ESA virtual machine, the subchannel information blocks (SCHIBs) and the access registers are dumped.
2. You can dump storage locations outside the range of your virtual machine size if they are within a saved segment. Any attempt to dump locations (or associated keys) between the upper limit of your virtual machine and the address at which the saved segment is saved causes the non-addressable storage response to appear in the printed output.
3. The operands HOME, *AREGareg.*, *ALETheyword.*, and *ALETheyword.ALraddr.* are valid only if the virtual machine is an ESA virtual machine.
4. When you use the operand *ALETheyword.ALraddr.*, the primary list bit in the ALET is ignored.
5. The operands L, PRI, SECO, HOME, *ASTERaddr.*, *STDhexword.*, *ASNasn.*, *AREGareg.*, *ALETheyword.*, and *ALETheyword.ALraddr.* use the access-register-translation (ART), the ASN translation and the dynamic-address-translation (DAT) processes. These contain special case translation processes:
  - ALET 0 always indicates the current primary address space designated by the STD in guest control register 1, regardless of the current contents of the dispatchable unit access list.
  - ALET 1 always indicates the current secondary address space designated by the STD in guest control register 7, regardless of the current contents of the dispatchable unit access list.
  - Access register 0 is always treated as containing ALET 0. The contents of access register 0 are not used during access register translation processing.
  - General register 0 is always treated as containing the value 0 when used as the base or index register. The contents of general register 0 are never used.
6. The BASE operand is primarily intended to be used in conjunction with the L operand. It lets you dump the storage used by the virtual machine in one less step than would otherwise be possible. Without the BASE operand, you may need to display the contents of a general register, add the displacement, and then enter the DUMP command to examine storage the program is using. With the use of access registers, the BASE option additionally lets you dump storage without needing to know whether your program is currently in access register mode. This is done automatically for you by CP.
7. If you use the *BASEnn* and *INDEXnn* operands together, the specified starting address for a dump is used as a displacement from the address formed from the sum of the contents of the two specified registers.

The values in the registers specified by the *BASEnn* and *INDEXnn* operands are treated as 24-bit or 31-bit real addresses according to the addressing mode (A) bit in the virtual machine's PSW. That is, if the A bit is 1, the value is a 31-bit address. If the A bit is 0, the value is a 24-bit address.

8. During DUMP command processing, the authorization mechanisms used during normal address translation are not used.
9. Special authorization is required to use the SPACE or ASIT operand of this command to dump any address space other the host-primary address space of the virtual CPU. In order to use this command to dump storage in an address space, one of the following conditions must be satisfied:

- Your virtual machine must be the owner of the address space. Your virtual machine is the owner of its host-primary address space and of any address space that it creates using the CREATE function of the ADRSPACE macro.
- If the address space is owned by another virtual machine, your virtual machine must have read-only or read-write authorization to the address space. The owner of the address space can grant authorization to your virtual machine using the PERMIT function of the ADRSPACE macro.

Authorization is granted on a space-by-space basis, so that you may be authorized to dump one address space of a virtual machine but may not be authorized to view a different space.

10. The operands V and W used in dumping third-level storage from guest primary and secondary storage are supported for compatibility. The PRI and SECO operands replace the V and W operands.
11. When the ASIT or SPACE operand is specified, the DUMP request fails if the specified address space does not exist, or if you are not authorized to access the address space. The current request is rejected, and processing of the command line is terminated. The rejected operands are displayed along with a message indicating the nature of the error.
12. The DUMP command requires a segment table designation (STD) to display third-level storage (storage that appears virtual to your virtual machine). It may receive the STD as an operand, find it in a control register, or use the access-register translation (ART) or the address space number (ASN) translation process to obtain the STD. The access-register translation and ASN translation processes may fail because of one of several program exception conditions. If the translation does not succeed, the current request is rejected, and processing of the command line is terminated. The rejected operands are displayed along with a response indicating the nature of the exception condition.
13. When multiple DUMP requests are entered on a single line, the BASE $nn$  and INDEX $nn$  operands are not applied to subsequent DUMP requests on the command line. They must be explicitly entered for each DUMP request.
14. If you use an underscore, it must be followed by 8 hexadecimal digits.
15. If you issue DUMP with the ASIT operand and specify the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the DUMP command is rejected and error message HCPCDL6156E is issued. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value by using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:
  - SYSTEM CLEAR
  - IPL by NSS name
  - IPL by device with the CClear option
  - SET MACHine (to a different machine architecture)
16. For more information, see [“Usage Notes” on page 395](#).

## Responses

### Notes:

1. The value *hexloc* is a hexadecimal storage address.
2. The character displayed for the variable *t* in the string *thexloc* indicates the type of storage:
  - R indicates real storage (second-level storage).
  - V indicates virtual storage (third-level storage).
3. In responses that include third-level storage, an *Rhexloc* trailer shows the second-level address that corresponds to the third-level address. The trailer is displayed on the first line of a range and at every page boundary.
4. Responses 10 and 11 appear on your display screen.

Response 1:

```
thexloc word1 word2... word8 [key] [*TRANSLATION*] [Rhexloc]
```

is the response you receive for the T or N option. The translation is given only for the T option and is in either EBCDIC or (if the TX option is specified) ASCII. The storage key is dumped on the first line and at every page boundary.

Response 2:

```
thexlochi_ Storage Key - [key]
hexloclo word1 word2 word3 word4 [*TRANSLATION*] [Rhexloc]
```

is the response you receive for the M option. The translation is displayed in either EBCDIC or (if the MX option is specified) ASCII. The storage key is displayed on the first line, and at every page boundary.

Response 3:

```
thexloc *TRANSLATION* [key] [Rhexloc]
```

is the response you receive for the U option. The value *hexloc* is the location of the first data byte to be dumped. A minimum of 1 character and a maximum of 64 characters per line are displayed. The contents of storage are dumped in translated form and are in either EBCDIC or (if the UX option is specified) ASCII. Periods in your dump represent unprintable characters. The storage key is dumped on the first line of a request and at every page boundary.

Response 4:

```
thexloc mnemonic1 x-x ... mnemonic5 x-x [key] [Rhexloc]
```

is the response you receive for the I option. The value *hexloc* is the location of the first instruction to be dumped. The value *mnemonic* is a character representation of the instruction code; this is a 7-character field in which the mnemonic is left-justified. The expression *x-x* is the actual hexadecimal contents of storage and is 2, 4, or 6 bytes as determined by the instruction length code. Unrecognizable instruction codes are indicated by a series of asterisks. A minimum of 1 instruction and a maximum of 5 instructions are dumped per line. The storage key is displayed on the first line of a request and at every page boundary.

Response 5:

```
thexloc stringhexadecimaldata [key] [Rhexloc]
```

is the response you receive for the S option. The storage key is displayed on the first line of a request and at every page boundary.

Response 6:

```
thexloc1 TO hexloc2 KEY = key
```

is the response you receive for the K option. The values *hexloc1* and *hexloc2* are storage locations, and *key* is the associated storage key for *hexloc1*. A response is dumped for every contiguous address range that has unique storage keys, and whenever a segment boundary is crossed.

Response 7:

The PSW is used to resolve a logical address. A PSW that is not valid causes the current request to be rejected, and processing continues with the next request (if any) on the command line. In all cases, a reset PSW (all-zero) is accepted. The rejected operands are displayed along with a response indicating that the PSW is not valid. The response is:

```
addr is not addressable because of an invalid PSW.
```

where *addr* is the rejected operand or operands; it specifies an address space and a storage location within that address space.

Response 8:

The dynamic address translation (DAT) process uses the segment table designator (STD) to convert a third-level address to a second-level address (storage that appears real to your virtual machine). The translation process may generate one of several exceptions, identifying why one or more pages of storage are not addressable. A range of rejected storage addresses are displayed along with a response indicating the nature of the exception condition. The responses are:

```

thexloc1 to hexloc2 nonaddressable storage
- protection exception
thexloc1 to hexloc2 nonaddressable storage
- addressing exception
thexloc1 to hexloc2 nonaddressable storage
- segment translation exception
thexloc1 to hexloc2 nonaddressable storage
- page translation exception
thexloc1 to hexloc2 nonaddressable storage
- translation specification exception

```

where *hexloc1* is the starting address and *hexloc2* the ending address of the non-addressable storage. The addresses take into account basing, indexing, and wrapping and are padded to 8 digits.

Response 9:

If your request includes a request to dump identical lines, you receive the following response:

```

thexloc1 TO hexloc2 SUPPRESSED LINE(S) SAME AS ABOVE ...

```

Response 10:

```

DUMPING LOC thexloc

```

is sent to your console to indicate that a segment boundary has been reached. Each segment boundary location has an address that ends in X'00000'. The value *hexloc* identifies the storage boundary reached.

Response 11:

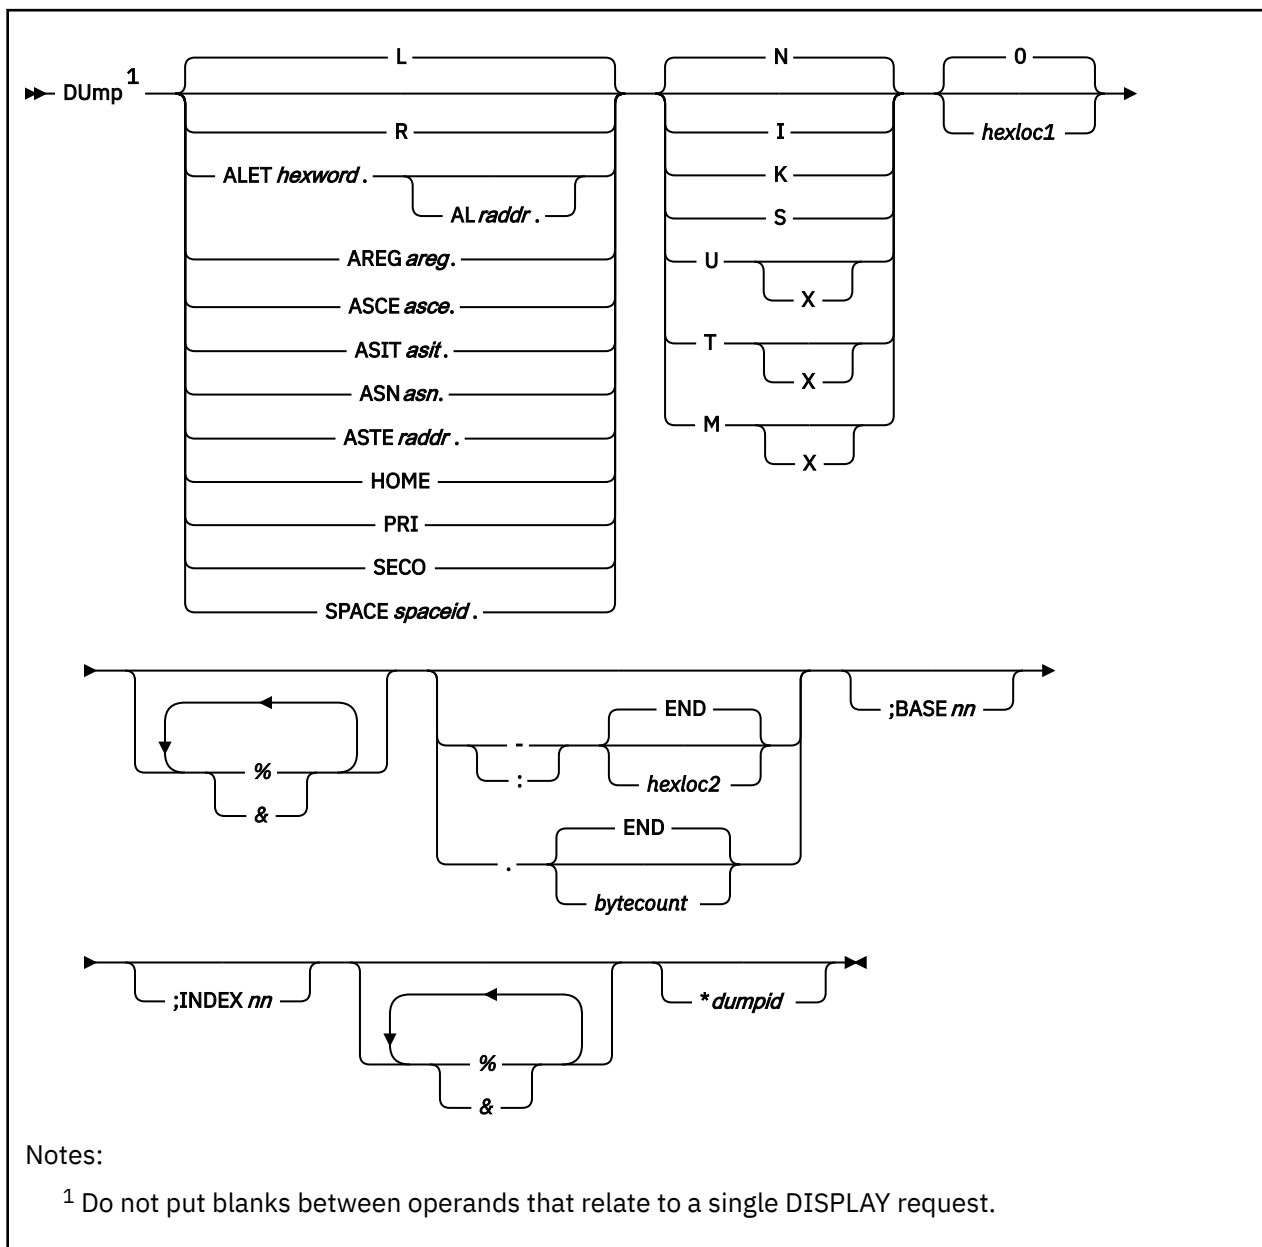

```

Command complete

```

is issued when the command completes successfully.

## DUMP (Guest Storage - z/Architecture)

### Authorization

Privilege Class: G

### Purpose

Use DUMP (Guest Storage - z/Architecture) to dump the storage contents of a virtual machine in z/Architecture mode.

### Operands

**L**

dumps the contents of second-level storage (storage that appears real to your virtual machine) if the virtual machine is operating in DAT OFF mode, or dumps the contents of third-level storage (storage

that appears virtual to your virtual machine) if the virtual machine is operating in DAT ON mode. This is the default.

The address space selected for dumping third-level storage corresponds with the setting of the address space control field in the guest PSW and is the primary, secondary, or (if the virtual machine is an ESA virtual machine) home space. When the PSW indicates access register mode, the primary space is selected for dumping unless a nonzero *BASEnn* operand is also specified and the virtual machine is an ESA virtual machine, in which case an access register-specified address space is dumped.

## R

.dumps the contents of second-level storage (storage that appears real to your virtual machine).

### **ALETheyword.**

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using the specified access list entry token (ALET). The ALET is used in conjunction with guest access register translation tables to locate the guest address space.

### **ALraddr.**

specifies an access list (AL) to be used in conjunction with the ALET to locate the guest address space. The guest real address of the access list may be 1 to 8 hexadecimal digits.

### **AREGareg.**

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using the contents of the specified access register. The *areg* may be specified as 1 hexadecimal or 2 decimal digits. The ALET within the access register is used in conjunction with guest access register translation tables to locate the guest address space.

### **ASCEasce.**

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using the specified address-space-control element (ASCE). The *asce* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional.

### **ASITasit.**

dumps the contents of absolute storage in the CP-created address space identified by the specified address space identification token (ASIT). The *asit* may be 1 to 16 hexadecimal digits; leading zeros are optional.

### **ASNasn.**

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using the specified address space number (ASN). The *asn* may be 1 to 4 hexadecimal digits. It is used in conjunction with guest ASN-translation tables to locate the guest address space.

### **ASTERaddr.**

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using the segment table designation contained within the specified ASN second table entry (ASTE) located at guest real address *raddr*.

## HOME

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using guest control register 13.

## PRI

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using guest control register 1.

## SECO

dumps the contents of third-level storage (storage that appears virtual to your virtual machine) using guest control register 7.

### **SPACEspaceid.**

dumps the contents of absolute storage in the CP-created address space identified by *spaceid*. The *spaceid* is a 1-character to 33-character string of the form:

where *owner* is an optional 1-character to 8-character user ID of the virtual machine that owns the CP-created address space, and *spacename* is the 1-character to 24-character address-space name assigned to the address space.

If *owner* is not specified, your virtual machine is assumed to be the owner of the address space. The *spacename* 'BASE' is preassigned by CP to be the name of your virtual machine's host-primary address space.

### **N**

dumps the contents of storage in hexadecimal without EBCDIC translation. This is the default. Storage is dumped in word segments. An address range is dumped starting at the fullword in which the specified address resides. Storage is dumped in fullword increments.

The storage key is dumped on the first line and at every page boundary.

### **I**

dumps the contents of storage in instruction format. The specified address is rounded down to the nearest halfword boundary.

The storage key is dumped on the first line and at every page boundary.

### **K**

dumps the storage keys in hexadecimal for all page frames or partial page frames included in the specified address range.

### **S**

dumps the contents of storage in hexadecimal translation. Storage is dumped as a string starting at the location specified. The specified address range is not boundary-aligned.

The storage key is dumped on the first line and at every page boundary.

### **T**

dumps the contents of storage in hexadecimal and character form. Storage is dumped in word segments. An address range is dumped starting at the X'10'-byte boundary in which the specified address resides. The hexadecimal words are followed by the storage as an EBCDIC string, or as an ASCII string if the X option is specified.

The storage key is dumped on the first line and at every page boundary.

### **U**

dumps the contents of storage in character form. Storage is dumped starting at the address specified as an EBCDIC string, or as an ASCII string if the X option is specified. The specified address range is not boundary-aligned.

The storage key is dumped on the first line and at every page boundary.

### **M**

dumps the contents of storage in hexadecimal and character form. A header is dumped as the first line, and at every page boundary and contains the high-order 32 bits of the 64-bit address along with the storage key. Storage is dumped in word segments. An address range is dumped starting at the X'10' byte boundary in which the specified address resides. The hexadecimal output is followed by the storage as an EBCDIC string, or as an ASCII string if the X option is specified.

### **0**

#### **hexloc1**

is the starting storage location that is to be dumped to your virtual printer. The address *hexloc1* may be 1 to 16 hexadecimal digits separated with an optional underscore for readability. Leading zeros are optional. The default is 0.

Storage locations and the minimum amount dumped are rounded according to the following conventions in hexadecimal:

Option	Start	Minimum Length
T	10	10
M	10	10
K	800	800
S	1	1
I	2	2 - 6 depending on the instruction
N	4	4
U	1	1

**%**

indicates 31-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 31 bits at the specified address (the high-order bit is turned off) are used as the new address for the Dump command.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**&**

indicates 64-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 64 bits at the specified address are used as the new address for the Dump command. A maximum of 16 indirection characters can be specified.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**-hexloc2**

**:hexloc2**

**-END**

**:END**

is the last of a range of hexadecimal storage locations whose contents are to be dumped to your virtual printer. If specified, *hexloc2* must be equal to or greater than *hexloc1* and must be within the virtual machine storage size. The address *hexloc2* may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. A colon (:) means the same as a dash (-) when you are specifying a range of addresses.

Specify END if you want to dump the remaining contents of storage. END is the default if you specify a dash (-) or a colon (:) without an address.

**.bytcoun**

**.END**

is a hexadecimal number designating the number of bytes of storage (starting with the byte at *hexloc1*) to be dumped to your virtual printer. If specified, the *bytcoun* must have a value of at least 1 and may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional.

Specify END if you want to dump the remaining contents of storage. END is the default if you specify a period (.) without a byte count value.

**BASEnn**

umps the contents of guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified general register (*nn*). The general register may be specified as a decimal number from 0 to 15 or as a hexadecimal number from 0 to F. *nn* specifies an AR/GR pair if all of the following are true:

- The L operand is specified.
- The virtual machine is an ESA virtual machine in z/Architecture mode.

## DUMP (Guest Storage - z/Architecture)

**Note:** An ESA virtual machine simulates ESA/390 architecture when initially defined. However, a guest may have the capability to switch the virtual machine from ESA/390 mode to z/Architecture mode.

- The virtual CPU is in access register mode.

The specified access register is used, in the same manner as if the *AREGareg.* operand had been specified, in conjunction with guest access-register-translation tables to locate the guest address space.

### INDEXnn

dumps the contents of guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified register. The specified register may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F.

### \*dumpid

is an asterisk followed by a 1-character to 80-character identifier that is to be assigned to the dump. If specified, *dumpid* must be the last operand you enter on the command line.

## Usage Notes

1. The DUMP (Guest Storage) command dumps the program status words (PSWs), and the contents of registers (general, floating-point, control, and prefix), along with the contents of the specified storage. If your virtual machine is an ESA virtual machine, the subchannel information blocks (SCHIBs) and the access registers are dumped.
2. You can dump storage locations outside the range of your virtual machine size if they are within a saved segment. Any attempt to dump locations (or associated keys) between the upper limit of your virtual machine and the address at which the saved segment is saved causes the non-addressable storage response to appear in the printed output.
3. When you use the operand *ALETheyword.ALaddr.*, the primary list bit in the ALET is ignored.
4. The operands *L*, *PRI*, *SECO*, *HOME*, *ASTERaddr.*, *ASCEasce.*, *ASNasn.*, *AREGareg.*, *ALETheyword.*, and *ALETheyword.ALaddr.* use the access-register-translation (ART), the ASN translation and the dynamic-address-translation (DAT) processes. These contain special case translation processes:
  - ALET 0 always indicates the current primary address space designated by the ASCE in guest control register 1, regardless of the current contents of the dispatchable unit access list.
  - ALET 1 always indicates the current secondary address space designated by the ASCE in guest control register 7, regardless of the current contents of the dispatchable unit access list.
  - Access register 0 is always treated as containing ALET 0. The contents of access register 0 are not used during access register translation processing.
  - General register 0 is always treated as containing the value 0 when used as the base or index register. The contents of general register 0 are never used.
5. The *BASE* operand is primarily intended to be used in conjunction with the *L* operand. It lets you dump the storage used by the virtual machine in one less step than would otherwise be possible. Without the *BASE* operand, you may need to display the contents of a general register, add the displacement, and then enter the DUMP command to examine storage the program is using. With the use of access registers, the *BASE* option additionally lets you dump storage without needing to know whether your program is currently in access register mode. This is done automatically for you by CP.
6. If the *BASEnn* and *INDEXnn* operands are used together, the specified starting address for a dump is used as a displacement from the address formed from the sum of the contents of the two specified registers.

The values in the registers specified by the *BASEnn* and *INDEXnn* operands are treated as 24-bit, 31-bit or 64-bit real addresses according to the addressing mode bits (EA and BA - bits 31 and 32) in the virtual machine's PSW. The addressing mode is determined as follows:

Bit 31	Bit 32	Addressing Mode
0	0	24-bit

Bit 31	Bit 32	Addressing Mode
0	1	31-bit
1	1	64-bit

7. During DUMP command processing, the authorization mechanisms used during normal address translation are not used.
8. Special authorization is required to use the SPACE or ASIT operand of this command to dump any address space other the host-primary address space of the virtual CPU. In order to use this command to dump storage in an address space, one of the following conditions must be satisfied:
  - Your virtual machine must be the owner of the address space. Your virtual machine is the owner of its host-primary address space and of any address space that it creates using the CREATE function of the ADRSPACE macro.
  - If the address space is owned by another virtual machine, your virtual machine must have read-only or read-write authorization to the address space. The owner of the address space can grant authorization to your virtual machine using the PERMIT function of the ADRSPACE macro.

Authorization is granted on a space-by-space basis, so that you may be authorized to dump one address space of a virtual machine but may not be authorized to view a different space.
9. The operands V and W used in dumping third-level storage from guest primary and secondary storage are supported for compatibility. The PRI and SECO operands replace the V and W operands.
10. When the ASIT or SPACE operand is specified, the DUMP request fails if the specified address space does not exist, or if you are not authorized to access the address space. The current request is rejected, and processing of the command line is terminated. The rejected operands are displayed along with a message indicating the nature of the error.
11. The DUMP command requires an address-space-control element (ASCE) to display third-level storage (storage that appears virtual to your virtual machine). It may receive the ASCE as an operand, find it in a control register, or use the access-register translation (ART) or the address space number (ASN) translation process to obtain the ASCE. The access-register translation and ASN translation processes may fail because of one of several program exception conditions. If the translation does not succeed, the current request is rejected, and processing of the command line is terminated. The rejected operands are displayed along with a response indicating the nature of the exception condition.
12. When multiple DUMP requests are entered on a single line, the BASE $nn$  and INDEX $nn$  operands are not applied to subsequent DUMP requests on the command line. They must be explicitly entered for each DUMP request.
13. If you use an underscore, it must be followed by 8 hexadecimal digits.
14. If you issue DUMP with the ASIT operand and specify the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the DUMP command is rejected and error message HCPCDL6156E is issued. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value by using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:
  - SYSTEM CLEAR
  - IPL by NSS name
  - IPL by device with the CClear option
  - SET MACHine (to a different machine architecture)
15. For more information, see [“Usage Notes” on page 395](#).

## Responses

### Notes:

## DUMP (Guest Storage - z/Architecture)

1. The value *hexloc* is a hexadecimal storage address.
2. The character displayed for the variable *t* in the string *thexloc* indicates the type of storage:
  - R indicates real storage (second-level storage).
  - V indicates virtual storage (third-level storage).
3. In responses that include third-level storage, an *Rhexloc* trailer shows the second-level address that corresponds to the third-level address. The trailer is displayed on the first line of a range and at every page boundary.
4. Responses 10 and 11 appear on your display screen.

Response 1:

```
thexloc word1 word2... word8 [key] [*TRANSLATION*] [Rhexloc]
```

is the response you receive for the T or N option. The translation is given only for the T option and is in either EBCDIC or (if the TX option is specified) ASCII. The storage key is dumped on the first line and at every page boundary.

Response 2:

```
thexlochi_ Storage Key - [key]  
hexloclo word1 word2 word3 word4 [*TRANSLATION*] [Rhexloc]
```

is the response you receive for the M option. The translation is dumped in either EBCDIC or (if the MX option is specified) ASCII. The storage key is displayed on the first line, and at every page boundary.

Response 3:

```
thexloc *TRANSLATION* [key] [Rhexloc]
```

is the response you receive for the U option. The value *hexloc* is the location of the first data byte to be dumped. A minimum of 1 character and a maximum of 64 characters per line are dumped. The contents of storage are dumped in translated form and are in either EBCDIC or (if the UX option is specified) ASCII. Periods in your dump represent unprintable characters. The storage key is dumped on the first line of a request and at every page boundary.

Response 4:

```
thexloc mnemonic1 x-x ... mnemonic5 x-x [key] [Rhexloc]
```

is the response you receive for the I option. The value *hexloc* is the location of the first instruction to be dumped. The value *mnemonic* is a character representation of the instruction code; this is a 7-character field in which the mnemonic is left-justified. The expression *x-x* is the actual hexadecimal contents of storage and is 2, 4, or 6 bytes as determined by the instruction length code. Unrecognizable instruction codes are indicated by a series of asterisks. A minimum of 1 instruction and a maximum of 5 instructions are dumped per line. The storage key is displayed on the first line of a request and at every page boundary.

Response 5:

```
thexloc stringhexadecimaldata [key] [Rhexloc]
```

is the response you receive for the S option. The storage key is displayed on the first line of a request and at every page boundary.

Response 6:

```
thexloc1 TO hexloc2 KEY = key
```

is the response you receive for the K option. The values *hexloc1* and *hexloc2* are storage locations, and *key* is the associated storage key for *hexloc1*. A response is dumped for every contiguous address range that has unique storage keys, and whenever a segment boundary is crossed.

Response 7:

The PSW is used to resolve a logical address. A PSW that is not valid causes the current request to be rejected, and processing continues with the next request (if any) on the command line. In all cases, a reset PSW (all-zero) is accepted. The rejected operands are displayed along with a response indicating that the PSW is not valid. The response is:

```
addr is not addressable because of an invalid PSW.
```

where *addr* is the rejected operand or operands; it specifies an address space and a storage location within that address space.

Response 8:

The dynamic address translation (DAT) process uses the segment table designator (ASCE) to convert a third-level address to a second-level address (storage that appears real to your virtual machine). The translation process may generate one of several exceptions, identifying why one or more pages of storage are not addressable. A range of rejected storage addresses are displayed along with a response indicating the nature of the exception condition. The responses are:

```
thexloc1 to hexloc2 nonaddressable storage
- protection exception
thexloc1 to hexloc2 nonaddressable storage
- addressing exception
thexloc1 to hexloc2 nonaddressable storage
- segment translation exception
thexloc1 to hexloc2 nonaddressable storage
- page translation exception
thexloc1 to hexloc2 nonaddressable storage
- translation specification exception
thexloc1 to hexloc2 nonaddressable storage
- ASCE type exception
thexloc1 to hexloc2 nonaddressable storage
- region-first-translation exception
thexloc1 to hexloc2 nonaddressable storage
- region-second-translation exception
thexloc1 to hexloc2 nonaddressable storage
- region-third-translation exception
```

where *hexloc1* is the starting address and *hexloc2* the ending address of the non-addressable storage. The addresses take into account basing, indexing, and wrapping and are padded to 8 digits.

Response 9:

If your request includes a request to dump identical lines, you receive the following response:

```
thexloc1 TO hexloc2 SUPPRESSED LINE(S) SAME AS ABOVE ...
```

Response 10:

```
DUMPING LOC thexloc
```

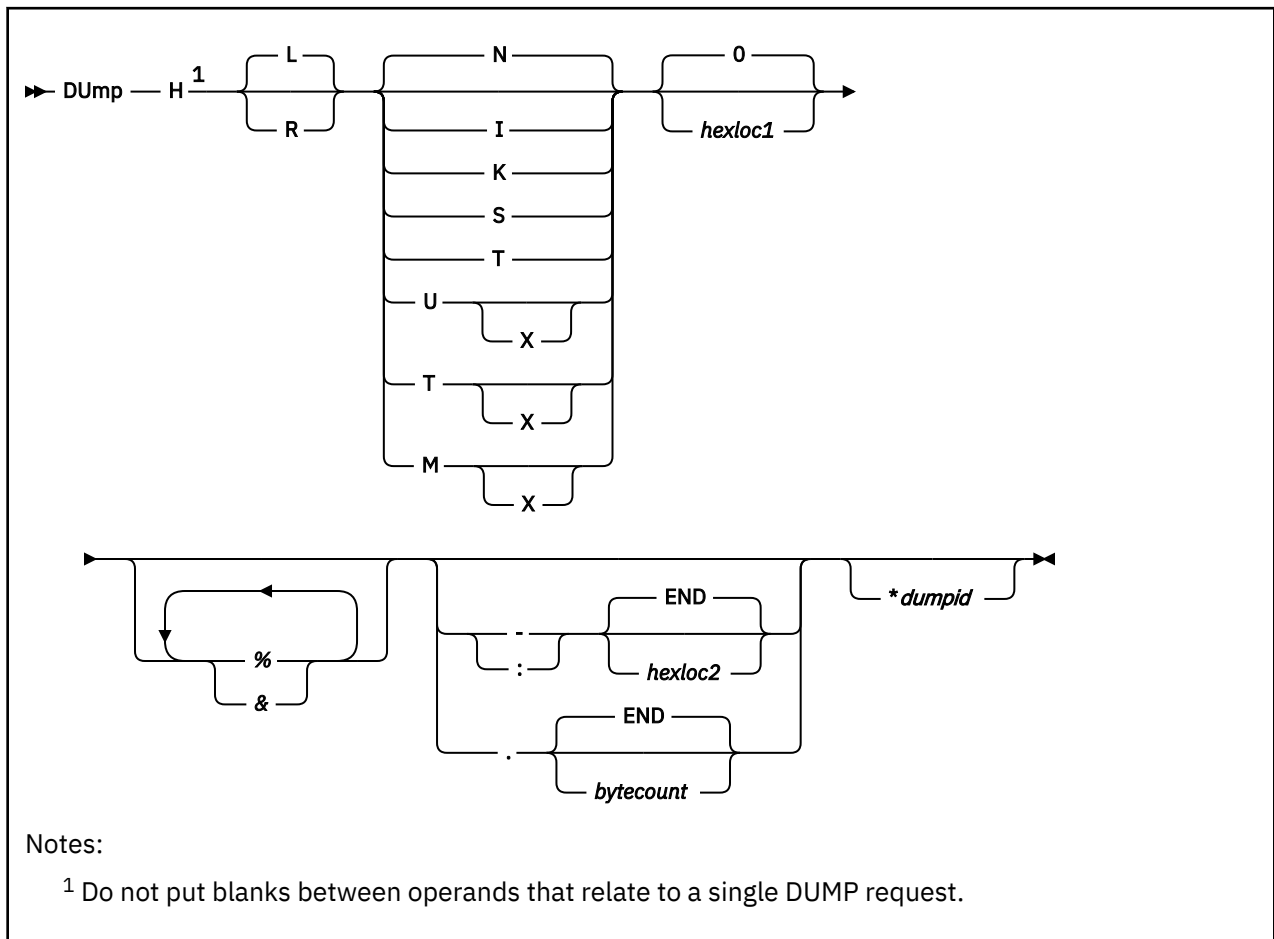

is sent to your console to indicate that a segment boundary has been reached. Each segment boundary location has an address that ends in X'00000'. The value *hexLoc* identifies the storage boundary reached.

Response 11:

```
Command complete
```

is issued when the command completes successfully.

## DUMP (Host Storage)

### Authorization

Privilege Class: C, E

### Purpose

Use DUMP (Host Storage) to dump the contents of host (first-level) storage to your virtual printer.

### Operands

**L**

specifies that host logical storage addresses are to be dumped. Host logical storage consists of 4 KB pages where each page boundary has an address that ends in X'000'. This is the default.

**R**

specifies that host real storage addresses are to be dumped. Host real storage consists of 4 KB frames where each frame boundary has an address that ends in X'000'.

**N**

.dumps the contents of storage in hexadecimal without character translation. This is the default. Storage is dumped in word segments. An address range is dumped starting at the fullword in which the specified address resides. Storage is dumped in fullword increments.

The storage key is included on the first line and at every page or frame boundary.

**I**

dumps the contents of storage in instruction format. The specified address is rounded down to the nearest halfword boundary.

The storage key is included on the first line and at every page or frame boundary.

**K**

dumps the storage keys in hexadecimal for all frames or partial frames included in the specified address range. If you are dumping host logical storage addresses, these are storage keys for the backing frames in host real storage.

**S**

dumps the contents of storage in hexadecimal translation. Storage is dumped as a string starting at the location specified. The specified address range is not boundary-aligned.

The storage key is included on the first line and at every page or frame boundary.

**T**

dumps the contents of storage in hexadecimal and character form. Storage is dumped in word segments. An address range is dumped starting at the X'10'-byte boundary in which the specified address resides. The hexadecimal words are followed by the storage as an EBCDIC string, or as an ASCII string if the X option is specified.

The storage key is included on the first line and at every page or frame boundary.

**U**

dumps the contents of storage in character form. Storage is dumped starting at the address specified as an EBCDIC string, or as an ASCII string if the X option is specified. The specified address range is not boundary-aligned.

The storage key is included on the first line and at every page or frame boundary.

**M**

dumps the contents of storage in hexadecimal and character form. A header is included as the first line and at every page or frame boundary. It contains the high-order 32 bits of the 64-bit address along with the storage key. Storage is dumped in word segments. An address range is dumped starting at the X'10' byte boundary in which the specified address resides. The hexadecimal output is followed by the storage as an EBCDIC string, or as an ASCII string if the X option is specified.

**0*****hexloc1***

is the starting storage location that is to be dumped. The address *hexloc1* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. The default is 0.

Storage locations and the minimum amount dumped are rounded according to the following conventions in hexadecimal:

Option	Start	Minimum Length
T	10	10
M	10	10
K	800	800
S	1	1
I	2	2 - 6 depending on the instruction
N	4	4
U	1	1

**%**

indicates 31-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 31 bits at the specified address (the high-order bit is turned off) are used as the new address for the DUMP command.

**&**

indicates 64-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 64 bits at the specified address are used as the new address for the DUMP command.

**-hexloc2**

**:hexloc2**

**-END**

**:END**

is the last of the range of hexadecimal storage locations whose contents are to be dumped. If specified, *hexloc2* must be equal to or greater than *hexloc1* and must be within the bounds of addressable storage (see usage note “3” on page 426). The address *hexloc2* may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. A colon (:) means the same as a dash (-) when you are specifying a range of addresses.

Specify END if you want to dump the remaining contents of storage. END is the default if you specify a dash (-) or a colon (:) without an address.

**.bytecount**

**.END**

is a hexadecimal integer designating the number of bytes of storage (starting with the byte at *hexloc1*) to be dumped. If specified, the *bytecount* must have a value of at least 1 and may be from 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. The sum of *hexloc1* and *bytecount* must be an address within the bounds of addressable storage (see usage note “3” on page 426).

Specify END if you want to dump the remaining contents of storage. END is the default if you specify a period (.) without a byte count value.

**\*dumpid**

is an asterisk followed by a 1-character to 97-character identifier (truncated to 80 characters for a z/Architecture guest), that is to be assigned to the dump. If specified, *dumpid* must be the last operand you enter on the command line.

## Usage Notes

1. While dumping host storage, the running of a virtual machine or someone using the STORE (Host Storage) command could cause data to be changed. This could create an inconsistency in the data that is viewed.
2. In a multiprocessor environment, each processor has a prefix register that it uses to relocate addresses between 0 and X'1FFF' (an 8 KB area known as the prefix area) to two other contiguous frames in real storage. The prefix register enables each processor to use a different prefix area to avoid conflict with other processors for such activity as interrupt code recording. Thus, the range 0 through X'1FFF' refers to different areas of storage, depending on which processor generates the address. All references to first-level storage are handled as if they were made on the IPL processor. Because those locations in the system execution space are identity-mapped, addresses in the range 0 through X'1FFF' have the same content in DUMP HL output and DUMP HR output.
3. For host logical storage (the system execution space), addressable storage includes the system execution area, which resides below 2 GB, plus the system frame table and the system execution space page management table, which reside above 2 GB. To display the storage address ranges used for the system execution space, issue the QUERY SXSSTORAGE command. The address range that you specify on the DUMP command must start and end in the same address range of the system execution space. If the END operand is specified (or allowed to default), it refers to the end of the range in which the starting address is located.

For host real storage, addressable storage is the lesser of CP's configured storage size (if specified at system generation) and the real machine storage size. To display the size of host real storage, issue the QUERY STORAGE command.

4. When dumping host logical storage, if you specify an address that is not backed with a real storage frame, error message HCP6151E is issued, even if the address is included in the ranges of in-use and usable addresses displayed by the QUERY SXSSORAGE command.
5. If you use an underscore, it must be followed by 8 hexadecimal digits.
6. For more information, see [“Usage Notes” on page 395](#).

## Responses

### Notes:

1. The variable *hexloc* represents a hexadecimal storage address. The variables *hexlochi* and *hexloclo* represent the high-order 32 bits and low-order 32 bits of a 64-bit hexadecimal storage address.
2. The character displayed for the variable *t* in the string *Hthexloc* indicates the type of storage:
  - L indicates host logical storage.
  - R indicates host real storage.
3. In responses that include host logical storage, an *Rhexloc* trailer shows the host real storage address that corresponds to the host logical storage address. The trailer is displayed on the first line of a range and at every page boundary.
4. Responses 8 and 9 appear on your display screen.

### Response 1:

```
Hthexloc word1 word2 word3 word4 [key] [*TRANSLATION*] [Rhexloc]
```

is the response you receive for the T or N option. The translation is dumped only if you have also entered the T option and is in either EBCDIC or (if the TX option is specified) ASCII. The storage key is dumped on the first line, and at every page or frame boundary.

### Response 2:

```
Hthexlochi_ Storage Key - [key]  
hexloclo word1 word2 word3 word4 [*TRANSLATION*] [Lhexloc] [Rhexloc]
```

is the response you receive for the M option. The translation is displayed in either EBCDIC or (if the MX option is specified) ASCII. The storage key is displayed on the first line, and at every page or frame boundary.

### Response 3:

```
Hthexloc *TRANSLATION* [key] [Rhexloc]
```

is the response you receive for the U option. The value *hexloc* is the location of the first data byte to be dumped. A minimum of 1 character and a maximum of 64 characters are dumped per line. The contents of storage are dumped in translated form and are in either EBCDIC or (if the UX option is specified) ASCII. Periods represent unprintable characters. The storage key is dumped on the first line and at every page or frame boundary.

### Response 4:

```
Hthexloc mnemonic1 x-x ... mnemonic5 x-x [key] [Rhexloc]
```

is the response you receive for the I option. The value *hexloc* is the location of the first instruction to be dumped. The value *mnemonic* is a character representation of the instruction code; this is a 7-character field in which the mnemonic is left-justified. The expression *x-x* is the actual hexadecimal contents of storage and is 2, 4, or 6 bytes as determined by the instruction length code. Unrecognizable instruction

## DUMP (Host Storage)

codes are indicated by a series of asterisks. A minimum of 1 instruction and a maximum of 5 instructions are dumped per line. The storage key is dumped on the first line and at every page or frame boundary.

Response 5:

```
Hthexloc stringhexadecimaldata [key] [Rhexloc]
```

is the response you receive for the S option. The storage key is dumped on the first line and at every page or frame boundary.

Response 6:

```
Hthexloc1 to hexloc2 KEY = key
```

is the response you receive for the K option. The values *hexloc1* and *hexloc2* are storage locations and *key* is the associated storage key for *hexloc1*. You receive this response for every contiguous address range that has unique storage keys, and whenever a segment boundary is crossed.

Response 7:

If your request includes a request to dump one or more lines identical with the previous line, you receive the following response:

```
Hthexloc1 to hexloc2 suppressed line(s) same as above ...
```

Response 8:

```
dumping LOC Hthexloc
```

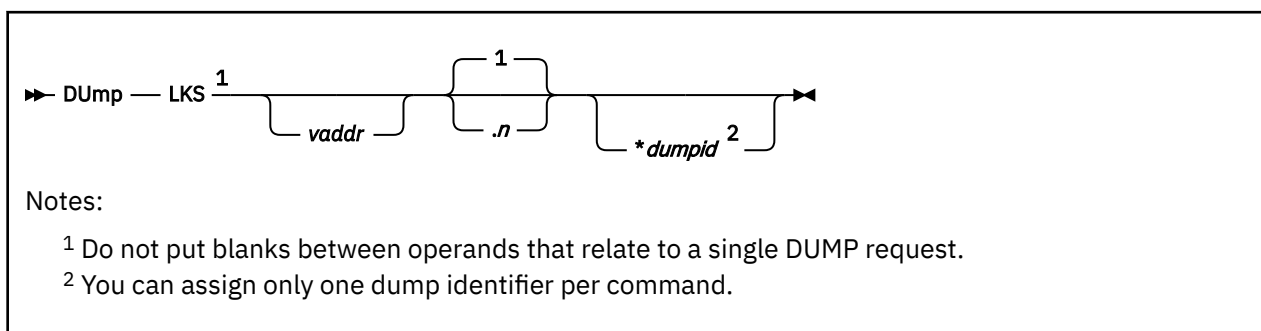

is sent to your console display screen to indicate that a segment boundary has been reached. Each segment boundary has an address that ends in X'00000'.

Response 9:

```
Command complete
```

is sent to your console display screen when the command completes successfully.

## DUMP LKS

### Authorization

Privilege Class: G

### Purpose

Use DUMP LKS to dump the state entries of the guest linkage stack.

### Operands

#### *vaddr*

dumps the branch or program-call linkage-stack state entry that contains the specified guest virtual address within the current home address space designated by guest control register 13. The default is the current linkage-stack state entry pointed to by guest control register 15.

#### **1**

#### *n*

is a decimal number, up to eight digits, specifying the number of branch and program-call linkage-stack state entries to be dumped. The dump starts with the specified/current entry and moves back toward the first entry on the linkage-stack. The default is 1, and 0 is treated as 1.

#### **\*dumpid**

is an asterisk followed by a 1-character to 97-character identifier that is to be assigned to the dump (may be truncated to 80 characters for a z/Architecture guest). If specified, *\*dumpid* must be the last operand you enter on the command line.

### Usage Notes

1. This command is valid only if the virtual machine is an ESA virtual machine.
2. The *first* linkage-stack state entry is the oldest state entry (the first one put on the stack). The *last* linkage-stack state entry is the current state entry (the most recent one put on the stack).
3. Unlike other DUMP command operands, using LKS does not define the default for subsequent operands of the current DUMP function.
4. The virtual address specified in *vaddr* must fall within the branch or program-call linkage-stack state entry, including the first and last bytes of the linkage-stack state entry.
5. A linkage-stack state entry is an entry on the linkage stack that describes the environment in an address space (such as access registers, general-purpose registers and PSWs).
6. For more information, see [“Usage Notes” on page 395](#).

## Responses

Heading	Description
ED-ADDR	The linkage-stack-entry description address, a guest home virtual address represented as eight hexadecimal digits (16 hexadecimal digits for a z/Architecture guest).
U	The unstack-suppression bit, either 0 or 1
ET	The entry type, either BRN for a branch state entry or PRC for a program-call state entry.
SI	The section identification, represented as two hexadecimal digits.
RFS	The remaining free space, represented as four hexadecimal digits.
NES	The next-entry size, represented as four hexadecimal digits.
PKM	The PSW-key mask, represented as four hexadecimal digits.
SASN	The secondary ASN, represented as four hexadecimal digits.
EAX	The extended authorization index, represented as four hexadecimal digits.
PASN	The primary ASN, represented as four hexadecimal digits.
PSW	The program-status word, represented as 16 hexadecimal digits (32 hexadecimal digits for a z/Architecture guest).
A	The addressing mode, which may be either a 0 or 1 for an ESA/390 mode guest or 24, 31, or 64 for a z/Architecture guest.
B-ADDR	The branch address, represented as eight hexadecimal digits.
MOD-AREA	The modifiable area, represented as 16 hexadecimal digits.
PC-NUM	The program call number, represented as eight hexadecimal digits.
CSID	The called-space identification, if any, represented as eight hexadecimal digits.
SINST	Secondary ASTE instance number, if any, represented as eight hexadecimal digits.
PIINST	Primary ASTE instance number, if any, represented as eight hexadecimal digits.
GPR	General purpose register, represented as eight hexadecimal digits.
GRG	General purpose register for z/Architecture guests, represented as 16 hexadecimal digits.
AR	Access register, represented as eight hexadecimal digits.

### Response 1:

The linkage-stack entry for an ESA/390 branch state entry has the following format:

```

ED-ADDR  U  ET  SI  RFS  NES  PKM  SASN  EAX  PASN
nnnnnnnn n  BRN nn  nnnn  nnnn  nnnn  nnnn  nnnn  nnnn

          PSW          A  B-ADDR          MOD-AREA
nnnnnnnn nnnnnnnn  n  nnnnnnnn  nnnnnnnnnnnnnnnn

GPR  0 = greg0  greg1  greg2  greg3
GPR  4 = greg4  greg5  greg6  greg7
GPR  8 = greg8  greg9  greg10 greg11
GPR 12 = greg12 greg13 greg14 greg15

AR   0 = areg0  areg1  areg2  areg3
AR   4 = areg4  areg5  areg6  areg7
AR   8 = areg8  areg9  areg10 areg11
AR  12 = areg12 areg13 areg14 areg15

```

The headings in this response are described under “Responses”.

Response 2:

The linkage-stack entry for a z/Architecture branch state entry has the following format:

```

ED-ADDR      U  ET  SI  RFS  NES  PKM  SASN  EAX  PASN
nnnnnnnnnn  n  BRN  nn  nnnn  nnnn  nnnn  nnnn  nnnn  nnnn

                PSW                      A          B-ADDR
nnnnnnnn  nnnnnnnn  nnnnnnnn  nnnnnnnn  nn  nnnnnnnnnnnnnnnnn

                MOD-AREA      SINST      PINST
nnnnnnnnnnnnnnnnnn  nnnnnnnn  nnnnnnnn

GRG  0 = greg0          greg1
GRG  2 = greg2          greg3
GRG  4 = greg4          greg5
GRG  6 = greg6          greg7
GRG  8 = greg8          greg9
GRG 10 = greg10         greg11
GRG 12 = greg12         greg13
GRG 14 = greg14         greg15

AR   0 = areg0  areg1  areg2  areg3
AR   4 = areg4  areg5  areg6  areg7
AR   8 = areg8  areg9  areg10 areg11
AR  12 = areg12 areg13 areg14 areg15

```

The headings in this response are described under “Responses”.

ED-ADDR and B-ADDR can be either 32 or 64 bits.

Response 3:

The linkage-stack entry for an ESA/390 program call state entry has the following format:

```

ED-ADDR  U  ET  SI  RFS  NES  PKM  SASN  EAX  PASN
nnnnnnnn  n  PRC  nn  nnnn  nnnn  nnnn  nnnn  nnnn  nnnn

                PSW      PC-NUM      MOD-AREA      CSID
nnnnnnnnn  nnnnnnnn  nnnnnnnnnnnnnnnnn  nnnnnnnnn

GPR  0 = greg0  greg1  greg2  greg3
GPR  4 = greg4  greg5  greg6  greg7
GPR  8 = greg8  greg9  greg10  greg11
GPR 12 = greg12  greg13  greg14  greg15

AR   0 = areg0  areg1  areg2  areg3
AR   4 = areg4  areg5  areg6  areg7
AR   8 = areg8  areg9  areg10  areg11
AR  12 = areg12  areg13  areg14  areg15

```

The headings in this response are described under “Responses”.

Response 4:

The linkage-stack entry for a z/Architecture program call state entry has the following format:

```

ED-ADDR      U  ET  SI  RFS  NES  PKM  SASN  EAX  PASN
nnnnnnnnnn  n  PRC  nn  nnnn  nnnn  nnnn  nnnn  nnnn  nnnn

                PSW                      PC-NUM
nnnnnnnnn  nnnnnnnn  nnnnnnnnnnnnnnnnn

                MOD-AREA      CSID      SINST      PINST
nnnnnnnnnnnnnnnnnn  nnnnnnnn  nnnnnnnn  nnnnnnnn

GRG  0 = greg0          greg1
GRG  2 = greg2          greg3
GRG  4 = greg4          greg5
GRG  6 = greg6          greg7
GRG  8 = greg8          greg9
GRG 10 = greg10         greg11
GRG 12 = greg12         greg13
GRG 14 = greg14         greg15

AR   0 = areg0  areg1  areg2  areg3
AR   4 = areg4  areg5  areg6  areg7

```

```
AR 8 = areg8 areg9 areg10 areg11
AR 12 = areg12 areg13 areg14 areg15
```

The headings in this response are described under “Responses”.

ED-ADDR can be either 32 or 64 bits.

Response 5:

If a guest virtual address from the home address space cannot be converted to a host address, the translation process generates one of several exceptions, identifying the first page that was not addressable. The responses are:

```
Vhexloc1 to hexloc2 nonaddressable storage
- protection exception
Vhexloc1 to hexloc2 nonaddressable storage
- addressing exception
Vhexloc1 to hexloc2 nonaddressable storage
- segment translation exception
Vhexloc1 to hexloc2 nonaddressable storage
- page translation exception
Vhexloc1 to hexloc2 nonaddressable storage
- translation specification exception
```

The operand *Vhexloc1* is the starting address and *hexloc2* is the ending address of the nonaddressable storage.

Response 6:

If a state entry that is neither a branch nor a program-call is reached, the following response is issued:

```
Vhexloc1 to hexloc2 are linkage stack state entries that are
not branch or program-call.
```

The operand *Vhexloc1* is the starting address and *hexloc2* the ending address of the block of contiguous state entries in a linkage stack section that are not branch or program calls.

Response 7:

```
The linkage stack is empty.
```

is issued if the linkage stack is empty.

Response 8:

```
Virtual address hexloc is not within a linkage
stack branch state entry or a program-call state entry.
```

is issued if the specified guest virtual address is not within a branch or program-call state entry. The operand *Hexloc* is the guest virtual address specified on the command line. Header and trailer state entries are not displayed.

Response 9:

```
The first state entry in the linkage stack has been reached.
```

is issued if the bottom of the stack is reached during command processing.

## DUMP PREFIX

### Authorization

Privilege Class: G

### Purpose

Use DUMP PREFIX to send prefix register contents to your virtual printer.

### Operands

#### *\*dumpid*

identifies a 1- to 97-character string that is to be assigned to the dump. If specified, *\*dumpid* must be the last operand you enter on the command line.

### Usage Notes

1. The prefix register contains the absolute location of guest page 0.
2. For more information, see [“Usage Notes” on page 395](#).

### Responses

Response 1:

```
PREFIX = xxxxxxxx
```

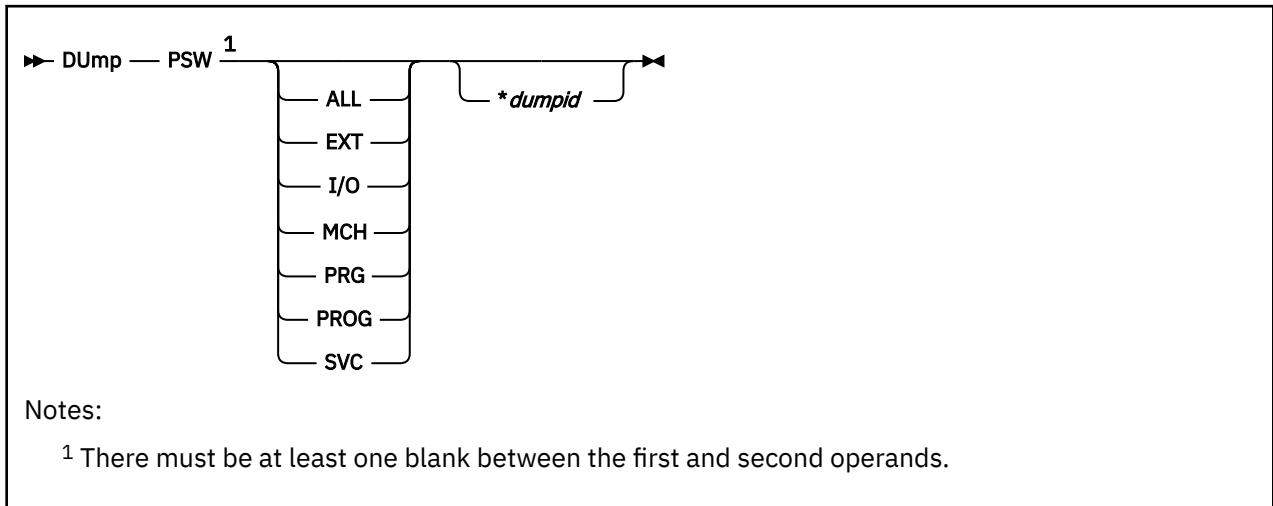

is the hexadecimal content of the prefix register.

Response 2:

```
Command complete
```

is issued when the command completes successfully.

## DUMP PSW

### Authorization

Privilege Class: G

### Purpose

Use DUMP PSW to send the program status word to your virtual printer.

### Operands

#### ALL

dumps the current values and appropriate interrupt information for the current PSW and all old and new interrupt PSWs (except restart).

#### EXT

#### I/O

#### MCH

#### PRG

#### PROG

#### SVC

dumps the current values and appropriate interrupt information for both the new and old PSWs specified—that is, SVC, program check, machine check, I/O, and external.

#### *\*dumpid*

identifies a 1-character to 97-character string that is to be assigned to the dump (may be truncated to 80 characters for a z/Architecture guest). If specified, *\*dumpid* must be the last operand you enter on the command line.

### Usage Notes

1. The DUMP PSW command is valid for a z/Architecture virtual machine only if SET PSWTRANS (with ALL or DISPLAY option) has been issued previously.
2. DUMP PSW ALL dumps the PSW as a 128-bit PSW for z/Architecture and z/XC virtual machines.
3. z/Architecture and z/XC expands the PSW to 128 bits to accommodate 64-bit instruction addresses. The expanded PSWs are referenced in the command output as "PSWG".

4. The SET PSWTRANS command formats the 128-bit PSWs from a z/Architecture or z/XC virtual machine to the 64-bit format that can be displayed and manipulated in an ESA/390 or ESA/XC virtual machine.

When the SET PSWTRANS and DUMP PSW commands are issued from a z/Architecture or z/XC virtual machine, the 128-bit format PSW is converted to a 64-bit format PSW by the following changes:

- Bit 12 of the 64-bit PSW is set to 1.
- Bit 31 of the 64-bit PSW is set to 0.
- Bits 0-11 and 13-30 of the 64-bit PSW are set to the value of the corresponding bits of the 128-bit PSW.
- Bits 33-63 of the 64-bit PSW are set to bits 97-127 of the 128-bit PSW.
- If bits 64-95 of the 128-bit PSW are not 0, then the PSW is flagged as non-translatable.
- Bit 32 is set as follows:
  - If bits 31 and 32 of the 128-bit PSW are both 1, then the PSW is flagged as non-translatable.
  - If bits 31 and 32 of the 128-bit PSW are both 0, then bit 32 of the 64-bit PSW is set to 0.
  - If bit 31 of the 128-bit PSW is 0 and bit 32 is 1, then bit 32 of the 64-bit PSW is set to 1.

## Responses

The response to all DUMP options is "Command complete". What follows is a description of the dump information in the generated print file.

Response 1:

The command DUMP PSW with no other options formats the current PSW for a print file. This is the response you receive on ESA/XC and ESA/390 virtual machines:

```
PSW = 03E40000 8003010C
```

Response 2:

The command DUMP PSW with no other options formats the current PSW for a print file. This is the response that you receive on z/Architecture and z/XC virtual machines:

```
PSW = 03EC0000 8003010C  PSWG = 03E40000 80000000 00000000 0003010C
```

Response 3:

The command DUMP PSW with no other options formats the current PSW for a print file. If the current PSW for a guest machine cannot be converted to a 64-bit PSW, then this is the response you receive on z/Architecture virtual machines:

```
PSW = NON TRANSLATABLE  PSWG = 03E40000 80000000 00000000 0003010C
```

Response 4:

The command DUMP PSW ALL formats the old and new PSWs and expands the interruption code into four hexadecimal digits in front of the old PSWs. *nnnn* represents the EC-mode interruption code. The numbers 18, 20, 28... are storage locations. Each *xxxxxxx xxxxxxxx* represents the content of a PSW. This is the response you receive on ESA/XC and ESA/390 virtual machines:

```
PSW = xxxxxxxx xxxxxxxx
EXT nnnn 18 OLD xxxxxxxx xxxxxxxx 58 NEW xxxxxxxx xxxxxxxx
SVC nnnn 20 OLD xxxxxxxx xxxxxxxx 60 NEW xxxxxxxx xxxxxxxx
PRG nnnn 28 OLD xxxxxxxx xxxxxxxx 68 NEW xxxxxxxx xxxxxxxx
MCH nnnn 30 OLD xxxxxxxx xxxxxxxx 70 NEW xxxxxxxx xxxxxxxx
I/O nnnn 38 OLD xxxxxxxx xxxxxxxx 78 NEW xxxxxxxx xxxxxxxx
```

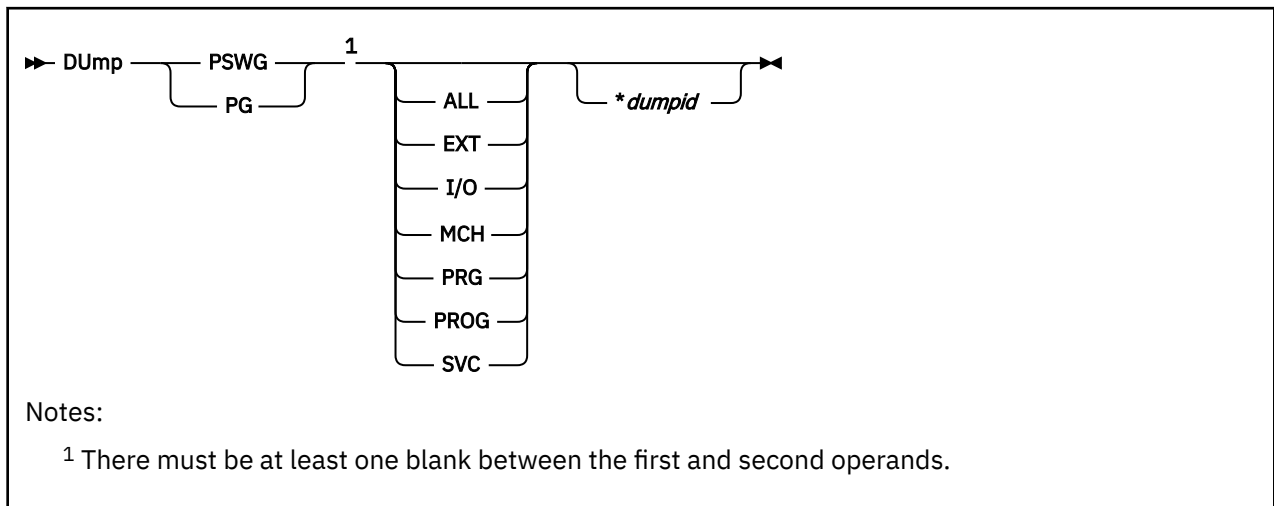

Response 5:

## DUMP PSW

The command DUMP PSW ALL formats the old and new PSWs and expands the interruption code into four hexadecimal digits in front of the old PSWs. *nnnn* represents the interruption code. The numbers 130, 140, 150, ... are storage locations. Each *xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx* represents the content of a PSW. This is the response that you receive on z/Architecture and z/XC virtual machines:

```
PSW = 03EC0000 8003010C   PSWG = 03E40000 80000000 00000000 0003010C
EXT nnnn 130 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
      1B0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
SVC nnnn 140 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
      1C0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
PRG nnnn 150 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
      1D0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
MCH nnnn 160 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
      1E0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
I/O nnnn 170 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
      1F0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
```

## DUMP PSWG

### Authorization

Privilege Class: G

### Purpose

Use DUMP PSWG to send the program status word of your z/Architecture or z/XC virtual machine to your virtual printer.

### Operands

#### ALL

dumps the current values and appropriate interrupt information for the current PSW and all old and new interrupt PSWs (except restart).

#### EXT

#### I/O

#### MCH

#### PRG

#### PROG

#### SVC

dumps the current values and appropriate interruption information for both the new and old PSWs specified—that is, SVC, program check, machine check, I/O, or external.

#### *\*dumpid*

identifies a 1- to 80-character string that is to be assigned to the dump. If specified, *\*dumpid* must be the last operand you enter on the command line.

### Usage Notes

1. To dump the PSW for an ESA/390 or ESA/XC virtual machine, use the DUMP PSW command.

### Responses

The response to all DUMP options is "Command complete". What follows is a description of the dump information in the generated print file.

Response 1:

## DUMP PSWG

The command DUMP PSWG with no other options formats the current PSW for a print file.

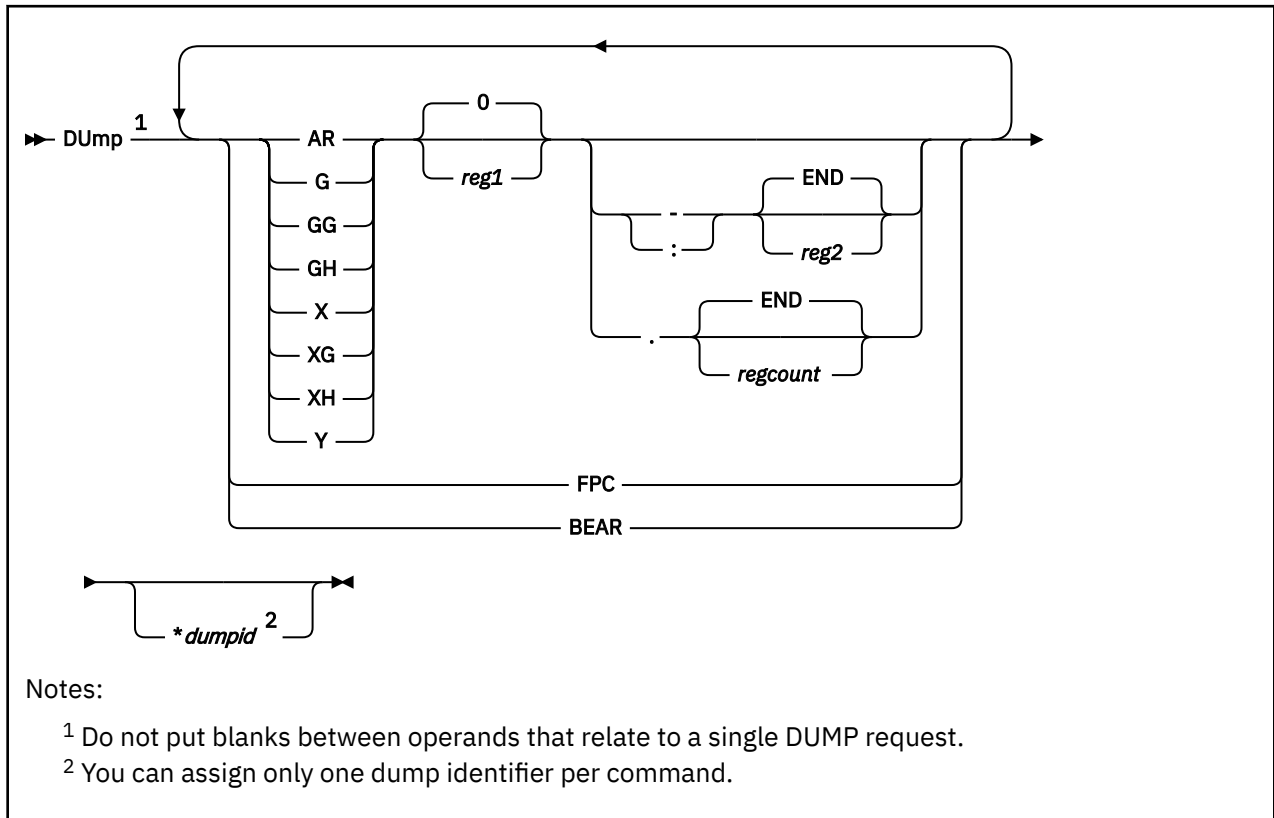

```
PSW = 03E40000 80000000 00000000 0003010C
```

Response 2:

The command DUMP PSWG ALL formats the old and new PSWs and expands the interruption code into four hexadecimal digits in front of the old PSWs. *nnnn* represents the interruption code. The numbers 130, 140, 150, ... are storage locations. Each *xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx* represents the content of a PSW.

```
PSW = 03E40000 80000000 00000000 0003010C
EXT nnnn 130 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
      1B0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
SVC nnnn 140 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
      1C0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
PRG nnnn 150 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
      1D0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
MCH nnnn 160 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
      1E0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
I/O nnnn 170 OLD xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
      1F0 NEW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
```

## DUMP (Registers)

### Authorization

Privilege Class: G

### Purpose

Use DUMP (Registers) to dump the following types of registers to your virtual printer:

- Access
- Control
- Floating-point
- Floating-point control
- General-purpose

### Operands

**0**

#### **AR***reg1*

is a decimal number from 0 to 15 or a hexadecimal integer from 0 to F representing the first, or only, access register whose contents are to be dumped to your virtual printer. If you specify AR without a register number, the contents of all the access registers are dumped.

#### **G***reg1*

G indicates a full register for an ESA/390 or ESA/XC guest or the low half of the register for a z/Architecture or z/XC guest. *reg1* is a decimal number from 0 to 15 or a hexadecimal integer from 0 to F representing the first, or only, general register whose contents are to be dumped to your virtual

## DUMP (Registers)

printer. If you specify G without a register number, the appropriate contents of all the general registers are dumped.

### **GGreg1**

GG indicates a full register (32 bits for an ESA/390 or ESA/XC guest, 64 bits for a z/Architecture or z/XC guest). *reg1* is a decimal number from 0 to 15 or a hexadecimal integer from 0 to F representing the first, or only, general register whose contents are to be dumped to your virtual printer. If you specify GG without a register number, the appropriate contents of all the general registers are dumped.

### **GHreg1**

GH indicates the upper half of a register for a z/Architecture or z/XC guest. This option is not valid for an ESA/390 or ESA/XC guest. *reg1* is a decimal number from 0 to 15 or a hexadecimal integer from 0 to F representing the first, or only, general register whose contents are to be dumped to your virtual printer. If you specify GH without a register number, the high halves of all of the general registers are dumped.

### **Xreg1**

X indicates a full control register for an ESA/390 or ESA/XC guest or the low half of the control register for a z/Architecture or z/XC guest. *reg1* is a decimal number from 0 to 15 or a hexadecimal number from 0 to F representing the first, or only, control register whose contents are to be dumped to your virtual printer. If you specify X without a register number, the appropriate contents of all the control registers are dumped.

### **XGreg1**

XG indicates a full register (32 bits for an ESA/390 or ESA/XC guest, 64 bits for a z/Architecture or z/XC guest). *reg1* is a decimal number from 0 to 15 or a hexadecimal number from 0 to F representing the first, or only, control register whose contents are to be dumped to your virtual printer. If you specify XG without a register number, the appropriate contents of all the control registers are dumped.

### **XHreg1**

XH indicates the upper half of a register for a z/Architecture or z/XC guest. This option is not valid for an ESA/390 or ESA/XC guest. *reg1* is a decimal number from 0 to 15 or a hexadecimal number from 0 to F representing the first, or only, control register whose contents are to be dumped to your virtual printer. If you specify XH without a register number, the high halves of all of the control registers are dumped.

### **Yreg1**

*reg1* is a decimal number from 0 to 15, or a hexadecimal number from 0 to F, representing the first, or only, floating-point register whose contents are to be dumped. If you specify Y without a register number, the contents of all the floating-point registers are dumped.

### **FPC**

FPC dumps the contents of the floating-point register.

### **BEAR**

BEAR dumps the contents of the breaking-event-address register if the PER-3 facility is available.

### **: END**

#### **- reg2**

*reg2* is a number of the last register whose contents are to be dumped. You must specify the dash (-) or colon (:) when you are requesting more than one register by register number. You must specify the range of registers in ascending order. Therefore, the value you specify for *reg2* must be equal to or greater than the value you specify for *reg1*.

The colon (:) means the same as a dash (-) when you are specifying a range of addresses.

If you specify AR, G, GG, GH, X, XG, XH, or Y, *reg2* may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F. The contents of register 1 through register 2 are dumped to your virtual printer.

Specify END to dump the contents of all remaining registers. END is the default.

**END****. regcount**

*regcount* is a decimal number from 1 to 16 or a hexadecimal number from 1 to F specifying the number of registers (starting with register 1) whose contents are to be dumped. If you specify AR, G, GG, GH, X, XG, XH, or Y, *regcount* can be a decimal number from 1 to 16 or a hexadecimal number from 1 to F.

The sum of *reg1* and *regcount* must be a number that does not exceed the maximum register number for the type of registers being dumped.

Specify END to dump the contents of all remaining registers. END is the default.

**\*dumpid**

is an asterisk followed by a 1- to 97- character identifier that is to be assigned to the dump (may be truncated to 80 characters for a z/Architecture guest). If specified, *\*dumpid* must be the last operand you enter on the command line.

**Usage Notes**

1. The G and X operands are valid for an ESA/390, ESA/XC, z/Architecture, or z/XC guest. For an ESA/390 or ESA/XC guest, these operands refer to the full four-byte register. For a z/Architecture or z/XC guest, these operands refer to the low-order four bytes of the full eight-byte register.
2. The GG and XG operands are valid for an ESA/390, ESA/XC, z/Architecture, or z/XC guest. For an ESA/390 or ESA/XC guest, these operands refer to the full four-byte register. For a z/Architecture or z/XC guest, these operands refer to the full eight-byte register.
3. The GH and XH operands are valid only for a z/Architecture or z/XC guest. These operands refer to the high-order four bytes of the full eight-byte register.
4. When a dash (-), colon (:), or period (.) is not preceded by a register number, the first register number defaults to 0. When a dash, colon, or period is not followed by a register number, the last register defaults to END.
5. For more information, see [“Usage Notes” on page 395](#).

**Responses**

Response 1:

Dump Register

```
GPR nn = genreg0 genreg1 genreg2 genreg3
```

is the response that is sent to the virtual printer when you dump the general registers using *D G* or *D GG* from an ESA/390 or ESA/XC guest. *nn* indicates the first (or only) register whose contents are dumped.

The content of each register is dumped in hexadecimal. Up to four registers per line are dumped for each range you specify. If required, multiple lines are dumped to a maximum of four lines.

Response 2:

```
HCPCDE6150E An option has been specified that is not valid in
ESA/390 mode.
```

is the response you receive when you dump general registers using *D GH* from an ESA/390 guest (an appropriate message will be issued from an ESA/XC guest).

Response 3:

Dump Register

```
GPR nn = genreg0l genreg1l genreg2l genreg3l
```

is the response that is sent to the virtual printer when you dump the general registers using *D G* from a z/Architecture or z/XC guest. *nn* indicates the first (or only) register whose contents are dumped.

## DUMP (Registers)

The content of each register is dumped in hexadecimal and represents the low half of the full 64-bit register. Up to four registers per line are dumped for each range you specify. If required, multiple lines are dumped to a maximum of four lines.

Response 4:

Dump Register

```
GRG nn = genreg0hgenreg0l genreg1hgenreg1l
```

is the response that is sent to the virtual printer when you dump the general registers using *D GG* from a z/Architecture or z/XC guest. *nn* indicates the first (or only) register whose contents are dumped.

The content of each register is dumped in hexadecimal and represents the full 64-bit register. Up to two registers per line are dumped for each range you specify. If required, multiple lines are dumped to a maximum of eight lines.

The high and low halves of each register may be separated by an optional underscore for readability. To have the underscore displayed, use the SET UNDERSCORE command.

Response 5:

Dump Register

```
GRH nn = genreg0h genreg1h genreg2h genreg3h
```

is the response that is sent to the virtual printer when you dump the general registers using *D GH* from a z/Architecture or z/XC guest. *nn* indicates the first (or only) register whose contents are dumped.

The content of each register is dumped in hexadecimal and represents the high half of the full 64-bit register. Up to four registers per line are dumped for each range you specify. If required, multiple lines are dumped to a maximum of four lines.

Response 6:

Dump Register

```
ECR nn = ctlreg0 ctlreg1 ctlreg2 ctlreg3
```

is the response that is sent to the virtual printer when you dump the control registers using *D X* or *D XG* from an ESA/390 or ESA/XC guest. *nn* indicates the first (or only) register whose contents are dumped.

The content of each register is dumped in hexadecimal. Up to four registers per line are dumped for each range you specify. If required, multiple lines are dumped to a maximum of four lines.

Response 7:

```
HCPCDE6150E An option has been specified that is not valid in  
ESA/390 mode.
```

is the response you receive when you dump the control registers using *D XH* from an ESA/390 guest (an appropriate message will be issued from an ESA/XC guest).

Response 8:

Dump Register

```
ECR nn = ctlreg0l ctlreg1l ctlreg2l ctlreg3l
```

is the response that is sent to the virtual printer when you dump the control registers using *D X* from a z/Architecture or z/XC guest. *nn* indicates the first (or only) register whose contents are dumped.

The content of each register is dumped in hexadecimal and represents the low half of the full 64-bit register. Up to four registers per line are dumped for each range you specify. If required, multiple lines are dumped to a maximum of four lines.

Response 9:

## Dump Register

```
CRG nn = ctlreg0hctlreg0l ctlreg1hctlreg1l
```

is the response that is sent to the virtual printer when you dump the control registers using *D XG* from a z/Architecture or z/XC guest. *nn* indicates the first (or only) register whose contents are dumped.

The content of each register is dumped in hexadecimal and represents the the full 64-bit register. Up to two registers per line are dumped for each range you specify. If required, multiple lines are dumped to a maximum of eight lines.

The high and low halves of each register may be separated by an optional underscore for readability. To have the underscore displayed, use the SET UNDERSCORE command.

Response 10:

## Dump Register

```
CRH nn = ctlreg0h ctlreg1h ctlreg2h ctlreg3h
```

is the response that is sent to the virtual printer when you dump the control registers using *D XH* from a z/Architecture or z/XC guest. *nn* indicates the first (or only) register whose contents are dumped.

The content of each register is dumped in hexadecimal and represents the high half of the full 64-bit register. Up to four registers per line are dumped for each range you specify. If required, multiple lines are dumped to a maximum of four lines.

Response 11:

## Dump Register

```
AR nn = areg0 areg1 areg2 areg3
```

is the response that is sent to the virtual printer when you dump the access registers; *nn* is the first (or only) access register whose contents are dumped.

The contents of the requested access registers are dumped in hexadecimal. Up to four registers per line are dumped. If required, multiple response lines are dumped to a maximum of four lines.

Response 12:

## Dump Register

```
FPR nn = xxxxxxxxxxxxxxxxxxx ±.ddddddddddddddd E dd
```

is the response that is sent to the virtual printer when you dump the floating-point registers. The *nn* is the floating-point register whose contents are dumped on the line. The contents of the floating-point registers are dumped in both the internal hexadecimal format and the E-format; the first part of the response is the contents of the register in hexadecimal, and the second part of the response is the contents in exponential decimal format. Only one register is dumped per line. If you specified a range of registers, multiple response lines are dumped.

Response 13:

## Dump Register

```
FPC = mmmmmmm
```

is the response that is sent to the virtual printer when you dump the floating-point control register. The contents of the floating-point control register are dumped in hexadecimal format.

Response 14:

## Dump Register

```
BEA = mmmmmmmmmmmmmmm
```

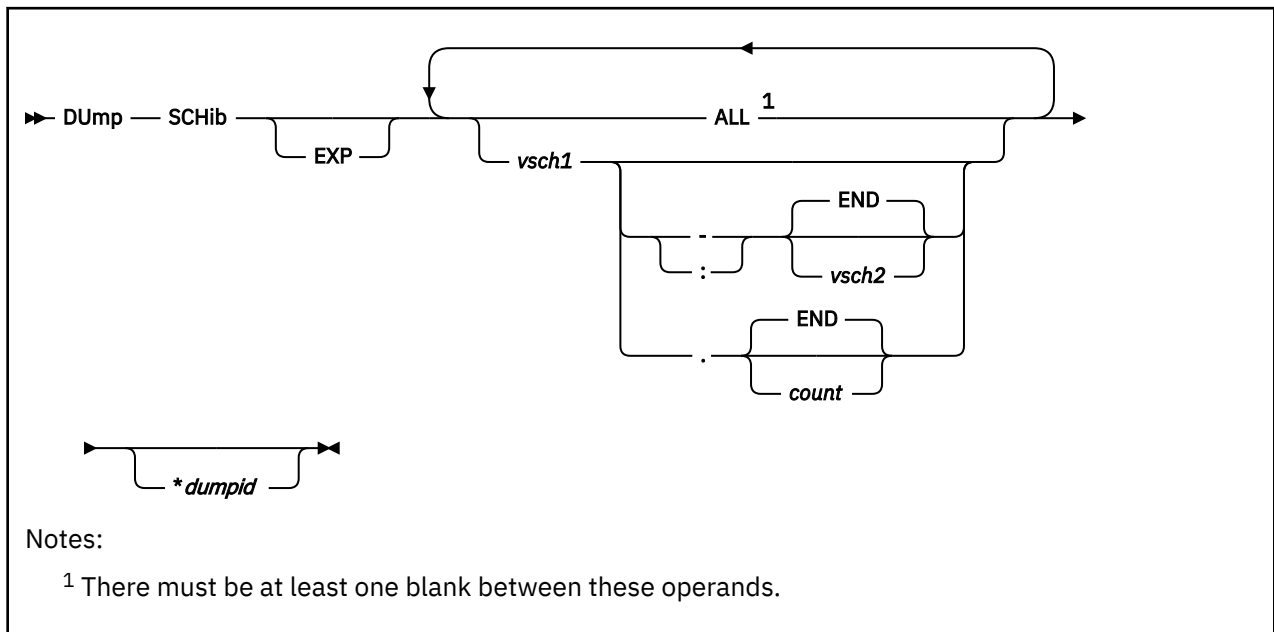

## **DUMP (Registers)**

is the response that is sent to the virtual printer when you dump the breaking-event-address register. The contents of the breaking-event-address register are in hexadecimal format.

For ESA/390 and ESA/XC mode guests, the breaking event address contains 4 bytes. In z/Architecture mode, the breaking event address contains 8 bytes.

In z/Architecture mode the high and low half of the register might be separated by an optional underscore for readability. To display the underscore, use the SET UNDERSCORE command.

## DUMP SCHIB

### Authorization

Privilege Class: G

### Purpose

Use DUMP SCHIB to send information from your subchannel information blocks (SCHIBs) to your virtual printer.

### Operands

#### EXP

specifies that extended channel measurement information is to be displayed.

#### ALL

specifies that SCHIBs for all virtual devices are to be dumped.

#### *vsch1*

*vsch2* identifies the starting (or only) virtual subchannel whose SCHIB is to be dumped.

#### : END

#### - *vsch2*

*vsch2* specifies that all SCHIBs in the range *vsch1* to *vsch2* are to be dumped. Specify END to dump all SCHIBs from *vsch1* to the highest number subchannel. END is the default.

A colon (:) means the same as a hyphen (-) when specifying a range.

#### END

#### . *count*

*count* specifies the number of consecutive SCHIBs starting at *vsch1* that are to be dumped. Specify END to dump all SCHIBs from *vsch1* to the highest number subchannel. END is the default.

#### \**dumpid*

identifies a 1- to 97-character string that is to be assigned to the dump. If specified, *dumpid* must be the last operand you enter on the command line.

## Usage Notes

1. If you specify a list of SCHIBS and one is not found, the DUMP command terminates at the first SCHIB found. For example, if you enter `dump SCHIB 0022 0033 0055 0011` and subchannel 0055 is not found, only SCHIB 0022 and 0033 will be displayed. If you specify a range of SCHIBs, the DUMP command terminates if the first SCHIB in the range is not found. Otherwise, all those SCHIBs that were found are dumped.
2. You can use the QUERY VIRTUAL command to determine the subchannel number associated with a virtual device.
3. The response to this command is a header line followed by a line of information for each SCHIB that you specify. (The header line identifies, column by column, the SCHIB information that follows it. See “Responses” below.)
4. For more information, see [“Usage Notes” on page 395](#).

## Responses

### Response 1: When EXP is not specified

```
SCHIB DEV INT-PARM ISC FLG LP PNO (Con't)
nnnn nnnn nnnnnnnnn n nn nn nn

LPU PI MBI PO PA CHPID0-3 CHPID4-7
nn nn nnnn nn nn nnnnnnnnn nnnnnnnnn
```

If an interrupt is pending for the virtual subchannel, the following additional line describes the pending interrupt:

```
KEY ECC FPI ZN SCTL CCW-ADDR DS SS CNT EXT-LOG
n n n n nnnn nnnnnnnnn nn nn nnnn nnnnnnnnn
```

### Response 2: When EXP is specified

```
SCHIB DEV INT-PARM ISC FLG MBI FLG2 MBA
nnnn nnnn nnnnnnnnn n nn nnnn nn nnnnnnnnnnnnnnnnn
```

### Response 3: When the command completes successfully

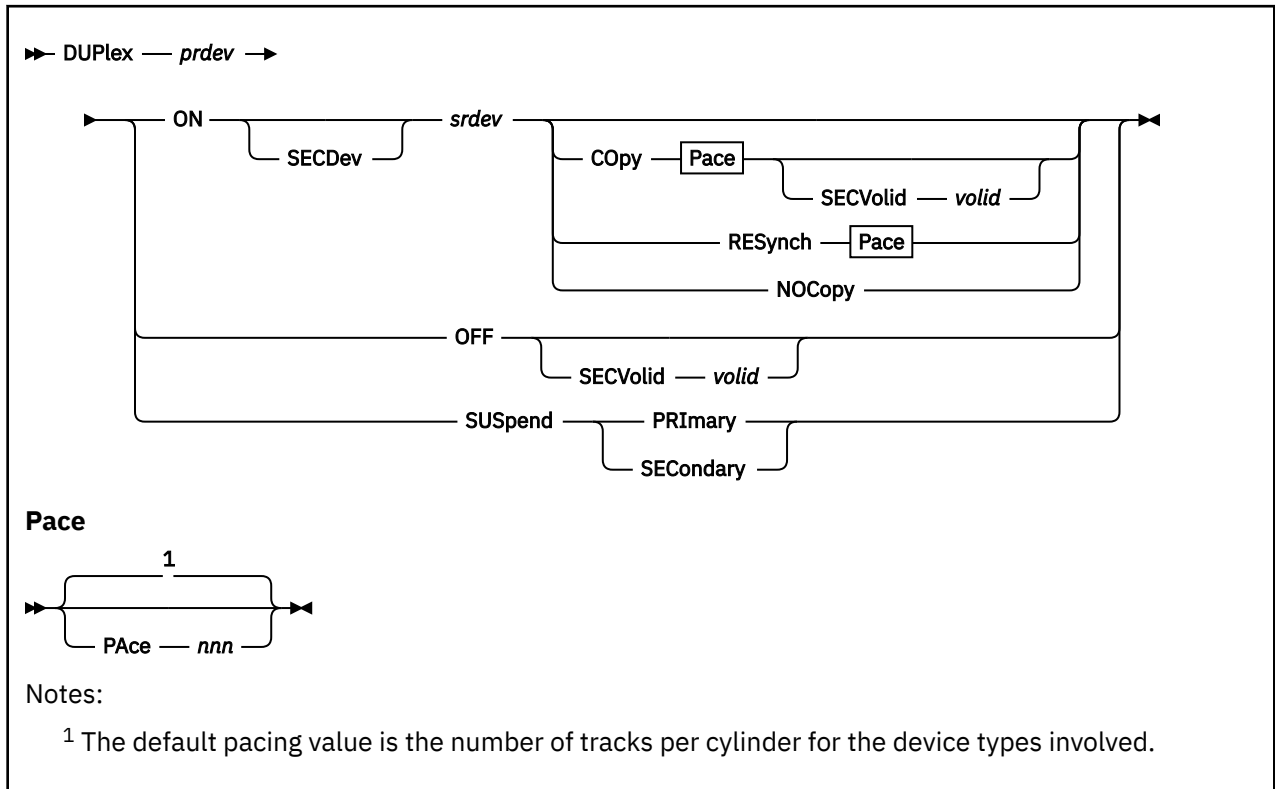

```
Command complete
```

Response header lines contain headings from the list below, a brief description is included.

Heading	Description
INT-PARM	The interrupt parameter
ISC	The interrupt subclass
FLG	The flag field
LP	The logical path mask
PNO	The path-not-operational mask
LPU	The last-path-used mask
PI	The path-installed mask
MBI	The measurement block index.
	<b>Note:</b> This will be ---- when format-1 measurement blocks are being used.
PO	The path-operational mask
PA	The path-available mask
CHPID	The channel path identifiers

<b>Heading</b>	<b>Description</b>
FLG2	The flag field (PMCW word 6, bits 24–31)
MBA	The measurement block address
KEY	The SCSW protect key
ECC	The logout condition code bits
FPI	The format, prefetch, and initial response bits
ZN	The initial status condition
SCTL	The function and activity control bytes
CCW-ADDR	The SCSW CCW address
DS	The SCSW device status bits
SS	The subchannel status bits
CNT	The SCSW residual CCW data count
EXT-LOG	The extended status/time word

# DUPLEX

## Authorization

Privilege Class: B

## Purpose

Use the DUPLEX command to perform duplex control operations (such as establishing or discontinuing a duplex pair) on devices attached to 3990 Model 3 and 3990 Model 6 subsystems.

This duplexing of devices makes use of the Dual Copy function, which allows two devices attached to the same 3990 Model 3 or 6 storage subsystem to operate in duplex mode. All data written to the primary device is automatically written to the specified secondary (copy) device. Thus, the host is relieved of performing this task when a duplicate copy of one or more DASD is desired.

## Operands

### prdev

is the real device number of the primary volume in the duplex pair.

### ON srdev

#### ON SECDev srdev

ON indicates that a duplex pair is to be established or re-established with the volumes specified.

SECDev is an optional keyword which may be used to clarify the fact that the real device number specified is the secondary device of a duplex pair.

The srdev is the real device number of the secondary volume which will be in the duplex pair when the command completes. This real device number specifies either:

- The secondary device of the duplex pair that is to be established or re-established after a SUSPEND

- A new secondary device to be used in establishing a new duplex pair by replacing the secondary device of an existing duplex pair.

**COPY**

indicates that synchronization of the contents of the two volumes by copying the entire contents of the primary volume to the secondary volume is to be performed to establish or re-establish the duplex pair. This is the default. See Usage Note 1.

**RESynch**

indicates that synchronization of the contents of the two volumes is to be performed to re-establish the duplex pair. Synchronization is accomplished by copying only modified tracks from the primary volume to the secondary volume. If the storage controller does not have a modified track map, the entire volume will be copied. See Usage Note 1.

**NOCopy**

indicates that synchronization of the contents of the two volumes is not to be performed to establish the duplex pair. See Usage Note 1.

**PAce *nnn***

indicates the rate at which synchronization of the two volumes is to take place if COPY or RESYNCH is specified. The value of *nnn* specifies the number of tracks to be copied by the control unit before allowing host access to the device for other operations. After allowing an interval for host access, the copying continues for another *nnn* tracks. This operation continues until the entire volume has been copied.

The value of *nnn* can be any number from 0 to 255. A value of 0 indicates that no pacing is to be performed. In other words, all tracks are to be copied without interruption, with the device being unavailable to all hosts.

If a pacing value is not specified for COPY or RESYNCH, the default pacing value is the number of tracks per cylinder for the device types involved. For example, the number of tracks per cylinder for 3380 devices is 15. Therefore, 15 would be the default for *nnn* of a 3380.

**Note:** Any volume that requires high availability (like a SYSRES) should use the smallest PAce value, which is 1.

**Attention:** Specifying PAce 0 can cause the primary volume of the duplex pair to be unavailable to **all** attached hosts for up to 10 to 20 minutes or more, depending on the size of the DASD. It may also severely disrupt ongoing operations for some, or all, hosts, depending on the data residing on the DASD and its use by the attached hosts.

You should use the default value. However, any value other than 0 will work, unless host missing-interruption intervals have been reduced to the 1- to 3-second range at your installation, in which case values above 60 should be avoided.

**SECVolid *valid***

specifies a new volume identification label for:

- The failed secondary volume. This occurs only when DUPLEX ON is issued to replace the failed volume of an existing duplex pair.
- The secondary volume of the duplex pair after duplexing is ended.

The *valid* is specified as a 1- to 6-character name. See Usage Note 6.

**SUSpend PRImary**

**SUSpend SECOndary**

indicates that the duplex pair identified by *prdev* is to be forced into suspended duplex state. The specified volume, either PRIMARY or SECONDARY, is marked as the suspended volume, and the other volume becomes the only operational volume of the duplex pair. See Usage Note 17.

**OFF**

indicates that the duplex relationship between the duplex pair specified by *prdev* is to be ended.

## Usage Notes

1. When using the DUPLEX ON command

- a. To establish a duplex pair, enter:

```
DUPlex prdev ON [SECDev] srdev [COPY] [PAce nnn]
```

or

```
DUPlex prdev ON [SECDev] srdev NOCOPY
```

**Note:** If NOCOPY is specified, the volumes must already be identical.

- b. To re-establish a suspended duplex pair, enter:

```
DUPlex prdev ON [SECDev] srdev [COPY] [PAce nnn]
```

or

```
DUPlex prdev ON [SECDev] srdev RESynch [PAce nnn]
```

- c. To replace the secondary volume of an existing suspended duplex pair, enter:

```
DUPlex prdev ON [SECDev] srdev
```

```
[COPY] [PAce nnn] [SECVolid volid]
```

***srdev***

is a new secondary volume to be used in establishing a new duplex pair.

2. This command requires that both the primary and the secondary volumes be in the CP I/O configuration.
3. Caching must be inactive for simplex devices being established as a duplex pair or joining an existing suspended duplex pair.
4. When re-establishing a suspended duplex pair, the pair must not have pinned data.
5. The PACE value is not allowed if NOCOPY is specified.
6. The volume identification label of the primary volume will be copied onto the secondary volume during the establishing of a new duplex pair, unless the NOCOPY option is specified. The SECVOLID option allows the primary and secondary volumes to have different identification labels after replacing the secondary volume of an existing duplex pair or ending a duplex pair.
7.  **Attention:** To assure that the secondary is a true copy of the primary when issuing DUPLEX OFF, the pair must not be pending or suspended and DASD fast write must be made inactive prior to issuing DUPLEX OFF.
8. The device identified by *srdev* must have a capacity that is equal to or greater than the capacity of the device identified by *prdev*.
9. DUPLEX ON requires that both cache and NVS be available to the subsystem.
10. When establishing a duplex pair where more than one host is sharing the environment, the device that is to be the secondary volume in the duplex pair must be varied offline to other hosts. For more information on [ungrouping storage paths](#), see *z/VM: System Operation*.
11. When establishing a new duplex pair, *prdev* and *srdev* must identify devices that are not currently in a duplex pair.
12. When re-establishing a duplex pair, *prdev* and *srdev* must be the primary and secondary volumes, respectively, of an established duplex pair.
13. When replacing the secondary volume of an existing duplex pair, *srdev* must identify a device that is not part of a duplex pair and *prdev* must identify an established duplex pair.

14. When re-establishing a duplex pair, or when replacing the secondary volume of an existing duplex pair, the duplex pair identified by *prdev* must be in suspended duplex state or the command will not complete successfully.
15. For DUPLEX ON, the secondary volume identified by *srdev* may be an offline device.
16. For DUPLEX SUSPEND, if the duplex pair is in suspended duplex state, the command will not complete successfully.
17. If DUPLEX SUSPEND PRIMARY is issued, the storage control will swap the primary and secondary device addresses as seen by the host. This allows a functioning device to continue to be represented by the primary device address. To determine the physical device address, see [“QUERY DASD” on page 867](#) and in particular Response 7 for that command.
  - If DUPLEX ON SECDEV is issued to re-establish the duplex pair, the addresses **will** be swapped back to their original state as part of the operation.
  - If DUPLEX OFF is issued to end the duplex pair, the addresses **will not** be swapped back to their original state.
  - If DUPLEX ON SECDEV is issued to replace the suspended secondary with another device, the addresses **will not** be swapped back to their original state. The freed device will be in simplex state on the physical address to which it is currently assigned. However, if the address of the new device, as seen by the host, is the same as the physical address of the suspended device, then the address of the new device will be swapped with the address of the freed device. This is possible if the device has been put in suspended duplex state several times and address swaps have occurred.
18. Once a duplex pair has been established, the caching status and the DASD fast write status of the primary volume becomes the caching and DASD fast write status of the duplex pair.
19. When DUPLEX OFF is used to discontinue a duplex pair, the caching status and the DASD fast write status of the former primary volume remains the same as the caching and DASD fast write status of the discontinued duplex pair. For the former secondary volume, the caching status is made active and the DASD fast write status is made inactive.
20. A volume attached to the system can only be duplexed with a free volume. The volume that is attached to the system must be the primary of the duplex pair.
21. A volume that is dedicated to a guest virtual machine can only be duplexed with a free volume or another volume dedicated to the same user. The volume that is dedicated to the guest must be the primary of the duplex pair.

The ATTACH command can be used to attach the secondary volume to the guest virtual machine after the duplex pair has been established.

**Attention:** Some guests, MVS for example, require that both the primary and the secondary be attached.

22. The primary device of the duplex pair can be a free volume only when the secondary device of the duplex pair is a free volume.
23. When a duplex pair has been established by CP, the guest will not be allowed to fail the primary if permanent errors occur on valid-defined minidisks. The recovery action will have to be done manually with the DUPLEX command.
24. The primary and secondary volumes should be on different DASD strings. This provides greater data availability than duplex pairs on the same DASD string.
25. This command may produce delayed responses.

## Responses

Response 1:

Response 1 has three types of responses. When establishing or re-establishing a duplex pair, one or more of the following response types will occur:

- Immediate Response

## DUPLEX

- Delayed Response
- Response to System Operator

*Immediate Response:* If a duplex pair is established or re-established immediately, this response will be displayed:

```
Duplex pair (prdev,srdev) - active
```

where:

**prdev**

is the real device number of the primary volume in the duplex pair.

**srdev**

is the real device number of the secondary volume in the duplex pair.

*Delayed Response:* If synchronization of the contents of the two volumes is in progress, this response will be displayed:

```
Command started:  
DUPLEX prdev ON srdev {COPY } PACE nnn [SECVolid valid]  
                {RESYNCH}
```

where:

**prdev**

is the real device number of the primary volume in the duplex pair.

**srdev**

is the real device number of the secondary volume in the duplex pair.

**nnn**

is the copy pace value.

**valid**

is the volume identification label for the former secondary volume after DUPLEX ON is issued to replace the secondary volume of an existing duplex pair.

When the duplex pair is established or re-established, the following response will be displayed.

```
Duplex pair (prdev,srdev) - active
```

Sometimes a cache storage subsystem will not notify CP when it has established or re-established a duplex pair. When this occurs, the appropriate command response cannot be generated. Under these circumstances, command processing is ended after generating the following response:

```
Command results lost:  
DUPLEX prdev ON srdev {COPY } PACE nnn [SECVolid valid]  
                {RESYNCH}
```

Then the QUERY DUPLEX command can be issued to determine the status of the duplex pair.

Errors can occur during the asynchronous processing of the DUPLEX command. If these errors prevent the successful completion of the command, the following response will be displayed:

```
Command failed:  
DUPLEX prdev ON srdev {COPY } PACE nnn [SECVolid valid]  
                {RESYNCH}
```

*Response to System Operator:* If the originator of the DUPLEX ON command is not the system operator, this response will be issued to the system operator when the duplex pair has been established or re-established.

```
Duplex pair (prdev,srdev) was activated by userid.
```

where:

***prdev***

is the real device number of the primary volume in the duplex pair.

***srdev***

is the real device number of the secondary volume in the duplex pair.

***userid***

is the ID of the user who issued the command.

Response 2:

```
Duplex pair (prdev,srdev) - suspended
```

This response is displayed when DUPLEX SUSPEND command is issued to place a duplex pair in the suspended duplex state.

where:

***prdev***

is the real device number of the primary volume in the duplex pair.

***srdev***

is the real device number of the secondary volume in the duplex pair.

If the originator of the command is not the system operator, the following response will be issued to the system operator.

```
Duplex pair (prdev,srdev) was suspended by userid.
```

where:

***prdev***

is the real device number of the primary volume in the duplex pair.

***srdev***

is the real device number of the secondary volume in the duplex pair.

***userid***

is the ID of the user who issued the command.

Response 3:

```
Devices prdev and srdev are no longer duplexed.
```

This response is displayed when DUPLEX OFF is issued to discontinue the duplex relationship between two devices.

where:

***prdev***

is the real device number of the volume that was the primary volume of the duplex pair.

***srdev***

is the real device number of the volume that was the secondary volume of the duplex pair.

If the originator of the command is not the system operator, the following response will be issued to the system operator.

```
Duplex relationship between prdev and srdev was discontinued by userid.
```

where:

***prdev***

is the real device number of the volume that was the primary volume of the duplex pair.

***srdev***

is the real device number of the volume that was the secondary volume of the duplex pair.

## DUPLEX

### **userid**

is the ID of the user who issued the command.

Response 4:

```
srdev Volume label is now 'XXXXXX'.
```

This response is displayed when DUPLEX ON or DUPLEX OFF is issued to specify a new volume identification label for the former secondary volume of the duplex pair.

where:

### **srdev**

is the real device number of the volume that was the secondary volume of the duplex pair.

### **XXXXXX**

is volume identification label.

If the originator of the command is not the system operator, the following response will be issued to the system operator.

```
srdev Volume label was changed by userid and is now 'XXXXXX'.
```

where:

### **srdev**

is the real device number of the volume that was the secondary volume of the duplex pair.

### **userid**

is the ID of the user who issued the command.

### **XXXXXX**

is volume identification label.

Response 5:

```
srdev Changing of volume label has failed.
```

This response is displayed when the DUPLEX ON or DUPLEX OFF command cannot specify a new volume identification label for the former secondary volume of the duplex pair.

where:

### **srdev**

is the real device number of the volume that was the secondary volume of the duplex pair.

Response 6:

```
Duplex pair (prdev,srdev) - not established  
because cache and/or non-volatile storage is not available.
```

This response is generated when DUPLEX ON is issued and cache and/or NVS was not available to the subsystem.

where:

### **prdev**

is the real device number of the volume specified as the primary volume of the duplex pair.

### **srdev**

is the real device number of the volume specified as the secondary volume of the duplex pair.

Response 7:

```
Duplex pair (prdev,srdev) - not established  
because caching is active for one or both devices.
```

This response is generated when DUPLEX ON is issued and caching was active for one or both of the devices.

where:

**prdev**

is the real device number of the volume specified as the primary volume of the duplex pair.

**srdev**

is the real device number of the volume specified as the secondary volume of the duplex pair.

Response 8:

```
Duplex pair (prdev,srdev) - not re-established
because the duplex pair is not suspended.
```

This response is generated when DUPLEX ON is issued to re-establish a duplex pair or to replace the secondary, and the duplex pair identified by *prdev* was not in suspended duplex state.

where:

**prdev**

is the real device number of the volume specified as the primary volume of the duplex pair.

**srdev**

is the real device number of the volume specified as the secondary volume of the duplex pair.

Response 9:

```
Duplex pair (prdev,srdev) - already suspended
```

This response is generated when DUPLEX SUSPEND is issued and the duplex pair was already in suspended duplex state.

where:

**prdev**

is the real device number of the volume that is the primary volume of the suspended duplex pair.

**srdev**

is the real device number of the volume that is the secondary volume of the suspended duplex pair.

Response 10:

```
Devices prdev and srdev cannot be duplexed.
```

This response is generated when DUPLEX ON is issued and the duplex pair cannot be created for one of the following reasons:

- The devices are not configured into the same storage subsystem.
- The devices do not have the same capacity.
- One or both of the devices are already duplexed with other devices.
- A volume attached to the system or to a guest was to be duplexed and either was not specified as the primary device, or the specified secondary device was not a free volume.
- The primary device is free and the secondary device is attached to the system or to a guest.

where:

**prdev**

is the real device number of the volume that was specified as the primary volume in the DUPLEX command.

**srdev**

is the real device number of the volume that was specified as the secondary volume in the DUPLEX command.

Response 11:

## DUPLEX

*prdev* The associated secondary volume in the duplex pair is not online to VM.

This response is displayed when the device number of the primary volume is specified on the DUPLEX SUSPEND or DUPLEX OFF command, and the device number of the secondary volume cannot be located.

where:

***prdev***

is the real device number of the primary volume in the duplex pair.

## ECHO

### Authorization

Privilege Class: G

### Purpose

Use ECHO to put your terminal in the echo environment.

**Note:** In the echo environment, any input line you enter is transmitted back to your terminal *nn* times.

### Operands

**1**

***nn***

identifies the number of times that the line is repeated. The default is 1. An entry that is not valid—that is, one that is less than 1 or greater than 99 or contains nonnumeric characters is treated as 1.

### Usage Notes

1. After the line has been repeated the specified number of times, CP issues another read to the display so you can enter another data line.
2. No line editing is done; the output line is the same as the input line and may contain any of the logical line editing symbols.
3. The responses and redisplayed input lines are sent to the terminal only. They are not passed to the virtual machine.

### Responses

Response 1:

```
ECHO entered; to terminate test, type end.
```

is displayed after you have issued the ECHO command to indicate that your virtual machine has entered the echo environment.

Response 2:

```
Enter line.
```

is displayed to prompt you to enter an input line. If you enter the reply END, you exit from the ECHO environment.

### Messages

- HCP002E Invalid operand - *operand*

## ENABLE (Device)

### Authorization

Privilege Class: A, B, F

### Purpose

Use ENABLE (device) to enable the following devices to access the host system:

- Disabled local 3270 display devices
- EP (Emulator Program) controlled lines in the 3745
- SNA/CCS terminals.

### Operands

#### ALL

enables all previously disabled or non-enabled locally attached 3270 display devices, including 328x printers, EP (Emulator Program) controlled lines in the 3745, and all SNA/CCS terminals.

#### *rdev*

#### *rdev1-rdev2*

is the device number, a list of device numbers, or a range of device numbers of display stations or lines that you want to enable. If you specify a list of device numbers, separate them by one or more blanks.

#### **SNA** *userid*

enables communication with the SNA/CCS terminals owned by the VTAM service machine whose user ID is specified. If no user ID is specified, communication is enabled with all SNA/CCS terminals for all VTAM service machines.

### Usage Notes

1. On a single command line you may combine device numbers, lists of device numbers, and ranges of device numbers.
2. Do not attempt to enable display devices that are not supported. Use unsupported console devices as dedicated devices attached to virtual machines.
3. If a display station or line is already enabled, it is not affected by the ENABLE (device) command.

### Responses

Response 1:

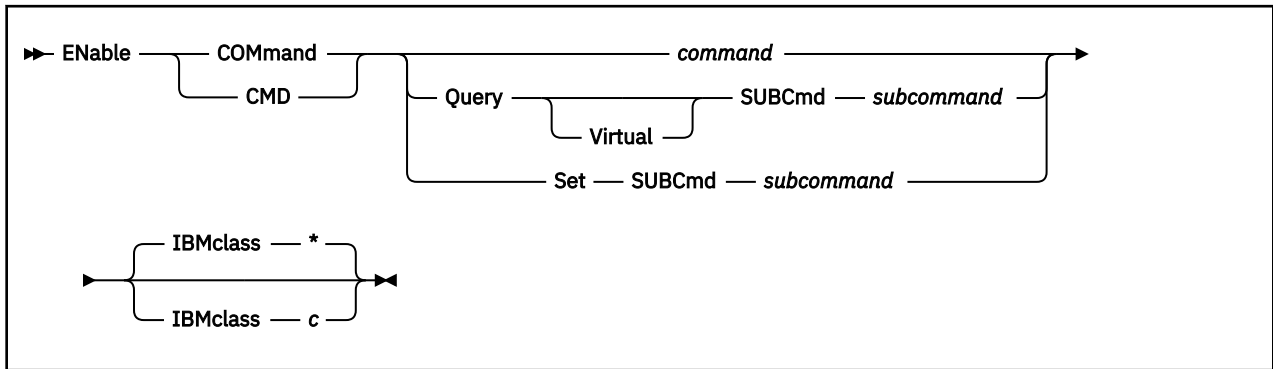

```
Command complete
```

is issued when the command completes successfully. No error indication is provided if no displays or lines are available to be enabled.

## Messages

## ENABLE COMMAND / CMD

### Authorization

Privilege Class: A

### Purpose

Use ENABLE COMMAND or CMD to permit CP to process requests for the specified CP command.

You can also permit processing of CP commands during initialization using the ENABLE COMMAND or CMD configuration file statements. For more information, see [ENABLE COMMAND / CMD Statement in z/VM: CP Planning and Administration](#).

### Operands

#### *command*

is the name of the command that you are enabling. The variable *command* is a 1- to 12-character alphanumeric string.

#### **Query SUBCmd *subcommand***

tells CP the name of the CP QUERY subcommand that you are enabling. The variable *subcommand* is a 1- to 12-character alphanumeric string.

#### **Query Virtual SUBCmd *subcommand***

tells CP the name of the CP QUERY VIRTUAL subcommand that you are enabling. The variable *subcommand* is a 1- to 12-character alphanumeric string.

#### **Set SUBCmd *subcommand***

tells CP the name of the CP SET subcommand that you are enabling. The variable *subcommand* is a 1- to 12-character alphanumeric string.

#### **IBMclass \***

tells CP to enable all versions of the specified command or subcommand. If omitted, IBMCLASS \* is the default.

#### **IBMclass c**

tells CP to enable a specific version of the specified command or subcommand. The variable *c* can be any 1 of the following:

- A** this is a system-control command to be used by the primary system operator.
- B** this is a command for operational control of real devices.
- C** this is a command to alter system storage.

- D** this is a command for system-wide control of spool files.
- E** this is a command to examine system storage.
- F** this is a command for service control of real devices.
- G** this is a general-use command used to control the functions of a virtual machine.
- O** (zero) this command has no specific IBM class assigned.

## Usage Notes

1. To load the command processing code into the system execution space, use the CPXLOAD command (see [“CPXLOAD” on page 111](#)).
2. To activate a CP command while defining it, use the ENABLE operand of the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD” on page 143](#)).
3. Both an alias and its base command must be enabled for the alias to function. If the command you want to enable is defined as an alias, then you must also enable the base command for the alias to function.
4. To deactivate a CP command:
  - While defining it, use the DISABLE operand of the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD” on page 143](#)).
  - After defining it, use the DISABLE COMMAND or CMD command (see [“DISABLE COMMAND / CMD” on page 313](#)).
5. To change the definition of an existing CP command, use the MODIFY COMMAND or CMD command (see [“MODIFY COMMAND / CMD” on page 683](#)).
6. To obtain information such as the enable/disable status and information as to whether a command is an alias or not, use the QUERY CPCMDS command (see [“QUERY CPCMDS” on page 817](#)).
7. To display the address of the CP command table entry block, the current IBM class, and the current privilege class for a specified CP command, use the LOCATE CMDBK command (see [“LOCATE CMDBK” on page 603](#)).
8. To remove the command processing code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD” on page 117](#)).

## Responses

### Response 1:

To activate the CP SHUTDOWN command (after a prior DISABLE COMMAND command or configuration file statement had deactivated it), enter the following:

```
enable command shutdown
Ready;
```

### Response 2:

To activate the class <ANY> version of the CP SET PRIVCLASS command (after a prior DISABLE COMMAND command or configuration file statement had deactivated it), enter the following:

```
enable command set subcmd privclass ibmclass 0
Ready;
```

### Messages

## ENABLE DIAGNOSE

### Authorization

Privilege Class: A

### Purpose

Use ENABLE DIAGNOSE to permit CP to process requests for one or more locally-developed DIAGNOSE codes.

You can also permit processing of locally-developed DIAGNOSE codes during initialization using the ENABLE DIAGNOSE configuration file statement. For more information, see [ENABLE DIAGNOSE Statement](#) in *z/VM: CP Planning and Administration*.

### Operands

#### ALL

tells CP to enable all existing DIAGNOSE codes.

**Note:** This operand enables all DIAGNOSE codes: the locally-defined ones, the IBM-supplied ones, and any supplied by third-party software vendors.

#### *diag*

#### *diag1-diag2*

is the number of the DIAGNOSE code that you are enabling. Each *diag* must be a hexadecimal number between X'0000' and X'03FC' and must be a multiple of 4. You can specify a single DIAGNOSE code, a range of DIAGNOSE codes, or any combination thereof.

### Usage Notes

1. To define a new DIAGNOSE code, use the DEFINE DIAGNOSE command (see [“DEFINE DIAGNOSE”](#) on page 172).
2. To load the DIAGNOSE processing code into the system execution space, use the CPXLOAD command (see [“CPXLOAD”](#) on page 111).
3. If you do not specify the ENABLE operand, a new DIAGNOSE code is initially in a disabled state after being defined. CP treats disabled DIAGNOSE codes as if they were never defined. If you try to use a disabled DIAGNOSE code in a program, CP will give you a program check specification exception.
4. To change the definition of an existing DIAGNOSE code after initialization, use the MODIFY DIAGNOSE command (see [“MODIFY DIAGNOSE”](#) on page 697).
5. To display information about a DIAGNOSE code (status, entry point name, and privilege class), use the QUERY DIAGNOSE command (see [“QUERY DIAGNOSE”](#) on page 885).
6. To display the address of the CP DIAGNOSE code table block for a DIAGNOSE code, use the LOCATE DGNBK command (see [“LOCATE DGNBK”](#) on page 608).
7. To deactivate a DIAGNOSE code:

## ENABLE DIAGNOSE

- While defining it, use the DISABLE operand of the DEFINE DIAGNOSE command (see [“DEFINE DIAGNOSE”](#) on page 172).
  - After defining it, use the DISABLE DIAGNOSE command (see [“DISABLE DIAGNOSE”](#) on page 316).
8. To remove the DIAGNOSE processing code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD”](#) on page 117).
  9. Many external security managers (ESMs) do not support DIAGNOSE codes above X'03FC'. For this reason, CP does not support DIAGNOSE codes above X'03FC'. The DIAGNOSE codes between X'0000' and X'03FC' are divided as follows:
    - X'0000' to X'00FC'**  
Reserved for IBM use
    - X'0100' to X'01FC'**  
Reserved for customer use
    - X'0200' to X'03FC'**  
Reserved for IBM use.
  10. For more information about user-defined DIAGNOSE codes, see [Defining and Modifying Commands and Diagnose Codes](#) in *z/VM: CP Exit Customization*.

## Responses

Response 1 (Enable One):

To enable DIAGNOSE code X'100', enter the following:

```
enable diagnose 100
Ready;
```

Response 2 (Enable All):

To enable all DIAGNOSE codes on your system, enter the following:

```
enable diagnose all
Ready;
```

Response 3 (Enable All Local):

To enable all locally-defined DIAGNOSE codes, enter the following:

```
enable diagnose 100-1fc
Ready;
```

Response 4 (Enable Almost All Local):

To enable all locally-defined DIAGNOSE codes except DIAGNOSE code X'180', enter the following:

```
enable diagnose 100-17c 184-1fc
Ready;
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP2751E Diagnose code *diag* does not exist
- HCP2751E Diagnose codes *diag1-dia2* do not exist
- HCP6704E Missing token at end of line
- HCP6706E Invalid Diagnose code - *diag*

## ENABLE EXITS

### Authorization

Privilege Class: A

### Purpose

Use ENABLE EXITS to permit CP to call all entry points and external symbols associated with one or more exit points.

You can also permit CP to call the entry points and external symbols associated with an exit point during initialization using the ENABLE EXITS configuration file statement. For more information, see [ENABLE EXITS Statement](#) in *z/VM: CP Planning and Administration*.

### Operands

#### ALL

tells CP to enable all existing CP exit points.

#### exit

#### exit1-exit2

is the number of the exit point (or exit points) that you want CP to start using. Each *exit* must be a hexadecimal number between X'0000' and X'FFFF'. You can specify a single exit point number, a range of exit point numbers, or any combination thereof.

### Usage Notes

1. To load the exit point code into the system execution space, use the CPXLOAD command (see [“CPXLOAD”](#) on page 111).
2. To associate one or more entry points or external symbols with a specific exit point and to enable or disable that exit point, use the ASSOCIATE EXIT command (see [“ASSOCIATE EXIT”](#) on page 20). You can also use the ASSOCIATE EXIT command to change the entry points and external symbols associated with a specific entry point. If the exit point is enabled when you change the list of entry points and external symbols, CP checks to see if that exit point is currently processing an exit request. If the exit point is not processing any requests, CP immediately updates the list with your changes. If the exit point is processing a request, CP waits until the current request is completed and then updates the list with your changes before processing any new exit requests.
3. If the list of entry points and external symbols associated with this exit point contain any entry points or external symbols that CP does not know about, CP just ignores them and continues normal processing. That is, CP will continue to process the other members of the list associated with this exit point. CP does not ignore an exit point because it cannot find one entry point or external symbol in the list. CP only ignores an exit point if it cannot find all the entry points and external symbols in the list.
4. To display whether there are any unknown entry points or external symbols associated with an exit point, use the QUERY UNRESOLVED command (see [“QUERY UNRESOLVED”](#) on page 1250).

5. To display status and usage statistics information about a specific exit point, use the QUERY EXITS command (see [“QUERY EXITS”](#) on page 907).
6. To display the address of the CP exit block for a specific exit point, use the LOCATE XITBK command (see [“LOCATE XITBK”](#) on page 649).
7. To display the address of the CP indirect call locator block for a specific exit point, use the LOCATE ICLBK command (see [“LOCATE ICLBK”](#) on page 614).
8. To change the definition of an existing dynamic exit point, or to remove the exit point from the system, use the MODIFY EXIT command (see [“MODIFY EXIT”](#) on page 700).
9. To stop CP from calling all the entry points and external symbols associated with one or more exit points after defining those exit points, use the DISABLE EXITS command (see [“DISABLE EXITS”](#) on page 319).
10. To remove the exit point code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD”](#) on page 117).
11. For more information about user-defined exit points, see [z/VM: CP Exit Customization](#).

## Responses

Response 1:

To have CP start using the entry points and external symbols associated with CP Exit 99, enter the following:

```
enable exits 99
Ready;
```

Response 2:

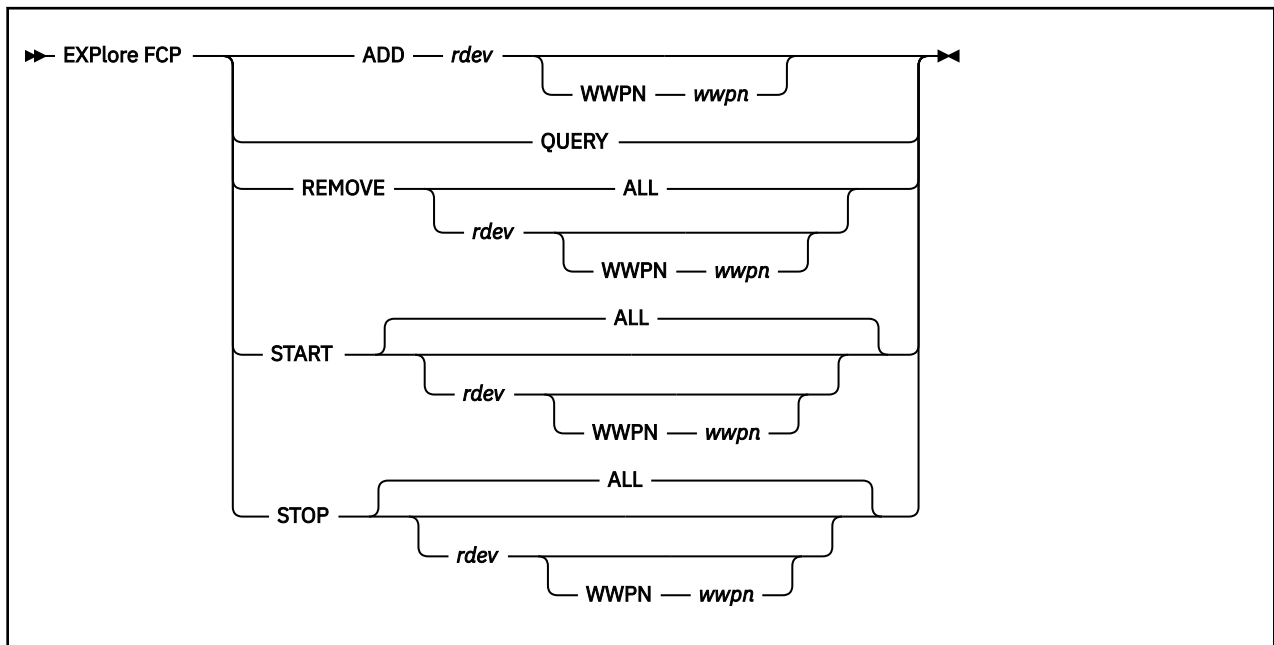

To have CP start using the entry points and external symbols associated with all CP exit points, enter the following:

```
enable exits all
Ready;
```

## Messages

## EXPLORE FCP

### Authorization

Privilege Class: B

### Purpose

Use EXPLORE FCP to define a set of FCP subchannels and WWPN ports to be tested, to manage the list, and to start and stop the devices. This command can be used to activate the FCP subchannels and open the WWPN ports so that they are visible to the SAN fabric and can be verified on storage array consoles.

### Operands

#### ADD

adds an FCP subchannel and optionally a WWPN port to the CP-managed list of SCSI devices to be tested.

#### QUERY

displays the FCP subchannels and WWPN ports, along with their current activation status, from the list of SCSI devices to be tested.

#### REMOVE

removes an FCP subchannel and optionally a WWPN port from the CP-managed list of SCSI devices to be tested.

#### START

activates FCP subchannels and opens WWPN ports in the list of SCSI devices to be tested.

#### STOP

deactivates FCP subchannels and closes WWPN ports in the list of SCSI devices to be tested.

### Options

#### ALL

forces the related subcommand to process all elements in the list of SCSI devices to be tested.

#### rdev

specifies the real device number of the FCP subchannel.

### WWPN *wwpn*

specifies the world wide port name to be processed.

### Usage Notes

1. When the ADD subcommand is issued, the FCP device specified must be free and will be attached to SYSTEM. The FCP device remains attached to SYSTEM until it, and all WWPNs associated with it, are removed using the REMOVE subcommand.
2. In order to remove a device using the REMOVE subcommand, the device must first be deactivated using the STOP subcommand.

### Responses

Response 1:

If you issue EXPLORE FCP QUERY after adding a port to the list, you will see the following:

```
explore fcp query
FCP: 1C20 STATUS: INACTIVE
FCP: 1C20 WWPN: 5005076300CD04DA STATUS: INACTIVE
```

Response 2:

If you issue EXPLORE FCP QUERY after an EXPLORE FCP START command, you will see the following:

```
explore fcp query
FCP: 1C20 STATUS: ACTIVE
FCP: 1C20 WWPN: 5005076300CD04DA STATUS: ACTIVE
```

Response 3:

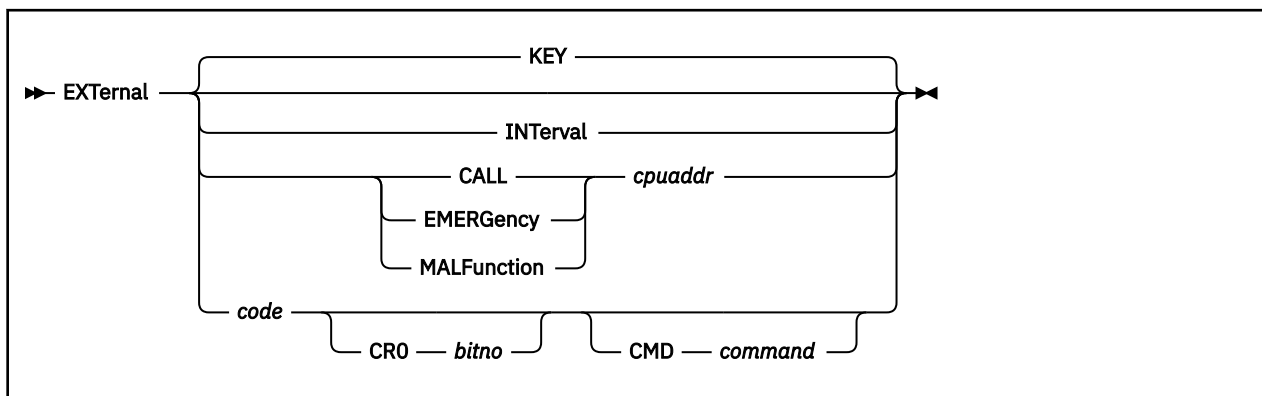

If you issue EXPLORE FCP QUERY after adding an FCP device without a WWPN to the list, you will see the following:

```
explore fcp query
FCP: 1C21 STATUS: INACTIVE
```

### Messages

- HCP8713E Duplicate port specified
- HCP8714E Port cannot be removed while it is active

- HCP8717E Failed to close port *wwpn* on device *rdev*

## EXTERNAL

**Authorization**

Privilege Class: G

**Purpose**

Use EXTERNAL to simulate external-interrupt-pending to your virtual machine.

**Note:** The virtual machine takes immediate control.

**Operands****KEY**

identifies the operator external interrupt key. KEY is the default.

**INTerval**

identifies the interval timer at location 80. You can specify INTERVAL only if the 370 Accommodation facility is active. Use the CP SET 370ACCOM ON command to activate the 370 Accommodation facility. When you specify INTERVAL, an interval timer interrupt is made pending.

**CALL**

identifies an external call SIGP signal from the specified virtual processor address and is accepted only when no external call is already pending.

**EMERgency**

identifies an emergency signal from the specified virtual processor address.

**MALFunction**

identifies a malfunction alert signal from the specified virtual processor address.

***cpuaddr***

identifies a virtual processor address from 0 to 3F (hexadecimal).

***code***

identifies an external interrupt code.

***CRO bitno***

indicates that a mask bit in CRO (control register 0) is to be applied to this interrupt. The operand *bitno* is the bit number in CRO that masks this interrupt; it is a decimal number from 16 to 31. For an ESA/390 virtual machine, specifying 16-31 refers to the masks in bits 16-31 of control register 0. For a z/Architecture mode virtual machine, specifying 16-31 refers to the corresponding masks that are in bits 48-63 of control register 0.

### **CMD command**

indicates that a CP command is to be issued when the interrupt is reflected. You must enter the command at the end of the command line; characters following CMD are interpreted as the CP command.

### **Usage Notes**

1. The BEGIN command is not required after you enter the EXTERNAL command.
2. Since there is no virtual processor address argument for code:
  - a. EXTERNAL 1200 cannot be an alternative syntax for EXTERNAL MALFUNCTION *cpuaddr*
  - b. EXTERNAL 1201 cannot be an alternative syntax for EXTERNAL EMERGENCY *cpuaddr*
  - c. EXTERNAL 1202 cannot be an alternative syntax for EXTERNAL CALL *cpuaddr*.

**Note:** This is true because of the architectural requirement that only 1 external call can be pending for a virtual processor at any one time.

A bit in CRO can be specified to mask this interrupt. Since the interrupt code does not imply a bit in CRO:

  - a. EXTERNAL 40 is not an alternative syntax for EXTERNAL KEY.
  - b. EXTERNAL 80 is not an alternative syntax for EXTERNAL INTERVAL.

**Note:** This is true because of the architectural requirement that only 1 interval timer interrupt can be pending for a virtual processor at any one time.
3. You can specify a CP command that you want to be processed after the interrupt is reflected to your virtual machine. Use this in system testing.

### **Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *{option|command contains extra option(s) starting with option}*
- HCP026E Operand missing or invalid

## FLASHCOPY

### Authorization

Privilege Class: B

### Purpose

Use FLASHCOPY to copy data from one virtual DASD to another.

### Operands

#### **vdev1**

is the address of the virtual DASD to be used as the source of the copy. The virtual DASD must be on a control unit that has the FLASHCOPY hardware feature. If a valid address is not specified, the command is rejected.

#### **scyl1**

is the first cylinder to be copied. If the whole virtual device is to be copied, this should be 0.

#### **ecyl1**

is the last cylinder to be copied. If the whole virtual device is to be copied, this should be END.

#### **TO**

#### **vdev2**

is the address of the virtual DASD to be used as the target of the copy. The virtual DASD must be on a control unit that has the FLASHCOPY hardware feature and must not be read only. If a valid address is not specified, the command is rejected. If multiple targets are entered, the same source device will be copied to each target device.

#### **scyl2**

is the first cylinder to be written. If the whole virtual device is to be written, this should be 0.

#### **ecyl2**

is the last cylinder to be written. If the whole virtual device is to be written, this may be END.

#### **SYNChronous**

(For FlashCopy Version 1 hardware) tells CP to process the command immediately and to wait until the hardware has accepted all parameters, all messages from the Enterprise Storage Server® (ESS) subsystem have been processed, and the FLASHCOPY command completes.

**SAVELABEL**

asks CP to preserve the volume label on *vdev2* virtual cylinder 0, head 0, record 3. This option attempts to read and verify the volume label from the target devices **before** the relationship is established. This means that a volume label should exist on the target before this command is issued. After the relationship is established, the same processing as for the LABEL option is performed to update the label.

**LABEL volser**

asks CP to change the volume label on *vdev2* virtual cylinder 0, head 0, record 3 to *volser*. This option reads and verifies the volume label on the target virtual cylinder 0, head 0, record 3 **after** the relationship has been established. This implies that the target must contain a valid label that was either copied from the source or not overwritten at all. Once the volume label has been verified, it is rewritten with the specified *volser* onto target cylinder 0, head 0, record 3.

**PRESERVEmirror**

requests that the Flashcopy operation must not change the target PPRC pair to a duplex-pending status.

**NOPRESERVEmirror**

requests that the Flashcopy operation can complete with no requirements on the PPRC status of the target devices.

**Usage Notes**

1. In order for this command to be successful, the source and target DASD must be correctly defined on control units that support the FLASHCOPY feature. If this is not the case, error message HCP332E is generated.
2. This command might produce delayed responses. Refer to [“Delayed Responses to CP Commands” on page 7](#) for more information.
3. Special care should be exercised when copying to cylinder zero of the target virtual device. If the target virtual device starts at real cylinder zero, the CP volume label will be overwritten. This could cause a duplicate volume to be created or a volume that cannot be mounted.
4. FLASHCOPY supports source-target pairs according to the DASD types of the source and target. [Table 18 on page 472](#) shows the source-target pairs FLASHCOPY supports. If you attempt to issue a FLASHCOPY command to an unsupported source-target DASD pair, you will receive message HCP6706E.

*Table 18. Source-target pairs supported by FLASHCOPY*

	<b>Target: Dedicated</b>	<b>Full-pack</b>	<b>Not full-pack</b>
<b>Source:</b>			
<b>Dedicated</b>	supported	supported	
<b>Full-pack</b>	supported	supported	
<b>Not full-pack</b>			supported

5. For FlashCopy Version 1 hardware, issuing the FLASHCOPY command to a minidisk will fail if the source and target minidisks occupy different physical extents with respect to their physical volumes. For example, minidisk 101 has a starting location of 101 and minidisk 102 has a starting location of 26. If the following command is issued:

```
FLASHCOPY 101 0 END 102 0 END
```

the following failure results:

```
HCPNFC319E Error processing subsystem command -  
FLASHCOPY for DASD 0101
```

6. The SYNCHRONOUS parameter is not necessary and is ignored when the Enterprise Storage Server FlashCopy Version 2 hardware feature is present on the server device. The ESS hardware FlashCopy

Version 2 feature supports synchronous responses. However, ESS FlashCopy Version 1 does not. When the SYNCHRONOUS parameter is specified and the ESS FlashCopy Version 1 hardware feature is present, CP will simulate a synchronous response.

7. For ESS FlashCopy Version 1 hardware, only one target can be specified. For ESS FlashCopy Version 2 hardware, a maximum of 12 targets can be specified per command. Note that the hardware limits the total number of active FLASHCOPY relationships by both volume and by target. Specifying multiple targets might exceed either of these limits if more than one FLASHCOPY is active on the server.
8. If multiple targets are specified and only FlashCopy Version 1 hardware support is available, you will receive message HCP293E.
9. If you receive an error message from processing, you must verify the state of the target device data.
10. Long-running, multiple target FLASHCOPY commands can be halted by the #CP CPHX command.
11. If both SAVELABEL and LABEL are omitted, the volume label is copied from *vdev1* by the FlashCopy operation if *scy11* and *scy12* are 0.
12. When SAVELABEL or LABEL are specified, the volume label on *vdev2* is always updated, even if *scy12* is nonzero.
13. Failure of LABEL will not prevent the establishment of the relationships.
14. Failure of SAVELABEL will not prevent the establishment of the relationships.
15. Guest FLASHCOPY support is restricted to dedicated or fullpack minidisks.
16. If PRESERVemirror and NOPRESERVemirror are not specified, the Flashcopy operation is attempted first as a PRESERVemirror request. If the first attempt fails, the I/O is retried one time as a NOPRESERVemirror request.
17. FLASHCOPY to Global Mirror (asynchronous PPRC) primary devices is supported.

## Examples

Example 1:

To copy virtual device F101 to F102 which are the same size, enter:

```
FLASHCOPY F101 0 END to F102 0 END
```

## Responses

The following are the command responses issued as a result of successful completion of the FLASHCOPY command:

Response 1: Immediate Response

If the command completes immediately, the following response is displayed:

```
Command complete: FLASHCOPY vdev1 scyl1 ecy11 TO vdev2 scyl2 ecy12
```

There might be one or more completion messages issued when multiple target *vdevs* are issued for the FLASHCOPY command.

- If the *vdev* targets in the command are all contained in one physical volume, only one completion message will be issued using the *vdev* of the last target copied.
- If the *vdev* targets in the command exist on more than one physical volume, the entry order of the targets is important. Each time the next *vdev* in the command list is found to be on a different physical volume from the last target *vdev* that was looked at, an internal FLASHCOPY order and a separate completion message will be issued. Therefore, grouping the *vdev* targets by physical volume will increase command performance and also minimize messages.

Response 2: Delayed Response

If the FLASHCOPY SYNCHRONOUS option is not specified, and only hardware FlashCopy Version 1 support is available, the FLASHCOPY command might not complete immediately. In this case, the following response is displayed:

```
Command started: FLASHCOPY vdev1 scyl1 ecyl1 TO vdev2 scyl2 ecyl2
```

When the copy is complete, the following response is issued:

```
Command complete: FLASHCOPY vdev1 scyl1 ecyl1 TO vdev2 scyl2 ecyl2
```

Under certain circumstances, it is possible that a storage subsystem does not notify CP when it has completed a FLASHCOPY. When this occurs, the appropriate command response cannot be generated. Under these circumstances, command processing ends after generating the following response:

```
Command results lost: FLASHCOPY vdev1 scyl1 ecyl1 TO vdev2 scyl2 ecyl2
```

## Messages

The messages listed apply to the FLASHCOPY, FLASHCOPY BACKGNDCOPY, FLASHCOPY ESTABLISH, FLASHCOPY RESYNC, FLASHCOPY TGTWRITE, and FLASHCOPY WITHDRAW commands.

Messages:

- HCP6790I FLASHCOPY processing halted. The next device that would have been processed is *vdev*

## FLASHCOPY BACKGNDCOPY

### Authorization

Privilege Class: B

### Purpose

For non-space-efficient relationships, use FLASHCOPY BACKGNDCOPY to initiate background copying of unmodified source data to its targets. This command reverses the effect of the NOCOPY option of the FLASHCOPY ESTABLISH command. Refer to [Track Space-Efficient Volumes and FlashCopy Backups in z/VM: CP Planning and Administration](#) for more information regarding background copying.

### Operands

#### SOURCE

specifies the readable disk and range of cylinders on a dedicated device, full-pack minidisk, or non-full-pack minidisk.

#### vdev1

defines a dedicated device or full-pack minidisk.

#### 0-END

identifies all the real cylinders of the dedicated device or full-pack minidisk.

#### numcyls

identifies the number of real cylinders in this extent. The value must be equal to the number of cylinders defined for the dedicated device or full-pack minidisk.

#### vdev2

defines a non-full-pack minidisk.

#### 0-END

identifies all the virtual cylinders of the minidisk.

#### startcylinder

identifies the first virtual cylinder number for this extent, starting with 0 to indicate the first cylinder. This can be a value from 0 to the number of cylinders on the minidisk minus 1.

**endcylinder**

identifies the last virtual cylinder number for this extent, starting with 0 to indicate the first cylinder. This can be a value from 0 to the number of cylinders on the minidisk minus 1 and must be greater than or equal to *startcylinder*.

**cylcount**

identifies the number of cylinders in this extent. The value of *startcylinder* plus *cylcount* must be less than or equal to the number of cylinders defined for the minidisk.

**Usage Notes**

1. This command has no effect if the relationship was not established with the implied or explicit NOCOPY option.
2. Issuing the command to any source cylinder within a relationship will cause all of the referenced relationship to begin its background copy operations. For example, if you specify:

```
FLASHCOPY ESTABLISH SOURCE 200 TARGET 300 310 NOCOPY
FLASHCOPY ESTABLISH SOURCE 200 TARGET 320 NOCOPY
FLASHCOPY BACKGNDCOPY SOURCE 200 1.1
```

the background copying will begin for all cylinders for targets 300, 310, and 320.

3. Multiple executions of this command to the same source extent have no additional effect.
4. Copying of the data from the source to its targets might not occur immediately, depending on the availability of storage subsystem resources.
5. It is suggested, but not required, that the NOSETARGET operand be specified when establishing a relationship for use with this command.
6. If one or more affected targets are track space-efficient volumes, the command will be rejected by the hardware. However, this will NOT prevent the background copy from being started on any targets that are NOT track space-efficient.

**Examples**

## Example 1:

```
define mdisk 0200 100 100 pack01
define mdisk 0300 100 100 pack02

flashcopy establish source 200 target 300 nocopy
Command complete: FLASHCOPY 0200 0 99 TO 0300 0 99
FLASHCOPY RELATIONSHIP 4A7AC71E ESTABLISHED
Ready; T=0.01/0.01 12:28:08

flashcopy withdraw target 300
HCPNFC2469E WITHDRAW failed because 1500 tracks remain to be copied to 300.
Ready(02469); T=0.01/0.01 12:28:10

flashcopy backgndcopy source 200
BACKGROUND COPY STARTED
Ready; T=0.01/0.01 12:28:19

flashcopy withdraw target 300
RELATIONSHIP WITHDRAW
Ready; T=0.01/0.01 12:29:00
```

**Responses**

## Response 1:

This FLASHCOPY BACKGNDCOPY command completed successfully:

```
flashcopy backgndcopy source 200
BACKGROUND COPY STARTED
Ready; T=0.01/0.01 12:28:19
```

### Messages

For a complete list of messages that can be issued by the FLASHCOPY BACKGNDCOPY command, see the [“FLASHCOPY” on page 471](#) command.

## FLASHCOPY ESTABLISH

### Authorization

Privilege Class: B

### Purpose

Use FLASHCOPY ESTABLISH to create a persistent FlashCopy relationship for point-in-time backups and test data replication scenarios.

### Operands

#### SOURCE

specifies the readable disk and range of cylinders that are to be copied by the FLASHCOPY command.

#### vdev1

defines a dedicated device or full-pack minidisk.

**O-END**

identifies all the real cylinders of the dedicated device or full-pack minidisk.

***numcyls***

identifies the number of real cylinders in this extent. The value must be equal to the number of cylinders that are defined for the dedicated device or full-pack minidisk.

**TARGET**

specifies the writable disks and extents that are to be copied by the FLASHCOPY command. You can supply up to 12 unique target *vdevs* and up to a total of 110 extents.

***vdev2***

defines a non-full-pack minidisk.

**O-END**

identifies all the virtual cylinders of the minidisk.

***startcylinder***

identifies the first virtual cylinder number for this extent, starting with 0 to indicate the first cylinder. This cylinder number can be a value from 0 to the number of cylinders on the minidisk minus 1.

***endcylinder***

identifies the last virtual cylinder number for this extent, starting with 0 to indicate the first cylinder. This cylinder number can be a value from 0 to the number of cylinders on the minidisk minus 1 and must be greater than or equal to *startcylinder*.

***cylcount***

identifies the number of cylinders in this extent. The value of *startcylinder* plus *cylcount* must be less than or equal to the number of cylinders defined for the minidisk.

**CHGRECORD**

creates an initial checkpoint for a subsequent FLASHCOPY RESYNC command. This option is implied by specifying the REVERSIBLE option.

**NOTGTWRITE**

inhibits writes on the target volume. This setting can be later changed with a FLASHCOPY TGTWRITE command. This option is implied when REVERSIBLE is specified. This option is mutually exclusive with the LABEL or SAVELABEL options.

**REVERSIBLE**

builds a reversible FLASHCOPY relationship that can later be altered by a FLASHCOPY RESYNC command with a reversed source and target. This option is mutually exclusive with the NOCOPY option and implies that CHGRECORD and NOTGTWRITE were specified. This option is mutually exclusive with the LABEL and SAVELABEL options.

Space-efficient volumes should not be used in reversible relationships.

**NOCOPY**

prevents the immediate background copying of unmodified SOURCE tracks to the targets. See [Using Persistent FlashCopy in z/VM: CP Planning and Administration](#) for a more detailed discussion of this feature. Note that the data might be copied despite the specification of the NOCOPY option. This option is implied when the target is a space-efficient volume. The NOCOPY option is mutually exclusive with the REVERSIBLE option.

**FAILNOSPACE**

causes the relationship to fail if the space-efficient target becomes out of space. This option is the default when the target is a space-efficient volume.

**NOSETARGET**

verifies that all target extents are NOT on space-efficient volumes. This option should be specified if you anticipate running a subsequent FLASHCOPY BACKGNDCOPY command. This option should also be used by applications that do not understand how to handle space-efficient out-of-space conditions. The default action is to allow space-efficient targets. If the specified target is a space-efficient volume, Reason Code BD is returned. This option is implied by specifying the REVERSIBLE option.

**LABEL *volser***

asks CP to change the volume label on the virtual cylinder 0, head 0, record 3 of targets to *volser*. This option reads and verifies the volume label on the target virtual cylinder 0, head 0, record 3 **after** the relationship is established. This implies that the target must contain a valid label that was either copied from the source or not overwritten at all. After the volume label is verified, it is rewritten with the specified *volser* onto target cylinder 0, head 0, record 3.

This option is mutually exclusive with the NOTGTWRITE and REVERSIBLE options.

**SAVELABEL**

tells CP to preserve the volume label on target virtual cylinder 0, head 0, record 3. This option attempts to read and verify the volume label from the target devices **before** the relationship is established. This means that a volume label should exist on the target before this command is issued. Note that initially space-efficient targets typically do not have any cylinders and therefore do not have a label record that can be read. Therefore, SAVELABEL with space-efficient targets typically fails with message HCP2459E. After the relationship is established, the same processing as for the LABEL option is completed to update the label.

This option is mutually exclusive with the NOTGTWRITE and REVERSIBLE options.

**ALLOCATE**

requests that the physical space required on a target Extent Space Efficient volume is allocated before the completion of the ESTABLISH command.

**PRESERVEmirror**

requests that the FlashCopy operation must not change the target PPRC pair to a duplex-pending status.

**NOPRESERVEmirror**

requests that the FlashCopy operation can complete with no requirements on the PPRC status of the target devices.

**Usage Notes**

1. A TARGET up to 12 *vdevs* can be specified with a limit of 110 extent descriptions that are shared among them.
2. Some operands are restricted to dedicated devices or full-pack minidisks. Restrictions can change as new hardware releases occur.
3. You cannot mix *fullext* and *miniext* specifications in a command, even if they describe areas of the same total space.
4. Each source cylinder can be the source for up to 12 relationships. This limit is enforced even when multiple FLASHCOPY ESTABLISH commands are issued. For example, if you specify:

```
FLASHCOPY ESTABLISH SOURCE 0200 TARGET 0300
```

and

```
FLASHCOPY ESTABLISH SOURCE 0200 TARGET 0310
```

you now have two of the limit of 12 relationships on 0200. This limit also applies to relationships established on other LPARS.

5. Specifying:

```
FLASHCOPY ESTABLISH SOURCE 0200 TARGET 0300 0310
```

is not quite the same as:

```
FLASHCOPY ESTABLISH SOURCE 0200 TARGET 0300
FLASHCOPY ESTABLISH SOURCE 0200 TARGET 0310
```

The difference is that in the first case, one sequence number that is assigned to the relationship encompasses all targets. In the second case, separate relationships have unique sequence numbers.

6. Cylinders are copied in the order they are specified. For example, if you specify:

```
FLASHCOPY ESTABLISH SOURCE 200 0.100TARGET 300 50.50 300 0.50
```

cylinders 0 - 49 are copied to cylinders 50 - 99, and cylinders 50 - 99 are copied to cylinders 0 - 49.

7. A T-disk (DEFINE T3390...) cannot be used as a persistent FlashCopy source or target.
8. Persistent FlashCopy relationships are visible to all LPARs that are attached to the Storage LSS.
9. It is possible that a persistent relationship that is created on one LPAR can be withdrawn from another.
10. If both SAVELABEL and LABEL are omitted, the volume label is copied from *vdev1* by the FlashCopy operation if source virtual cylinder 0 is copied onto target virtual cylinder 0. The volume label is copied to the corresponding target cylinder.
11. When SAVELABEL or LABEL is specified, the volume label is always updated on target virtual cylinder 0, even if the target virtual cylinder 0 was not copied.
12. Failure of LABEL will not prevent the establishment of the relationships.
13. Failure of SAVELABEL does not prevent the establishment of relationships.
14. FLASHCOPY ESTABLISH is not supported on PAV or HYPERPAV ALIAS *vdevs*.
15. FlashCopy to track space-efficient targets is only supported by hardware with full volume targets.
16. Due to the CP command-line length limit of 240 characters, it might not be possible to specify the full 110 extents in some command entry modes.
17. When a relationship is created with the NOTGTWRITE option, any attempt to write on the volume (other than by FlashCopy itself) places the volume into the Intervention Required state. The situation can cause the writing virtual machine to stop.
18. If PRESERVemirror and NOPRESERVemirror are not specified, the FlashCopy operation is attempted first as a PRESERVemirror request. If the first attempt fails, the I/O is retried one time as a NOPRESERVemirror request.
19. FLASHCOPY to Global Mirror (asynchronous PPRC) primary devices is supported.

## Examples

Example 1: Basic command

```
flashcopy establish source 200 target 300
Command complete: FLASHCOPY 0200 0 99 TO 0300 0 99
FLASHCOPY RELATIONSHIP 4A07BA0F ESTABLISHED
Ready; T=0.01/0.01 10:19:27

q flashcopy hardware 5100
-----SOURCE----- TARGET-----
SEQUENCE FLGS RDEV VOLSER CC...CC/HH RDEV VOLSER CC...CC/HH REMAINING/TOTAL
4A07BA0F 1800 5100 PACK01 100/00 5101 PACK02 100/00 0/1500
Ready; T=0.01/0.01 10:19:30
```

**For More Information**, see [Using Persistent FlashCopy in z/VM: CP Planning and Administration](#) for a detailed discussion of potential uses of persistent FlashCopy relationships.

Example 2: Multiple Copies

When you specify multiple target *vdevs*, the total number of cylinders that are specified or implied for each target *vdev* must be equal to the number of cylinders that are specified or implied for the source. For example, if you specify: SOURCE 200 0.50 TARGET 300 0.25 310 0.25, you receive an error:

```
flashcopy establish source 200 0.50 target 300 0.25 310 0.25
HCPNFC2458E SOURCE 0200 specifies 50 cylinders but TARGET 0300 specifies 25
cylinders.
Ready(02458); T=0.01/0.01 15:49:49
```

However, SOURCE 200 0.50 TARGET 300 0.20 310 0.50 300 20.30 is valid:

```
flashcopy establish source 200 0.50 target 300 0.20 310 0.50 300 20.30
Command complete: FLASHCOPY 0200 0 19 TO 0300 0 19
Command complete: FLASHCOPY 0200 20 49 TO 0300 20 49
Command complete: FLASHCOPY 0200 0 49 TO 0310 0 49
FLASHCOPY RELATIONSHIP E796AB5B ESTABLISHED
Ready; T=0.01/0.01 15:54:06
```

You can mix and match the extents, but in the end the total number of cylinders for each *vdev* must be the same. To accomplish what was intended in the first example, you can use the following parameters:

```
SOURCE 200 0.25 TARGET 300 0.25
```

and then the following parameters:

```
SOURCE 200 25.25 TARGET 310 0.25
```

However, these actions yield two relationships, not one.

### Example 3: Cylinder Rearranging

```
flashcopy establish source 200 0.100 target 300 50.50 300 0.50
Command complete: FLASHCOPY 0200 0 49 TO 0300 50 99
Command complete: FLASHCOPY 0200 50 99 TO 0300 0 49
FLASHCOPY RELATIONSHIP 4A04A166 ESTABLISHED
Ready; T=0.01/0.01 10:16:00
```

### Example 4: Multiple Copies With Cylinder Rearranging

```
flashcopy establish source 200 target 300 50.50 310 75.25 300 0.50 310 0.75
Command complete: FLASHCOPY 0200 0 49 TO 0300 50 99
Command complete: FLASHCOPY 0200 50 99 TO 0300 0 49
Command complete: FLASHCOPY 0200 0 24 TO 0310 75 99
Command complete: FLASHCOPY 0200 25 99 TO 0310 0 74
FLASHCOPY RELATIONSHIP 4A540B4F ESTABLISHED
Ready; T=0.01/0.01 11:44:49
```

```
q flashcopy hardware 5101
-----SOURCE----- TARGET-----
SEQUENCE FLGS RDEV VOLSER CC...CC/HH RDEV VOLSER CC...CC/HH REMAINING/TOTAL
4A540B4F 8800 5100 PACK01 150/00 5101 PACK02 100/00 0/750
4A540B4F 8800 5100 PACK01 100/00 5101 PACK02 150/00 0/750
4A540B4F 8800 5100 PACK01 125/00 5101 PACK02 200/00 0/1125
4A540B4F 8800 5100 PACK01 100/00 5101 PACK02 275/00 0/375
Ready; T=0.01/0.01 10:45:47
```

## Responses

Response 1:

This FLASHCOPY ESTABLISH command completed successfully:

```
flashcopy establish source 200 12-24 target 300 0-4 300 20.7 300 7.1
Command complete: FLASHCOPY 0200 12 16 TO 0200 0 4
Command complete: FLASHCOPY 0200 17 23 TO 0200 20 26
Command complete: FLASHCOPY 0200 24 24 TO 0200 7 7
FLASHCOPY RELATIONSHIP 58BA8440 ESTABLISHED
Ready; T=0.01/0.01 11:15:03
```

Response 2:

It is possible for a FLASHCOPY ESTABLISH command to partially complete and then fail. In such cases, when any of the requested relationships are formed, the relationship ID is presented along with a nonzero return code.

To verify that no relationships exist on the target volume:

```
q flashcopy hardware 5101
HCPQFL2466E Device 5101 - No FlashCopy relationships reported.
Ready(02466); T=0.01/0.01 16:01:20
```

## FLASHCOPY ESTABLISH

To issue an ordinary command:

```
flashcopy establish source 200 target 300
Command complete: FLASHCOPY 0200 0 99 TO 0300 0 99
FLASHCOPY RELATIONSHIP E79D8AB4 ESTABLISHED
Ready; T=0.01/0.01 16:01:47
```

To issue a command that cannot succeed because you have duplicate targets:

```
flashcopy establish source 200 target 310 300
Command complete: FLASHCOPY 0200 0 99 TO 310 0 99
HCPPFC3201E: DASD Error: Command Reject
HCPPFC3201E: Message F: Status not as required
HCPPFC3201E: Reason AE: A FlashCopy operation cannot complete because
it has specified that an existing target track become a target track.
Any single track must not be both a source and a target and a target
track can only have one source.
FLASHCOPY RELATIONSHIP E79DA36F ESTABLISHED
Ready(03201); T=0.01/0.01 16:01:55
```

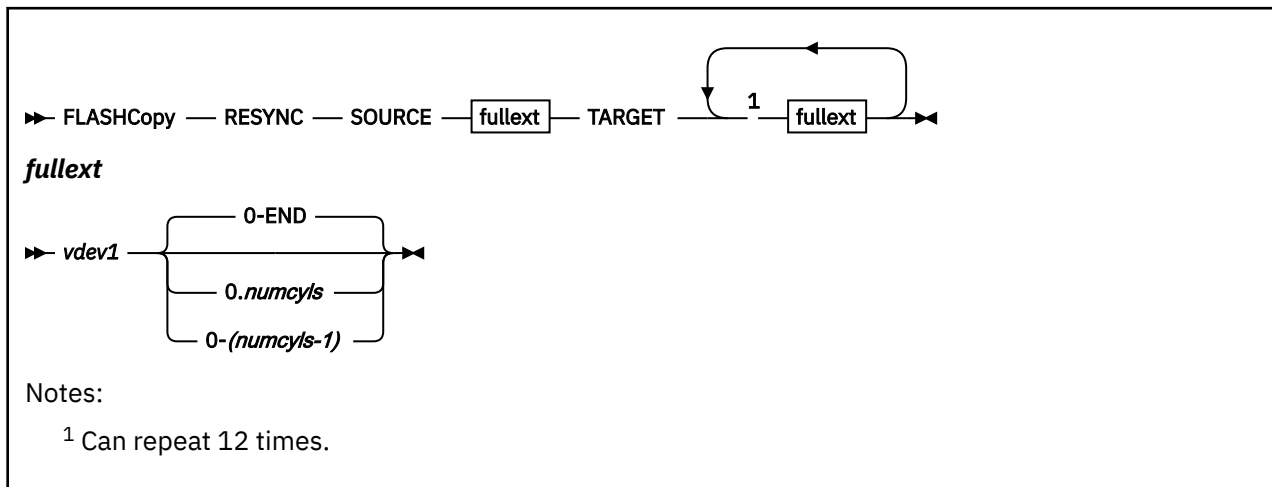

```
q flashcopy hardware 5101
-----SOURCE----- -----TARGET-----
SEQUENCE FLGS RDEV VOLSER CC...CC/HH RDEV VOLSER CC...CC/HH REMAINING/TOTAL
E79D8AB4 8800 5100 RWS001 100/00 5101 RWS002 100/00 0/1500
E79DA36F 8800 5100 RWS001 100/00 5101 RWS002 200/00 0/1500
Ready; T=0.01/0.01 16:02:00
```

## Messages

For a list of general messages that can be issued by the FLASHCOPY ESTABLISH command, see the [“FLASHCOPY” on page 471](#) command.

## FLASHCOPY RESYNC

### Authorization

Privilege Class: B

### Purpose

Use FLASHCOPY RESYNC to resynchronize the specified target of a persistent checkpointed FlashCopy relationship to make the specified target consistent with the current state of the specified source and to establish a new checkpoint. The source volume is not changed.

Checkpoints are established at the completion of the FLASHCOPY ESTABLISH CHGRECORD, FLASHCOPY ESTABLISH REVERSIBLE, AND FLASHCOPY RESYNC commands.

Table 19. FlashCopy Resync Operation

Source Track Changed	Target Track Changed	Action
N	N	None
N	Y	Target track rolled back to current source track
Y	N	Target track rolled forward from current source track
Y	Y	Target track rolled back from current source track

Reversible RESYNC:

A relationship can be reversed by specifying the corresponding source and target operands reversed from their specification during a prior ESTABLISH or RESYNC like this:

```
flashcopy establish source fce0 target fee0 reversible
Command complete: FLASHCOPY FCE0 0 END TO FEE0 0 END
FLASHCOPY RELATIONSHIP 2F41267E ESTABLISHED
Ready; T=0.01/0.01 16:15:51

q flashcopy hardware fce0
-----SOURCE-----
SEQUENCE FLGS RDEV VOLSER CC...CC/HH RDEV VOLSER CC...CC/HH REMAINING/TOTAL
2F41267E 5900 FCE0 RWSCE0 0/00 FEE0 RWSEE0 0/00 0/50085
Ready; T=0.01/0.01 16:16:08

flashcopy resync source fee0 target fce0
RESYNC COMPLETED
Ready; T=0.01/0.01 16:16:30
```

```

q flashcopy hardware fce0
-----SOURCE----- TARGET-----
SEQUENCE FLGS RDEV VOLSER CC...CC/HH RDEV VOLSER CC...CC/HH REMAINING/TOTAL
2F41BC80 C900 FEE0 RWSCE0      0/00 FCE0 RWSCE0      0/00 0/50085
Ready; T=0.01/0.01 16:16:32

```

In the FLGS of the QUERY FLASHCOPY HARDWARE command in the above example, the source of the relationship has become FEE0 and the target has become FCE0.

Prior to reversing a relationship, all of the tracks must have been copied (using the Background Copy Function) onto the target. If this condition is not met, you will receive error B4. In the following example, the FLASHCOPY ESTABLISH command specified NOCOPY which prevented the tracks from being copied to the original target.

```

FLASHCOPY ESTABLISH SOURCE FCE0 TARGET FEE0 CHGRECORD NOCOPY
Command complete: FLASHCOPY FCE0 0 END TO FEE0 0 END
FLASHCOPY RELATIONSHIP 2F267DD5 ESTABLISHED
Ready; T=0.01/0.01 16:15:51

q flashcopy hardware fce0
-----SOURCE----- TARGET-----
SEQUENCE FLGS RDEV VOLSER CC...CC/HH RDEV VOLSER CC...CC/HH REMAINING/TOTAL
2F267DD5 6918 FCE0 RWSCE0      0/00 FEE0 RWSCE0      0/00 49795/50085
Ready; T=0.01/0.01 15:46:45

```

Here is the resulting error:

```

FLASHCOPY RESYNC SOURCE FEE0 TARGET FCE0
HCPPFC3201E DASD Error: Command Reject
HCPPFC3201E Message F: Status not as required
HCPPFC3201E Reason B4: A FlashCopy operation attempted to reverse the
order of the FlashCopy relationship and the target bitmap was not all
zeros (that is, changes pending).
Ready(03201); T=0.01/0.01 15:46:37

```

Because of this limitation, the use of the NOCOPY option is discouraged when you are planning to use reversible relationships. Also, because NOCOPY is forced for space-efficient volumes, then space-efficient volumes cannot be used in this context.

To assist with correctly creating relationships that are reversible, the REVERSIBLE option of the FLASHCOPY ESTABLISH command should be specified.

## Operands

### SOURCE

describes a FlashCopy source volume that is a dedicated device or full-pack minidisk. This is the master volume for the resynchronization.

### TARGET

describes the target volumes that are dedicated devices or full-pack minidisks that are to be resynchronized to the source master volume.

### *vdev1*

defines a dedicated device or full-pack minidisk.

### **0-END**

identifies all the real cylinders of the dedicated device or full-pack minidisk.

### *numcyls*

identifies the number of real cylinders in this extent. The value must be equal to the number of cylinders defined for the dedicated device or full-pack minidisk.

## Usage Notes

1. This relationship is not withdrawn.
2. It is possible to reverse a relationship by specifying the current source and target volumes reversed from their original specification. To accomplish this, the relationship must have been ESTABLISHED with the REVERSIBLE option.

3. The relationship to be resynchronized must have been created with the CHGRECORD or REVERSIBLE option.
4. It does not matter in what order the changes are made to the tracks. For example, if you change source track 100 to value 'X' and later change target track 100 to value 'Y', the RESYNC operation will end with target track 100 having a value of 'X'. In other words, the RESYNC operation proceeds based solely upon the current state of the volumes, not the order in which changes were made.
5. Space-efficient volumes cannot be used for reversible RESYNC operations.
6. We recommend that you do not update the target volume while a RESYNC operation is in progress because some tracks might be written by the application and then rewritten by RESYNC processing. This will likely result in creating a volume that is a mixture of the source and the updates that are being attempted.

## Examples

Example 1:

```
flashcopy establish source 0200 target 0300
flashcopy resync source 0200 target 0300

flashcopy establish source 0200 target 0300 reversible
flashcopy resync source 0300 target 0200
```

## Responses

Response 1:

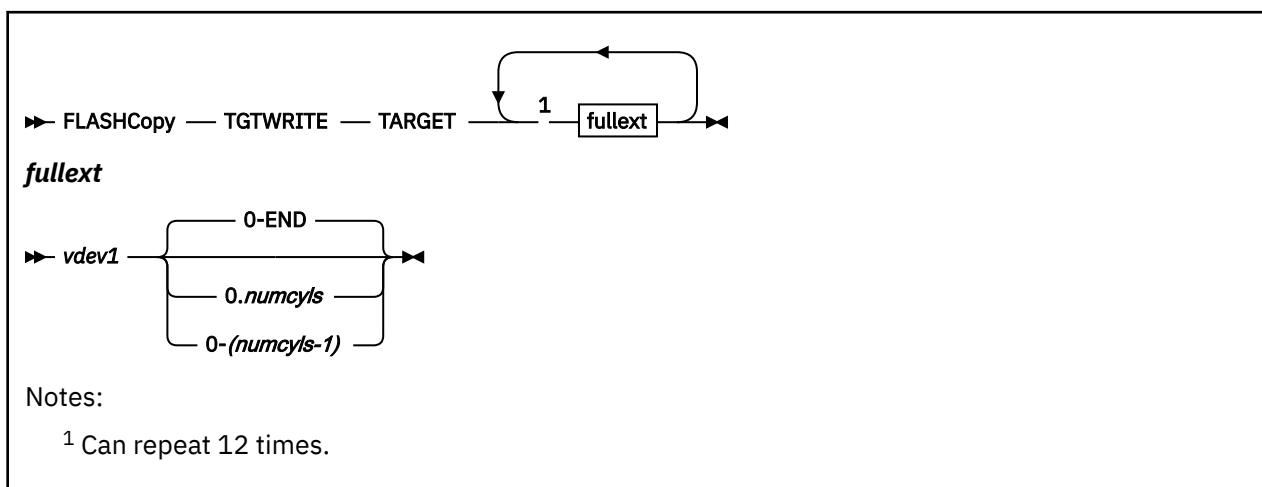

This FLASHCOPY RESYNC command completed successfully:

```
flashcopy resync source 0200 target 0300
RESYNC COMPLETED
Ready;
```

## Messages

For a complete list of messages that can be issued by the FLASHCOPY RESYNC command, see the [“FLASHCOPY”](#) on page 471 command.

## FLASHCOPY TGTWRITE

### Authorization

Privilege Class: B

### Purpose

Use FLASHCOPY TGTWRITE to enable writing on a target full volume that was write-inhibited with the FLASHCOPY ESTABLISH NOTGTWRITE option.

### Operands

#### TARGET

describes the volumes that are dedicated devices or full-pack minidisks that are to be affected.

#### vdev1

defines a dedicated device or full-pack minidisk.

#### 0-END

identifies all the real cylinders of the dedicated device or full-pack minidisk.

#### numcyls

identifies the number of real cylinders in this extent. The value must be equal to the number of cylinders defined for the dedicated device or full-pack minidisk.

### Usage Notes

1. This relationship will not be withdrawn.
2. Applying this command to a REVERSIBLE relationship makes it no longer reversible.

### Examples

Example 1:

```
flashcopy tgtwrite 0300
```

### Responses

Response 1:

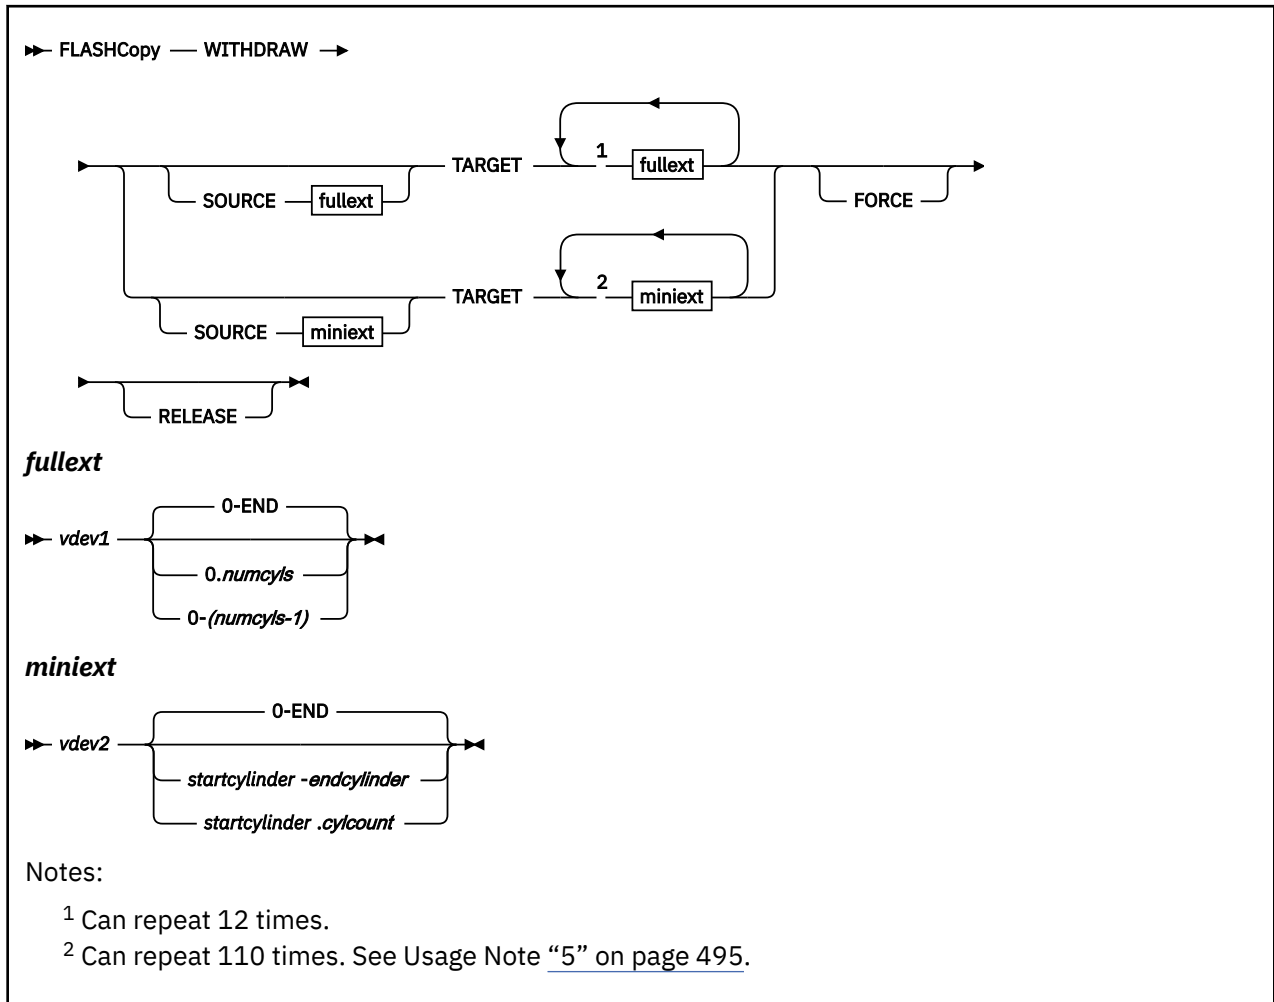

This FLASHCOPY TGTWRITE command completed successfully:

```
flashcopy tgtwrite 0300  
TARGET WRITING NOW ENABLED  
Ready;
```

## Messages

For a complete list of messages that can be issued by the FLASHCOPY TGTWRITE command, see the [“FLASHCOPY” on page 471](#) command.

## FLASHCOPY WITHDRAW

### Authorization

Privilege Class: B

### Purpose

Use FLASHCOPY WITHDRAW to remove a persistent FlashCopy relationship.

### Operands

#### SOURCE

specifies the readable disk and range of cylinders on a dedicated device, full-pack minidisk, or non-full-pack minidisk. If specified, those tracks that are within the source extent and target extent are withdrawn. If source is not specified, the appropriate source extents are determined from the targets.

#### vdev1

defines a dedicated device or full-pack minidisk.

#### 0-END

identifies all the real cylinders of the dedicated device or full-pack minidisk.

**numcyls**

identifies the number of real cylinders in this extent. The value must be equal to the number of cylinders defined for the dedicated device or full-pack minidisk.

**TARGET**

specifies the writable disks and extents that are to be withdrawn. Not all of the cylinders within the specified extents are required to be in an active persistent relationship.

**vdev2**

defines a non-full-pack minidisk.

**0-END**

identifies all the virtual cylinders of the minidisk.

**startcylinder**

identifies the first virtual cylinder number for this extent, starting with 0 to indicate the first cylinder. This can be a value from 0 to the number of cylinders on the minidisk minus 1.

**endcylinder**

identifies the last virtual cylinder number for this extent, starting with 0 to indicate the first cylinder. This can be a value from 0 to the number of cylinders on the minidisk minus 1 and must be greater than or equal to *startcylinder*.

**cylcount**

identifies the number of cylinders in this extent. The value of *startcylinder* plus *cylcount* must be less than or equal to the number of cylinders defined for the minidisk.

**FORCE**

specifies the immediate and unconditional withdrawal of the specified relationships. When FORCE is specified, the target extents might not be usable because the SOURCE data might not have been completely copied.

**RELEASE**

specifies that all TARGET space-efficient tracks or extents are to be destroyed and returned to the space-efficient repository for reassignment.

**Usage Notes**

1. When the last target extent is withdrawn, the corresponding source relationships are withdrawn automatically.
2. If background source-to-target copies are pending and the relationship was established with NOCOPY, you must issue a separate FLASHCOPY BACKGNDCOPY command to initiate the copying process. The FORCE option will not initiate a background copy.
3. After a WITHDRAW FORCE, it is likely that the target will not be in a consistent state. This is because the background copy operation might not have completed and therefore some of the target tracks will not contain the correct data. Issuing a WITHDRAW FORCE during a point-in-time instant backup will likely lead to a backup tape that is not usable.
4. If the number of remaining tracks to be copied is unknown, the value is computed as the size of the extent plus one track.
5. Due to the CP command line length limit of 240 characters, it might not be possible to specify the full 110 extents in some command entry modes.
6. FORCE is required for space-efficient targets.
7. The FORCE option does NOT initiate a background copy operation.

**Examples**

Example 1:

```
define mdisk 0200 100 100 pack01
define mdisk 0300 100 100 pack02

flashcopy establish source 200 0.60 target 300 0.50 300 70-79
Command complete: FLASHCOPY 0200 0 49 TO 0300 0 49
```

## FLASHCOPY WITHDRAW

```
Command complete: FLASHCOPY 0200 50 59 TO 0300 70 79
FLASHCOPY RELATIONSHIP 4A20BAC2 ESTABLISHED
Ready; T=0.01/0.01 10:47:25
```

```
q flashcopy hardware 5101
-----SOURCE----- -----TARGET-----
SEQUENCE FLGS RDEV VOLSER CC...CC/HH RDEV VOLSER CC...CC/HH REMAINING/TOTAL
4A20BAC2 8800 5100 PACK01 100/00 5101 PACK02 100/00 0/750
4A20BAC2 8800 5100 PACK01 150/00 5101 PACK02 170/00 0/150
Ready; T=0.01/0.01 10:47:32
```

### Example 2:

To show that a hole was created in the relationship by withdrawing some of the cylinders in the middle of it:

```
flashcopy withdraw target 300 10-19
RELATIONSHIP WITHDRAWN
Ready; T=0.01/0.01 10:48:11

q flashcopy hardware 5101
-----SOURCE----- -----TARGET-----
SEQUENCE FLGS RDEV VOLSER CC...CC/HH RDEV VOLSER CC...CC/HH REMAINING/TOTAL
4A20BAC2 8800 5100 PACK01 100/00 5101 PACK02 100/00 0/150
4A20BAC2 8800 5100 PACK01 120/00 5101 PACK02 120/00 0/450
4A20BAC2 8800 5100 PACK01 150/00 5101 PACK02 170/00 0/150
Ready; T=0.01/0.01 10:48:21
```

### Example 3:

To withdraw the first 40 cylinders of the target:

```
flashcopy withdraw target 300 0.40
RELATIONSHIP WITHDRAWN
Ready; T=0.01/0.01 10:48:49

q flashcopy hardware 5101
-----SOURCE----- -----TARGET-----
SEQUENCE FLGS RDEV VOLSER CC...CC/HH RDEV VOLSER CC...CC/HH REMAINING/TOTAL
4A20BAC2 8800 5100 PACK01 140/00 5101 PACK02 140/00 0/150
4A20BAC2 8800 5100 PACK01 150/00 5101 PACK02 170/00 0/150
Ready; T=0.01/0.01 10:48:51
```

### Example 4:

To withdraw the entire minidisk: (Note that some of the specified cylinders did not participate in the original relationship.)

```
flashcopy withdraw target 300 0.100
RELATIONSHIP WITHDRAWN
Ready; T=0.01/0.01 10:48:58

q flashcopy hardware 5101
HCP2466E Device 5101 - No FlashCopy relationships reported.
Ready(02466); T=0.01/0.01 10:49:15
```

### Example 5:

A sample REXX script and its invocation that could be used to wait for a relationship to be withdrawn:

```
type withdraw exec
/* REXX Example for FLASHCOPY WITHDRAW */
ARG DEVNO .
DO FOREVER
CMD='FLASHCOPY WITHDRAW TARGET' DEVNO
SAY CMD
CMD
IF RC= 2469 THEN EXIT RC
'SLEEP 5 SEC'
END
Ready; T=0.01/0.01 21:18:59

flashcopy establish source 2000 target 3000
Command complete: FLASHCOPY 2000 0 1999 TO 3000 0 1999
FLASHCOPY RELATIONSHIP 20098185 ESTABLISHED
Ready; T=0.01/0.01 21:17:05
```

```

withdraw 3000
FLASHCOPY WITHDRAW failed because 30000 tracks remain to be copied to 3000.
FLASHCOPY WITHDRAW TARGET 3000
FLASHCOPY WITHDRAW failed because 24600 tracks remain to be copied to 3000.
FLASHCOPY WITHDRAW TARGET 3000
FLASHCOPY WITHDRAW failed because 19137 tracks remain to be copied to 3000.
FLASHCOPY WITHDRAW TARGET 3000
FLASHCOPY WITHDRAW failed because 13641 tracks remain to be copied to 3000.
FLASHCOPY WITHDRAW TARGET 3000
FLASHCOPY WITHDRAW failed because 8001 tracks remain to be copied to 3000.
FLASHCOPY WITHDRAW TARGET 3000
FLASHCOPY WITHDRAW failed because 2514 tracks remain to be copied to 3000.
FLASHCOPY WITHDRAW TARGET 3000
RELATIONSHIP WITHDRAWN
Ready; T=0.01/0.01 21:17:37

```

## Responses

### Response 1:

This FLASHCOPY WITHDRAW command completed successfully:

```

flashcopy withdraw target 300 0.100
RELATIONSHIP WITHDRAWN
Ready;

```

### Response 2:

This FLASHCOPY WITHDRAW command did not completed successfully:

```

q flashcopy hardware 5100
-----SOURCE----- -----TARGET-----
SEQUENCE FLGS RDEV VOLSER CC...CC/HH RDEV VOLSER CC...CC/HH REMAINING/TOTAL
1FCE5D61 1800 5100 RWS001 500/00 5101 RWS002 600/00 26112/30000
Ready; T=0.01/0.01 20:11:48

flashcopy withdraw target 3000
HCPNFC2469E WITHDRAW failed because 26112 tracks remain to be copied to
3000.
Ready(02469); T=0.01/0.01 20:11:52

```

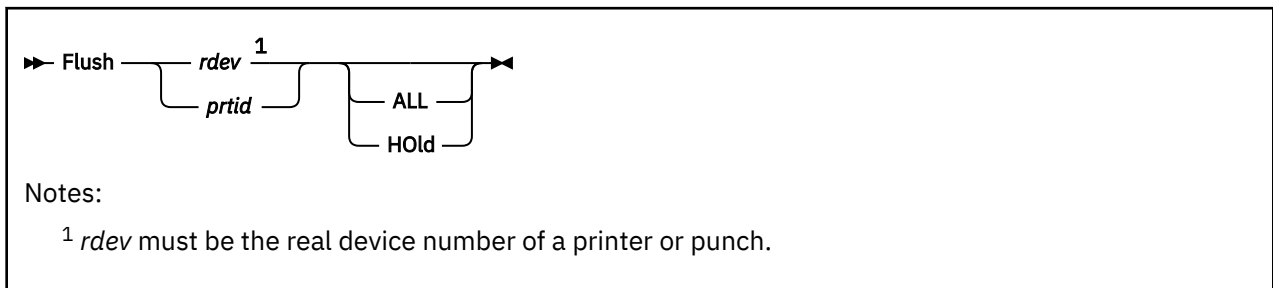

## Messages

For a complete list of messages that can be issued by the FLASHCOPY WITHDRAW command, see the [“FLASHCOPY” on page 471](#) command.

### Messages:

- HCP2469E WITHDRAW failed because *n* tracks remain to be copied to *vdev*.

## FLUSH

### Authorization

Privilege Class: D

### Purpose

Use FLUSH to do the following:

- Halt and immediately purge output on a real unit record device

It resumes activity with the next available spool file, if the unit record device meets the following conditions:

- No intervention is required.
- The device was not drained.
- The device was not taken offline.

### Operands

#### *rdev*

identifies the real device number of the real printer or punch whose current file is to be terminated. Each *rdev* must be a hexadecimal device address between X'0000' and X'FFFF'.

#### *prtId*

indicates that the entire command is to be passed for processing to the print server virtual machine designated by *prtId*. The operand *prtId* is provided by the print server virtual machine, which will enter the FLUSH command to an AFP. It is 1 to 8 alphanumeric characters long. If you specify a *prtId* of four or fewer characters, *prtId* must not contain all hexadecimal characters; because CP then interprets *prtId* as *rdev*.

#### ALL

deletes all copies of the current output file. If more than one copy of the current output file is being printed or punched and you specify ALL, all copies are deleted. If you do not specify ALL, only the current copy is deleted; and the next copy, if any, is printed or punched.

#### HOLD

places the spool file in system hold status; the file is not purged. You can reset the file status using the CHANGE command.

### Usage Notes

1. You normally use the FLUSH command when a mistake in output queuing has occurred or a high-priority job must be started before the current job has finished. For example, you would enter FLUSH if a file was directed to a printer equipped with the wrong printer train or a file was misdirected to the real punch rather than to a user's virtual reader.

2. Special handling is required if a spool file is started on a real output device that cannot be made ready. If this condition occurs, the operator receives an error message, recovers the file, and restarts it. To do so, enter **flush rdev hold**.
3. If the operator has specified HOLD, the file is placed in system hold status. If not and multiple copies of the file are to be processed, the file is requeued and started on another device, if one is available.
4. The virtual machine associated with *prt* processes the FLUSH command. Therefore, the options given on the FLUSH command must be valid for the virtual machine processing it.

## Responses

Response 1:

```
PRT rdev FILE FLUSHED userid FILE spoolid RECS nnnn COPY [*]nnn SEQ sss CL c type
PUN      FILE HELD          nnnK
        COPY FLUSHED      nnnM
```

### PRT

### PUN

identifies the type of device you have flushed.

### rdev

identifies the real device number of the printer or punch to be affected.

### FILE FLUSHED

### FILE HELD

### COPY FLUSHED

indicates the disposition for the file.

### userid

identifies the user who was to receive the output.

### spoolid

identifies the system-assigned number by which CP refers to the file.

### RECS nnnn

### RECS nnnK

### RECS nnnM

identifies the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines in thousands rounded to the nearest 1000 records. If the number is greater than 999499, then the number is shown as *nnnM*, where M represents the number of lines in millions rounded to the nearest million.

### COPY nnn

### COPY \*nnn

specifies the number of file copies you want printed or punched when the file is produced.

When the optional asterisk (\*) is specified, the 3800 printer prints each page from the spooled output files *nnn* times before going on to the next page.

If a file is not spooled to the 3800 printer, the function indicated by the asterisk (\*) is ignored and duplication occurs normally.

### SEQ sss

identifies the sequence number for the file on the printer or punch.

**Note:** CP itself does not provide a response for *prtids*. The virtual machine associated with *prt* provides the response.

### CL c

is the spool file class.

### type

shows the device type that originally produced the spool file. The type can be RDR, PRT, PUN, CON, DMP, or SYS.

### Messages

- HCP003E Invalid option - *{option|command}* contains extra option(s) starting with *option*
- HCP021E A real device number was not supplied or it is invalid.
- HCP040E Device *{rdev/vdev/ldev}* does not exist
- HCP046E *type rdev* offline
- HCP140E *type {rdev/ldev}* attached to *userid*
- HCP141E *type rdev* not active
- HCP417E *{rdev/vdev}* is not an output spooling device.
- HCP418E *{rdev/vdev}* is not a spooled device.
- HCP422E The same option was specified twice.
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP1043E *{Printer|Punch} rdev* was not flushed because SPXTAPE is using the file which is active on the *{printer|punch}*. Wait until SPXTAPE has finished and reissue the command.

## FOR

## Authorization

Privilege Class: C, G

## Purpose

Use FOR to execute a CP command on another virtual machine and receive the command's responses and return code either to your terminal or over an IUCV connection to the [Asynchronous CP Command Response system service \(\\*ASYNCCMD\)](#) in *z/VM: CP Programming Services*.

## Operands

### *userid*

identifies the virtual machine that is to be the target for the CP command.

### PATH *pathid*

specifies which IUCV connection to the Asynchronous CP Command Response system service should be used to receive the command's responses and return code. The *pathid* may be specified as either 1 - 4 hexadecimal digits or as an asterisk (\*). When specifying an asterisk, the most recent connection is used. When a path is not specified, command responses and the return code will be sent to the console of the FOR command issuer.

### TOKEN *token\_value*

specifies the correlation token included on each command response record and each command return code record. The *token\_value* is a 1 - 16 character, blank-delimited user-specified string. The correlation token is used to sort out interleaved responses from consecutively issued FOR commands or for any other purpose.

### CMD

indicates that the command text follows.

### *text*

specifies the CP command to issue. If *text* contains multiple commands, each command and its associated parameters must be separated from adjacent commands by the value X'15'.

## Usage Notes

1. The return code from the FOR command will be received immediately. Then, asynchronously, the CP command is executed on the target virtual machine.
2. The FOR command captures only synchronous responses from CP commands issued to the target virtual machine. Commands which generate asynchronous responses, such as SPXTAPE, REWIND, and XAUTOLOG without the SYNCH option, are not recommended for use with the FOR command. For more information, see [“Delayed Responses to CP Commands”](#) on page 7.
3. The target of the FOR command will not receive any command responses.
4. If you specify the IUCV connection to the \*ASYNCCMD system service, the format of the data sent via IUCV by the [Asynchronous CP Command Response system service \(\\*ASYNCCMD\)](#) is described in *z/VM: CP Programming Services*.

5. The format of command responses directed to the console of the FOR command issuer is as follows:

```
userid : token : text
```

where:

**userid**

is the user ID specified on the FOR command which is the target of the CP command. This field is 8 characters long and delimited by a colon with spaces on both sides.

**token**

is the correlation value specified on the FOR command. This field is 16 characters long and delimited by a colon with spaces on both sides. This field, including the delimiter and spaces, is not displayed when a token value is not specified.

**text**

is the actual response that would have displayed on the target virtual machine's console using the EMSG ON setting. The virtual processor running the CP command is not displayed as a prefix in the command response.

After all command responses are displayed to the console of the FOR command issuer, a final command return code is displayed. The *text* field will have the following format where *nnnn* is the return code value.

```
Command Complete. CP return code = nnnn
```

6. Unlike the SEND command, the FOR command does not translate the receiver's logical line-end character.
7. A class G user can issue CP commands to a virtual machine for which the user can provide secondary console services. A class C user can issue CP commands to any virtual machine.
8. The target virtual machine needs to have the correct privilege or authorization to execute the issued CP command.
9. If the FOR command is executing multiple commands and encounters an invalid command, processing stops and the remaining commands are ignored.

## Examples

Example 1:

To see a list of commands authorized for a user to issue, enter:

```
for user1 cmd commands
Ready;
USER1   : ADJUNCT  ATTN      BEGIN    CHANGE   CLOSE    COMMANDS
USER1   : COUPLE   CPU       DEFINE   DETACH   DIAL     DISCONNECT
USER1   : DISPLAY  DUMP     ECHO     EXTERNAL FOR     INDICATE
USER1   : IPL      LINK     LOADVFCB LOCATEVM
...
USER1   : DIAG278  DIAG27C  DIAG280  DIAG288  DIAG29C  DIAG2A0
USER1   : DIAG2A4
USER1   : HCPFOR069I Command Complete. CP return code = 0000.
```

Example 2:

To receive a list of commands authorized to be issued for a user with responses directed to path ID 5, an IUCV connection to \*ASYNCMD, and the token value COMMANDLIST1 included in the output, enter:

```
for user1 path 5 token COMMANDLIST1 cmd commands
```

Example 3:

To display the resources occupied by a user enter:

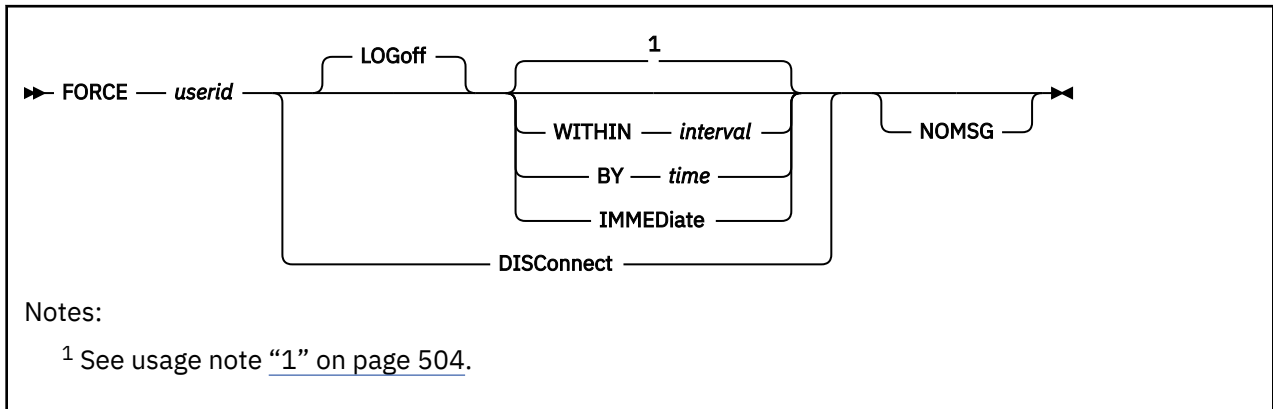

```
for user2 cmd indicate user
Ready;
USER2   : USERID=USER2  MACH=XA  STOR=128M VIRT=V XSTORE=---
```

```
USER2 : IPLSYS=CMS      DEVNUM=00016
USER2 : PAGES: RES=00001291 WS=00000625 LOCKEDREAL=00000000
USER2 : NPREF=00000000  PREF=00000000  READS=00000000  WRITES=00000000
USER2 : CPU 00: CTIME=00:03 VTIME=000:00 TTIME=000:00 IO=000533
USER2 :          RDR=000000 PRT=000000 PCH=000000
USER2 : HCPFOR069I Command Complete. CP return code = 0000.
```

## FORCE

### Authorization

Privilege Class: A

### Purpose

Use FORCE to disconnect or log off an active user.

### Operands

#### *userid*

identifies the user to be logged off or disconnected.

#### **LOGoff**

indicates that the user should be logged off. Logoff is the default action. When the action is logoff, you can also specify one of the WITHIN, BY, or IMMEDIATE timing operands.

#### **DISConnect**

indicates that the user should be disconnected.

#### **NOMSG**

indicates that the asynchronous FORCE response message should be suppressed. This option has no affect when issued by the primary system operator.

#### **WITHIN *interval***

sends the user a shutdown signal and delays logging them off until either the specified interval has elapsed or the user machine indicates that it has shut down, whichever occurs first. The *interval* specifies a number of seconds in the range 1 - 65535. If the user is not enabled for shutdown signals, this operand is ignored and the user is logged off immediately. See usage note “8” on page 505.

#### **BY *time***

sends the user a shutdown signal and delays logging them off until either the designated time of day is reached or the user machine indicates that it has shut down, whichever occurs first. The *time* can be specified as *hh:mm* or *hh:mm:ss*. The equivalent interval in seconds must be in the range 1 - 65535. If the user is not enabled for shutdown signals, this operand is ignored and the user is logged off immediately. See usage note “8” on page 505.

#### **IMMEDIATE**

logs off the user immediately without first sending them a shutdown signal. If the user is in the process of being logged off, any delay to allow the guest to process a shutdown signal is terminated. See usage note “8” on page 505.

### Usage Notes

- Notes about logoff timing:

- a. If the user is not enabled for shutdown signals, then the logoff begins immediately.
- b. If the user is enabled for shutdown signals, then the logoff timing is determined as follows:
  - If the user is currently in a status-pending condition, then the logoff begins immediately.
  - If the user is not in a status-pending condition, then the logoff timing is determined as follows:
    - If a timing operand (WITHIN, BY, IMMEDIATE) is specified, then the timing operand determines the logoff timing.
    - If a timing operand (WITHIN, BY, IMMEDIATE) is not specified, then the logoff is delayed by up to the amount of time that is defined by the system-default shutdown-signal timeout interval. The logoff is delayed until the system-default shutdown-signal timeout interval elapses or until the user machine indicates that it is shut down, whichever occurs first.
2. FORCE may not be able to cause the logoff of a hung-up user or a user with I/O outstanding, because either of these conditions may prevent completion of the LOGOFF function. As an alternative, the DISCONNECT option may be used to disassociate the user ID from its terminal, thus freeing up the device.
3. If the user's virtual machine is hung waiting for a device which is not operational or the system operator can determine the I/O device involved and either make that device ready or enter a HALT command; this allows the user to continue operation or be forced from the system. (Use QUERY to determine the status of all or selected devices) For more information see the description of the HALT command.
4. The disconnect performed by the FORCE command may take significant time to complete because of the attempt made to process the disconnect even in the case of a hung terminal.
5. If a user is force disconnected while a read is posted from the user's virtual machine or from CP, and that user does not have a logged on secondary user, the user then has some installation-defined grace period (usually 15 minutes) in which to log on or else the user's virtual machine is automatically logged off.
6. Users who are being forced from the system will be given QUICKDSP designation to expedite the logoff of the user.
7. If the user who is being forced from the system has an open RDR file and the user's virtual reader is spooled NOHOLD and NOKEEP, the open file will be retained on the user's RDR queue in USER hold status.
8. A user is enabled for signals only when a guest operating system is running in the virtual machine and has enabled to receive these signals.
 

If the FORCE *userid* command is specified with no operands (other than NOMSG), and the specified user is enabled for shutdown signals, and a system default shutdown signal timeout interval greater than 0 is defined (by the SET SIGNAL SHUTDOWNTIME system configuration statement or command), that timeout value is used to delay the logoff, and a shutdown signal is sent to the user to give the guest system an opportunity to do its own shutdown processing. If the system default shutdown signal timeout interval is 0, or no value is defined (which defaults to 0), or the specified user is not enabled for shutdown signals, no signal is sent, and the user is immediately logged off. Refer to [“SET SIGNAL” on page 1701](#) for additional information about this behavior.

If the specified user is enabled for shutdown signals but is currently in a status-pending condition, the user will be logged off immediately.
9. The FORCE (of the relocating guest by another user) command will fail if issued when VMRELOCATE is in progress.
10. If the forced-off user is enabled for signals, the FORCE *user* command sends a shutdown signal to the forced user and this message is sent to the primary system operator:

```
HCP2118I Shutdown signal sent to user because a FORCE was issued at
yyy-mm-dd hh:mm:ss by userid
```

If a user is enabled for shutdown signals and is currently in a status-pending condition, message HCP2118I is *not* sent to the primary operator's console when this user is forced.

## Responses

Response 1:

```
{LOGOFF } AT hh:mm:ss zone weekday mm/dd/yy BY {SYSTEM}
{DISCONNECT} {userid}
```

In addition, if LOGOFF was selected, then this response will accompany the normal accounting message produced at logoff.

### LOGOFF DISCONNECT

indicates whether the virtual machine was logged off or disconnected.

#### **hh:mm:ss**

identifies the current time in hours:minutes:seconds.

#### **zone**

identifies the time zone.

#### **weekday**

identifies the current day of the week.

#### **mm/dd/yy**

identifies the current date in month/day-of-month/year format.

### SYSTEM

#### **userid**

indicates who forced the logoff or disconnect your virtual machine. If you were forced by another user, and not the system, that user's *userid* appears in the message.

Response 2:

```
{type {rdev} } {LOGOFF AS } userid USERS = nnnnn FORCED BY {userid}
{ {ldev} } {DISCONNECT}
{luname }
```

is the message received by the primary system operator. In addition, if the Class A issuer of the command is not the primary system operator and the NOMSG option was not specified, then the command issuer also receives this response.

### LOGOFF AS DISCONNECT

indicates whether the user was logged off or disconnected.

#### **type**

identifies the display device type.

#### **rdev**

#### **ldev**

identifies the real or logical device number.

#### **luname**

identifies an SNA/CCS terminal controlled by a VTAM service machine. It is the name from the VTAM definition of the terminal as an SNA logical unit.

#### **userid**

identifies the user who was forced.

#### **USERS = nnnnn**

identifies the number of users remaining on the system.

#### **userid**

### SYSTEM

indicates who forced the virtual machine. If forced by another user, and not the system, that user's *userid* appears in the message.

Response 3:

```
USER DSC LOGOFF AS userid USERS = nnnnn FORCED BY {SYSTEM} {userid}
```

is issued to the primary system operator and the command issuer (when the issuer is not the primary system operator and the NOMSG option was not specified) if the user is already disconnected, and the FORCE command is used to log that user off the system.

### **USER DSC**

indicates that the user's virtual machine was disconnected when the FORCE command was issued.

### ***userid***

identifies the user who was forced off.

### **USERS = *nnnnn***

identifies the number of users who remain on the system.

Response 4:

```
Shutdown signal may delay logoff for up to interval seconds
```

is issued to the command issuer (when the NOMSG option was not specified) if the FORCE may be delayed in order to allow the user time to shut down.

### ***interval***

is the amount of time (in seconds) that the guest will be given to terminate before it is logged off.

## **Messages**

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP013E Conflicting option - *option*
- HCP045E *userid* not logged on
- HCP361E [XAUTOLOG failed for *userid*:] LOGOFF/FORCE pending for user *userid*
- HCP1514E *userid* already disconnected
- HCP1801E Command *command* could not be completed due to a relocation in progress
- HCP2114I User *userid* termination may be delayed for up to *interval* seconds
- HCP2118I Shutdown signal sent to *user* because a FORCE was issued at *yyyy-mm-dd hh:mm:ss* by *userid*
- HCP6704E Missing token at end of line

## FORWARD

Notes:

<sup>1</sup> *rdev* must be the real device number of a printer or punch.

### Authorization

Privilege Class: D

### Purpose

Use FORWARD to reposition current spool output on a real printer or punch.

### Operands

***rdev***

identifies the device number of the real printer/punch you want spaced forward.

**1**

***nnnnn***

specifies the number of pages or cards to be spaced forward. The limit is 32,767; the default is 1.

### Usage Notes

Pages are counted in FORWARD operations by looking for page ejects. If a file contains no page ejects, 66 output lines (including blanks) are treated as a “page.” The count begins at the end of the current buffer.

### Responses

Response 1:

```
{PRT} rdev FORWARD userid FILE spoolid RECS {nnnn}
{PUN} {nnnK}
{nnnM}
```

```
COPY [*]nnn SEQ sss CL c typ
```

**PRT**

**PUN**

identifies the device type.

***rdev***

identifies the real device number.

***userid***

identifies the user whose file was active and spaced forward.

***spoolid***

identifies the system-assigned number of the spool file.

**RECS *nnnn*****RECS *nnnK*****RECS *nnnM***

identifies the number of logical records left in the file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines in thousands rounded to the nearest 1000 records. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines in millions rounded to the nearest million.

**COPY [*\**]*nnn***

identifies the remaining number of file copies to be produced, where 001 is the last copy. The asterisk (\*) is for the 3800 printer and indicates that the printer copies each page *nnn* times before going to the next page.

**SEQ *sss***

identifies the sequence number of the printer/punch file.

**CL *c***

is the spool file class.

***typ***

shows the device type that originally produced the spool file. The type can be RDR, PRT, PUN, CON, DMP, or SYS.

**Messages**

- HCP003E Invalid option - *{option|command}* contains extra option(s) starting with *option*}
- HCP021E A real device number was not supplied or it is invalid.
- HCP040E Device *{rdev/vdev/ldev}* does not exist
- HCP046E *type rdev* offline
- HCP140E *type {rdev/ldev}* attached to *userid*
- HCP141E *type rdev* not active
- HCP417E *{rdev/vdev}* is not an output spooling device.
- HCP418E *{rdev/vdev}* is not a spooled device.

## FREE LOGON

---

```
►► FRee — userid — LOGon ◄◄
```

### Authorization

Privilege Class: B

### Purpose

Use FREE LOGON to release a user ID from hold logon status, and allow the user to access the host system.

### Operands

#### *userid*

identifies the user to be removed from logon hold status.

#### LOGon

allows the specified user to access the host system.

### Usage Notes

1. Use FREE LOGON in conjunction with hold logon.
2. When this command is issued on a member of an SSI cluster for a user ID that is defined as a single-configuration virtual machine, the command is propagated to all the other members of the SSI cluster. If the user ID is defined as a multiconfiguration virtual machine, this command is not propagated across the SSI cluster.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP007E Invalid userid - *userid*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP053E [XAUTOLOG failed for *userid*:] *userid/value* not in CP directory
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP1553I *userid* is not in hold status for {*printer*|*punch*|*logon*|all devices}.

## FREE PRINTER/PUNCH

### Authorization

Privilege Class: D

### Purpose

Use FREE PRINTER/PUNCH to release user spool files from system hold.

### Operands

#### *userid*

identifies the user whose spool files are to be released. The user need not be logged on.

#### **ALL**

specifies that all print/punch files are to be freed. This is the default.

#### **Printer**

#### **PRT**

specifies that print files are to be freed.

#### **PUnch**

#### **PCH**

specifies that punch files are to be freed.

### Usage Notes

1. Use FREE PRT/PUN in conjunction with HOLD PRT/PUN.
2. After you enter the FREE command, all new files are put into nohold status.
3. A spool file can be freed from either or both of two types of hold status:
  - User
  - System.

All files in user hold status can be freed by the user who created the file or by a class D user.

All files in system hold status can be freed by the class D user only; the commands used are FREE and CHANGE NOSYS.

A spool file in both types of hold status must be freed from each one before the file can be processed.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP007E Invalid userid - *userid*
- HCP020E Userid missing or invalid

## FREE PRINTER/PUNCH

- HCP026E Operand missing or invalid
- HCP053E [XAUTOLOG failed for *userid*:] *userid/value* not in CP directory
- HCP475I Fatal I/O error trying to read directory from *volid* [for user *userid*]
- HCP1553I *userid* is not in hold status for {printer|punch|logon|all devices}.

## GIVE

---

### Authorization

Privilege Class: B

### Purpose

Use GIVE to transfer control either permanently or temporarily to a:

- Dedicated virtual tape drive from *your virtual machine* to another user's virtual machine.
- Dedicated real tape drive from *another user's virtual machine* to a third user's virtual machine.

### Usage Notes

(General for GIVE)

1. SET IMSG OFF suppresses informational messages for this command.
2. If you enter a command to transfer a real tape drive from your virtual machine, it is still treated as transferring the virtual tape drive. In such a case, if you have different device numbers for the real device and the virtual device associated with the tape drive, the responses refer to the virtual device number, even though you specified the real device number in your command.
3. The receiver and the giver in a command cannot be the same user.
4. The GIVE command will not alter the ASSIGN/UNASSIGN state of the device.
5. Any encryption settings that were defined to the device via SET RDEV and/or ATTACH are retained across a GIVE command.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *option*
- HCP006E Invalid device type - *device*
- HCP007E Invalid userid - *operand*
- HCP013E Conflicting option - *option*
- HCP020E Userid missing or invalid
- HCP021E A device number was not supplied or it was invalid.
- HCP022E A virtual device number was not supplied or it was invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {*rdev|vdev*} does not exist
- HCP045E *userid* not logged on
- HCP120E *type* {*rdev|vdev*} not given.; *userid vdev* already defined
- HCP121E *type rdev* not attached to *userid*
- HCP153E Device *vdev* exceeds maximum number of virtual devices
- HCP422E The same option was specified twice.
- HCP1105E Tape *rdev* not attached; Tape assigned elsewhere.
- HCP1107E Attach failed; I/O error on tape *rdev*
- HCP1115E Device [*vdev|rdev*] was not given. A [GIVE|return] is (already) pending for device [*vdev|rdev*].
- HCP1116E Tape *rdev* not attached; the tape is being rewind.

## GIVE

- HCP1118E Device [*vdev*|*rdev*] was not given. GIVE cannot be performed on a device attached MULTIUSER.
- HCP1120E The requested GIVE for device *rdev* did not complete in the allotted time.
- HCP1123E Multiple options are possible for operand *operand*. Resolution is impossible.
- HCP1128E Device *rdev* not attached; *user* is not authorized.
- HCP1561I Real device *rdev* forced R/O; unauthorized for R/W.
- HCP6863E *userid*: Device *rdev* has not been attached because it is a DPS=NO device and the CHPIDVirtualization option is specified for the user in the directory.

## GIVE (Real Device)

### Authorization

Privilege Class: B

### Purpose

Use GIVE (Real Device) to transfer control of a real tape drive dedicated to one user, from that user's virtual machine to another user's virtual machine.

### Operands

#### *rdev*

is a real device number of the tape drive to be transferred from the indicated user.

#### *userid1*

#### **FRom *userid1***

\*

identifies the virtual machine to which the device is currently attached. The specified user must be logged on and not in the process of logging off. If you are issuing the GIVE (Real Device) command to give a device from your own virtual machine, you can specify *userid1* as an asterisk (\*).

Use the keyword FROM when:

- You specify a user ID with four numbers or fewer
- You specify a user ID that could also be a valid hexadecimal device address (for example, ABC)
- You specify *userid1* as "to" or "fr" or "fro" or "from".

#### *userid2*

#### **TO *userid2***

\*

identifies the virtual machine that receives the tape drive. If you are issuing the GIVE (Real Device) command to transfer the ownership from another user to your virtual machine, you can specify *userid* as an asterisk (\*). The receiver must be logged on to the system. The specified user ID must not be that of the giver (the virtual machine to which the device is currently attached). If the user ID of the specified receiver is also a valid hexadecimal number of not more than 4 digits and the immediate operand following this operand is not "[AS] *vdev*", the command is rejected with error message HCP1123E.

Use the keyword TO when:

- You specify a user ID with four numbers or fewer
- You specify a user ID that could also be a valid hexadecimal device address (for example, ABC)

## GIVE (Real Device)

- You specify *userid2* as "TO" or "FR" or "FRO" or "FROM".

### **vdev**

#### **AS vdev**

is the virtual number to be assigned to the tape drive when it is attached to the target virtual machine. If this is omitted, the real device number is assigned as the virtual device number. If *vdev* is specified, it should be the last operand before the options.

Use the keyword AS when device number to be specified can also be a valid user ID.

## Options

Options may be specified in any order. Conflicting options (for example, RETurn/NORETurn) cause an error message to be issued and the command to be terminated. The only valid options are:

### **RETurn**

specifies that the invoker wishes to regain control of the transferred tape drive when detached by the receiver. If this is the case, RETurn must be explicitly specified.

### **NORETurn**

specifies that the invoker does not wish to regain control of the transferred tape drive when detached by the receiver. NORETurn is the default and need not be explicitly specified.

### **R/O**

causes the tape drive to be attached to the target virtual machine in read only mode. Attempting to write to a tape drive given with R/O specified results in an error.

### **R/W**

causes the tape drive to be attached to the target virtual machine in read/write mode. R/W is the default and need not be explicitly specified.

### **LEAVE**

specifies that the tape is to be left in its position when it is detached and returned to the original owner. LEAVE is the default when RETurn is specified.

### **UNLOAD**

specifies that the tape is to be rewound and unloaded when it is detached from the receiver.

## Usage Notes

1. If a class B user issues the DETACH command to detach a GIVEN tape drive, any UNLOAD or LEAVE options specified on the DETACH command override the option that was specified on the GIVE command. If no option was specifically requested on the DETACH command, the option specified on GIVE is in effect. If LEAVE or UNLOAD are not specified on either the GIVE or DETACH command, the tape is rewound and unloaded.
2. "FRom *userid1*" and "TO *userid2*" need not be specified in the order shown if "FRom" and "TO" are used.
3. If "FROM" "TO" and "AS" are omitted, the first valid operand for a user ID is taken as the GIVER and the second valid operand for a user ID is taken as the RECEIVER.
4. "FROM *userid*" and "TO *userid*" can be interchanged in the command syntax order.
5. The LEAVE option is valid only when the RETurn option is specified.

## Responses

The following are the command responses issued to the giver and receiver as a result of successful completion of the GIVE command.

Response 1:

*giver*

```
tape vdev1 given to userid vdev2 [R/O]
```

This response is issued to the invoking virtual machine to inform the user that the tape drive was successfully transferred. If read-only access was specified, R/O is appended to the response.

Response 2:

*operator*

```
tape rdev given to userid1 vdev
from userid2 by userid3 [R/O]
```

This response is issued to the primary system operator to inform the operator that ownership of the tape drive was transferred from *userid2* to *userid1* and is attached to *userid1* at virtual device number *vdev*. If read-only access was specified, R/O is appended to the response.

Response 3:

*receiver*

```
tape vdev2 attached [R/O]
```

This response is issued to the receiving virtual machine to inform the user that a tape drive is attached. If read-only access was specified on the GIVE command, the R/O is appended to the response.

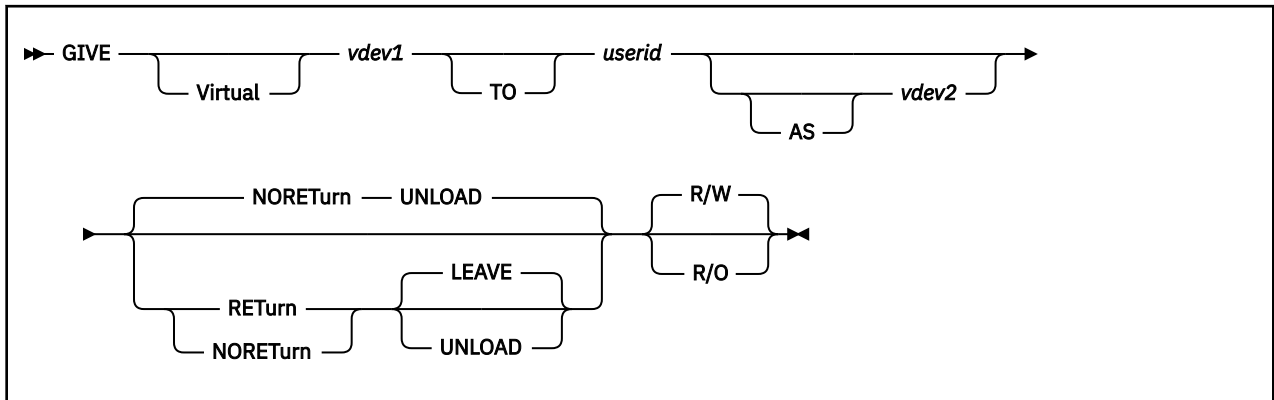

Response 4:

*originator*

```
tape rdev given to userid1 vdev
from userid2 [R/O]
```

This response is issued to the originator of the command to inform the user of the successful completion of the command. If the originator is the same as the GIVER or the operator or receiver then this response is not issued. *userid1* is the receiver of the device and *userid2* is the receiver of the device. If read-only access was specified, then R/O is appended to the response.

## GIVE (Virtual Device)

### Authorization

Privilege Class: B

### Purpose

Use GIVE (Virtual Device) to transfer control of a dedicated tape drive from your virtual machine to another virtual machine.

### Operands

#### *vdev1*

is the virtual address of the tape drive to be transferred. If this is not specified, the command is rejected.

#### *userid*

##### **TO *userid***

identifies the virtual machine that receives the tape drive. The receiver must be logged on to the system. The specified user ID must not be that of the invoking virtual machine (for example, one cannot GIVE a tape drive to oneself). If a valid user ID is not specified, the command is rejected.

Use the keyword TO when:

- You specify a user ID with four numbers or fewer
- You specify a user ID that could also be a valid hexadecimal device address (for example, ABC)
- You specify for giver or receiver a user ID that is "TO" or "FR" or "FRO" or "FROM".

#### *vdev2*

##### **AS *vdev2***

is the virtual number to be assigned to the tape drive when it is attached to the target virtual machine. If this is omitted, the real device number is assigned as the virtual device number.

Use the keyword AS when the device number to be specified can also be a valid user ID.

### Options

Options may be specified in any order. Conflicting options (for example, RETURN/NORETURN) cause an error message to be issued and the command to be terminated. The only valid options are:

#### **RETurn**

specifies that the invoker wishes to regain control of the transferred tape drive when detached by the receiver. If this is the case, RETurn must be explicitly specified.

**NORETurn**

specifies that the invoker does not wish to regain control of the transferred tape drive when detached by the receiver. NORETurn is the default and need not be explicitly specified.

**R/O**

causes the tape drive to be attached to the target virtual machine in read-only mode. Attempting to write to a tape drive given with R/O specified results in an error.

**R/W**

causes the tape drive to be attached to the target virtual machine in read/write mode. R/W is the default and need not be explicitly specified.

**LEAVE**

specifies that the tape is to be left in its position when it is detached and returned to the original owner. LEAVE is the default when RETurn is specified.

**UNLOAD**

specifies that the tape is to be unloaded and rewound when it is detached from the user. This is the default and is accepted even if RETURN is not specified.

**Usage Notes**

1. If a class B user issues the DETACH command to detach a GIVEN tape drive, any UNLOAD or LEAVE options specified on the DETACH command override the option that was specified on the GIVE command. If no option was specifically requested on the DETACH command, the option specified on GIVE is in effect.
2. The LEAVE option is valid only when the RETurn option is specified.

**Responses**

The following are the command responses issued to the giver and receiver as a result of successful completion of the GIVE command.

Response 1:

*giver*

```
tape vdev1 given to userid vdev2 [R/O]
```

This response is issued to the invoking virtual machine to inform the user that the tape drive was successfully transferred. If read-only access was specified, then R/O is appended to the response.

Response 2:

*operator*

```
tape rdev given to userid1 vdev by userid2 [R/O]
```

This response is issued to the primary system operator to inform the operator that ownership of the tape drive was transferred from *userid2* to *userid1* and is attached to *userid1* at virtual device number vdev. If read-only access was specified, R/O is appended to the response.

Response 3:

*receiver*

```
tape vdev2 attached [R/O]
```

This response is issued to the receiving virtual machine to inform the user that a tape drive is attached. If read-only access was specified on the GIVE command, the R/O is appended to the response.

# HALT

```
▶▶ HALT — rdev ◀◀
```

## Authorization

Privilege Class: A

## Purpose

Use HALT to end execution of an active channel program.

**Attention:** Use this command only in extreme cases and after careful consideration. Indiscriminate use of this command may cause unwanted results.

## Operands

*rdev*

is the device number of the real device to be stopped.

## Usage Notes

1. After issuing HALT, enter the QUERY (real devices) command to determine the status of the device. If the device requires intervention, you should make the device ready.

## Responses

Response 1:

```
HALT INITIATED TO type rdev
```

indicates that the system has accepted the command and initiated action to halt the device.

Response 2:

```
HALT NOT INITIATED BECAUSE type rdev IS NOT ACTIVE
```

indicates that a HALT was issued to an idle device and that the system has not accepted the command.

*type*

identifies the device halted. The possible *type* values are:

Type	Meaning
DASD	Direct access storage device
FCP	SCSI device adapter
TAPE	Magnetic tape
RDR	Card reader
PRT	Printer
PUN	Card punch
GRAF	Display device
CONS	Console
CTCA	Channel-to-channel adapter

Type	Meaning
OSA	Open Systems Adapter
CTLR	3745 Communications Controller
MSC	Mass Storage Controller
SWCH	Dynamic Switching Device
DEV	Any other device
LINE	Communication line.

**rdev**

identifies the real device.

**Messages**

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP021E A real device number was not supplied or it is invalid.
- HCP040E Device {*rdev/vdev/ldev*} does not exist

## HOLD LOGON

```
►► Hold — userid — LOGon ◄◄
```

### Authorization

Privilege Class: B

### Purpose

Use HOLD LOGON to prevent a user from accessing the host system.

### Operands

#### *userid*

identifies the user you want to prevent accessing the host system. The user need not be logged on.

#### LOGon

prevents the specified user logging on the host system.

### Usage Notes

1. Use the FREE command to release a user from logon hold status.
2. The HOLD LOGON command is not allowed for the user ID defined as the primary system operator on the SYSTEM\_USERIDS statement in the system configuration file.
 

**Note:** If a primary system operator user ID is not specified, the default is OPERATOR.
3. A maximum of 32 users can be put into hold at any one time.
4. If a guest is logged onto one system in an SSI cluster, it cannot be relocated to another system that has a logon hold in effect for that user. The VMRELOCATE command will fail if this is attempted.
5. When this command is issued on a member of an SSI cluster for a user ID that is defined as a single-configuration virtual machine, the command is propagated to all the other members of the SSI cluster. If the user ID is defined as a multiconfiguration virtual machine, this command is not propagated across the SSI cluster.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP007E Invalid *userid* - *userid*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP053E [XAUTOLOG failed for *userid*:] *userid/value* not in CP directory
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP1503E Hold status is not set because the hold queue is full.

## HOLD PRINTER/PUNCH

### Authorization

Privilege Class: D

### Purpose

Use HOLD PRINTER/PUNCH to place user spool files into hold status.

**Note:** Until you enter the FREE command, all new files are put into hold status.

### Operands

#### *userid*

identifies the user whose spool files are to be placed in system hold status. The user need not be logged on.

#### **ALL**

specifies that all printer/punch files are to be put into hold.

#### **Printer**

#### **PRT**

#### **PUnch**

#### **PCH**

specifies the type of file to be put into hold.

### Usage Notes

1. Use FREE PRT/PUN in conjunction with HOLD PRT/PUN.
2. After you enter the HOLD command, all new files are put into hold status.
3. A spool file can be put into either or both of two types of hold status:
  - User
  - System.

A spool file is put into user hold status by its creator; the commands used are SPOOL, CLOSE, or CHANGE.

A spool file is put into system hold status by the privilege class D user; the command used is CHANGE SYS. Also, the operating system can place a file into system hold status if an error occurs.

The user of the HOLD command can put the files of any user into system hold status.

A spool file in both types of hold status must be freed from each one before the file can be processed.

4. User hold status is maintained across a warm start regardless of whether the user is logged on.
5. When a user is put into hold, all current files are changed to system hold, and new files are put into hold status also.

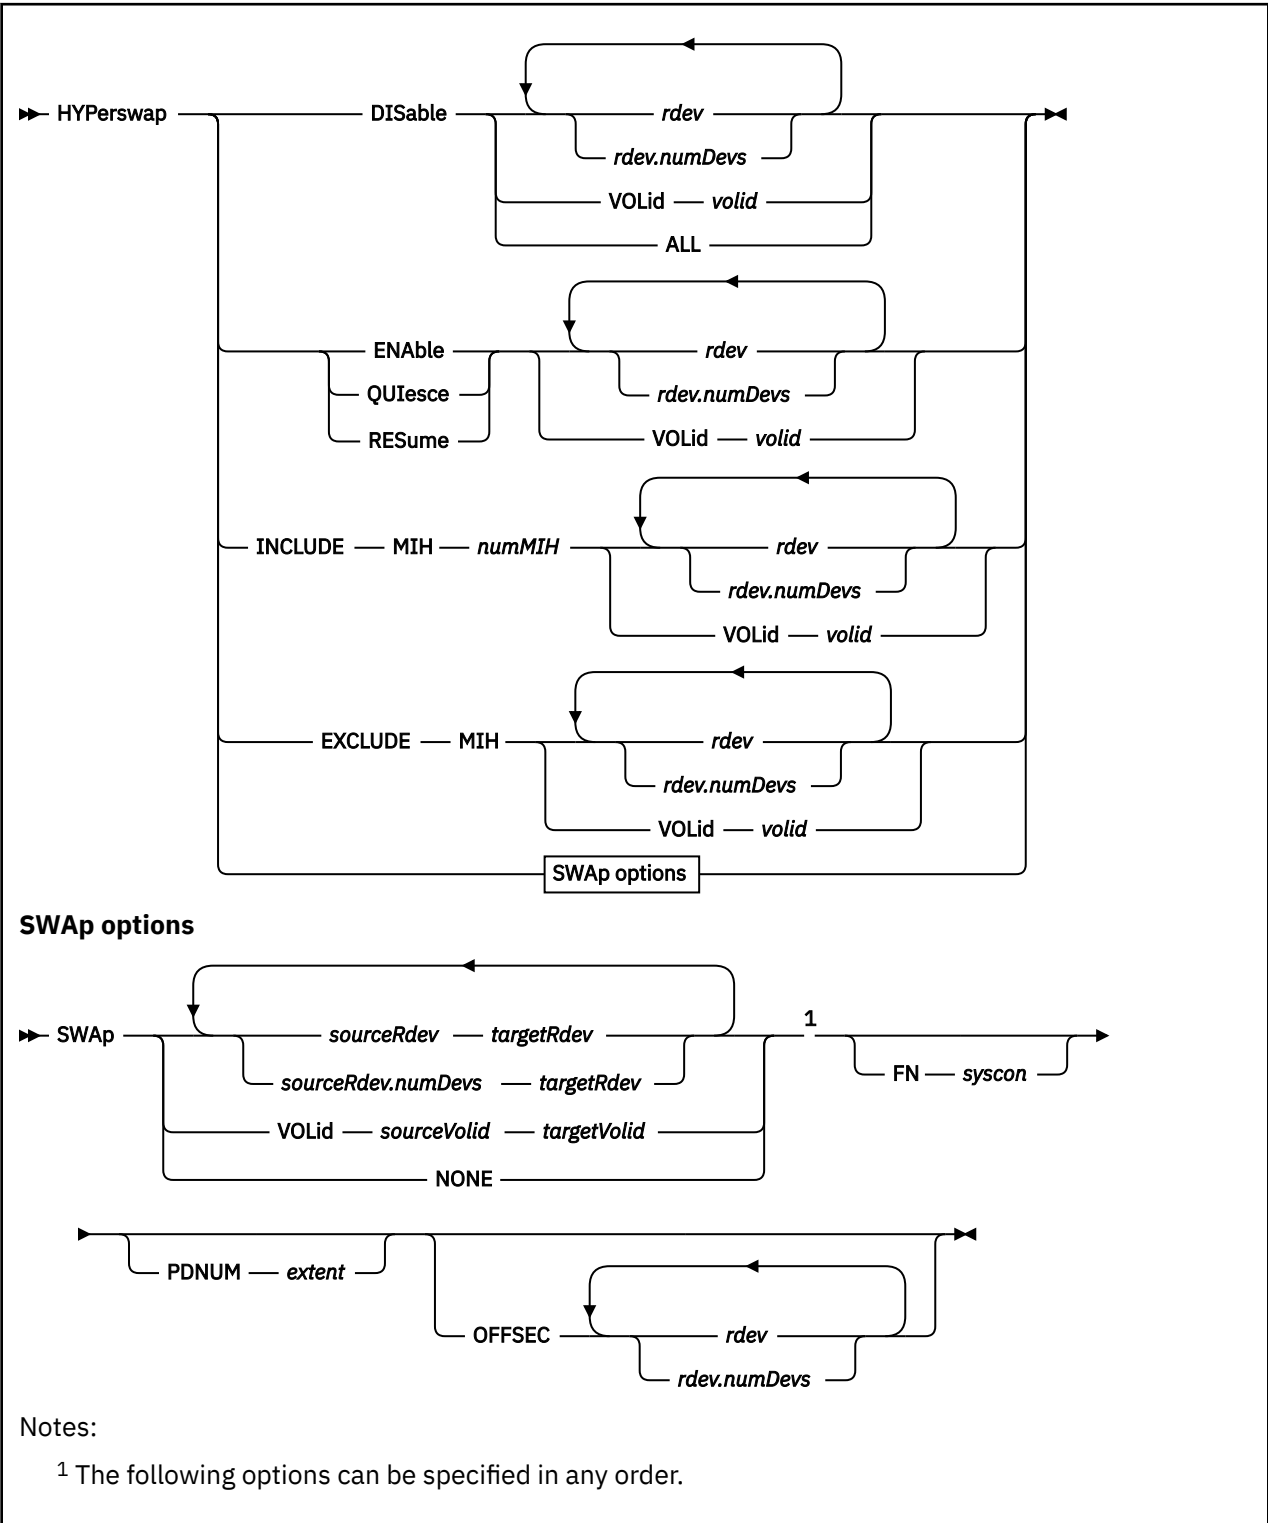

## HOLD PRINTER/PUNCH

6. Spool files in hold status are not selected for processing by a real printer or punch. Use the HOLD command to temporarily detain a file or a group of files so that you can correct or modify a spooling condition.
7. A maximum of 32 users can be put into hold at any one time.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP007E Invalid userid - *userid*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP053E [XAUTOLOG failed for *userid*:] *userid* not in CP directory
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP1503E Hold status is not set because the hold queue is full.

# HYPERSWAP

## Authorization

Privilege Class: B

## Purpose

Use the HYPERSWAP command to perform Disaster Recovery failover processing on PPRC-linked DASD.

The DISABLE function disables the real devices for HyperSwap® automatic quiesce processing.

The ENABLE function enables the real devices for HyperSwap automatic quiesce processing.

The QUIESCE function stops de-queuing all Start I/O requests hanging off the queues for the real devices entered.

The RESUME function starts de-queuing all Start I/O requests hanging off the queues for the previously quiesced devices.

The INCLUDE function indicates the devices can be automatically quiesced on a missing interrupt condition. The *numMIH* parameter specifies the number of times missing interrupt recovery will take place before automatic quiesce will take place.

The EXCLUDE function indicates a missing interrupt condition will not trigger an automatic quiesce for the specified devices.

The SWAP function will swap all relevant real device information associated with the primary Peer-to-Peer Remote Copy (PPRC) device (source) entered as the first device in the device pair with the secondary PPRC device (target) that is entered as the second device in the device pair. When operating on ranges of device pairs the range length (*numDevs*) is equal for both devices and there exists a one-to-one correspondence device number.

## Operands

### DISable

tells CP to perform the Disable function.

### ENABle

tells CP to perform the Enable function.

### QUIesce

tells CP to perform the Quiesce function.

### RESume

tells CP to perform the Resume function.

### INCLUDE

tells CP to perform the INCLUDE function.

### EXCLUDE

tells CP to perform the EXCLUDE function.

### *rdev*

#### *rdev.numDevs*

specifies a single real device (*rdev*) or a real device combined with a decimal range count (*numDevs*). A single value (*rdev*), a series (*rdev rdev*), a range (*rdev.numDevs*) or a combination of all can be entered. For a device in the active configuration, the device number entered must be a 4-digit hexadecimal number between X'0000' and X'FFFF'. For a device in the standby configuration, the device number must be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is configured.

### VOLid *valid*

tells CP to use a volume serial identifier. The value for *valid* is a 1- to 6-character alphanumeric identifier. Only one *valid* can be entered.

### ALL

specified on the Disable function to disable all real devices previously enabled for automatic quiesce processing.

**MIH****numMIH**

indicates whether the missing interrupt handler (MIH) is included or excluded as a trigger for automatic quiesce and *numMIH* indicates the number of times missing interrupt recovery will take place before a HyperSwap is initiated by an automatic quiesce. The *numMIH* value must be 1 to 99. The default for all DASD, which is set at IPL time, is that MIH would not trigger an automatic quiesce.

**SWAP**

tells CP to perform the SWAP function.

**sourceRdev targetRdev****sourceRdev.numDevs targetRdev**

specifies a single source real device (*sourceRdev*) and target real device (*targetRdev*) pair or source real device combined with a decimal range count (*numDevs*) and target real device range pair. A single source/target pair, a series of source/target pairs (*sourceRdev targetRdev sourceRdev targetRdev*), a range of source/target pairs (*sourceRdev.numDevs targetRdev*) or a combination of all can be entered. The devices entered must be hexadecimal real device numbers between X'0000' and X'FFFF' or, for target devices, a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is configured.

**VOLid sourceVolid targetVolid**

specifies a source volume serial identifier (*sourceVolid*) and target volume serial identifier (*targetVolid*) pair. Only one source/target pair can be entered.

**NONE**

specifies that no real devices will be swapped by the command. This operand should be used with the OFFSEC operand in particular scenarios where a large number of additional secondary devices need to be varied offline.

**FN syscon**

identifies to CP the file name of the new system configuration file that CP will use after a shutdown re-IPL or software restart. The file type of the new system configuration file must be CONFIG. The value of *syscon* can be 1 to 8 characters.

**PDNUM extent**

identifies the extent number of the PARM disk that CP will use after a shutdown re-IPL or software restart. The value of *extent* can be an integer between 1 and 32767.

**OFFSEC**

tells CP to vary offline specified additional secondary devices in a Multi-Target PPRC scenario.

**Usage Notes**

1. All real devices entered on the command must be DASD devices and a DASD type of 3390.
2. The ENABLE function requires an Escon or Ficon attached ECKD IBM DASD storage controller in support of 'PPRC' failover processing.
3. The SWAP function requires the state of the devices being swapped be either quiesced, offline or online, and free. An attempt will be made to VARY ON any offline devices.
4. The SWAP function requires that the device pair be the same DASD type, have matching subclass information, be free of any active I/O and the target device's size be at least as big as the source devices.
5. When the SWAP function completes successfully for a device pair, the source and target devices are left in a quiesce state. The source device is also placed in an offline state.
6. The RESUME function will only complete successfully on devices that are quiesced.
7. Error messages will be issued for individual devices and device pairs for which the command processing fails, but the command processing continues for those devices that don't fail.
8. Once the real devices in a PPRC pair are enabled for automatic quiesce processing, the devices can be automatically quiesced on a missing interrupt condition for the source device. The following steps must be taken in order to enable automatic quiesce processing:

- a. The source device must be enabled for HyperSwap.
- b. The source device must be set to check for missing interrupts, which can be enabled via the SET MITIME command.
- c. The source device must be enabled for automatic quiesce on a missing interrupt condition using the HYPERSWAP INCLUDE command.

Once triggered, the automatic quiesce process creates an error record that can be used by the Geographically Dispersed Parallel Sysplex (GDPS<sup>®</sup>) service to trigger a swap between the two devices.

9. The SWAP function will transfer a real reserve held on the source device for fullpack minidisks. The real reserve state is tracked by VM for fullpack minidisks on DASD marked SHARED by an RDEV statement or SET RDEV command and for all DASD in an SSI cluster. Virtual reserves are also maintained as part of the SWAP command. Note that there is no VM software tracking of reserve state for dedicated DASD. Reserves on such devices will be lost following a HyperSwap, resulting in a data integrity exposure. You can, however, use dedicated DASD that do not use reserve/release. Dedicated DASD using reserve/release must not be used in a GDPS environment that is enabled for HyperSwap.
10. HYPERSWAP ENABLE, INCLUDE, QUIESCE, and SWAP are not allowed for a static Parallel Access Volume (PAV) or HyperPAV base device with a guest dedicated or guest exploited alias configuration. For a base PAV, this means the specified RDEV/VOLID is either dedicated to a guest with at least one alias associated with the base PAV also dedicated to the guest or is system attached and has one or more alias PAVs defined using DEFINE PAVALIAS, DASDOPT PAVALIAS, or MINIOPT PAVALIAS. For a base HyperPAV, this means the RDEV/VOLID is either dedicated to a guest with at least one alias associated with the base HyperPAV also dedicated to the guest or is system attached and has one or more alias HyperPAVs defined using DEFINE HYPERPAVALIAS which reside in the same pool as the specified base HyperPAV.
11. The RDEV/VOLID specified on the HYPERSWAP command cannot be an alias HyperPAV or alias PAV device.
12. When used by an IBM Geographically Dispersed Parallel Sysplex<sup>®</sup> (IBM GDPS) offering, the HYPERSWAP command is not supported for real devices accessed by z/OS guests, either as dedicated devices or minidisks. Environments other than IBM GDPS have not been tested.
13. SSI members running as second-level guests of an underlying z/VM partition are not supported when HYPERSWAP is used on the underlying first-level z/VM system.
14. GDPS does not support HYPERSWAP issued from second-level z/VM systems.
15. When the SWAP function is used to swap primary and secondary devices in different subchannel sets, the low-order 4 digits of the source and target device numbers must be identical. The high-order digit, if specified, is the subchannel set where the device is configured.
16. If a HYPERSWAP ENABLE is performed on a PPRC secondary device, an attempt is made to SWAP that device with its counterpart (same device number in the other subchannel set). If the SWAP is successful, the PPRC primary is enabled. If the SWAP fails, it reports an error and the ENABLE is not performed.
17. A single Multi-Target PPRC configuration requires at least three devices. Each pair of these three devices has the potential to initiate a SWAP function.
18. As part of HyperPAV or PAV alias device processing during hyperswap, when a SWAP is done between subchannel sets, alias devices associated with the target base device are brought into the active RDEV configuration. This allows those alias device to then be referenced directly with 4 digit RDEVs following the completion of the SWAP.

## Responses

Response 1:

When you issue the HYPERSWAP command and an option, you will receive one of the following responses:

```
{Disable} processing completed
{Enable }
{Quiesce}
```

```
{Resume }
{Include}
{Exclude}
```

Response 2:

When you issue the HYPERSWAP QUIESCE or RESUME command, the system operator will receive one of the following responses respectively:

```
Hyperswap processing {beginning}
                    {completed}
```

## Examples

Example 1:

To QUIESCE real device 500 enter the following:

```
HYP QUI 500
```

Example 2:

To QUIESCE the device with a volume serial id of MNT500 enter the following:

```
HYP QUI VOL MNT500
```

Example 3:

To QUIESCE real devices 500 and 502 through 504 enter the following:

```
HYP QUI 500 502.3
```

Example 4:

To SWAP real device 500 with real device 505 enter the following:

```
HYP SWA 500 505
```

Example 5:

To SWAP real device 500 with real device 505 and 501 with 506 enter the following:

```
HYP SWA 500.2 505
```

Example 6:

To SWAP the device with a volume serial ID of MNT500 with a device that has volume serial ID MNT505 enter the following:

```
HYP SWA VOL MNT500 MNT505
```

Example 7:

To RESUME real devices 500 through 503 enter the following:

```
HYP RESU 500.4
```

- HCP6706E Invalid address range - *range*

## INDICATE

---

### Purpose

Use the INDICATE commands to display at your console the use of, and contention for, system resources.

If you are a class G user, use the INDICATE command to:

1. Display recent contention for system resources. This can be helpful to predict system throughput and response time characteristics that your virtual machine may experience now and in the near future.
2. Display environment characteristics of your virtual machine. This includes machine type, the origin of the system IPLed (loaded) in your virtual machine, and the presence or quantity of system resources available to your virtual machine.
3. Display measurements of resources used by your virtual machine. Such measurements are accumulators—that is, always increasing after virtual machine logon.

If you are a class E user (and, in some cases, a class B user), the INDICATE command provides all class G functions and the following also:

1. Detailed information on use of, and contention for, system resources. User IDs of virtual machines currently using certain resources can be displayed.
2. The status of currently active virtual machines as determined by the system scheduler and dispatcher.
3. Environment characteristics of, and measurements of resources used by, any virtual machine logged on.

### Messages

- HCP002E Invalid operand - *operand*

- HCP1001E An operand is missing for *option*
- HCP1006E The command processing cannot complete because system resources are not available.
- HCP2970E The SSI cluster member name is missing or invalid.
- HCP2971I Specified SSI cluster member is not joined.
- HCP6005E Option *option* is not supported by z/VM.

## INDICATE ACTIVE

### Authorization

Privilege Class: E

### Purpose

Use INDICATE ACTIVE to do the following:

- Display the total number of users active in a specified time interval.
- Display the number of users in the dispatch, eligible, and dormant lists that were active in a specified time interval.

### Operands

#### *nnnnn*

identifies an integer number specifying the time interval. The valid time period is 0 to 9 hours or 540 minutes or 32400 seconds. The default is 60 seconds.

#### **SEC**

identifies that *nnnnn* was specified in seconds. This is the default.

#### **MIN**

identifies that *nnnnn* was specified in minutes.

#### **HRS**

identifies that *nnnnn* was specified in hours.

### Usage Notes

1. The number of active users indicated by the response is the actual number of users that were active in the period, not an averaged number.
2. CP's virtual processor management has been improved so that no user stays in the eligible list more than an instant before being added to the dispatch list. Therefore users are rarely shown to be in the eligible list, and the count of users in the eligible list is usually 0.

### Responses

Response 1:

```
tttt USERS, aaaa DISP, bbbb ELIG, cccc DORM
```

#### **tttt**

the total number of users that were active in the specified time interval.

#### **aaaa**

the total number of users that were active in the specified time interval, currently in the dispatch list.

**bbbb**

the total number of users that were active in the specified time interval, currently in the eligible list.

**cccc**

the total number of users that were active in the specified time interval, currently in the dormant list.

**Messages**

- HCP002E Invalid operand - *operand*

## INDICATE I/O

---

►► INDicate — I/O ◄◄

### Authorization

Privilege Class: B, E

### Purpose

Use INDICATE I/O to do the following:

- List all virtual machines currently in an I/O wait state
- List, by virtual machine, the real device number to which the most recent virtual I/O operation was mapped.

### Usage Notes

1. Because the response indicates only an instantaneous sample, enter the INDICATE I/O command several times before you assume a condition to be persistent.

### Responses

Response 1:

```
userid1 xxxx userid2 yyyy...
(as many as five users per line)
```

#### **userid**

identifies the user ID of the virtual machine.

#### **xxxx**

#### **yyyy**

identifies the real device to which the most recent I/O operation was mapped. When the I/O device cannot be determined, four hyphens (----) are displayed.

#### **Note:**

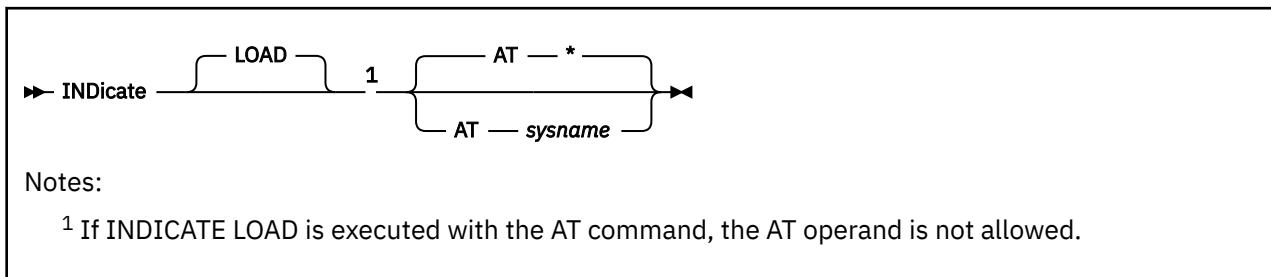

1. Where a virtual machine might have issued multiple I/O operations, the response indicates the real device corresponding to the most recent operation issued.
2. Guest I/O operations that are initiated on a PAV or HyperPAV alias minidisk will appear as I/O waiting on the appropriate real base device.

Response 2:

```
NO USERS IN I/O WAIT
```

is issued when appropriate.

## INDICATE LOAD

### Authorization

Privilege Class: E, G

### Purpose

Use INDICATE LOAD to display the operating load on the host system:

- The percentage of usage and CPU type for each online processor in your system
- Information concerning the minidisk cache
- The paging rate
- The number of users in the dispatch, eligible, and dormant lists.

**Note:** LOAD is the default operand of the INDICATE command.

### Operands

#### AT \*

displays operating load information for the system where you are logged on.

#### AT *sysname*

displays operating load information for a specific system in the SSI cluster to which this system belongs.

### Usage Notes

1. The term user(s) for the INDICATE LOAD command does not map one to one with the number of logged on users but instead maps to the number of entities that are dispatched by the dispatcher. In addition to logged on users, the dispatcher also dispatches each user's additional virtual CPUs, logon skeleton users, and other pseudo users.
2. The values listed as rates or utilizations are actually smoothed averages. At certain times, these values might differ from the values obtained from other sources (such as Performance Toolkit for z/VM), which use different algorithms.
3. A logical partition in which z/VM is running can polarized either horizontally or vertically. When a partition is horizontally polarized, all CPUs in the partition (within a given CPU type) receive access to approximately equal real CPU resources on the machine. When a partition is vertically polarized, CPUs in the partition receive different real CPU entitlements. High entitlement allows a CPU to consume approximately an entire real CPU. Medium entitlement CPUs are entitled to some percentage of a real CPU. Low entitlement CPUs receive no entitlement to real CPU resources and can consume only spare CPU resources that become available when a logical partition on the machine does not consume its entitlement. Utilization values might be lower on medium or low entitlement CPUs than on high entitlement CPUs of the same type. The utilization levels will depend on whether there are spare cycles available for consumption and whether the z/VM system requires the cycles. To change the polarization of the logical partition, use the SET SRM command with the POLARIZATION operand.

## INDICATE LOAD

4. When multithreading is enabled, use the INDICATE MULTITHREAD command to display processor core utilization information.
5. CP's virtual processor management has been improved so that no user stays in the eligible list more than an instant before being added to the dispatch list. Therefore users are rarely shown to be in the eligible list, and the count of users in the eligible list is usually 0.

## Responses

Response 1:

The class G response appears as:

```
AVGPROC-nnn% pppp
MDC READS-n..n/SEC WRITES-m..m/SEC HIT-RATIO-hhh%
PAGING-n..n/SEC
Q0-nnnnn Q1-nnnnn          Q2-nnnnn EXPAN-nnn Q3-nnnnn EXPAN-nnn
```

Response 2:

The class E response appears as:

```
AVGPROC-nnn% pppp
MDC READS-n..n/SEC WRITES-m..m/SEC HIT-RATIO-hhh%
PAGING-n..n/SEC
Q0-nnnnn (zzzzz)          DORMANT-nnnnn
Q1-nnnnn (zzzzz)          E1-nnnnn (zzzzz)
Q2-nnnnn (zzzzz) EXPAN-nnn E2-nnnnn (zzzzz)
Q3-nnnnn (zzzzz) EXPAN-nnn E3-nnnnn (zzzzz)

PROC adr1-nnn% {CP } pe   PROC adr2-nnn% {CP } pe
                {IFL }
                {ZIIP}
                {ICF }
PROC adrn-nnn% {CP } pe   PROC adrn-nnn% {CP } pe
                {IFL }
                {ZIIP}
                {ICF }
:
LIMITED-mnnnn
```

### AVGPROC-*nnn*%

identifies the average processor use percentage for all processors combined. The *nnn* value is 0 through 100 percent. This value represents an average value of the portion of a real CPU that each logical CPU was able to consume.

### *pppp*

identifies the number of processors.

### READS-*n..n* /SEC

identifies the number of data pages read from the minidisk cache instead of from DASD. The *n..n* value will be displayed as 6 - 8 digits.

### HIT RATIO-*hhh*%

identifies the percentage of successful lookups in the minidisk cache. This is the percentage of eligible read I/Os that were avoided because of the minidisk cache.

### WRITES-*m..m* /SEC

identifies the number of data pages inserted into the minidisk cache. The *m..m* value will be displayed as 6 - 8 digits.

### PAGING-*n..n* /SEC

identifies a value that indicates the current system paging activity in decimal, including migration writes, but does not include spooling information. The *n..n* value will be displayed as 1 - 8 digits.

### Qn

indicates a smoothed average of the number of Qn users in the dispatch list. A Qn user is an En user who is now in the dispatch list.

**Q0**

indicates the users that were added to the dispatch list with no delay in the eligible list, regardless of the length of their current transaction.

**Q1**

indicates the users that have just begun a transaction, and therefore are assumed to be currently processing short transactions.

**Q2**

indicates the users that did not complete their current transactions during their first dispatch list stay and therefore are assumed to be running medium-length transactions.

**Q3**

indicates the users that did not complete their current transactions during their second dispatch stay and therefore are assumed to be running long transactions.

**EXPAN-*nnn***

indicates the total delay in response time that a virtual machine experiences because of contention for scheduled resources. *Q2* gives the expansion factor for those completing in *Q2* (medium-length), and *Q3* for those completing in *Q3* (long-running transactions).

**En**

indicates a smoothed average of the number of *En* users in the eligible list. Although a user may briefly be considered an *E0* user, no *E0* counts appear. This is because, by definition, such a user spends virtually no time in the eligible list. After smoothing, this count would always be 0 if shown. If, by unusual timing circumstances, a user is found in an *E0* category, the user is counted with the *Q0* user counts.

**E1**

indicates the users that have just begun a transaction and therefore are assumed to be currently processing short transactions.

**E2**

indicates the users that did not complete their current transactions during their first dispatch list stay and therefore are assumed to be running medium-length transactions.

**E3**

indicates the users that did not complete their current transaction during their second dispatch list stay and therefore are assumed to be running long transactions.

**ZZZZ**

identifies the number of users within the *Qn* or *En* counts that are designated as *loading users*. A loading user is a user assumed to be loading a working set into storage. A user is labeled loading or not loading based primarily on the number of page reads done during the user's last dispatch time slice. A high count of page reads is assumed to designate a loading user. A user also may be labeled as loading if the system has moved any of the user's referenced pages out to DASD while the user was not in the dispatch list. The loading designation is given in anticipation of the user's need to read pages back into storage when next dispatched.

**DORMANT-*nnnnn***

identifies a smoothed average of the number of dormant list users.

**PROC *adrn-*nnn**%**

represents the percentage of time that the system is running on the logical processor indicated. The operand *adrn* represents the processor ID in hexadecimal. The *nnn* value is 0 through 100 percent. This value represents the portion of a real CPU that this logical CPU was able to consume.

**CP**

indicates the CPU is a central processor (that is, a general-purpose processor).

**IFL**

indicates the CPU is an IBM Integrated Facility for Linux processor.

**ZIIP**

indicates the CPU is an IBM z Integrated Information Processor.

## INDICATE LOAD

### **ICF**

indicates the Internal Coupling Facility processor.

### **pe**

indicates the polarization and entitlement of a CPU.

### **HZ**

indicates the CPU is horizontally polarized.

### **VH**

indicates the CPU is vertically polarized with high entitlement.

### **VM**

indicates the CPU is vertically polarized with medium entitlement.

### **VL**

indicates the CPU is vertically polarized with low entitlement.

### **LIMITED-*mmmmm***

is the instantaneous number of users in the limit list. These users are also in the dispatch list.

## Messages

- HCP1142E The AT option is not allowed when this command is executed remotely with the AT command.

## INDICATE MULTITHREAD

### Authorization

Privilege Class: E

### Purpose

Use INDICATE MULTITHREAD to display the system's multithreading (MT) status and processor core utilization information.

### Usage Notes

1. For information about configuring multithreading, see the [Multithreading Statement](#) in *z/VM: CP Planning and Administration*. To display thread information, use the QUERY MULTITHREAD command.  
To modify the multithreading configuration, use the [“SET MULTITHREAD”](#) on [page 1578](#)
2. The values listed as rates or utilization are averaged over the interval time. These values might differ from the values obtained from other sources (such as Performance Toolkit for z/VM), which use different algorithms.
3. The values for productivity, utilization, capacity factor, and maximum capacity factor are rounded to the nearest whole number. More precise numbers and core run times are available from sample monitor records.
4. The interval time is listed on the second line of output when multithreading is enabled. Usually this interval time will be 30 seconds; however, certain long running tasks (for example, SNAPDUMP) might cause the interval time to be longer.

### Responses

Response 1:

```
The Multithreading Facility is not installed.
```

is displayed if the multithreading facility is not installed on the hardware or the logical partition, or if the z/VM system is running as a guest.

Response 2:

```
Multithreading is disabled.
```

is displayed if the processor or configuration supports multithreading but multithreading is disabled. There are a number of reasons why multithreading might be disabled. For example, a MULTITHREADING statement might not be included in the system configuration file. Review the system initialization messages in the operator's console log.

Response 3:

```
Multithreading is enabled.  
An error occurred in the HISMT service. Use of the service is disabled.
```

is displayed if the processor or configuration supports multithreading but an error occurred while setting up the HISMT service to collect multithreading statistics. At the time of the error, an MTC001 soft abend should have been generated. Collect the dump and contact your IBM Support Center personnel.

Response 4:

```
Multithreading is enabled.
Statistics from the interval hh:mm:ss - hh:mm:ss
Core Type xxxx Busy bbb% TD ee.ee of tt Prod ddd% Util ggg%
CF ffff% MaxCF mmmm%
Core Type xxxx Busy bbb% TD ee.ee of tt Prod ddd% Util ggg%
CF ffff% MaxCF mmmm%
:
```

is displayed if the processor or configuration supports multithreading and multithreading is enabled in the system configuration file. A Core Type section is displayed if a core of that CPU type is online in the configuration.

**hh:mm:ss**

is the time stamp for the start and end times of the statistics interval shown in this response. Leading zeros are not removed.

**Core Type xxxx**

indicates the start of a section of information about cores of a certain CPU type. A Core Type section is displayed for each CPU type with at least one processor online in the configuration. The core type xxxx is one of the following:

**CP**

indicates this section pertains to central processor (that is, general-purpose processor) cores.

**IFL**

indicates this section pertains to IBM Integrated Facility for Linux processor cores.

**ZIIP**

indicates this section pertains to IBM z Integrated Information Processor cores.

**ICF**

indicates this section pertains to Internal Coupling Facility processor cores.

**Busy bbb%**

indicates the multithreading core busy time for cores of a certain CPU type. Multithreading core busy time is the percentage of the interval time that the core was in use. The value bbb is a decimal number 0 - 100 with leading zeros removed. If all cores of this type were recently varied online, or if there was an error collecting data, the value will be "---".

**TD ee.ee**

indicates the average of the multithreading core thread density for cores of a certain CPU type. Multithreading core thread density is the average number of threads in use while the core was in use. Periods of time when no thread was in use are ignored. The value ee.ee is dependent on the number of threads per core. Leading zeros are removed. If all cores of this type were recently varied online, or if there was an error collecting data, the value will be "-----".

**of tt**

indicates the number of online (activated) threads per core for this CPU type. This number is based on the available hardware, software, and information from the system configuration file. The value tt is a 1- to 2-digit decimal number with leading zeros removed. For the definition of activated threads, see the explanation of the "Activated Threads" field in the response for the QUERY MULTITHREAD command.

**Prod ddd%**

indicates the multithreading core productivity for cores of a certain CPU type. Multithreading core productivity is the percentage of the maximum core capacity that was used while the logical core was dispatched on physical hardware. The value ddd is a decimal number 0 - 100 with leading zeros removed. If the value is 100, all threads on the core are executing work and all core resources are being used. If all cores of this type were recently varied online, or if there was an error collecting data, the value will be "---".

**Util ggg%**

indicates the multithreading core utilization for cores of a certain CPU type. Multithreading core utilization is the percentage of the maximum core capacity that was used during the interval. The

value *ggg* is a decimal number 0 - 100 with leading zeros removed. If all cores of this type were recently varied online, or if there was an error collecting data, the value will be "----".

### CF *ffff*%

indicates the multithreading capacity factor (CF) for cores of a certain CPU type. The multithreading capacity factor is an estimate of the ratio of the amount of work that has been accomplished to the amount of work that would have been accomplished if multithreading was disabled. The value *ffff* is a 1- to 4-digit decimal number with leading zeros removed. A value over 100% indicates that more work was accomplished with multithreading enabled. If all cores of this type were recently varied online, or if there was an error collecting data, the value will be "----".

### MaxCF *mmmm*%

indicates the multithreading maximum capacity factor for cores of a certain CPU type. The multithreading maximum capacity factor is an estimate of the ratio of the maximum amount of work for the current workload that could be accomplished if all activated threads of the core were kept running, to the amount of work that would have been accomplished if multithreading was disabled. The value *mmmm* is a 1- to 4-digit decimal number with leading zeros removed. If every thread can run this workload concurrently with no interference from the activity of other threads on the same core, the MaxCF value is the number of threads multiplied by 100%. If all cores of this type were recently varied online, or if there was an error collecting data, the value will be "----".

Response 5:

```
A speed change was detected during this interval.
```

is displayed if a change in the speed for a processor type was detected during this interval. In this case, the statistics for utilization, productivity, capacity factor, and maximum capacity factor might not be valid. Wait until the next interval to get a valid sample. This line will appear after the capacity factor information for each core type affected by the change.

Response 6:

```
A multithreading configuration change was detected during this
interval for CPU types <CP > <ZIIP> <ICF > <IFL >
```

is displayed if a change in the multithreading configuration for a processor type occurred during the interval or is in progress due to a request made by a SET MULTITHREAD command. This response line follows the rest of the normal response and includes a list of the CPU types affected by the change. In the response for each of the affected CPU types, the statistics for utilization, productivity, capacity factor, and maximum capacity factor will usually contain dashes if they cannot be calculated due to the transition. Wait until the next interval to get a valid sample.

## Example

If the ENABLE operand was specified on the MULTITHREADING statement in the system configuration file, and you issue the INDICATE MULTITHREAD command on a system that is capable of multithreading, you might see a response similar to the following example.

```
indicate mt
Multithreading is enabled.
Statistics from the interval 13:00:30 - 13:01:00
Core Type CP   Busy  8%   TD  1.00 of 1   Prod 100%   Util  8%
   CF 100%   MaxCF 100%
Core Type IFL  Busy  67%  TD  1.24 of 2   Prod  82%   Util  55%
   CF 107%   MaxCF 131%
Core Type ZIIP Busy  5%   TD  1.00 of 1   Prod 100%   Util  5%
   CF 100%   MaxCF 100%
```

If a speed change was detected for CP and specialty processors, you might see a response similar to the following example.

```
indicate mt
Multithreading is enabled.
Statistics from the interval 13:00:30 - 13:01:00
Core Type CP   Busy  8%   TD  1.00 of 1   Prod 100%   Util  8%
```

## INDICATE MULTITHREAD

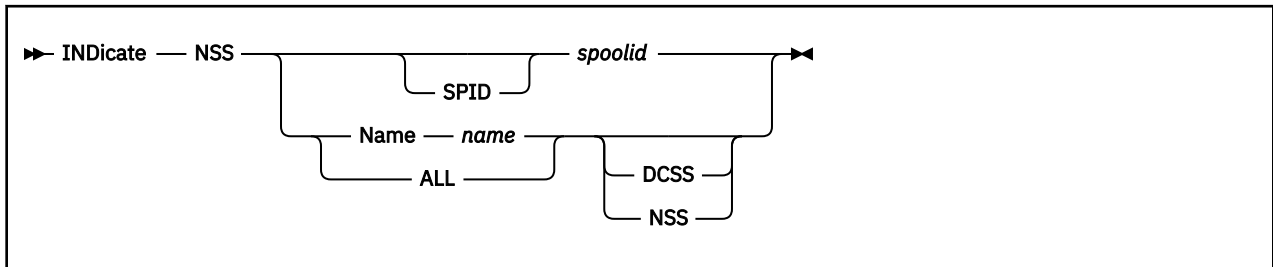

```
CF 100% MaxCF 100%
A speed change was detected during this interval.
Core Type IFL Busy 67% TD 1.24 of 2 Prod 82% Util 55%
CF 107% MaxCF 131%
A speed change was detected during this interval.
Core Type ZIIP Busy 5% TD 1.00 of 1 Prod 100% Util 5%
CF 100% MaxCF 100%
A speed change was detected during this interval.
```

If an SMT configuration change is detected for IFL processors, you might see a response similar to the following example.

```
indicate mt
Multithreading is enabled.
Statistics from the interval 16:07:30 - 16:08:00
Core Type CP Busy 8% TD 1.00 of 1 Prod 100% Util 8%
CF 100% MaxCF 100%
Core Type IFL Busy ---% TD ----- of -- Prod ---% Util ---%
CF ---% MaxCF ---%
Core Type ZIIP Busy 5% TD 1.00 of 1 Prod 100% Util 5%
CF 100% MaxCF 100%
A multithreading configuration change was detected during this
interval for CPU types IFL
```

For an example showing the relationship among the INDICATE MULTITHREAD, QUERY MULTITHREAD, and QUERY PROCESSORS commands, see [“QUERY MULTITHREAD”](#) on page 1026.

## INDICATE NSS

### Authorization

Privilege Class: E

### Purpose

Use INDICATE NSS to display information about the named saved systems (NSSs) and saved segments that are loaded in the system and are in use by at least one user.

The information returned by the INDICATE NSS command pertains to the system owned storage for NSSs and saved segments, not to any virtual machine's storage.

### Operands

#### SPID

indicates that the next operand is a spool ID.

#### *spoolid*

is the system spool file identifier for a system data file containing an NSS or saved segment.

#### Name *name*

identifies the name of the NSS or saved segment that information is requested about.

#### ALL

indicates a request for information about all NSSs or saved segments that are loaded.

#### DCSS

#### NSS

indicates whether information is requested about saved segments (DCSS operand) or named saved systems (NSS operand). If neither operand is specified, information is returned for both.

### Usage Notes

1. Processing of an INDICATE NSS command might be delayed if DIAGNOSE code X'64' is concurrently performing the initial load of a large DCSS.

### Responses

Response 1:

The system displays this response for each NSS or saved segment.

```
Filename=filename Filetype=filetype Class=cl Spoolid=nnnn
Time loaded=ddd hh:mm Size={nnnnM}
                               {nG}
Pages: Main=nnnnnn Xstore=--- Dasd=nnnnnnnnnn Locked=---
       Instan=n...n Reserved=n...n
Paging:
Xstore: Reads=--- Writes=--- Migrates=---
Dasd: Reads=nnnnnnnnnn Writes=nnnnnnnnnn
```

**Filename=filename**

is the file name of the system data file containing the NSS or saved segment. It is also the name of the NSS or saved segment.

**Filetype=filetype**

is the file type of the system data file containing the NSS or saved segment:

<b>File Type</b>	<b>Meaning</b>
NSS	Named saved system.
DCSS	Discontiguous saved segment (DCSS) below 2047 MB.
DCSSG	DCSS above 2047 MB.
DCSS-S	Segment space.
CPNSS	CP system service NSS.
CPDCSS	CP system service DCSS.

**Class=cl**

is the spool file class of the NSS or saved segment.

**Spoolid=nnnn**

is the system spool file identifier of the system data file containing the NSS or saved segment.

**Time loaded=ddd hh:mm**

is the length of time that this NSS or saved segment has been loaded, in days, hours, and minutes.

**Size=nnnnM****Size=nG**

is the size of the NSS or saved segment (number of 1 MB segments in which pages are defined).

**Pages**

includes information about pages for this NSS or saved segment:

**Main=nnnnnn**

is the number of pages resident in real storage.

**Xstore=---**

is included for compatibility only. It is always displayed as dashes.

**Dasd=nnnnnnnnnn**

is the number of pages allocated on DASD paging space.

**Locked=---**

is included for compatibility only. It is always displayed as dashes.

**Instan=n...n**

is the number of instantiated pages. Since NSS/DCSS pages can exist in multiple levels of the storage hierarchy (for example, central storage and in auxiliary), the instantiated count of pages may be less than the total of the resident and DASD page counts. A copy of a page in multiple places in the paging hierarchy counts as one instantiation.

**Reserved=n...n**

the number of pages allocated for reserved storage.

**Paging**

includes the information about paging for this NSS or saved segment.

**Xstore: Reads=--- Writes=--- Migrates=---**

is included for compatibility only. It is always displayed as dashes.

**Dasd**

includes information about paging between DASD paging space and real storage for this NSS or saved segment.

**Reads=nnnnnnnnnn**

is the total number of page reads.

**Writes=nnnnnnnnnn**

is the total number of page writes.

Response 2:

If ALL was specified and no NSS or saved segment is loaded in the system, the following is displayed:

```
No NSS or DCSS was found
```

Response 3:

If ALL NSS was specified and no NSS is loaded in the system, the following is displayed:

```
No NSS was found
```

Response 4:

If ALL DCSS was specified and no saved segment is loaded in the system, the following is displayed:

```
No DCSS was found
```

**Messages**

- HCP008E Invalid spoolid-*spoolid*
- HCP1013E An invalid operand was supplied for NAME - *operand*
- HCP1042E NSS or saved segment with {name *name* | spoolid *spoolid*} is not loaded, is a member segment, or does not exist.
- HCP1042E NSS with name *name* is not loaded or does not exist.
- HCP1042E Saved segment with name *name* is not loaded, is a member segment, or does not exist.

## INDICATE PAGING

### Authorization

Privilege Class: E

### Purpose

Use INDICATE PAGING to do the following:

- Display a list of the virtual machines in page wait status
- Display page residency data for all system users

### Operands

#### WAIT

identifies the virtual machines currently in page wait and displays the number of pages allocated on auxiliary storage for each one. This is the default.

Use PAGING WAIT when the INDICATE QUEUES command has shown that a significant proportion of the active users of the system are persistently in page wait.

#### ALL

displays the page residency data for all users of the system.

### Usage Notes

1. The number of pages on DASD will include pages associated with any address space owned by that user.
2. INDICATE PAGING WAIT identifies users in page wait and indicates the number of pages on DASD for that user. A user waiting for a page that is in another user's address space would not be counted in the number of DASD pages reported.
3. If a large virtual machine is logged off multiple times and two or more logged-off instances are still going through memory reset, the user ID (transformed from uppercase to lowercase) will appear multiple times in the responses to this command. Eventually, each instance will finish memory reset and will disappear from the responses.

The following sequence of events is an example of this type of situation:

- a. A user logs on virtual machine "LARGEONE" and runs a workload that instantiates a large amount of memory.
- b. The user logs off the virtual machine. This instance of virtual machine "LARGEONE" becomes known as instance "largeone."
- c. Responses to INDICATE PAGING include "largeone --- yyyyyyyyyy LOGOFF."
- d. The user logs back on to virtual machine "LARGEONE" and runs a workload that instantiates a large amount of memory.
- e. The user logs off. This instance of virtual machine "LARGEONE" also becomes known as instance "largeone."

- f. Responses to INDICATE PAGING now include two occurrences of "largeone --- yyyyyyyyyy LOGOFF."
- g. Eventually instance "largeone" from Step "3.b" on page 546 completes reset and disappears.
- h. Responses to INDICATE PAGING now include only one occurrence of "largeone --- yyyyyyyyyy LOGOFF."
- i. Eventually instance "largeone" from Step "3.e" on page 546 completes reset and disappears.

## Responses

Response 1:

```

  USERID      XSTORE      DASD STATUS
  -----
userid1      --- yyyyyyyyyy zzzzzz
userid2      --- yyyyyyyyyy zzzzzz
userid3      --- yyyyyyyyyy zzzzzz
...
useridn ...

```

### **userid**

identifies the virtual machine.

---

is included for compatibility only. It is always displayed as dashes.

### **yyyyyyyyyy**

is the decimal number of pages this user has on DASD.

### **zzzzzz**

is the virtual machine status and is either LOGOFF, if the user has logged off but its memory is still in the process of being released, or --- otherwise.

Response 2:

```
NO USERS IN PAGE WAIT
```

is issued when appropriate.

## Examples

Example 1:

You can receive responses for one or more virtual machines. For example, the following response indicates that two users are in page wait:

```

indicate paging wait
  USERID      XSTORE      DASD STATUS
  -----
userid1      ---      110 ---
userid2      ---      127 ---

```

## INDICATE QUEUES

### Authorization

Privilege Class: E

### Purpose

Use INDICATE QUEUES to display, in order of their priority, current members of the dispatch and eligible lists.

**Note:** Each **member** is a virtual processor with a transaction in progress. Status critical to the system scheduler and dispatcher is also displayed.

### Operands

#### EXP

displays expanded information about virtual processors with a transaction in progress.

### Usage Notes

1. When INDICATE QUEUES consistently shows *En* virtual processors, an eligible list is forming because one or more system resources appears to be constrained. Under such conditions, forcing users with a transaction in progress to wait in the eligible list increases virtual machine throughput as a whole, and also reduces system overhead. The appearance of a constrained resource is affected by:
  - a. The amount of resources available on the system.
  - b. The total demand for the resources.
  - c. The fraction of resource that is available to certain user classes. For example, the SET SRM STORBUF and SET SRM DSPBUF commands can affect the amount of resources available to certain user classes.

The system resources tracked are: storage, paging capacity, and CPU.

2. When you enter INDICATE QUEUES EXP and the *bbb* field is TI (virtual processor in test-idle state), the associated priority field shows 99999. This should not be read literally as a 99,999 second deadline priority; the 99999 value is used by the scheduler to temporarily place the virtual processor at the bottom of the dispatch list.
3. The format of Response 2 is extremely sensitive to the product release and service level.
4. All virtual processors on the limit list are also part of the dispatch list. However, they have exceeded the limit of the CPU resource that they are allowed to use and will not run until they leave the limit list.
5. CP's virtual processor management has been improved so that no user stays in the eligible list more than an instant before being added to the dispatch list. Therefore users are rarely shown to be in the eligible list.

### Responses

**Notes:** The response you receive lists users in the following order:

1. All dispatch list users (*Qn*) in dispatch priority order
2. All eligible list users (*En*) in eligible list priority order.

The data displayed by this command represents the system at a single, self-consistent instant. (The system is locked briefly so that no changes occur while the data is being gathered.)

Response 1:

```
userid1 ttnn aa bbb s...s/t...t
(1 user per line)
```

**userid1**

**userid2**

each identifies a virtual machine.

**tt**

is a code for the VMATYPE, if other than the user. It can be:

- MP for virtual MP. Each virtual CPU defined for a user shows up separately with the same user ID and a type of MP. Each is a separately dispatchable unit.
- Blank if the virtual processor is any other type.

**nn**

is the virtual CPU number of this virtual processor for virtual MP guests, or is blank if not for virtual MP guests.

**aa**

is the current list status of the user:

**Status**

**List the User Is On**

**Q0**

The dispatch list and exempt from eligible list delays

**Q1**

The dispatch list and entered as an E1 user

**Q2**

The dispatch list and entered as an E2 user

**Q3**

The dispatch list and entered as an E3 user

**E1**

The E1 eligible list

**E2**

The E2 eligible list

**E3**

The E3 eligible list

**LN**

The limit list (subset of dispatch list) due to SHARE LIMITHARD setting.

**L0**

The limit list and exempt from eligible list delays.

**L1**

The limit list and the user entered the dispatch list as a class "1" user.

**L2**

The limit list and the user entered the dispatch list as a class "2" user.

**L3**

The limit list and the user entered the dispatch list as a class "3" user.

**Note:** Users who have been defined as QUICKDSP are in Q0 status whenever they are in the dispatch list. Other users may show up briefly as Q0 if they really belong in the eligible list, but must make brief appearances in the dispatch list (for example, to finish with and release a lock). These users could also appear in the L0 status.

## INDICATE QUEUES

### **bbb**

is one of the following status indicators:

#### **Rnn**

indicates that the user is the current RUNUSER on the specified real processor, where *nn* is the processor ID (in hexadecimal).

#### **PG**

indicates that the user is in page wait; the user's virtual machine is not executing because CP is trying to bring in a page from a paging device.

#### **IO**

indicates that the user is in I/O wait. The user's virtual machine cannot run and has I/O either queued by CP or already in progress.

**Note:** When a user performs I/O through a synchronous DIAGNOSE instruction (as when running CMS), *userid* shows up as I/O, not as EX, while the instruction waits for the I/O.

#### **AP**

indicates that the user is waiting for an APPC/VM function to complete. The APPC/VM function was invoked with the WAIT=YES option.

#### **EX**

indicates that the user is in instruction simulation wait; that is, the user's virtual machine is waiting for the completion of instruction simulation.

#### **PS**

indicates that the user is in PSW wait; that is, the user's virtual machine is in an enabled wait state.

#### **TI**

indicates that a user is in the test-idle state; that is, the user is idle, but has not been idle long enough to be dropped from the dispatch list.

#### **R**

indicates that a user is in the ready state.

–

indicates that a user is in another state not described by the above indicators.

**Note:** In cases where a virtual machine may be in more than one of the above states, only one state is displayed; the state displayed is the first one encountered in the order of priority indicated above.

### **s...s**

is a decimal number indicating the number of pages resident in real storage for this user. The *s...s* value is displayed as 8 - 10 digits.

### **t...t**

is a decimal number indicating the number of pages estimated by the dispatcher as the working set of this user. The *t...t* value is displayed as 8 - 10 digits.

Response 2:

```
userid tnn aa bbb s...s/t...t wxyz sppppp  
(1 user per line)
```

is the response received when INDICATE QUEUES is issued with the EXP option. All fields to the left of *wxyz* are the same as described for Response 1.

### **wxyz**

contains the following 4 status indicators:

#### **w**

##### **H**

The user is receiving a hotshot.

##### **L**

The user is receiving a lock-shot.

**x****I**

The user is receiving interactive bias.

**y**

is one of the following status indicators that refers to a user's eligible list stay, or last eligible list stay if the user is currently in the dispatch list. If more than one of these conditions applies, the one closer to the top of this list applies.

**D**

The user is currently past its eligible list deadline.

**M**

The user was put in the eligible list for exceeding the maximum allowed working set size (WSS).

**P**

The user returned to the eligible list temporarily because of preemption.

**G**

The user returned to the eligible list temporarily for exceeding WSS-growth-limit.

**L**

The user is in the eligible list after having been in the dispatch list for lock-shot.

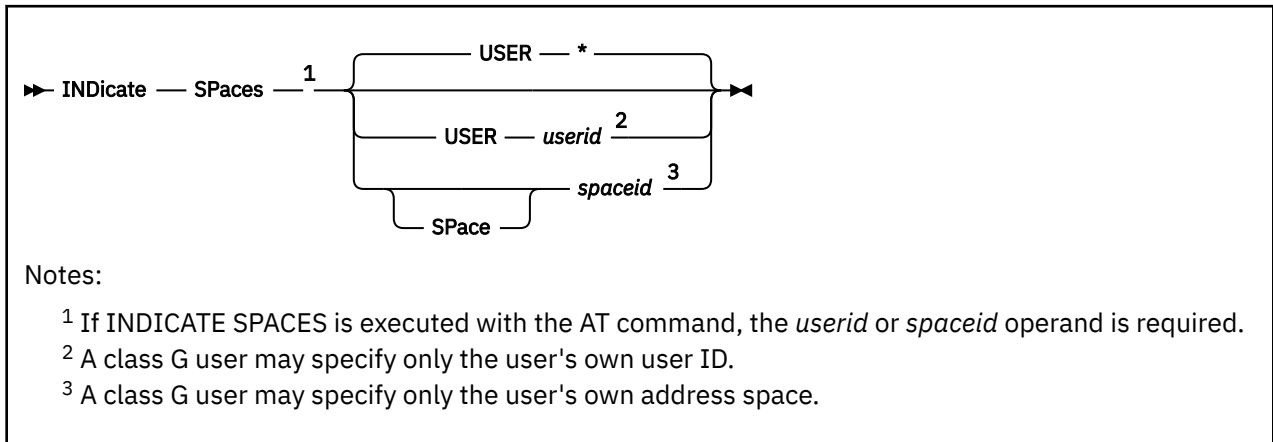

**z****L**

The user is a loading user; that is, the user is considered to be actively bringing in its working set from DASD.

***sppppp***

indicates a user's priority in the eligible or dispatch list, depending on which list the user is in. The priority is expressed in seconds and is represented as an offset from the deadline. The deadline is the time that a dispatch list user is expected to finish its next dispatching minor time slice, or the time that an eligible list user is expected to move to the dispatch list. If the value is zero, the user is at the deadline. If the value is less than zero, the user already has passed the deadline. In this case, the priority is expressed as a negative value and a dash (–) is displayed in the "s" column. If the value is greater than zero, the user has not reached the deadline. The priority is expressed as a positive number, and no sign is displayed in the "s" column.

## INDICATE SPACES

### Authorization

Privilege Class: E, G

### Purpose

Use INDICATE SPACES to display information about a specific address space or all of the address spaces owned by a user. A class G user can display information about the user's own address spaces. A class E user can display information about any address spaces.

### Operands

#### USER \*

returns information about all address spaces owned by the command issuer. This is the default.

#### USER *userid*

returns information about all address spaces owned by *userid*.

#### SPACE

indicates that the next operand is a *spaceid*.

#### *spaceid*

is the name of the specific space for which data is requested.

The *spaceid* is a 1- to 33-character string of the form:

where *owner* is an optional 1- to 8-character user ID of the virtual machine that owns the address space, and *spacename* is the 1- to 24-character name assigned to the address space. If *owner* is not specified, the command issuer's virtual machine is assumed to be the owner of the address space.

The *spacename* 'BASE' is preassigned by CP to be the name of your virtual machine's host-primary address space.

An example of a valid *spaceid* is "OPERATOR:BASE".

Examples of *spaceids* that are not valid are ":BASE" and "BASE". These *spaceids* are not valid only when the command is issued with the AT command.

## Usage Notes

- Any field containing cumulative data from the time the user logged on (reads, writes, and migrates) is preserved during a guest relocation. As a result, the counters might wrap over time.

## Responses

Response 1:

```
Spaceid=ssssssssssssssssssssssssssssssssssssssss Owned size=nu {PRIVATE}
                                                                {SHARED }
Pages: Main=n...n Xstore=--- Dasd=nnnnnnnnnn Locked=---
      Instan=n...n
Private paging:
  Xstore: Reads=---          Writes=---          Migrates=---
  Dasd:   Reads=nnnnnnnnnn   Writes=nnnnnnnnnn
Shared paging:
  Xstore: Reads=---          Writes=---          Migrates=---
  Dasd:   Reads=nnnnnnnnnn   Writes=nnnnnnnnnn
```

### **Spaceid=ssssssssssssssssssssssssssssssssss**

is the fully-qualified address space ID (1 to 33 characters), to which the following data applies.

#### **Owned size=nu**

is the size of the storage within the address space that is owned by the owner of the address space, where  $n$  is a decimal number and  $u$  is the unit of measure. This value can differ from the defined size of the address space only for a primary address space. This value is displayed in units of measure appropriate to the storage size. Shared portions of NSSs or DCSSs that are imbedded in the address space(s) are not considered to be owned by the virtual machine and are not included in the storage size.

<i>Table 20. Storage Units of Measure</i>	
<b>Units suffix</b>	<b>Maximum allowed</b>
K - Kilobytes	2096128
M - Megabytes	17592186044416
G - Gigabytes	17179869184
T - Terabytes	16777216
P - Petabytes	16384
E - Exabytes	16

#### **PRIVATE**

#### **SHARED**

indicates whether the address space is in the private state or in the shareable state.

#### **Pages**

includes information about pages for this space.

#### **Main=n...n**

is the number of pages that are resident in real storage for this address space.

#### **Xstore=---**

is included for compatibility only. It is always displayed as dashes.

#### **Dasd=nnnnnnnnnn**

is the number of pages allocated on DASD paging space for this address space.

#### **Locked=---**

is included for compatibility only. It is always displayed as dashes.

### **Instan=*n...n***

indicates the number of instantiated pages for this address space. A page is considered instantiated when it takes up resource in the paging hierarchy (that is, occupies a real frame or a slot on paging DASD). A copy of a page in multiple places in the paging hierarchy counts as one instantiation.

### **Private paging**

includes information about private paging for this space. The values include counts only for private pages owned by the address space owner. These counts are cumulative for the life of the address space and do not change when the state (private or shared) of the address space changes.

#### **Xstore: Reads=--- Writes=--- Migrates=---**

is included for compatibility only. It is always displayed as dashes.

### **Dasd**

includes information about paging between DASD paging space and real storage.

#### **Reads=*nnnnnnnnnn***

is the number of pages read from DASD to real storage for this address space.

#### **Writes=*nnnnnnnnnn***

is the number of pages written from main storage to DASD for this address space.

### **Shared paging**

includes information about shared paging for this space. The values include counts only for shared pages owned by the address space owner. These counts are cumulative for the life of the address space and do not change when the state (private or shared) of the address space changes.

#### **Xstore: Reads=--- Writes=--- Migrates=---**

is included for compatibility only. It is always displayed as dashes.

### **Dasd**

includes information about paging between DASD paging space and real storage.

#### **Reads=*nnnnnnnnnn***

is the number of pages read from DASD to real storage for this address space.

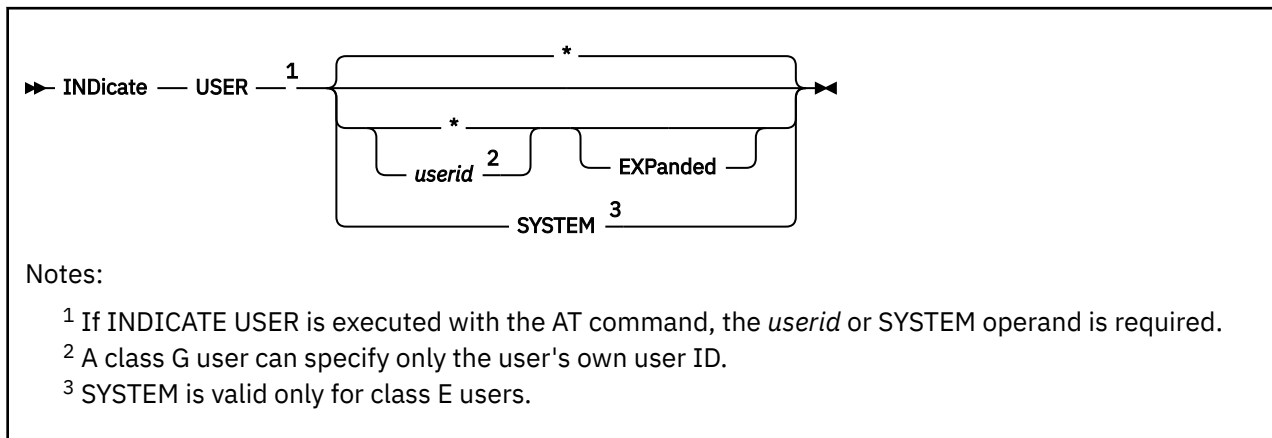

#### **Writes=*nnnnnnnnnn***

is the number of pages written from real storage to DASD for this address space.

## **Messages**

- HCP007E Invalid userid - *userid*.
- HCP1041E Address space *spaceid*. does not exist
- HCP6578E Invalid address space identifier - *option*.

## INDICATE USER

### Authorization

Privilege Class: E, G

### Purpose

Use INDICATE USER to display the resources that are used or occupied by a virtual machine or by the system. A class G user can display information about the user's own virtual machine. A class E user can display information about any virtual machine or the system.

### Operands

\*

#### *userid*

specifies the virtual machine for which you are requesting information. The default is an asterisk (\*), which obtains the information for your own virtual machine.

#### EXPanded

requests an expanded response.

#### SYSTEM

requests information about system resource usage.

See Usage Note “11” on page 556 for a list of the response fields that are meaningful for INDICATE USER SYSTEM.

### Usage Notes

1.  **Attention:** In Response 1, a user's counts for the IO, RDR, PRT, and PCH fields are reset to zero whenever an ACNT command is processed for that user ID. In Response 2 (EXPANDED operand), these fields are not reset when an ACNT command is processed for the user ID.
2. In Response 1, a user's counts for RDR, PRT, and PCH are no longer updated after they reach a value of 999999. These counts are reset to zero when the ACNT command is processed for the user or when the user logs off. If you want to see these counts when they become greater than 999999, refer to Response 2 (EXPANDED operand).
3. Any field containing cumulative data from the time the user logged on (reads, writes, and migrates) is preserved during a guest relocation. As a result, the counters might wrap over time.
4. Only one or no virtual CPUs have an IPLed device or a named saved system that is displayed at any given time. The rest is NONE.

## INDICATE USER

5. Use INDICATE USER to display the total amount of certain resources used by your virtual machine during the current session.
6. Use INDICATE USER before and after the execution of a program to determine the execution characteristics of that program in terms of the resources used.
7. All displayed numbers are in decimal, except for *vdev* and CPU *nn*.
8. When the wait-state interpretation capability is used, the guest virtual machine remains dispatched, even when it enters a PSW enabled-wait state. Time spent dispatched in the wait state is included in the virtual and total CPU time reported for the guest.
9. For compatibility, CP continues to accept the designation XA. XA and ESA are synonymous.
10. If the EXPANDED response is given for a user who is logging on or off and does not have a base address space, then the primary space name and primary space type will be filled with asterisks in the response.
11. The following response fields are meaningful for the INDICATE USER SYSTEM response:
  - USERID is always SYSTEM.
  - STOR is the size of that portion of the system execution space below 2G.
  - DEVNUM is the number of CPACCESSed minidisks.
  - Paging statistics (RES, LOCKEDREAL, NPREF, PREF, READS and WRITES) pertain to pages in system-owned CP utility address spaces. Examples are the "system virtual space" that is used for spooling and spaces for virtual free storage, pageable page tables, VDISKS, and ISFC communication.
  - CTIME is time since system IPL or restart.

Not meaningful in INDICATE USER SYSTEM output are: INSTAN, MACH, VIRT, IPLSYS, WS, RESVD, CPU, VTIME, TTIME, IO, RDR, PRT, and PCH.

## Responses

### Response 1:

This is the response format when the EXPANDED operand is *not* specified. This format is also displayed when the SYSTEM operand is specified. See Usage Note “11” on page 556 for more information about what is meaningful and not meaningful in INDICATE USER SYSTEM output.

This response gives all data from the user VMDBK relevant to the user's virtual machine paging activity, resource occupancy, processor usage, and accumulated I/O activity counts since logon. Time and count values are ever-increasing accumulators.

```
USERID=userid MACH={ESA} STOR=nu VIRT=V XSTORE=---
                {XA }
                {XC }
                {Z  }
IPLSYS={DEV vdev} DEVNUM=nnnnn
        {DEV NONE}
        {sysname }
PAGES: RES=n...n WS=n...n LOCKEDREAL=n...n RESVD=n...n
        INSTAN=n...n
NPREF=n...n PREF=0 READS=n...n WRITES=n...n
CPU nn: CTIME=hh:mm VTIME=mmm:ss TTIME=mmm:ss IO=nnnnnn
        RDR=nnnnnn PRT=nnnnnn PCH=nnnnnn TYPE={CP } CPUAFFIN={ON }
                {IFL } {SUPP}
                {ZIIP} {OFF }
                {ICF }
```

### **USERID=*userid***

identifies the virtual machine. If the SYSTEM operand was specified, *userid* is SYSTEM.

**MACH=ESA****MACH=XA****MACH=XC****MACH=Z**

indicates the virtual machine operating mode.

**STOR=*nu***

indicates the virtual machine storage size, where *n* is a decimal number and *u* is the unit of measure. If the SYSTEM operand was specified, this indicates the size of the system execution area of the system execution space.

<i>Table 21. Storage Units of Measure</i>	
<b>Unit of measure (<i>u</i>)</b>	<b>Maximum allowed (<i>n</i>)</b>
K - Kilobytes	2096128
M - Megabytes	17592186044416
G - Gigabytes	17179869184
T - Terabytes	16777216
P - Petabytes	16384
E - Exabytes	16

**VIRT=V**

appears for compatibility purposes.

**XSTORE=---**

is included for compatibility only. It is always displayed as dashes.

**IPLSYS=DEV *vdev*****IPLSYS=DEV NONE****IPLSYS=*sysname***

indicates the device number (*vdev*) of the last IPLed device for the virtual configuration, or the name (*sysname*) of the last named saved system to be IPLed. (The named saved system was previously saved through the SAVESYS command.) DEV NONE indicates that no device or named saved system was IPLed.

**DEVNUM=*nnnnn***

indicates the number of devices that are attached to this user.

**PAGES**

includes information about pages for this user.

**RES=*n...n***

indicates the number of pages for this user that are resident in real storage at the time the command is issued.

**WS=*n...n***

indicates the most recent system estimate of the user's working set size.

**LOCKEDREAL=*n...n***

indicates the current number of pages for this user that are locked to real storage frames.

**RESVD=*n...n***

indicates the current number of real storage frames that are reserved for pages for this user.

**INSTAN=*n...n***

indicates the number of instantiated pages for this user. A page is considered instantiated when it takes up resource in the paging hierarchy (that is, occupies a real frame or a slot on paging DASD). A copy of a page in multiple places in the paging hierarchy counts as one instantiation.

## INDICATE USER

### **NPREF=*n...n***

indicates the number of private address space pages owned by this user that are currently residing on paging space. If the SYSTEM operand was specified, this indicates the number of shared address space pages that are owned by the system that are currently residing on paging space.

### **PREF=0**

appears for compatibility purposes.

### **READS=*n...n***

indicates the total number of page reads for this user since logon.

### **WRITES=*n...n***

indicates the total number of page writes for this user since logon.

### **CPU *nn***

indicates to which virtual processor the following information refers.

### **CTIME=*hh:mm***

indicates total connect time for the user, in hours and minutes.

### **VTIME=*mmm:ss***

indicates the total virtual time for the user, in minutes and seconds. If multithreading is enabled, this is reported as MT-1 equivalent time.

### **TTIME=*mmm:ss***

indicates the total virtual and simulation time for the user, in minutes and seconds. If multithreading is enabled, this is reported as MT-1 equivalent time.

### **IO=*nnnnnn***

indicates the total number of nonspooled I/O requests issued by the user since the user logged on, or an ACNT command was issued for the user.

### **RDR=*nnnnnn***

indicates the total number of virtual cards read since the user logged on or an ACNT command was issued for the user.

### **PRT=*nnnnnn***

indicates the total number of virtual lines printed since the user logged on or an ACNT command was issued for the user.

### **PCH=*nnnnnn***

indicates the total number of virtual cards punched since the user logged on or an ACNT command was issued for the user.

### **TYPE=CP**

indicates the virtual CPU is a central processor.

### **TYPE=IFL**

indicates the virtual CPU is an IBM Integrated Facility for Linux. The virtual CPU can run on a real IFL or it can be simulated.

### **TYPE=ZIIP**

indicates the virtual CPU is an IBM z Integrated Information Processor. The virtual CPU can run on a real zIIP or it can be simulated.

### **TYPE=ICF**

indicates the Internal Coupling Facility. The virtual CPU can run on a real ICF or it can be simulated.

### **CPUAFFIN=ON**

indicates CPU affinity has been set on with the SET CPUAFFINITY command and this virtual CPU is dispatched on a real CPU of the same TYPE.

### **CPUAFFIN=SUPP**

indicates CPU affinity is suppressed. CPU affinity has been set on with the SET CPUAFFINITY command but there is currently no matching real processor on which to run.

**CPUAFFIN=OFF**

indicates CPU affinity has not been set on. When OFF is in effect the virtual CPU is dispatched on only real CPUs of primary type.

If your virtual machine is a virtual multiprocessor (MP) configuration, the first response is for the base processor. Responses for the additional virtual processors follow the response for the base.

The following fields are meaningful only for the virtual MP configuration as a whole:

MACH  
STOR  
VIRT  
DEVNUM  
RES  
LOCKEDREAL  
RESVD  
NPREF  
PREF  
READS  
WRITES  
WS

The values in the response for additional virtual processors in your configuration are identical with the values in the base processor response for the fields previously listed.

CTIME represents the total connect time only in the base processor response. For your other virtual processors, CTIME indicates the total elapsed time since creation of the virtual processor. If you use the DEFINE command to define the virtual processor after you logged on, this value differs from the value returned in the base processor response.

The following fields are tracked separately for each virtual processor in your virtual machine configuration:

VTIME  
TTIME  
IO  
RDR  
PRT  
PCH  
TYPE  
AFFINITY

IPLSYS reflects the device number of the last device or the name of the last named saved system IPLed on that virtual configuration.

Response 2:

This is the response format when the EXPANDED operand is specified.

This response gives all data from the user VMDBK relevant to the user's virtual machine paging activity, resource occupancy, processor usage, and accumulated I/O activity counts since logon. Time and count values are ever-increasing accumulators.

This response is repeated once for each virtual multiprocessor (MP) configuration owned by the specified user.

```

```

### **Userid=userid**

identifies the virtual machine.

### **Mach=ESA**

### **Mach=XA**

### **Mach=XC**

### **Mach=Z**

indicates the virtual machine operating mode.

### **V=V**

appears for compatibility purposes.

### **Attached xstore=---**

is included for compatibility only. It is always displayed as dashes.

### **Iplsys=DEV vdev**

### **Iplsys=DEV NONE**

### **Iplsys=sysname**

indicates the device number (*vdev*) of the last IPLed device for the virtual configuration, or the name (*sysname*) of the last named saved system to be IPLed. (The named saved system was previously saved through the SAVESYS command.) DEV NONE indicates that no device or named saved system was IPLed.

### **Devnum=nnnnn**

indicates the number of devices attached to this user.

### **SecureIpl=No**

### **SecureIpl=Yes**

indicates whether the last IPL of this virtual machine was a secure IPL. A secure IPL occurs when LOADDEV or DUMPDEV parameters are set and the IPL is started by using the LOADDEV or DUMPDEV operand of the IPL command or IPL directory statement.

### **Spool**

includes information about utilization of DASD spooling space by this user.

### **Reads=nnnnnnnnnn**

indicates the total number of spooling page reads by this user since this user logged on.

**Writes=nnnnnnnnnn**

indicates the total number of spooling page writes by this user since this user logged on.

**Owned spaces**

includes information about all address spaces owned by this virtual machine.

**Number=nnnnn**

indicates the total number of address spaces, shared or private, owned by this virtual machine.

**Owned size=nu**

indicates the total size of all storage owned by this virtual machine in all address spaces, shared or private, owned by this virtual machine, where  $n$  is a decimal number and  $u$  is the unit of measure (see [Table 21 on page 557](#)).

Shared portions of a NSS or DCSS that are imbedded in the address space(s) are not considered to be owned by the virtual machine and thus are not included in the storage size. The size is displayed in units of measure appropriate to the storage size. Owned sizes which are a multiple of kilobytes, but larger than 16 megabytes, are rounded to the nearest megabyte.

**Pages**

includes information about pages for this user.

**LockedReal=n...n**

indicates the current number of pages for this user that are locked to real storage frames.

**LockedLogical=n...n**

indicates the current number of pages for this user that are locked to host logical storage pages.

**Primary space**

includes information about the user's base address space.

**ID=spaceid**

indicates the fully-qualified space ID (3 to 33 characters) of the user's base address space.

**PRIVATE  
SHARED**

indicates whether the user's base space is private or shared.

**Defined size=nu**

indicates the size of the base address space, where  $n$  is a decimal number and  $u$  is the unit of measure (see [Table 21 on page 557](#)).

**Address limit=nu**

indicates the maximum address addressable by the virtual machine in the base address space, plus one, where  $n$  is a decimal number and  $u$  is the unit of measure (see [Table 21 on page 557](#)). This value includes any discontinuous shared storage.

**Private spaces**

includes information about all private address spaces owned by this virtual machine.

**Number=nnnnn**

indicates the total number of private address spaces owned by this virtual machine.

**Owned size=nu**

indicates the total size of all storage owned by this virtual machine in all private address spaces owned by this virtual machine, where  $n$  is a decimal number and  $u$  is the unit of measure (see [Table 21 on page 557](#)).

Shared portions of NSSs or DCSSs that are imbedded in the address space(s) are not considered to be owned by the virtual machine and thus are not included in the storage size.

**Pages**

includes information about user-owned pages for all private spaces owned by this user.

**Main=n...n**

indicates the number of pages that are resident in real storage for all private spaces owned by this user.

**Xstore=---**

is included for compatibility only. It is always displayed as dashes.

**Dasd=nnnnnnnnnn**

indicates the number of pages allocated on system paging space for all private spaces owned by this user.

**Instan=n...n**

indicates the number of instantiated pages for all private spaces owned by this user. A page is considered instantiated when it takes up resource in the paging hierarchy (that is, occupies a real frame or a slot on paging DASD). A copy of a page in multiple places in the paging hierarchy counts as one instantiation.

**WS=nnnnnn**

indicates the most recent system estimate of the user's working set size. This working set size only accounts for all private spaces owned by this user.

**Reserved=nnnnnn**

indicates the number of real storage frames that are reserved for pages for all private spaces owned by this user.

**ResidentLogical=n...n**

indicates the number of pages that are resident in host logical storage for all private spaces owned by this user.

**LockedLogical=n...n**

indicates the number of pages that are locked to host logical storage for all private spaces owned by this user.

**Shared spaces**

includes information about all shared address spaces owned by this virtual machine.

**Number=nnnnn**

indicates the total number of shared address spaces owned by this virtual machine.

**Owned size=nu**

indicates the total size of all storage owned by this virtual machine in all shared address spaces owned by this virtual machine, where  $n$  is a decimal number and  $u$  is the unit of measure (see [Table 21 on page 557](#)).

Shared portions of NSSs or DCSSs that are imbedded in the address space(s) are not considered to be owned by the virtual machine and thus are not included in the storage size. Owned sizes which are a multiple kilobytes but larger than 16 megabytes, are rounded to the nearest megabyte.

**Pages**

includes information about user-owned pages for all shared spaces owned by this user.

**Main=n...n**

indicates the number of pages that are resident in real storage for all shared spaces owned by this user.

**Xstore=---**

is included for compatibility only. It is always displayed as dashes.

**Dasd=nnnnnnnnnn**

indicates the number of pages that are allocated on system paging space for all shared spaces owned by this user.

**Instan=n...n**

indicates the number of instantiated pages for all shared spaces owned by this user. A page is considered instantiated when it takes up resource in the paging hierarchy (that is, occupies a real frame or a slot on paging DASD). A copy of a page in multiple places in the paging hierarchy counts as one instantiation.

**ResidentLogical=n...n**

indicates the number of pages that are resident in host logical storage for all shared spaces owned by this user.

**LockedLogical=n...n**

indicates the number of pages that are locked to host logical storage for all shared spaces owned by this user.

**Private paging**

includes information about paging of user-owned private pages for this virtual machine.

**Xstore: Reads=--- Writes=--- Migrates=---**

is included for compatibility only. It is always displayed as dashes.

**Dasd**

includes information about DASD paging for all private spaces owned by this user.

**Reads=nnnnnnnnnn**

indicates the total number of user-owned pages read from DASD paging space to real storage for all private spaces owned by this user since the user logged on. This number reflects private reads for all spaces owned by this user, regardless of whether the space is currently private or shared. This count does not include shared pages read to a private space.

**Writes=nnnnnnnnnn**

indicates the total number of user-owned pages written to DASD paging space from real storage for all private spaces owned by this user since the user logged on. This number reflects private writes for all spaces owned by this user, regardless of whether the space is currently private or shared. This count does not include shared pages written from a private space.

**Shared paging**

includes information about paging of user-owned shared pages for this virtual machine.

**Xstore: Reads=--- Writes=--- Migrates=---**

is included for compatibility only. It is always displayed as dashes.

**Dasd**

includes information about DASD paging for all shared spaces owned by this user.

**Reads=nnnnnnnnnn**

indicates the total number of user-owned pages read from DASD paging space to real storage for all shared spaces owned by this user since the user logged on. This number reflects reads of user-owned shared pages for all spaces owned by this user, regardless of whether the space is currently private or shared.

**Writes=nnnnnnnnnn**

indicates the total number of user-owned pages written to DASD paging space from real storage for all shared spaces owned by this user since the user logged on. This number reflects writes of user-owned shared pages for all spaces owned by this user, regardless of whether the space is currently private or shared.

**Note:** The section beginning with CPU *nn* includes information about each virtual CPU in the virtual machine configuration. This section is repeated for each virtual CPU in the virtual machine configuration.

**VCONFIG: MODE=ESA390**

indicates the virtual configuration mode of the virtual machine is ESA390.

**VCONFIG: MODE=GENERAL**

indicates the virtual configuration mode of the virtual machine is GENERAL. VCONFIG modes ESA390 and GENERAL are functionally equivalent. ESA390 is displayed when MACHINE is set to XA, ESA, or XC, and GENERAL is displayed when MACHINE is set to Z.

**VCONFIG: MODE=LINUX**

indicates the virtual configuration mode of the virtual machine is LINUX.

**VCONFIG: MODE=VM**

indicates the virtual configuration mode of the virtual machine is VM.

**VCONFIG: MODE=CF**

indicates the virtual configuration mode of the virtual machine is CF.

**CPU nn**

indicates the virtual processor to which the following information refers.

**Ctime=ddd hh:mm:ss**

indicates the total create time for the virtual CPU in days, hour, minutes, and seconds.

**Vtime=ddd hh:mm:ss**

indicates the total virtual time for the virtual CPU in days, hours, minutes, and seconds. If multithreading is enabled, this is reported as MT-1 equivalent time.

**Ttime=ddd hh:mm:ss**

indicates the total virtual and simulation time for the virtual CPU in days, hours, minutes, and seconds. If multithreading is enabled, this is reported as MT-1 equivalent time.

**Rdr=nnnnnnnnnn**

indicates the total number of virtual cards read by this virtual CPU since the virtual CPU was created.

**Prt=nnnnnnnnnn**

indicates the total number of virtual lines printed by this virtual CPU since the virtual CPU was created.

**Pch=nnnnnnnnnn**

indicates the total number of virtual cards punched by this virtual CPU since the virtual CPU was created.

**IO=nnnnnnnnnn**

indicates the total number of nonspooled I/O requests issued by this virtual CPU since the virtual CPU was created.

**Type=CP**

indicates that the virtual CPU is a central processor.

**Type=IFL**

indicates that the virtual CPU is an IBM Integrated Facility for Linux. The virtual CPU can run on a real IFL or it can be simulated.

**Type=ZIIP**

indicates that the virtual CPU is an IBM z Integrated Information Processor. The virtual CPU can run on a real zIIP or it can be simulated.

**Type=ICF**

indicates that the virtual CPU is an Internal Coupling Facility. The virtual CPU can run on a real ICF or it can be simulated.

**CPUAffinity=ON**

indicates that CPU affinity has been set on with the SET CPUAFFINITY command and this virtual CPU is dispatched on a real CPU of the same TYPE.

**CPUAffinity=SUPP**

indicates that CPU affinity is suppressed. CPU affinity has been set on with the SET CPUAFFINITY command but there is currently no matching real processor on which to run.

**CPUAffinity=OFF**

indicates that CPU affinity is not set on. When OFF is in effect the virtual CPU is dispatched on only real CPUs of primary type.

**VtimePrimary=ddd hh:mm:ss**

indicates for the virtual CPU the total virtual time consumed while running on a primary processor. The time is displayed in days, hours, minutes, and seconds. If multithreading is enabled, this is reported as MT-1 equivalent time.

**TtimePrimary=ddd hh:mm:ss**

indicates for the virtual CPU the total virtual and simulation time while running on a primary processor. The time is displayed in days, hours, minutes, and seconds. If multithreading is enabled, this is reported as MT-1 equivalent time.

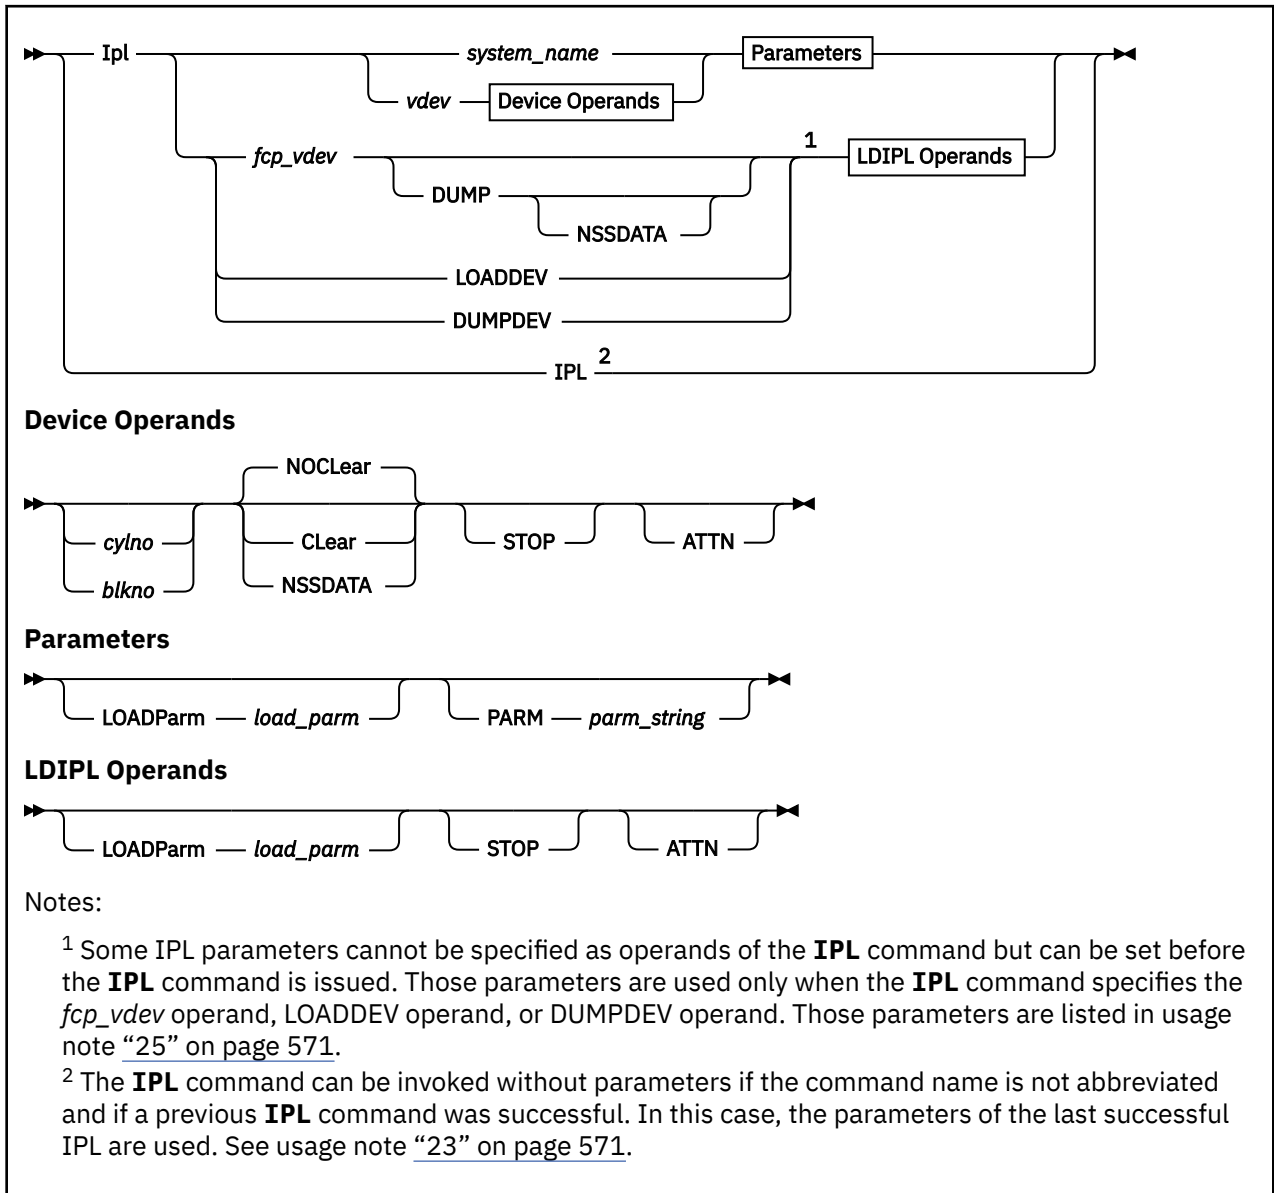

**VtimeSecondary=ddd hh:mm:ss**

indicates for the virtual CPU the total virtual time consumed while running on a secondary processor. The time is displayed in days, hours, minutes, and seconds. If multithreading is enabled, this is reported as MT-1 equivalent time.

**TtimeSecondary=ddd hh:mm:ss**

indicates for the virtual CPU the total virtual and simulation time while running on a secondary processor. The time is displayed in days, hours, minutes, and seconds. If multithreading is enabled, this is reported as MT-1 equivalent time.

## IPL

## Authorization

Privilege Class: G

## Purpose

Use the **IPL** command to simulate an initial program load (IPL) function for your virtual machine.

The **IPL** command can specify four methods to IPL a virtual machine:

- Load a named saved system.
- Use an ECKD device that is specified by the **IPL** command. Optionally specify ECKD device parameters.
- Use a SCSI device that is specified by the **IPL** command's *fcp\_vdev* operand and use required IPL information that is specified in **LOADDEV** or **DUMPDEV** parameters. A list-directed IPL is initiated.

- Use required IPL information, including the virtual device number, that is specified in LOADDEV or DUMPDEV parameters. The device can be an ECKD device or a SCSI device. A list-directed IPL is initiated.

The **IPL** command can specify optional IPL information for any of the four methods.

#### Notes:

1. The **IPL** command is not supported for secondary processors.

## Operands

### *system\_name*

The *system\_name* operand specifies the 1- to 8-character alphanumeric name of a named saved system. The system was saved by using the **SAVESYS** command.

### *vdev*

The *vdev* operand specifies the virtual device number of a device to IPL. The value must be a hexadecimal number in the range X'0000' - X'FFFF'. A guest IPL from the specified device is initiated.

**Note:** DASD that is defined as being unsupported cannot be IPLed by CP. Unsupported DASD can be used only by a virtual machine that is IPLed from a supported device or from a named saved system. See [Direct access storage devices \(DASD\) in z/VM: General Information](#).

### *fcp\_vdev*

The *fcp\_vdev* operand initiates a list-directed IPL operation from an FCP-attached (SCSI) device. The *fcp\_vdev* operand specifies the virtual device number of the attached FCP device.

If the **IPL** command's DUMP operand is specified, some storage is saved for the dump. The system dumper program is then loaded and stores data to the device that it is configured to use.

The *fcp\_vdev* operand indicates a list-directed IPL, in which some required IPL information is specified by LOADDEV or DUMPDEV parameters. For more information, see usage notes [“25” on page 571](#) and [“26” on page 573](#).

If the LOADDEV or DUMPDEV parameters specify a virtual device number, you can omit the **IPL** command's *fcp\_vdev* operand and instead use the **IPL** command's LOADDEV or DUMPDEV operand. If both the **IPL** command's *fcp\_vdev* operand and the LOADDEV or DUMPDEV parameters specify a virtual device number, then the *fcp\_vdev* operand must specify the same virtual device number as the LOADDEV or DUMPDEV parameters specify.

The *fcp\_vdev* operand is not allowed if the LOADDEV or DUMPDEV parameters specify the SECURE parameter.

If the *fcp\_vdev* and NSSDATA operands are specified, the DUMP operand must also be specified.

## LOADDEV

### DUMPDEV

The LOADDEV and DUMPDEV operands initiate a list-directed IPL operation from an FCP-attached (SCSI) device or an ECKD device. All information that is required for IPL, including the device number, must be set in the LOADDEV or DUMPDEV parameters.

The LOADDEV operand indicates a list-directed IPL that uses preset LOADDEV parameters to load an operating system program without dump.

The DUMPDEV operand indicates a list-directed IPL that uses preset DUMPDEV parameters to load a system dumper program. The device that is IPLed is also used to store the dump data.

A secure IPL is possible only when the SECURE parameter is set and the **IPL** command specifies the LOADDEV or DUMPDEV operand.

For more information, see usage notes [“25” on page 571](#) and [“26” on page 573](#).

***cylno******blkno***

The *cylno* and *blkno* operands specify the location of the IPL data when the *vdev* operand specifies a DASD device. For CKD and ECKD DASD devices, the *cylno* operand specifies the cylinder number that contains the IPL data. For FBA DASD devices, the *blkno* operand specifies the starting block number where the IPL data is located. If not specified and the *vdev* operand identifies a DASD device, virtual cylinder 0 or block number 0 are defaulted. This operand is only for virtual direct access storage devices.

**NOClear**

The NOCLEAR operand allows the contents of your virtual machine's storage to remain unchanged before program load. NOCLEAR is the default.

**Clear**

The CLEAR operand sets the contents of your virtual machine's storage to binary zeros before the operating system is loaded.

**DUMP**

The DUMP operand initiates a guest IPL from SCSI disk with dump. The following requirements apply when the DUMP operand is specified:

- The *fcp\_vdev* operand specifies an attached FCP device.
- DUMPDEV parameters were set by using the **SET DUMPDEV** command. If the DUMPDEV parameters include a device number, then the *fcp\_vdev* operand matches that device number.

A list-directed IPL with dump is similar to a list-directed IPL without dump but has three differences:

1. Before the machine loader is loaded into storage, a model-dependent amount of guest storage is saved in simulated HSA. The anchor and size of the storage area is saved in the base VMDBK of the guest that requests the dump.
2. A system image is not loaded from the SCSI device that is identified by using a **SET LOADDEV** command. A system dumper is loaded from the SCSI device that is identified by the **SET DUMPDEV** command. The same device is also used to store the dump data. The operands that are valid for the **SET LOADDEV** command are the same operands that are valid for the **SET DUMPDEV** command.
3. The system dumper calls DIAG X'308' with subcode 2 to release the data that is saved in simulated HSA.

**NSSDATA**

The NSSDATA operand preserves a private copy of the contents of the existing embedded NSS (named saved system) in memory after the **IPL** command completes.

If the NSSDATA operand is specified when an FCP device is IPLed, then the DUMP operand must also be specified.

Because the NSSDATA operand is not permitted when the LOADDEV or DUMPDEV operand is specified, the NSSDATA operand cannot be used with a secure IPL. The NSSDATA operand is deprecated and might be removed in the future.

The following requirements apply when the DUMP operand is specified:

- The NSS is fully contained within the first extent of guest memory.
- The NSS does not contain SW, SN or SC pages.
- The NSS is not a VMGROUP NSS.

If any of these requirements are not satisfied, the command fails and the system remains unchanged.

**STOP**

The STOP operand halts the virtual machine during the IPL procedure just after the initial PSW is loaded. After the halt, you can simulate an IPL procedure for your virtual machine in instruction step mode. When your virtual machine stops, you can enter CP commands. To restart the virtual machine, enter the **BEGIN** command.

**ATTN**

The ATTN operand sends an attention interrupt to the virtual machine during the IPL procedure.

**LOADPARM** *load\_parm*

The LOADPARM operand specifies a load parameter of 1-8 characters. The parameter value can be retrieved by the guest operating system during its IPL sequence. Its use is determined by the guest operating system, such as indicating the nucleus to be loaded during the IPL sequence. If the LOADPARM operand is not specified, a load parameter of eight EBCDIC blanks is formed.

Use single quotation marks to preserve leading and embedded blanks. If fewer than eight characters are specified, the parameter value is left-justified and padded with blanks.

The parameter value is converted to uppercase and can include only the uppercase alphabetic characters (A-Z), digits 0-9, the period, and the blank.

**PARM** *parm\_string*

The PARM operand specifies a parameter string up to 64 bytes long to pass to the virtual machine in general purpose registers at completion of IPL. The parameter string begins with the first nonblank character that follows the PARM keyword. It consists of all remaining characters that follow on the command line, including trailing blanks. If you specify other optional parameters on the **IPL** command, you must enter the PARM operand last.

If you are IPLing a device, the parameter string is inserted into the virtual machine registers, four bytes per register, starting with register 0. If the string is less than 64 bytes, a single byte of binary zeros is inserted following the string. If you omit PARM, the virtual machine registers are unchanged. If you IPL an NSS that was defined with the PARMREGS=*m-n* option on the **DEFSYS** command, the parameter string is inserted into the virtual machine registers *m* through *n*. Before insertion, the virtual machine registers *m* through *n*, initialized to binary zeros. For more information, refer to the **DEFSYS** command. If you enter a string that is too large to fit in the designated registers, an error message is issued, and the command is not processed. If you specify PARM followed by all blanks or if you omit PARM, the virtual machine registers specified by the PARMREGS option on the **DEFSYS** command contains all zeros.

If you IPL an NSS that was defined with the PARMREGS=NONE option on the **DEFSYS** command, the PARM option yields an error message. The command is not processed.

If you are IPLing an NSS that was defined without the PARMREGS=*m-n* option on the **DEFSYS** command, the parameter string is inserted into the virtual machine registers 0 - 15. The registers are not first initialized to binary zeros. If you specify PARM followed by all blanks or if you omit PARM, the virtual machine registers are unchanged.

**Usage Notes**

1. The **IPL** command can be entered from the virtual machine console as the first or only command on a CP command line. A CP command line is when TERMINAL MODE is CP or CP READ is displayed or the command line begins with #CP. In that case, VM attempts to break out of certain wait states that might exist. Thus the **IPL** command can be entered to cause breakout of certain virtual machine wait states.

The breakout attempt occurs when the **IPL** command is entered, not when the command is processed. Command errors do not prevent the breakout attempt. In some cases, a breakout resets the virtual machine.

2. If you want to use the AUTOOCR, BATCH, NOSPROF, INSTSEG, or SAVESYS parameters of the **IPL** command, you must have PARMREGS=0-15 in the **DEFSYS** command for the CMS named saved system.
3. IPL simulates the LOAD operation on the real system console. The specified virtual device is accessed, and the required input/output operations are performed to retrieve the IPL data. This does not pertain to named saved systems.
4. Optionally, you can stop the IPL procedure after the virtual PSW is loaded. Also, you can pass parameters to the virtual machine's general registers. When the simulated load function is complete,

CP initiates execution of the virtual machine by loading the IPL PSW, which was stored during the simulation process.

5. If you enter `ipl system_name` or `ipl vdev clear`, the **IPL** command performs a system-reset-clear function on your virtual machine as if the **SYSTEM CLEAR** command were processed.

You can enter `ipl vdev noclear` or enter `ipl vdev` and take the NOCLEAR default. In this case, the **IPL** command performs a system-reset-normal function on your virtual machine as if the **SYSTEM RESET** command were processed.

The effects of a system-reset-normal or system-reset-clear function are described in detail in the description for the **SYSTEM RESET** and **SYSTEM CLEAR** commands.

6. Any logical lines that follow the **IPL** command are ignored because execution of the **IPL** command transfers control from the CP environment to the virtual machine environment.
7. The IPL sequence for the program that you want to IPL must use only format 0 CCWs.
8. After you enter the **IPL** command, the pseudo page fault facility is deactivated. To activate (or reactivate) the pseudo page fault facility, you must enter the **SET PAGEX** command with the ON operand. For more information, see usage note [“2” on page 1594](#) in the description of the **SET PAGEX** command.
9. Care must be used when parameters are passed to a named saved system (*system\_name*). Named saved systems might expect certain registers to be initialized when they are given control. Indiscriminate use of the PARM operand might overlay a previously initialized register, causing unpredictable results.
10. The **IPL** command fails if issued when VMRELOCATE is in progress.
11. When *system\_name* is equal to a hexadecimal device number, the device is IPLed if it exists; otherwise, the named saved segment (NSS) is IPLed.
12. The NSS name `"_0___1__"` is reserved for IBM use.
13. The LOADDEV and DUMPDEV keywords are not valid for use as NSS names.
14. Processing of an **IPL** command on an NSS might be delayed if DIAGNOSE code X'64' is concurrently performing the initial load of a large DCSS.
15. The contents of an NSS preserved by processing the NSSDATA parameter includes storage keys that are accurately preserved except for the reference bit, which is unreliable. The change bit is always off for SR and ER pages of an NSS and they cannot be changed by the user. Therefore, the change bit is never on for preserved SR or ER pages.
16. Immediately after an NSS is restored by the **IPL** command, the virtual machine's architecture mode is determined by its MACHINE setting. In some cases, the virtual machine's architecture mode is also determined by the architecture mode when the NSS was saved. The interaction of the MACHINE setting and the architecture mode when the NSS was saved has the following outcomes:

**MACHINE setting: ESA**

**Architecture mode when NSS was saved: ESA/390 or ESA/XC**

If the MACHINE setting is ESA and the NSS was saved while in ESA/390 mode or ESA/XC mode, then the architecture mode is ESA/390.

**Architecture mode when NSS was saved: z/Architecture or z/XC**

If the MACHINE setting is ESA and the NSS was saved while in z/Architecture mode or z/XC mode, then the architecture mode is z/Architecture.

**MACHINE setting: XC**

**Architecture mode when NSS was saved: ESA/390 or ESA/XC**

If the MACHINE setting is XC and the NSS was saved while in ESA/390 mode or ESA/XC mode, then the architecture mode is ESA/XC.

**Architecture mode when NSS was saved: z/Architecture or z/XC**

If the MACHINE setting is XC and the NSS was saved while in z/Architecture mode or z/XC mode, then the architecture mode is z/XC. However, if the virtual machine's relocation domain excludes z/XC capability, then IPL sets the architecture mode to ESA/XC.

**MACHINE setting: Z**

If the MACHINE setting is Z, then the architecture mode is z/Architecture.

If the architecture mode on completion of the **IPL** command differs from the mode at SAVESYS, the PSW is converted to the appropriate format (that is, from a 64-bit ESA/390 or ESA/XC PSW to a 128-bit z/Architecture or z/XC PSW, or vice versa).

17. If you IPL an NSS that was created with the VMGROUP option on the **DEFSYS** command, your virtual machine becomes a member of the virtual machine group that is known by the NSS name. Members of a virtual machine group are permitted to connect to the signal system service and to provide intragroup signaling. Signaling includes awareness messages (signal-in and signal-out) about members that join or leave the group.

If your machine is a member of a virtual machine group, a user with an appropriate privilege class can authorize trace data recording into a system data file for the group. Issue a **TRSAVE** command and specify FOR *sysname*.

18. If you do not want leading blanks or embedded blanks in the LOADPARM operand, you can specify the parameter value as a single blank-delimited token. Single quotation marks preserve leading and embedded blanks.
19. The LOADPARM operand cannot contain a X'15' character.
20. You can specify both the LOADPARM and PARM options when IPLing by either *vdev* or *system\_name*. Both options can be specified on the same command line. However, if you specify the PARM option, it must be the last option on the command.
21. If the tape drive specified is in a Given State, the issuer must be the user ID to whom the tape drive was given, or the command is not performed.
22. This command terminates all Concurrent Copy (CONCOPY) sessions for your virtual machine.
23. The **IPL** command can be invoked without operands if both of the following conditions are true:
- A previous **IPL** command was successful.
  - The **IPL** command is entered without abbreviation (that is, is entered as IPL rather than I or IP).

In such a case, the operands of the last successful **IPL** command are used.

If the **IPL** command is invoked without operands and either of the conditions are false, then an error message is issued.

24. If an external security manager is installed on your system, you might not be authorized to enter this command. For additional information, contact your security administrator.
25. A list-directed IPL is an IPL that is initiated when an **IPL** command or IPL directory statement specifies one of the following operands:
- *fcv\_vdev*
  - LOADDEV
  - DUMPDEV (DUMPDEV is not a valid operand for IPL directory statements)

In these cases, the **IPL** command or IPL directory statement operands do not provide all required information for the IPL. List-directed IPL parameters (LOADDEV and DUMPDEV parameters) provide the IPL information that the **IPL** command or IPL directory statement operands don't provide.

Most list-directed IPL parameters specify information that cannot be entered as operands on the **IPL** command or IPL directory statement. (The one exception is the DEVICE parameter, which value can be specified by the *fcv\_vdev* operand of the **IPL** command or IPL directory statement.)

Table 22 on page 571 lists parameters that are used in list-directed IPLs.

Table 22. LOADDEV and DUMPDEV parameters			
Parameter	Description	Device type	Default value
DEVICE	The number of the virtual device that is IPLed	SCSI and ECKD	There is no default value

Parameter	Description	Device type	Default value
PORTNAME	The fibre channel port name of the device that is IPLed	SCSI only	0 <sup>1</sup>
LUN	The logical unit number of the device that is IPLed	SCSI only	0 <sup>1</sup>
BR_LBA	The logical-block address of the boot record	SCSI only	0
BOOTPROG	The number of the boot program	SCSI and ECKD	0
SECURE/ NOSECURE	Specifies whether the IPL is a secure IPL	SCSI and ECKD	NOSECURE
SCPDATA	Information that is passed to the program that is loaded during IPL	SCSI and ECKD	There is no default value
BOOTREC	The boot record location on the device that is IPLed	ECKD only	LABEL

**Note:**

1. The default value 0 is not a valid device port name and not a valid device LUN. An IPL attempt that uses the default value for the PORTNAME or LUN parameter will fail.

Table 23 on page 572 shows which LOADDEV and DUMPDEV parameters have default values that must be set (changed from the default) before each type of list-directed IPL can be started. Other parameters might need to be set if the default values are not appropriate for your environment.

IPL type	DEVICE parameter	PORTNAME parameter	LUN parameter	SECURE parameter
<b>IPL <i>fcp_vdev</i></b>	The DEVICE parameter is not set or matches <i>fcp_vdev</i> on the <b>IPL</b> command	Required	Required	Not allowed
<b>IPL <i>fcp_vdev</i> DUMP</b>				
<b>IPL LOADDEV</b> from SCSI device	Required	Required	Required	Required if the SECUREIPLREQ option is specified in the OPTION directory statement
<b>IPL LOADDEV</b> from ECKD device	Required	Not applicable	Not applicable	
<b>IPL DUMPDEV</b> from SCSI device	Required	Required	Required	Required if the previous IPL used the SECURE parameter or if the SECUREIPLREQ option is specified in the OPTION directory statement
<b>IPL DUMPDEV</b> from ECKD device	Required	Not applicable	Not applicable	

There are two groups of parameters for list-directed IPLs:

**LOADDEV parameters**

LOADDEV parameters provide IPL specifications when the IPL does not include a dump.

### DUMPDEV parameters

DUMPDEV parameters provide IPL specifications when the IPL does include a dump.

In each group, a value can be set for each parameter that is listed in [Table 22 on page 571](#). The values of the LOADDEV and DUMPDEV parameters are independent of each other and do not affect each other. The settings for LOADDEV parameters are displayed by the **QUERY LOADDEV** command. The settings for DUMPDEV parameters are displayed by the **QUERY DUMPDEV** command.

For more information, see [QUERY LOADDEV](#) and [QUERY DUMPDEV](#) in *z/VM: CP Commands and Utilities Reference*.

26. Parameters for a list-directed IPL without dump (also called LOADDEV parameters) are set by using any of the following methods:

- **SET LOADDEV** command.
- LOADDEV user directory statement. The LOADDEV user directory statement can be modified by a directory management tool such as IBM Directory Maintenance (DirMaint). To set load parameters by using DirMaint, use the **DIRM LOADDEV** command. The LOADDEV user directory statement can be modified also by the `Image_IPL_Characteristics_Define_DM` API function.

Parameters for a list-directed IPL **with** dump (also called DUMPDEV parameters) are set by using the CP **SET DUMPDEV** command.

For more information, see [SET LOADDEV](#) and [SET DUMPDEV](#), [LOADDEV Directory Statement](#) in *z/VM: CP Planning and Administration*, [DIRM LOADDEV](#) in *z/VM: Directory Maintenance Facility Commands Reference*, and [Image\\_IPL\\_Characteristics\\_Define\\_DM](#) API function in *z/VM: Systems Management Application Programming*.

27. A secure IPL is required in the following situations:

- A user's OPTION directory statement includes the SECUREIPLREQUIRED option. For a secure IPL, the **IPL** command must use the LOADDEV operand (for IPL without dump) or the DUMPDEV operand (for IPL with dump).
- A guest's previous IPL was a secure IPL and the current IPL includes a dump. For a secure IPL in this case, the **IPL** command must use the DUMPDEV operand.

28. To initiate a secure IPL by using the **IPL** command, the following conditions must be satisfied:

- The **IPL** command uses the LOADDEV or the DUMPDEV operand.
- The DEVICE parameter specifies the virtual device number.
- The SECURE parameter is set.
- Other list-directed IPL parameters are set to appropriate values for your environment.
- The program that is loaded must be signed. The appropriate certificate must be loaded in the HMC and assigned to the LPAR on which the IPL occurs.

29. z/VM does not support list-directed IPL of a z/VM system from ECKD or a secure IPL of a z/VM system from SCSI or ECKD. The z/VM stand-alone dump utility does not support list-directed IPL from ECKD, and does not support secure IPL from SCSI or ECKD. For more information, see [SET LOADDEV](#) and [SET DUMPDEV](#).

## Options

**Optional CMS Initialization Parameters:** The following CMS parameters are passed to the system profile EXEC (SYSPROF EXEC). Any unrecognized parameters are ignored by CMS initialization, but are still passed to the SYSPROF EXEC.

CMS users can use the PARM operand to specify any of the following CMS parameters:

### AUTOOCR

is the automatic carriage return parameter that simulates the pressing of the ENTER key as input to the virtual machine at the initial VM READ. Your PROFILE EXEC is automatically executed if it exists on your file mode A.

**BATCH**

indicates that the CMS IPL is being performed in a batch instead of an interactive virtual machine.

Use of this parameter does not affect execution of the SYSPROF EXEC. Execution of the SYSPROF EXEC is suppressed only if the NOSPROF parameter was specified.

At the beginning of each job, the batch facility work disk is accessed and immediately erased, preventing the current user job from accessing files that might remain from the previous job. Because of this, execution of the PROFILE EXEC is disabled for the CMS Batch Facility machine. However, if the BATPROF EXEC exists on an accessed system disk, it is invoked instead of the PROFILE EXEC.

**FILEPOOL *filepoolid***

specifies the default file pool that is established as the user's file mode A. If FILEPOOL is not specified, 191 is established as the file mode A.

The following parameters are ignored by the SYSPROF EXEC, but processed by CMS initialization.

**NOSPROF**

indicates that the SYSPROF EXEC is bypassed. You must specify NOSPROF if you intend to enter the **CMSBATCH** command when the initial VM READ is issued. When the SYSPROF EXEC does not exist, you do not have to specify NOSPROF to enter the **CMSBATCH** command.

**INSTSEG YES**

links the default CMS installation saved segment for this CMS session. The CMS installation-saved segment is an optional shared segment that contains EXECs and editor macros that your installation provides.

**INSTSEG NO**

indicates that you do not want to use the CMS installation-saved segment during this CMS session.

**INSTSEG *name***

links the named CMS installation saved segment for this CMS session. The segment can be a physical or a logical saved segment.

**SAVESYS *sysname***

is used while creating named systems. The SAVESYS parameter is available only to Class E users. It saves a virtual machine storage space with registers and PSW as they currently exist. The operand *sysname* must be a predefined name that represents a definition of installation requirements of named system. The definition indicates the number of pages to be saved, the DASD volume on which the system is to be saved, and the shared segments, if any.

After the system is saved, initialization continues, all CMS parameters that are entered on the **IPL** command are ignored, and SYSPROF EXEC is processed. The parameters that are entered on the original **IPL** command are not passed to SYSPROF EXEC.

No other parameters can be specified with this parameter. If any other parameters are specified, all parameters are ignored, and a CONFLICT parameter is passed to SYSPROF EXEC, as well as the parameters entered on the **IPL** command.

**MTSEG YES**

links the default CMS multitasking segment for this CMS session. The CMS multitasking segment is an optional shared segment that contains the CMS multitasking enablement code.

**Note:** The CMS multitasking segment is no longer used because the multitasking enablement code is now included in the CMS nucleus. This parameter has no effect and is retained only for compatibility.

**MTSEG NO**

indicates that you do not want to use the CMS multitasking segment during this CMS session.

**Note:** The CMS multitasking segment is no longer used because the multitasking enablement code is now included in the CMS nucleus. This parameter has no effect and is retained only for compatibility.

**MTSEG *name***

links the named CMS multitasking segment for this CMS session. The segment can be a physical or a logical multitasking segment.

**Note:** The CMS multitasking segment is no longer used because the multitasking enablement code is now included in the CMS nucleus. This parameter has no effect and is retained only for compatibility.

## Optional CMS Initialization usage notes

1. If you want to use the NOSPROF, INSTSEG, or SAVESYS parameters of the **IPL** command, you must have PARMREGS=0-15 specified on the **DEFSYS** command for the CMS named saved system.
2. You can indicate that the CMS initial program load is being performed in a batch rather than an interactive virtual machine. Specify either the BATCH parameter on the **IPL** command or the NOSPROF parameter, and then enter the **CMSBATCH** command at the VM READ. Then, a BATPROF EXEC is processed in the batch machine, rather than a PROFILE EXEC. This option causes the CMS nucleus to issue the **CMSBATCH** command to load the batch processor. Specifying the BATCH option eliminates the need for operator intervention between jobs. See [The CMS Batch Facility in z/VM: CMS Planning and Administration](#) for information.
3. AUTOOCR should not be used for AUTOLOG users if SET AUTOREAD OFF is in the user's profile.

**Note:** For a disconnected CMS service virtual machine, this mechanism can be useful. The name of a CMS restart routine can be specified in the CMS nucleus. In case of an abend, the specified restart routine receives control instead of the service virtual machine entering a disabled wait state. If this routine issues an **IPL CMS PARM AUTOOCR** command, the PROFILE EXEC processes initial setup procedures that allow the service virtual machine to reestablish itself.

4. The SYSPROF EXEC contains some of the CMS initialization function. When you IPL CMS, it is executed by default before any file modes are accessed. The user PROFILE EXEC is invoked after the SYSPROF EXEC. You can bypass the SYSPROF EXEC by specifying the NOSPROF parameter on the **IPL** command.
5. If you defined disks with virtual device numbers 190 and 19E in the system directory, or if they are defined before you IPL CMS, these disks are accessed as the S- and Y-disks. After you IPL CMS, you must enter explicit **ACCESS** commands to access other disks. Ordinarily, you have access only to files with a file mode number of 2 on the system disk.

If you defined disk address 191 and the FILEPOOL parameter is omitted, the 191 disk is accessed as file mode A. However, if the FILEPOOL parameter is specified, your top directory in the identified file pool is accessed as file mode A, even if you also have a 191 minidisk defined. If the access of the top directory fails (perhaps because the file pool is unavailable), the 191 minidisk is accessed. If there is no 191 minidisk, nothing is accessed as file mode A.

When **ACCESS** is the first command that is issued after an IPL of the CMS system, file mode A is not automatically defined. Another **ACCESS** command must be issued to define file mode A.

For more information, see [CMS ACCESS](#) command in *z/VM: CMS Commands and Utilities Reference*.

6. If you have a disk that is defined as virtual device number 192, the following special rules apply when CMS is IPLed:
  - If 192 is an unformatted temporary minidisk or virtual disk in storage, CMS formats it and accesses it as file mode D.
  - If 192 is a CP-formatted temporary minidisk or virtual disk in storage, CMS reformats it for CMS use and accesses it as file mode D.
  - If 192 is a CMS-formatted temporary minidisk, virtual disk in storage, or permanent minidisk that is accessed as a file mode other than D, CMS reaccesses it as file mode D.
  - If 192 is an unformatted or CP-formatted permanent minidisk, CMS does not automatically format, reformat, access, or reaccess it.

When CMS accesses a 192 minidisk as file mode D, any minidisk or SFS directory that is already accessed as D is released.

## Responses

Usually, after a successful IPL, any responses you receive are those from the operating system that was loaded and initialized.

Response 1:

```
Trace active at IPL
```

is issued when trace is active.

Response 2:

```
IPL stop at xxxxxxxx
```

is issued after the IPL is complete when the STOP option is specified.

**XXXXXXXX**

is the address where execution of the loaded program starts.

After this response is issued, your virtual console is placed into CP READ so that you can enter CP commands (for example, **TRACE**). After you enter all wanted CP commands, issue the **BEGIN** command to start the loaded program.

## Messages

**Note:** A guest IPL from a SCSI, NVMe, or ECKD device might cause non-CP messages to be displayed. For descriptions of non-CP messages, see *IBM Z: IPL Machine Loader Messages (SC28-7046)*.

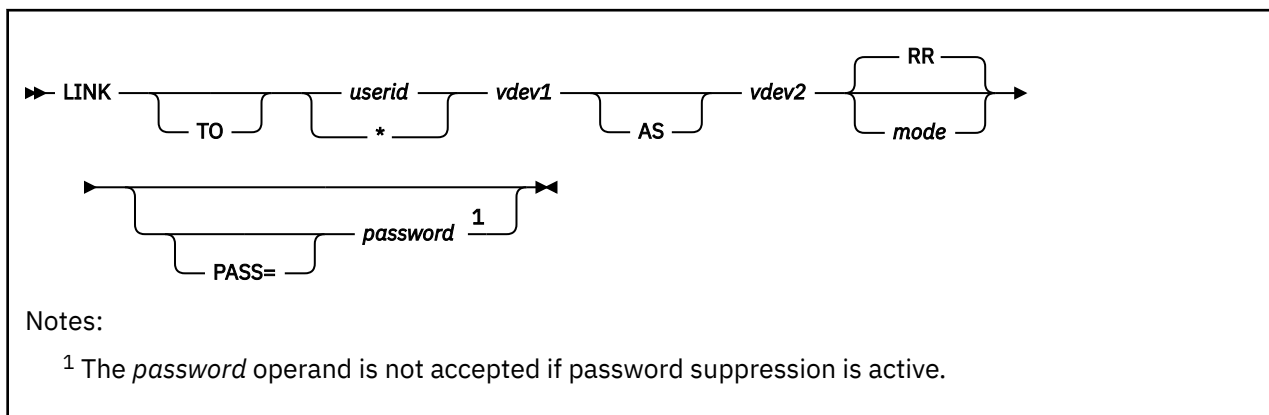

Messages:

- HCP799E IPL failed due to insufficient or faulty storage
- HCP819I Traceid *traceid* disabled; group *group* enabled by *traceid*
- HCP838E The request process cannot complete due to a processor controller failure.
- HCP1001E An operand is missing for *option*.
- HCP1013E An invalid operand was supplied for *option - operand*
- HCP1015E [XAUTOLOG failed for *userid*:] Insufficient storage is available to satisfy your request.
- HCP1122E *command* was not performed. Tape *vdev* has been given to user *userid*.
- HCP1352E System *name* cannot be processed.
- HCP1600E Specified cylinder number *cylinder* is not on the virtual DASD.
- HCP1601E The PARM option is not allowed for the system specified with the IPL command.
- HCP1612E Conflicting device numbers were specified on the IPL and SET LOADDEV or SET DUMPDEV commands.
- HCP1614E An IPL without the SECURE option cannot be performed because the system being dumped was IPLed with the SECURE option.
- HCP1614E An IPL without the SECURE option cannot be performed because the virtual machine has the SECUREIPLREQUIRED option set in its directory entry.
- HCP1615E IPL LOADDEV|DUMPDEV failed because not all necessary parameters have been set.
- HCP1616E IPL of a dump program failed because no dump save areas are available. Try again later.
- HCP1617E IPL by device number failed because secure IPL can be done only when using the LOADDEV or DUMPDEV form of the command.
- HCP2813E CP is running on a processor or in a mode that does not support IPL with DUMP to SCSI or ECKD devices.
- HCP2813E CP is running on a processor or in a mode that does not support IPL from SCSI or ECKD devices.
- HCP2815E The virtual storage size must be greater than *nnnnM* to perform a list-directed IPL.
- HCP2815E The virtual storage size of the CF Service Machine must be greater than *nnnnM* to load the message processor.
- HCP2815E The virtual storage size must be greater than *nnnnM* to perform a list-directed IPL with the DUMP option.
- HCP2816I Acquiring the machine loader from the processor controller.
- HCP2817I Load completed from the processor controller. Now starting the machine loader.
- HCP2818E The request to load the machine loader from the processor controller has been cancelled.
- HCP2824E No {LOADDEV|DUMPDEV} parameters are currently defined
- HCP6056I XAUTOLOG information for *userid*: The IPL command is verified by the IPL command processor.
- HCP6061I APPC wait canceled; virtual machine has been reset.
- HCP6086I Traceid *traceid1* is no longer superseded by VMGROUP trace *traceid2*.
- HCP6094I User *userid* will not be traced by trace *traceid*.
- HCP6097I User *userid* has restricted tracing to traces defined as BLOCK.
- HCP6525E Authorization request failed.

## LINK

## Authorization

Privilege Class: G

## Purpose

Use LINK to make a device associated with another virtual machine available to your virtual machine configuration.

## Operands

### *userid*

is the user ID in the system directory whose entry is to be searched for device *vdev1*. If you omit the TO operand, you cannot specify *userid* as T or TO.

\*

indicates that your devices are to be searched for device *vdev1*. When the LINK command is issued in an adjunct configuration, the asterisk refers to the directory entry for the issuing user, that is, the entry defining the user's principal configuration.

### *vdev1*

is the specified user's virtual device number, as defined in the user's entry in the system directory.

### *vdev2*

is the virtual device number that is to be assigned to the device for your virtual machine configuration.

### *mode*

is the link mode. Valid modes are:

#### Mode

##### Meaning

#### R

Read-only link. A read link is established, unless another user has an existing write or exclusive mode link to the disk.

#### RR

Read-only link. A read link is established, unless another user has an existing exclusive mode link. This is the default.

#### W

Write link. A write link is established, unless another user has an existing link (any mode) to the disk.

**WR**

Write link. A write link is established unless another user has an existing link (any mode) to the disk. If the write link is denied, a read link is established unless another user has an existing exclusive mode link for the disk.

**M**

Multiple-write link. A write link is established unless another user has an existing write, stable, or exclusive mode link to the disk.

**MR**

Multiple-write link. A write link is established unless another user has an existing write, stable, or exclusive mode link to the disk. In the case of a previous write or stable link, a read-only link is established. In the case of an exclusive mode link existing, the link is denied.

**MW**

Multiple-write link. A write link is established in all cases except when another user has an existing stable or exclusive mode link to the disk.

**Note:** A stable link means that the user holding the (SR, SW or SM) link can be assured that the disk remains stable, unchanged by others, until the link is released.

**SR**

Stable read-only link. A read link is established unless another user has an existing write or exclusive mode link to this disk. All requests for a write link to a disk with an existing SR mode link are denied.

**SW**

Stable write link. A write link is established unless another user has an existing link (any mode) to this disk. All requests for a write link to a disk with an existing SW mode link are denied.

**SM**

Stable multiple link. A write link is established unless another user holds either a write, a stable or an exclusive mode link to this disk. All requests for a write link to a disk with an existing SM mode link are denied.

**Note:** An EXCLUSIVE link (ER, EW), is a stable link with the added restriction that no one else has, or can get a link to, the specified minidisk until the link is released.

**ER**

Exclusive read-only link. A read link is established unless another user has an existing link to this disk. All requests for links to a disk with an existing exclusive mode link are denied.

**EW**

Exclusive write link. A write link is established unless another user has an existing link (any mode) to the disk. All requests for links to a disk with an existing exclusive mode link are denied.

If you do not specify a mode, the default is R if you are linking to another user's device. If you are linking to one of your own devices, the default is the user link mode specified in your entry in the system directory.

**Attention:**

- Permanent data loss can result if more than one user is writing to the same virtual disk.
- Unpredictable results can occur when one user has a read-only link to a disk that is being updated by another user who has a write link to the disk.

***password***

is a 1-character to 8-character string that matches the link mode password defined for device *vdev1* in the system directory entry for the user ID that you specify. If you do not specify a password but one is required, you are prompted for one.

To determine whether password suppression is active for this command, use the QUERY PASSWORD LINK command. If password suppression is active, you cannot specify a password on the command line. See usage note [“11” on page 580](#).

## Usage Notes

1. SET IMSG OFF suppresses informational messages for this command.
2. When linking to another user's non-fullpack minidisk on a cached control unit, you are granted the cache access that is found in that user's directory.
3. When linking to another user's fullpack minidisk on a cached control unit, you get a subsystem control level of NOCTL. NOCTL means that no CCWs are accepted that can exercise control of subsystem resources or functions, regardless of whether they directly relate to the device. For example, subsystem storage may not be turned on or off, and caching may not be turned on or off, for the device.  
  
If you have a LINK statement for a fullpack minidisk in your directory, and DETACH the device after LOGON, you can get the device back with the same DASDOPT specified in the directory by LINK \* vdev1 AS vdev2. This is because this LINK is handled as a LINK to your own device.
4. CP verifies the LINK command operands you enter against the information contained in the other user's entry in the system directory. If the other user has temporarily redefined any of this information, you must still specify the information as it is indicated in the directory, or you receive an error message.
5. Do not confuse a link mode password with a user logon password. You specify a user logon password to gain access to the z/VM system. A link mode password controls whether you can link another user's DASD using the LINK command.
6. If the operand immediately following vdev2 is not a valid link mode, the default link mode is established, and the operand is interpreted as the link mode password. If you are using the default for the link mode, the link mode password you enter cannot be the same as any of the link modes (R, RR, W, WR, M, MR, MW, SR, SW, SM, ER, or EW).
7. If you are linking to one of your own disks, or if the link mode password is ALL (indicating that any user can use the disk), you do not have to enter the password. You can specify *userid* as an asterisk (\*) to indicate that the device is in your entry in the system directory; if you do specify a password, the system does not check it. If you have a LINK statement in your directory and an External Security Manager (ESM) is installed, the ESM may be called to see if you are in the access list for the minidisk.
8. If an ESM is installed on your system, you may not be authorized to enter the LINK command for all minidisks and all access modes. The ESM may downgrade certain requests for write access to read access. For additional information, contact your security administrator.
9. You cannot request virtual reserve/release processing using the LINK command. Use the MDISK directory statement to request virtual reserve/release processing. For more information about the [MDISK Statement](#), see *z/VM: CP Planning and Administration*.
10. The use of the stable and exclusive link modes (SR, SW, SM, ER, EW) is controlled by the LNKSTABL and LNKEXCLU options on the OPTION directory statement. For more information about the [OPTION Directory Statement](#), see *z/VM: CP Planning and Administration*.
11. If your installation is using the password suppression facility for this command (controlled by the PASSWORDS\_ON\_CMDs operand of FEATURES system configuration statement or by the SET PASSWORD command), you receive an error message if you enter the link mode password on the LINK command line. Wait for the ENTER PASSWORD prompt before you type in the password. The password is automatically masked, thereby improving system security.
12. In some responses and messages, *userid* refers to another virtual machine affecting the LINK command.
13. Messages are given to the user if:
  - a. A WRITE link exists to the requested disk or
  - b. A READ link exists to the disk and you are linking with mode WR, M, MR, or MW.

No messages are given if no other links exist, or a READ link exists, and you are linking with mode R or RR.

14. LINK response #2 is issued when CP does the link. If you issue the LINK command from CMS mode then no response is issued. If you issue LINK from CP READ mode, response #2 is issued. Also, if you issue #CP LINK, from either mode, response #2 is issued.
15. An informational response is not always generated after a read link is established.
16. LINK is used to obtain access directly to another user's minidisk, or to obtain access indirectly, through linking to another user's LINK or MDISK directory statement (LINKS to LINKS). Up to 50 of these *indirect* links (LINK indirections) are allowed. For example:

```

USER0
  MDISK 393 3390 1 10 USRVOL ALL ALL ALL
USER1
  LINK USER0 393 393 RR
USER2
  LINK USER1 393 393 RR
USER3
  LINK USER2 393 393 RR

```

Since USER1 has had to first access the 393 minidisk through a direct link to USER0, USER2's link to the 393 minidisk is considered an indirect link. USER3's link to the 393 minidisk through USER2 is thus also an indirect link. Up to 50 of these indirect links are allowed before the following message is issued:

**HCP109E**

*userid vdev* not linked; excessive LINK indirections

**Note:** This limit of 50 indirect links includes the original link. (In the example, USER1 to USER0.)

17. State change interrupts will not be reflected to guests who dynamically link to any fullpack minidisk. To receive state change interrupts for fullpack minidisks, a static link should be defined in the user directory followed by the DASDOPT statement specifying DEVCTL or SYSCTL level of control.
18. The link allowed by the LINK command to the *vdev1* device belonging to *userid* is summarized in the tables that follow.

Table 24. Linking to a Device in READ Mode

Link Mode You Entered	READ Password Specified in the System Directory?	Any Other Links to this Device?	Link Type You Will Establish
R	No	Not applicable	None
	Yes	No	READ
	Yes	Yes—READ, stable READ	READ
	Yes	Yes—WRITE, stable WRITE, exclusive (READ or WRITE)	None
SR	No	Not applicable	None
	Yes	No	Stable READ
	Yes	Yes—READ, stable READ	Stable READ
	Yes	Yes—WRITE, stable WRITE, exclusive (READ or WRITE)	None
ER	No	Not applicable	None
	Yes	No	Exclusive READ
	Yes	Yes—Any	None
RR	No	Not applicable	None
	Yes	No	READ
	Yes	Yes—READ, WRITE, stable (READ or WRITE)	READ
	Yes	Yes—Exclusive (READ or WRITE)	None

Table 25. Linking to a Device in WRITE Mode

Link Mode You Entered	WRITE Password Specified in the System Directory?	Any Other Links to this Device?	Link Type You Will Establish
W	No	Not applicable	None
	Yes	No	WRITE
	Yes	Yes—Any other link	None
EW	No	Not applicable	None
	Yes	No	Exclusive WRITE
	Yes	Yes—Any other link	None
SW	No	Not applicable	None
	Yes	No	Stable WRITE
	Yes	Yes—Any link	None
WR	No	Not applicable	None
	Yes	No	WRITE
	Yes	Yes—READ, WRITE, stable (READ, WRITE)	READ
	Yes	Yes—exclusive (READ, WRITE)	None

Table 26. Linking to a Device in Multiple WRITE Mode

Link Mode You Entered	MULT Password Specified in the System Directory?	Any Other Links to this Device?	Link Type You Will Establish
M	No	Not applicable	None
	Yes	No	WRITE
	Yes	Yes—READ	WRITE
	Yes	Yes—WRITE, stable (READ, WRITE), exclusive (READ, WRITE)	None
SM	No	Not applicable	None
	Yes	No	Stable WRITE
	Yes	Yes—READ	Stable WRITE
	Yes	Yes—WRITE, stable (READ, WRITE), exclusive (READ, WRITE)	None
MR	No	Not Applicable	None
	Yes	No	WRITE
	Yes	Yes—READ	WRITE
	Yes	Yes—WRITE, stable (READ, WRITE)	READ
	Yes	Yes—exclusive (READ, WRITE)	None

Table 26. Linking to a Device in Multiple WRITE Mode (continued)

Link Mode You Entered	MULT Password Specified in the System Directory?	Any Other Links to this Device?	Link Type You Will Establish
MW	No	Not Applicable	None
	Yes	No	WRITE
	Yes	Yes—READ, WRITE	WRITE
	Yes	Yes—stable (READ, WRITE), exclusive (READ, WRITE)	None

19. If the target minidisk is a virtual disk in storage that is defined in the specified user's directory entry but currently does not exist, the virtual disk in storage is created to satisfy your request, as long as it does not exceed the system limit on the storage available for virtual disks in storage. Note that a new virtual disk in storage must be formatted before it can be used.

**Attention:** Do not format an existing virtual disk in storage that you have linked to, or you will destroy all the data on it.

20. If you link a minidisk as virtual device number 192, the following special rules apply when you IPL CMS:
- If 192 is an unformatted virtual disk in storage, CMS formats it and accessed it as file mode D.
  - If 192 is a CP-formatted virtual disk in storage, CMS reformats it for CMS use and accesses it as file mode D.
  - If 192 is a CMS-formatted virtual disk in storage or permanent minidisk that is accessed as a file mode other than D, CMS reaccesses it as file mode D.
  - If 192 is an unformatted or CP-formatted permanent minidisk, CMS does not automatically format, reformat, access, or reaccess it.

When CMS accesses a 192 minidisk as file mode D, any minidisk or SFS directory already accessed as D is released.

21. If the directory definition of a permanent minidisk is changed while users are linked to it, existing links are unchanged, but any new links are made using the new definition of the minidisk. Unpredictable results may occur.
22. If the directory definition of a virtual disk in storage is changed while users are linked to it, existing links are unchanged, and any new links are made to the existing virtual disk in storage. The existing virtual disk in storage is used until the last user detaches it or logs off, at which time the virtual disk in storage is destroyed. After that, any new links use the new definition of the virtual disk in storage.
23. The CMS VMLINK command provides all the function of LINK and also allows you to specify a nickname for *userid vdev1*, finds a free virtual device number for *vdev2*, and also accesses the disk at a free mode letter. See *z/VM: CMS Commands and Utilities Reference*.
24. When linking to a minidisk that has at least one cylinder that is the target of a persistent FlashCopy relationship, warning message HCP116I is issued. The link is not prevented when a FlashCopy relationship exists.
25. Table 27 on page 584 shows how link conflicts are handled when virtual reserve/release is authorized and the minidisks have overlapping or matching extents. That is, the existing link and the requested link are to the same minidisk (one MDISK directory statement), or the links are to different minidisks (two MDISK directory statements) that partially or fully overlap.

Each link can be an explicit link obtained with a LINK directory statement or LINK command, or an instantiated link established for an MDISK directory statement when that user logs on.

Subsequent links will be analyzed individually for conflicts.

The following terms are used in this table:

## LINK

### Normal

means link conflict analysis is performed as documented in [Table 24 on page 581](#), [Table 25 on page 582](#), and [Table 26 on page 582](#).

### None

means link conflict analysis is not performed.

### V

means the minidisk is defined with access mode suffix V, which authorizes CP to use virtual reserve/release.

### 1-sys

means a non-SSI environment where both links are on the same system or an SSI cluster where both links are on the same member.

### 2-sys

means an SSI cluster where the existing link and the requested link are on different members.

### Convert to V

means the requested link is established with virtual reserve/release, although the minidisk is not defined with access mode suffix V.

Requested Link To	Existing Link To			
	Fullpack	Non-Fullpack	Fullpack V	Non-Fullpack V
Fullpack	Normal	None	<b>Pre-6.2:</b> Normal (V given to existing link but not to requested link) <b>1-sys and 2-sys:</b> Convert to V with message HCP6648I.	None
Non-Fullpack	None	Normal	<b>Pre-6.2:</b> None <b>1-sys and 2-sys:</b> Reject link.	<b>Pre-6.2:</b> Normal <b>1-sys:</b> Convert to V with message HCP6648I. <b>2-sys:</b> Reject link.
Fullpack V	<b>Pre-6.2:</b> Normal (V given to requested link but not to existing link.) <b>1-sys and 2-sys:</b> Reject link.	<b>Pre-6.2:</b> None <b>1-sys and 2-sys:</b> Reject link.	Normal	<b>Pre-6.2:</b> None <b>1-sys and 2-sys:</b> Reject link.
Non-Fullpack V	None	<b>Pre-6.2:</b> Normal (V given to requested link but not to existing link.) <b>1-sys and 2-sys:</b> Reject link.	<b>Pre-6.2:</b> None <b>1-sys and 2-sys:</b> Reject link.	<b>Pre-6.2:</b> Normal <b>1-sys:</b> Normal <b>2-sys:</b> Reject link.

26. Table 28 on page 585 shows how link conflicts are handled when simulated working allegiance is active and the minidisks have overlapping or matching extents. That is, the existing link and the requested link are to the same minidisk (one MDISK directory statement), or the links are to different minidisks (two MDISK directory statements) that partially or fully overlap.

Each link can be an explicit link obtained with a LINK directory statement or LINK command, or an instantiated link established for an MDISK directory statement when that user logs on.

Subsequent links will be analyzed individually for conflicts.

The following terms are used in this table:

**Normal**

means link conflict analysis is performed as documented in [Table 24 on page 581](#), [Table 25 on page 582](#), and [Table 26 on page 582](#).

**None**

means link conflict analysis is not performed.

**WRKALLEG**

means simulated working allegiance is active for the minidisk.

**Note:** If the links have already been established and you use the SET WRKALLEG command to turn on working allegiance, the new SET WRKALLEG becomes a requested link and is evaluated accordingly.

**1-sys**

means a non-SSI environment where both links are on the same system or an SSI cluster where both links are on the same member.

**2-sys**

means an SSI cluster where the existing link and the requested link are on different members.

Requested Link To	Existing Link To			
	Fullpack	Non-Fullpack	Fullpack WRKALLEG	Non-Fullpack WRKALLEG
Fullpack	Normal	None	<b>Pre-6.2:</b> Normal <b>1-sys:</b> Normal (HCP6648I issued to indicate WRKALLEG in effect.) <b>2-sys:</b> Reject link.	<b>Pre-6.2:</b> None <b>1-sys:</b> None <b>2-sys:</b> Reject link.

Table 28. Link Conflict Analysis When Simulated Working Allegiance is Active (continued)

Requested Link To	Existing Link To			
	Fullpack	Non-Fullpack	Fullpack WRKALLEG	Non-Fullpack WRKALLEG
Non-Fullpack	None	Normal	<b>Pre-6.2:</b> None <b>1-sys and 2-sys:</b> Reject link.	<b>Pre-6.2:</b> Normal (If extents match, both links have WRKALLEG in effect. If extents overlap but do not match, the existing link will have WRKALLEG in effect and the requested link will not.) <b>1-sys:</b> Normal (If extents match, both links have WRKALLEG in effect and message HCP6648I is issued for the link requested. If extents partially overlap, the existing link will have WRKALLEG in effect and the requested link will not.) <b>2-sys:</b> Reject link.
Fullpack WRKALLEG	<b>Pre-6.2:</b> Normal and neither link has WRKALLEG <b>1-sys:</b> Add WRKALLEG to existing link and issue unsolicited message HCP6648I to user with original link to indicate WRKALLEG has been added. <b>2-sys:</b> Reject link.	<b>Pre-6.2:</b> None <b>1-sys and 2-sys:</b> Reject link.	<b>Pre-6.2:</b> Normal <b>1-sys:</b> Normal <b>2-sys:</b> Reject link.	<b>Pre-6.2:</b> None <b>1-sys and 2-sys:</b> Reject link.

Requested Link To	Existing Link To			
	Fullpack	Non-Fullpack	Fullpack WRKALLEG	Non-Fullpack WRKALLEG
Non-Fullpack WRKALLEG	<b>Pre-6.2:</b> None <b>1-sys:</b> None <b>2-sys:</b> Reject link.	<b>Pre-6.2:</b> Normal. If extents match, the requested link does not get WRKALLEG. If extents partially overlap, the requested link gets WRKALLEG. <b>1-sys:</b> If extents match, add WRKALLEG to existing link and requested link and issue unsolicited message HCP6648I to user with original link to indicate WRKALLEG has been added. If extents overlap but do not match, the requested link will have WRKALLEG in effect and the existing link will not. <b>2-sys:</b> Reject link.	<b>Pre-6.2:</b> None <b>1-sys and 2-sys:</b> Reject link.	<b>Pre-6.2:</b> Normal <b>1-sys:</b> Normal <b>2-sys:</b> Reject link.

27. If the system has been IPLed in repair mode, a subconfiguration ID can be specified as the user ID on the LINK command.

## Responses

Response 1:

If your installation is using the password suppression facility, one of the following messages prompts you to enter the link mode password:

```
ENTER READ PASSWORD:
```

```
ENTER WRITE PASSWORD:
```

```
ENTER MULT PASSWORD:
```

Enter the appropriate password to obtain a link to the desired disk.

### Note:

1. There is a system threshold value that disables the LINK command when a user continues to enter trial passwords to obtain a link to a minidisk. The maximum is 10 incorrect passwords before the command is disallowed for the remainder of the logon session. The user is still able to link to the user's own minidisks or other's minidisks that have a password of ALL.
2. Responses 2 and 3 and redisplayed input lines are sent to the terminal only. They are not passed to the virtual machine when issued from the CMS environment or any environment which passes commands to CP by issuing a DIAGNOSE X'08'.

Response 2:

```
DASD vdev2 LINKED R/O
```

indicates that a read-only link has been established to the indicated disk with a mode of R, RR, SR or ER. To see all the links that exist for the minidisk, issue the QUERY LINKS command.

Response 3:

```
DASD vdev2 LINKED R/W
```

indicates that a read/write link has been established to the indicated disk with a mode of (W, WR, M, MR, MW, SW, SM or EW). To see all the links that exist for the minidisk, issue the QUERY LINKS command.

Response 4:

```
DASD vdev2 LINKED R/O; R/W BY {nnnnn USERS          }
                               {userid              }
                               {userid at sysname     }
                               {userid ADJUNCT        }
                               {userid ADJUNCT at sysname}

[;R/O BY {nnnnn USERS          }
         {userid              }
         {userid at sysname     }
         {userid ADJUNCT        }
         {userid ADJUNCT at sysname}]
```

indicates that a read-only link has been established to the indicated disk with a mode of RR, WR, or MR and warns that the disk is linked read/write by one or more users and possibly linked read-only by one or more users. If only one user has the indicated type of link, the number of links (*nnnnn* USERS) is replaced by that user's user ID or that user's user ID and the system name when the user ID is an instance of a multiconfiguration virtual machine on another system in the SSI cluster. To see all the links that exist for the minidisk, issue the QUERY LINKS command.

Response 5:

```
DASD vdev2 LINKED R/W; R/O BY {nnnnn USERS          }
                               {userid              }
                               {userid at sysname     }
                               {userid ADJUNCT        }
                               {userid ADJUNCT at sysname}
```

indicates that a read/write link has been established to the indicated disk with a mode of M, MR, MW, SW or SM and informs you that the disk is also linked read-only by one or more other users. No other read/write links to the disk exist. If only one user has a link, the number of links (*nnnnn* USERS) is replaced by that user's user ID or that user's user ID and the system name when the user ID is an instance of a multiconfiguration virtual machine on another system in the SSI cluster. To see all the links that exist for the minidisk, issue the QUERY LINKS command.

Response 6:

```
DASD vdev2 LINKED R/W; R/W BY {nnnnn USERS          }
                               {userid              }
                               {userid at sysname     }
                               {userid ADJUNCT        }
                               {userid ADJUNCT at sysname}

[;R/O BY {nnnnn USERS          }
         {userid              }
         {userid at sysname     }
         {userid ADJUNCT        }
         {userid ADJUNCT at sysname}]
```

indicates that a read/write link has been established to the given disk with a mode of MW, and warns you that the disk is linked read/write by one or more users and possibly linked read-only by some users. If only one user has a link, the number of links (*nnnnn* USERS) is replaced by that user's user ID. To see all the links that exist for the minidisk, issue the QUERY LINKS command.

Response 7:

When linking to minidisks that are in a FlashCopy relationship, you will see this response:

```
flashcopy establish source 200 0.10 target 300 50.10
Command complete: FLASHCOPY 0200 0 9 TO 0300 50 59
FLASHCOPY RELATIONSHIP 4AF7BDB3 ESTABLISHED

- HCP6640E *userid vdev* not linked. Minidisk is linked with the MDISK DEVNO parameter by {*userid|userid* at *sysname*}.
- HCP6640E *userid vdev* not linked. No EQID exists for RDEV *rdev*.
- HCP6640E *userid vdev* not linked. SSI cluster error, code *code*.
- HCP6645E *userid vdev* not linked; SSI cluster is in safe mode.
- HCP6648I MDISK *vdev* has virtual reserve/release support in effect.
- HCP6648I MDISK *vdev* has working allegiance simulation in effect.
- HCP6761E *userid vdev* not linked; volume *valid* marked draining by Operations personnel.

## LOADBUF

### Authorization

Privilege Class: D

### Purpose

Use LOADBUF to load the following:

- The universal character set (UCS) buffer with a specified print chain/train image for the IBM 3203 model 5 printer, 3262 printer, or a device that emulates a 3211 printer.
- The forms control buffer (FCB) with a specified image for the IBM 3203 model 5, 3262, 4245, 4248 printer, or a device that emulates a 3211 printer.

### Note:

1. You cannot load a UCS for a 4245 or 4248 printer.
2. The INDEX option is valid only for devices that emulate the 3211 printer.
3. To load the forms control buffer (FCB) with a specified image for a **virtual printer**, use the LOADVFCB command.
4. The number of lines to be printed on the separator page is determined by the FCB loaded on the printer. The default separator page contains 58 lines of data. If the page length defined by the FCB is less than the default separator page length, the separator page data must be customized in order to fit on a single page. This may be done using CP Exit points that are provided in separator page processing. See [z/VM: CP Exit Customization](#) for details.

### Operands

#### rdev

indicates the real device number of the printer whose buffer is to be loaded.

#### NOFOLD

#### Fold

If FOLD is specified, all characters will be printed in uppercase.

If NOFOLD is specified, the characters will not be not folded into uppercase.

If neither FOLD nor NOFOLD is specified with the UCS option, then NOFOLD is the default. FOLD is used when a file specifies lowercase, but no lowercase UCS is available.

If neither FOLD nor NOFOLD is specified with the FCB option, then the FOLD/NOFOLD selection on the printer will not be changed.

**Note:** If you specify the FOLD option, the control unit ignores bit positions 0 and 1 of the EBCDIC code when comparing the character codes from the UCS buffer and the print line buffer. Only uppercase characters are printed from either uppercase or lowercase data codes.

**Attention:** Misuse of the FOLD option can cause multiple characters to be printed for the same EBCDIC bit configuration.

**UCS name**

**FCB name**

specifies that you are loading a print chain image (UCS) or a forms control buffer (FCB). If you are loading both a print chain image and a forms control buffer, you must enter two LOADBUF commands for the specified printer.

The operand *name* is the 1- to 4-character name of the UCS or FCB image that you are loading. The IBM-supplied names are given in the tables that follow. IBM supplies the following UCS buffer images for the 3203 model 5 printer:

**Name**

**Meaning**

**AN**

Normal alphanumeric notation character set arrangement

**HN**

Normal hexadecimal notation character set arrangement

**PCAN**

Preferred alphanumeric notation character set arrangement

**PCHN**

Preferred hexadecimal notation character set arrangement

**QN**

PL/I—60 graphics

**QNC**

PL/I—60 graphics

**RN**

FORTRAN, COBOL commercial

**YN**

High-speed alphanumeric

**TN**

Text printing 120 graphics

**PN**

PL/I—60 graphics

**SN**

Text printing 84 graphics

IBM supplies the following UCS buffer images for a device that emulates the 3211 printer:

**Name**

**Meaning**

**A11**

Standard commercial

**H11**

Standard scientific

**G11**

ASCII

**P11**

PL/I

## LOADBUF

## LOADBUF

<b>58</b>	6
<b>59</b>	7
<b>60</b>	8
<b>61</b>	10
<b>62</b>	11
<b>63</b>	12
<b>64</b>	9

For the exact contents of these buffer images, see *IBM 3211 Printer, 3216 Interchangeable Train Cartridge*, and *3811 Printer Control Unit Component Description and Operator's Guide*.

For information on how to add more FCB and UCS images, see [Creating and Modifying Image Libraries for Printers in z/VM: CP Planning and Administration](#).

### Ver

prints the contents of the buffer on the specified printer. This lets you verify visually that the correct buffer was loaded.

### Index *nn*

starts printing the output in the designated (*nn*) print position. The indexing value *nn* must be a number from 0 through 31; a leading zero need not be specified. If you do not specify INDEX or if you specify an INDEX of 0 then indexing is turned off and no indexing is performed.

If you specify the INDEX keyword without an indexing value then the value coded in the FCB becomes the indexing value. If there is no value coded in the FCB then message 036E is issued. If you specify an indexing value from 1 to 31 then that value overrides the value in the FCB and is used as the indexing value.

Note that the INDEX option is valid only for a device emulating a 3211 printer.

## Usage Notes

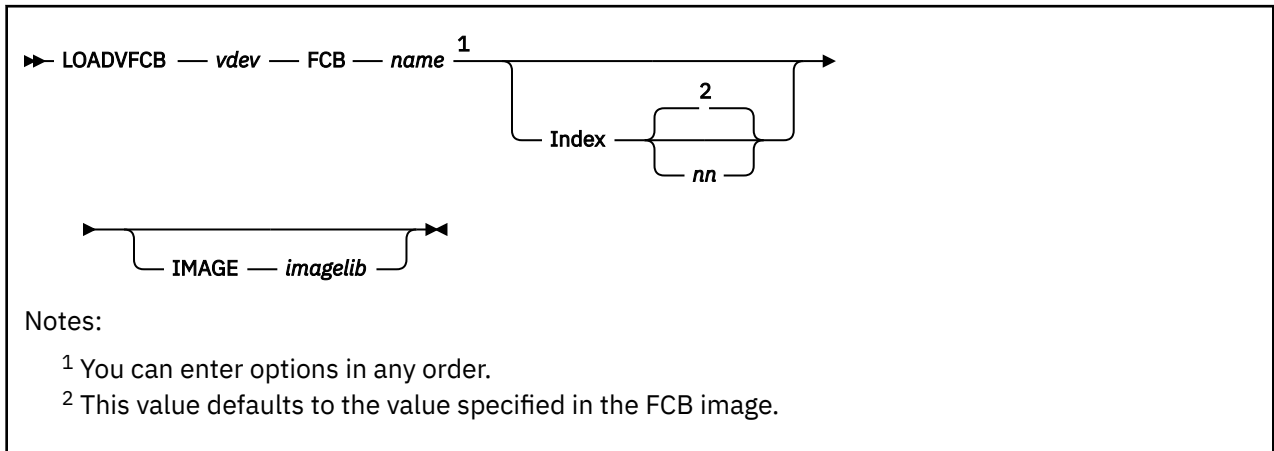

1. You must drain the printer before you enter the LOADBUF command.
2. The operator who is authorized to load the UCS and FCB buffers should use this command whenever:
  - The printer or control unit is powered on
  - The print chain or train is to be changed
  - The buffer has been causing an excessive amount of parity errors
  - The printer was previously attached to a user's virtual machine.
3. Load the FCB buffer whenever:
  - The FCB buffer is to be changed
  - The printer was previously attached to a user's virtual machine.
4. The LOADBUF command automatically sets the Block Data Check latch for a UCS buffer load. The Block Data Check latch is also set when the FOLD/NOFOLD option is selected for the LOADBUF command.
5. If you specify VER, the image of the UCS load will be printed on the printer you indicated. The printed output must correspond to the description of the buffer load in the publications:
  - *IBM 2821 Control Unit*

- *IBM 3203 Printer model 5 Component Description and Operator's Guide*
- *IBM 3211 Printer, 3216 Interchangeable Train Cartridge*
- *IBM 3262 Printer model 1 and 11 Component Description*
- *IBM 3811 Printer Control Unit Component Description and Operator's Guide.*

## LOADVFCB

### Authorization

Privilege Class: G

### Purpose

Use LOADVFCB to specify the forms control buffer image for a virtual impact printer.

**Note:** To load the forms control buffer (FCB) with a specified image for a *real* printer, use the LOADBUF command.

### Operands

#### *vdev*

identifies the virtual device number of your virtual spooled impact printer.

#### **FCB *name***

specifies the forms control buffer image for your virtual printer. The operand *name* is the 1- to 4-character name of the FCB image. You may specify either the name of an IBM-supplied FCB image or the name of another FCB image supplied by your system programmer. The three IBM-supplied FCB images are FCB1, FCB8, and FCBS. The default FCB image is FCB1. The formats of the IBM-supplied FCB images are as follows:

#### **Name**

##### **Meaning**

#### **FCB1**

Space 6 lines/inch, Length 66 lines per page

#### **Line**

##### **Channel Skip Specification**

<b>57</b>	5
<b>58</b>	6
<b>59</b>	7
<b>60</b>	8
<b>61</b>	10
<b>62</b>	11
<b>63</b>	12
<b>64</b>	9

For the exact contents of these FCB images, see *IBM 3211 Printer, 3216 Interchangeable Train Cartridge*, and *3811 Printer Control Unit Component Description and Operator's Guide*.

**Index *nn***

identifies the first print position. The operand *nn* must be a number from 1 through 31; a leading zero need not be specified. If you enter the keyword INDEX without a value, the value defaults to the value specified in the FCB image.

Note that the INDEX option is valid only for a virtual spooled 3211 printer; it is not valid for other impact printers.

**IMAGE *imagelib***

specifies the image library that contains the specified FCB. If you do not specify the IMAGE option, you get the default image library for the device type. The default image library is IMAGxxxx, where xxxx is the device type; for example, the default image library is IMAG1403 for a 1403 type printer.

**Usage Notes**

1. The virtual FCB image should match the FCB image on the real printer. If it does not, results are unpredictable.  
If the spool file is printed on a real 1403 printer, the virtual FCB image is ignored, and channel skipping is controlled by the carriage tape.
2. If you are running a program in your virtual machine that requires printer overflow sensing information and you are printing on a real 1403, you need to take special steps to retrieve the sensing information. First, ensure that the CP directory entry for your virtual machine indicates that the printer is a 3203, 3211, 3262, 4245, or 4248, even though the program and the guest operating system in which the

program runs define the printer as a 1403. Then use the LOADVFCB command to specify a virtual FCB image that matches the 1403. CP uses this virtual FCB image as a basis for retrieving sensing information.

3. If the virtual machine operating system issues a LOAD FCB channel command word to the virtual spooled printer, the LOAD FCB CCW image replaces the virtual FCB image provided on the LOADVFCB command line. Note that the CMS PRINT command issues a LOAD FCB CCW and thereby replaces the virtual FCB image.
4. The LOADVFCB command allows specification of the extended FCB image for a virtual 4248 printer. If an attempt is made to send the extended FCB image to a printer that does not support the extended FCB format, an error message results.
5. If the default FCB image has been modified, the virtual FCB image from the spooled printer is stored in any file created on that printer. When the file is printed on a real printer, the FCB is loaded into the real printer according to the FILEFCB or DEFFCB option specified on the START command. The file then prints properly on the real printer.

## LOCATE

---

### Authorization

Privilege Class: C, E

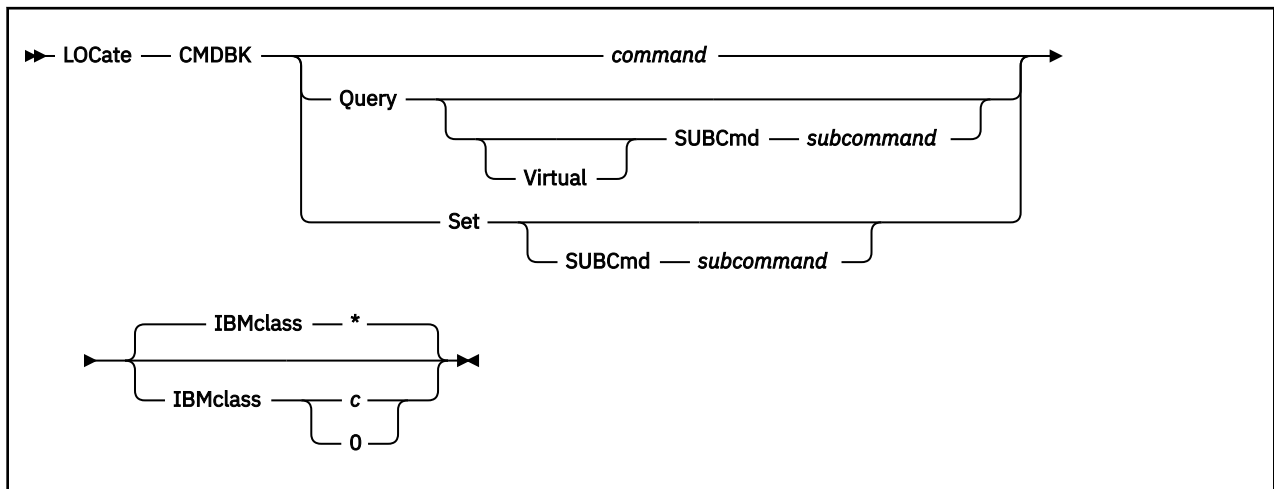

### Purpose

The LOCATE command is provided to enable you to perform CP problem diagnosis.

Use LOCATE to display the addresses of control information within CP. You can use the LOCATE command to find the addresses of:

- A command's CP command table entry block (CMDBK)
- A DIAGNOSE code's diagnose control block (DGNBK)
- A user's spool file identification entry (FILID)
- A system frame table entry (FRAMETBL)
- An exit point's indirect call locator block (ICLBK)
- A system logical device block (LDEV)
- A system real device block (RDEV)
- A real PCI function block (RPCI)
- A system shared system name block (SHPBK)
- A system SNA control block (SNABK)
- A user's spool file block (SPFBK)
- Data within host storage (Storage)
- A system execution space page management table entry (SXSTE)
- A system external symbol address (SYMBOL)
- A user's virtual device block (VDEV)
- A user's virtual machine definition block (VMDBK)
- A user's virtual PCI function block (VPCI)
- A system VTAM service machine block (VSMBK)
- An exit point's exit control block (XITBK).

## LOCATE CMDBK

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE CMDBK to display the address of the CP command table entry block (CMDBK) for a specified CP command.

### Operands

#### *command*

tells CP to locate the command table entry blocks for the specified CP command. The variable *command* is any valid CP command, any valid abbreviation of that command, or any character string (including the pattern matching characters, \* and %) representing that command. For more information about minimum abbreviations, see Usage Note “2” on page 604.

#### Query

tells CP to locate the command table entry blocks for the root CP QUERY command. To locate the command table entry blocks for a specific QUERY subcommand, specify the SUBCMD operand.

#### Virtual

tells CP that you are locating a QUERY VIRTUAL subcommand.

#### SUBCmd *subcommand*

specifies the name of the QUERY or SET subcommand whose command table entry blocks you want to locate. The variable *subcommand* is any valid QUERY or SET subcommand, any valid abbreviation of that subcommand, or any character string (including the pattern matching characters, \* and %) representing that subcommand. For more information about minimum abbreviations, see Usage Note “2” on page 604.

#### Set

tells CP to locate the command table entry blocks for the root CP SET command. To locate the command table entry blocks for a specific SET subcommand, specify the SUBCMD operand.

#### IBMclass \*

specifies that you want to find the command table entry blocks for all the IBM classes associated with the specified CP command. If omitted, IBMCLASS \* is the default.

**IBMclass c**

specifies that you only want to find the command table entry blocks for the specific IBM class associated with the specified CP command. The variable *c* is the IBM-defined privilege class A, B, C, D, E, F, or G.

**IBMclass 0**

specifies that you only want to find the command table entry blocks for CP commands with no assigned IBM class. Only commands with privilege class "ANY" have no assigned IBM class.

**Usage Notes**

1. For each command, CP has at least one command table entry block. If the command has more than one IBM class, CP has one command table entry block for each version of the command. For example, the DEFINE command has three IBM classes: A, E, and G. To locate the command table entry block for the DEFINE GRAF command, you want the command table entry block for the class G DEFINE command:

```
locate cmdbk define ibmclass g
```

The only exceptions to this are the QUERY and SET commands. CP has at least one command table entry block for each QUERY and SET subcommand. To locate the command table entry block for the QUERY TIMEZONES subcommand, you would issue one of the following commands:

```
locate cmdbk query subcmd timezones
locate cmdbk query subcmd timezones ibmclass g
```

2. You can use the minimum abbreviation of the command or subcommand name. For example, issuing either of the following commands produces the same results:

```
locate cmdbk query subcmd privclass
locate cmdbk q subcmd priv
```

3. To define a new CP command or a new version (by IBM class) of an existing CP command, use the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD”](#) on page 143).
4. To define a new alias for an existing CP command, use the DEFINE ALIAS command (see [“DEFINE ALIAS”](#) on page 127).
5. To load the command processing code into the system execution space, use the CPXLOAD command (see [“CPXLOAD”](#) on page 111).
6. To activate a CP command:
  - While defining it, use the ENABLE operand of the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD”](#) on page 143).
  - After defining it, use the ENABLE COMMAND or CMD command (see [“ENABLE COMMAND / CMD”](#) on page 460).
7. To change the definition of an existing CP command, use the MODIFY COMMAND command (see [“MODIFY COMMAND / CMD”](#) on page 683).
8. To deactivate a CP command:
  - While defining it, use the DISABLE operand of the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD”](#) on page 143).
  - After defining it, use the DISABLE COMMAND or CMD command (see [“DISABLE COMMAND / CMD”](#) on page 313).
9. To remove the command processing code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD”](#) on page 117).
10. For more information about user-defined commands, see [z/VM: CP Exit Customization](#).

## Responses

Response 1:

Command	CMDBK	Alias	IBMCLASS	Privilege
<i>command</i>	<i>nnnnnnnn</i>	<i>alias</i>	<i>c</i>	<i>p</i>
:				

### Command

shows the command name you specified, or a command name that matches the pattern you specified. When locating a QUERY or SET subcommand, the column header changes to **Subcommand** and the rows of data contain the name of the subcommand. See Example 5.

### CMDBK

shows the host logical storage address of the command table entry block for that command.

### Alias

tells you whether the command is an alias for another command. The possible values are:

**\***

this command is not an alias for any other command.

**hhhhhhhh**

this command is an alias for the command whose CMDBK is located at host logical storage address *hhhhhhhh*.

### IBMCLASS

shows the IBM class of the command. The possible values are:

**A**

this is a system-control command to be used by the primary system operator.

**B**

this is a command for operational control of real devices.

**C**

this is a command to alter system storage.

**D**

this is a command for system-wide control of spool files.

**E**

this is a command to examine system storage.

**F**

this is a command for service control of real devices.

**G**

this is a general-use command used to control the functions of a virtual machine.

**0**

(zero) this command has no IBM class.

**-**

this is an alias to the command located at the specified command table entry block address. As an alias, it has the same IBM class as the existing command. Thus, the information is not duplicated here.

### Privilege

shows the privilege class (or classes) of the command. This column usually contains one or more privilege classes in the range A to Z and 1 to 6. This column may also contain:

**<ANY>**

this command can be issued by users with any privilege class.

**-**

this is an alias to the command located at the specified command table entry block address. As an alias, it has the same privilege classes as the existing command. Thus, the information is not duplicated here.

**0**

this command has no privilege classes.

**Examples****Example 1:**

To find the command table entry block addresses for the CP MESSAGE command, enter the following:

```
locate cmdbk message
Command  CMDBK   Alias   IBMCLASS Privilege
MESSAGE  00344858 *       A       A
MESSAGE  003448A0 *       B       B
MESSAGE  003448E8 *       0       <ANY>
Ready;
```

**Example 2:**

The CP MSG command is actually an alias for the CP MESSAGE command. CP displays different information for an alias than it does for a command. For example, to find the command table entry block addresses for the CP MSG command alias, enter the following:

```
locate cmdbk msg
Command  CMDBK   Alias   IBMCLASS Privilege
MSG      00344A50 00344858 -       -
MSG      00344A98 003448A0 -       -
MSG      00344AE0 003448E8 -       -
Ready;
```

**Example 3:**

The CP MESSAGE and MSG commands also share the same minimum abbreviation, M. This means you can display information about both commands by specifying their common minimum abbreviation:

```
locate cmdbk m
Command  CMDBK   Alias   IBMCLASS Privilege
MESSAGE  00344858 *       A       A
MESSAGE  003448A0 *       B       B
MESSAGE  003448E8 *       0       <ANY>
MSG      00344A50 00344858 -       -
MSG      00344A98 003448A0 -       -
MSG      00344AE0 003448E8 -       -
Ready;
```

**Example 4:**

To find the command table entry block addresses for all CP commands whose name begins with the letter M, enter the following:

```
locate cmdbk m*
Command  CMDBK   Alias   IBMCLASS Privilege
MESSAGE  00344858 *       A       A
MESSAGE  003448A0 *       B       B
MESSAGE  003448E8 *       0       <ANY>
MIGRATE  00344930 *       A       A
MONITOR  00344978 *       A       M
MONITOR  003449C0 *       E       S
MSGNOH   00344A08 *       B       KRZ
MSG      00344A50 00344858 -       -
MSG      00344A98 003448A0 -       -
MSG      00344AE0 003448E8 -       -
Ready;
```

In this example, note that the classes for the MONITOR and MSGNOH commands were redefined by this installation through user MODIFY commands.

**Example 5:**

To find the command table entry block addresses for the SET PRIVCLASS subcommand, enter the following:

```
locate cmdbk set subcmd privclass
Subcommand  CMDBK      Alias      IBMCLASS  Privilege
PRIVCLASS   003B00C0 *          C          C
PRIVCLASS   003B0108 *          0         <ANY>
Ready;
```

### Example 6:

If someone had used a MODIFY COMMAND command or configuration file statement to override an existing CP DISABLE command, you would see something like this:

```
locate cmdbk disable
Command     CMDBK      Alias      IBMCLASS  Privilege
DISABLE     1251EF80 *          A          A
DISABLE     1131EE80 *          B          Z6
-----
DISABLE     12535560 *          B          B
DISABLE     11140780 *          F          F
Ready;
```

This response shows you there are command table entry blocks for four DISABLE commands: one for IBM class A, two for IBM class B, and one for IBM class F. The first IBM class B DISABLE command is the one that is active. The second IBM class B DISABLE command was the original IBM class B command.

To return to the original IBM class B DISABLE command, enter the following:

```
modify command disable ibmclass b reset
```

This causes the first IBM class B DISABLE command to disappear from the display and changes the ----- to DISABLE. Thus, the response would look like this:

```
locate cmdbk disable
Command     CMDBK      Alias      IBMCLASS  Privilege
DISABLE     1251EF80 *          A          A
DISABLE     12535560 *          B          B
DISABLE     11140780 *          F          F
Ready;
```

## LOCATE DGNBK

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE DGNBK to display the address of the CP DIAGNOSE code control block (DGNBK) for a specific DIAGNOSE code.

### Operands

*diag*

*diag1-diag2*

is the number of the DIAGNOSE code whose control block address you want to display. Each *diag* must be an existing DIAGNOSE code between X'0000' and X'03FC' and must be a multiple of 4. You can specify a single DIAGNOSE code, a range of DIAGNOSE codes, or any combination thereof.

### Usage Notes

1. To define a new DIAGNOSE code, use the DEFINE DIAGNOSE command (see [“DEFINE DIAGNOSE” on page 172](#)).  
If you do not specify the ENABLE operand, a new DIAGNOSE code is initially in a disabled state after being defined. CP treats disabled DIAGNOSE codes as if they were never defined. If you try to use a disabled DIAGNOSE code in a program, CP will give you a program check specification exception.
2. To load the DIAGNOSE processing code into the system execution space, use the CPXLOAD command (see [“CPXLOAD” on page 111](#)).
3. To activate a new DIAGNOSE code:
  - While defining it, use the ENABLE operand of the DEFINE DIAGNOSE command (see [“DEFINE DIAGNOSE” on page 172](#)).
  - After defining it, use the ENABLE DIAGNOSE command (see [“ENABLE DIAGNOSE” on page 463](#)).
4. To change the definition of an existing DIAGNOSE code after initialization, use the MODIFY DIAGNOSE command (see [“MODIFY DIAGNOSE” on page 697](#)).
5. To display information about a DIAGNOSE code (status, entry point name, and privilege class), use the QUERY DIAGNOSE command (see [“QUERY DIAGNOSE” on page 885](#)).
6. To deactivate a DIAGNOSE code:
  - While defining it, use the DISABLE operand of the DEFINE DIAGNOSE command (see [“DEFINE DIAGNOSE” on page 172](#)).
  - After defining it, use the DISABLE DIAGNOSE command (see [“DISABLE DIAGNOSE” on page 316](#)).
7. To remove the DIAGNOSE processing code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD” on page 117](#)).

8. Many external security managers (ESMs) do not support DIAGNOSE codes above X'03FC'. For this reason, CP does not support DIAGNOSE codes above X'03FC'. The DIAGNOSE codes between X'0000' and X'03FC' are divided as follows:

**X'0000' to X'00FC'**

Reserved for IBM use

**X'0100' to X'01FC'**

Reserved for customer use

**X'0200' to X'03FC'**

Reserved for IBM use.

9. For more information about user-defined DIAGNOSE codes, see the [Introduction](#) in *z/VM: CP Exit Customization*.

## Responses

Response 1:

```
Code DGNBK
code nnnnnnnn
:
```

### Code

shows the DIAGNOSE code you specified, or a DIAGNOSE code within the range you specified.

### DGNBK

shows the host logical storage address of the DIAGNOSE code control block for that DIAGNOSE code.

## Examples

Example 1:

To display the address of the DIAGNOSE code table entry for DIAGNOSE code X'0C', enter the following:

```
locate dgnbk c
Code DGNBK
000C 005F09C8
Ready;
```

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP009E Invalid range - *range*
- HCP026E Operand missing or invalid

- HCP2751E Diagnose codes *diag1-dia2* do not exist
- HCP6706E Invalid Diagnose code - *diag*

## LOCATE FILID

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE FILID to display the address of a user's spool file identification (FILID) entry.

### Operands

#### SYSTEM

tells CP to locate the FILID entries for all user IDs on your system.

#### *userid*

tells CP to locate the FILID entries for the user ID, user ID pattern, or pseudo-user ID (\*IMG, \*NLS, \*NSS, \*UCR, or \*SDF) specified. For more information on user ID patterns, see Usage Note [“1”](#) on [page 610](#).

**\***

tells CP to locate the FILID entry for your user ID.

#### **\*IMG**

tells CP to locate the FILID entry for all printer image library files owned by the system.

#### **\*NLS**

tells CP to locate the FILID entry for all National Language Support files owned by the system.

#### **\*NSS**

tells CP to locate the FILID entry for all named saved system files owned by the system.

#### **\*SDF**

tells CP to locate the FILID entries for all system data files owned by the pseudo-user IDs (\*IMG, \*NLS, \*NSS, and \*UCR).

#### **\*UCR**

tells CP to locate the FILID entry for all user class restructure files owned by the system.

### Usage Notes

1. Pattern matching follows the rules used by the CMS LISTFILE command. Use an asterisk (\*) to match any number of characters; use a percent symbol (%) to match any single character. Because there are operands for pseudo-user ID files (\*IMG, \*NLS, \*NSS, \*UCR, and \*SDF) and because a single asterisk (\*) indicates your user ID, there are exceptions to the asterisk rule.

To specify a pattern that you would normally specify as one of these special cases, use an additional asterisk. For example, specify **\*\*NSS** to match all user IDs that end with the 3 characters NSS, including the pseudo-user ID **\*NSS**.

## Responses

Response 1:

```
OwnerID  FILID
ID       nnnnnnnn
:
```

### OwnerID

shows the user ID or pseudo-user ID.

### FILID

shows the host logical storage address of the spool file identification entry for that user ID or pseudo-user ID.

## Examples

Example 1:

When you enter a LOCATE FILID command with the **\*SDF** operand, you may see something like this:

```
locate filid *sdf
OwnerID  FILID
*IMG     0764D058
*NLS     0764D0A0
*NSS     0764D034
*UCR     0764D07C
Ready;
```

Example 2:

When you enter LOCATE FILID **\***, you may see this:

```
locate filid *
OwnerID  FILID
EMILY    0764D97C
Ready;
```

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*

- HCP026E Operand missing or invalid
- HCP6720I No items found to satisfy selection criteria.

## LOCATE FRAMETBL

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE FRAMETBL, LOCATE FRMTBL, or LOCATE FRMTE to display the address of the frame table entry (FRMTE) for a specific storage frame, or the address of the frame for a specific FRMTE.

### Operands

#### **addr1**

is the host real storage address of the frame whose FRMTE you want CP to locate. This address need not be frame-aligned; CP will adjust it.

#### **ENTRY addr2**

tells CP to locate the frame whose FRMTE is located at *addr2*. Because FRMTEs reside above 2 GB in the system execution space, *addr2* must be a host logical storage address above 2 GB. This address need not be aligned with the boundary of a FRMTE; CP will adjust it.

### Responses

**Note:** If SET UNDERSCORE ON has been specified, an underscore is used to separate 16-digit addresses for readability.

Response 1:

If the frame address is < 4 GB, the response format is:

```
Frame Address FRMTE
nnnnnnnn      nnnnnnnnnnnnnnnnnnn
```

#### **Frame Address**

shows the host real storage address of the frame.

#### **FRMTE**

shows the host logical storage address of the frame table entry.

Response 2:

If the frame address is > 4 GB, the response format is:

```
Frame Address  FRMTE
nnnnnnnnnnnnnnnnnn  nnnnnnnnnnnnnnnnnnn
```

### Examples

Example 1:

To find the frame table entry for the frame at host real storage address 12f000, enter:

```
locate frmte 12f000
Frame Address FRMTE
0012F000      00000001390025E0
Ready;
```

The response shows that the FRMTE is located at host logical storage address 1390025E0.

Example 2:

To find the frame table entry for the frame at host real storage address 100000000, enter:

```
locate frmte 100000000
Frame Address FRMTE
0000000100000000 000000013B000000
Ready;
```

The response shows that the FRMTE is located at host logical storage address 13B000000.

Example 3:

To find the frame whose FRMTE is located at host logical storage address 139000100, enter:

```
locate frmte entry 139000100
Frame Address FRMTE
00008000      0000000139000100
Ready;
```

The response shows that the frame is located at host real storage address 8000.

Example 4:

To find the frame whose FRMTE is located at host logical storage address 13C100000, enter:

```
locate frmte entry 13c100000
Frame Address FRMTE
00000001_88000000 00000001_3C100000
Ready;
```

The response shows that the frame is located at host real storage address 188000000. Note that SET UNDERSCORE ON is in effect.

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP004E Invalid hexloc - *addr*
- HCP025E Storage missing or invalid
- HCP026E Operand missing or invalid
- HCP094E Storage exceeds allowed maximum of *maximum* {M|K}
- HCP6762E Frame table entry is outside the extents of the frame table: *addr1-addr2*

## LOCATE ICLBK

```
▶▶ LOCate — ICLBK — epname ▶▶
```

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE ICLBK to display the address of the CP indirect call locator block (ICLBK) for a specific entry point.

### Operands

#### *epname*

is the name of the entry point whose CP indirect call locator block address you want to display. The variable *epname* must be a 1-character to 8-character string. The first character must be alphabetic or one of the following special characters: dollar sign (\$), number sign (#), underscore (\_), or at sign (@). The rest of the string can be alphanumeric characters, the four special characters (\$, #, \_, and @), or any combination thereof.

You can use generic entry point names to request information about a specific subset of entry point names. A generic entry point name is a 1-character to 8-character string with asterisks (\*) in place of one or more characters and percent signs (%) in place of exactly one character. For example,

```
locate iclbk hcp%rc*
```

lists all the entry points that start with HCP and have RC as their fifth and sixth characters.

### Usage Notes

1. To load customer-written CP routines into the system execution space, use the CPXLOAD command (see [“CPXLOAD” on page 111](#)).
2. To add to, change, or replace the list of entry points and external symbols associated with an exit point and to enable or disable that exit point, use the ASSOCIATE EXIT command (see [“ASSOCIATE EXIT” on page 20](#)).
3. To display usage statistics information about indirect calls to external entry points, use the QUERY ICLNAME command (see [“QUERY ICLNAME” on page 943](#)).
4. For more information about the indirect call locator block, see [Available Diagnostic Facilities in z/VM: CP Exit Customization](#).

### Responses

Response 1:

```
Symbol   ICLBK
symbol   nnnnnnnn
:
```

#### Symbol

shows the entry point name you specified, or an entry point name that matches the pattern you specified.

**ICLBK**

shows the host logical storage address of the CP indirect call locator block for that entry point.

**Examples**

## Example 1:

To display the address of the indirect call locator block for entry point HCPSRC00, enter the following:

```
locate iclbnk hcpsrc00
Symbol   ICLBK
HCPSRC00 06FE09C8
Ready;
```

## Example 2:

To display the address of all the indirect call locator blocks for entry points that have "HCPSRC" as the first six characters of their name, enter the following:

```
locate iclbnk hcpsrc*
Symbol   ICLBK
HCPSRC00 061E09C8
HCPSRC04 06F109C8
HCPSRC08 06FE01C8
HCPSRC10 06FE19C8
Ready;
```

**Messages**

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid
- HCP6706E Invalid entry point name - *epname*
- HCP6720I No items found to satisfy selection criteria.

## LOCATE LDEV

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE LDEV to find the addresses of a system logical device block and its associated control blocks.

### Operands

*ldev*

*ldev1-ldev2*

is a logical device number, range of logical device numbers, or a combination of logical device numbers and ranges of logical device numbers.

### Responses

Response 1:

```
Dev  RDEV  LddbK  LSOBJ  Host
dev  nnnnnnn nnnnnnn nnnnnnn host
:
```

#### Dev

shows the logical device number.

#### RDEV

shows the host logical storage address of the corresponding real device block.

#### LddbK

shows the host logical storage address of the logical display device simulation block.

#### LSOBJ

shows the host logical storage address of the logical subchannel object.

#### Host

shows the user ID of the virtual machine that created the logical device.

### Examples

Example 1:

If you enter a LOCATE LDEV command for a range of device numbers, you may see something like this:

```
locate ldev 0000-0FFF
Dev  RDEV  LddbK  LSOBJ  Host
L0001 07AC71E8 07B80200 07AA31C8 TCPIP
L0006 07AC9788 07B80E00 07AA3C48 TCPIP
L0008 07AB95A8 07B80D40 07AA3A88 TCPIP
L000D 004A5008 07B80B60 01D4E008 TCPIP
L0010 004A53C8 07B80AA0 07AA3468 TCPIP
L0011 004A55A8 07B80B00 07AA38C8 TCPIP
```

```
L0012 07AC95A8 07B80DA0 01D4E2A8 TCPIP  
L0014 004A5968 07B80A40 01D4E8C8 TCPIP  
L0015 004A5B48 07B80980 01D4E7E8 PVM  
L001A 0188A008 07B80E60 01D4E388 TCPIP  
Ready;
```

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP009E Invalid range - *range*
- HCP026E Operand missing or invalid
- HCP1100E A logical device number was not supplied or it was invalid.

## LOCATE RDEV

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE RDEV to display the addresses of a real device block and its associated control blocks.

### Operands

*rdev*

*rdev1-rdev2*

specifies a real device number, a range of real device numbers, or a combination of real device numbers and ranges of real device numbers displays the address of the real device block (RDEV) and, if there are any, the addresses of its associated control blocks. For a device in the active configuration, the device number entered must be a 4-digit hexadecimal number between X'0000' and X'FFFF'. For a device in the standby configuration, the device number must be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is configured. A range of devices cannot span subchannel sets.

### Usage Notes

1. Because there are several LOCATE commands that treat the qualifying keyword as optional (LOCATE RDEV, LOCATE SYMBOL, LOCATE VDEV, LOCATE VMDBK), specifying the RDEV keyword is recommended to avoid undesired results. Using RDEV also allows you to specify more than one real device number.
2. LOCATE *rdev* is not a valid command for SNA/CCS terminals, which are connected through a VTAM service machine and have no real device address known to CP. However, each logged-on or dialed SNA/CCS terminal has a dynamic RDEV control block. For SNA/CCS terminals, the user finds the RDEV control block by using the LOCATE VDEV *userid vdev* command (see “LOCATE VDEV” on page 639). This command returns the address of the VDEV control block, and the VDEV contains a pointer to the RDEV.

### Responses

Response 1:

```

Dev  RDEV    CPVOL    VEXBK    RSPBK    SPFBK
dev  hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh
:
```

#### Dev

shows the real device number.

#### RDEV

shows the host logical storage address of the corresponding real device block.

**CPVOL**

shows the host logical storage address of the system volume list entry.

**VEXBK**

shows the host logical storage address of the volume extent block, which contains information on all the extents on a CP-owned volume.

**RSPBK**

shows the host logical storage address of the real spool device block.

**SPFBK**

shows the host logical storage address of the spool file control block.

**Note:**

1. If a single device is specified on the command, the Dev field is omitted from the response.
2. An asterisk (\*) in a response field indicates there is no information for that field.
3. If there is no information for a response field for all of the devices listed in the response, the column is omitted.

**Examples****Example 1:**

If you enter a LOCATE RDEV command for multiple devices, you may see something like this:

```
locate rdev 0500-0504 30100 0a01-0a02 0e0e
Dev RDEV CPVOL VEXBK RSPBK SPFBK
0500 07AFB3C8 * * * *
0501 07AFB5A8 * * * *
0502 07AFB788 * * * *
0503 07AFB968 * * * *
0504 07AFBB48 * * * *
30100 07B1A3C8 * * * *
0A01 07AF05A8 07B1CB30 07B6602C * *
0A02 07AF0788 07B1CB68 07B6B02C * *
0E0E 07ADC1E8 * * 07AA30E8 075ECD28
Ready;
```

**Example 2:**

```
locate rdev 30100
RDEV
07B1A3C8
Ready;
```

This example shows that there are no control blocks associated with this real device block from a device in the standby configuration.

**Example 3:**

```
locate rdev 0a01
RDEV CPVOL VEXBK
07AF05A8 07B1CB30 07B6A02C
Ready;
```

This example shows that the CPVOL and VEXBK control blocks are associated with this real device block, and the response gives their addresses.

**Example 4:**

```
locate rdev 0e0e
RDEV RSPBK SPFBK
07ADC1E8 07AA40E8 0760BB68
Ready;
```

This example shows that the RSPBK and SPFBK control blocks are associated with this real device block, and the response gives their addresses.

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP009E Invalid range - *range*

## LOCATE RPCI

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE RPCI to display the address of a real PCI function block and its associated control blocks.

### Operands

**rpfid**

**rpfid1-rpfid2**

specifies a real PCI function ID or a range of PCI function IDs whose control block addresses are to be displayed. Specify a PCI function ID as 8 hexadecimal digits. You may omit leading zeros. The total number of PCI functions specified cannot exceed 256.

### Responses

Response 1:

```
PCIF      RPCI      VPCI
nnnnnnnn nnnnnnnn -----
```

Response 2:

```
PCIF      RPCI      VPCI
nnnnnnnn nnnnnnnn nnnnnnnn
```

Where:

#### PCIF

shows the real PCI function ID

#### RPCI

shows the host logical storage address of the corresponding real PCI block.

#### VPCI

shows the virtual PCI function block address if the PCI function is attached to a user ID.

### Examples

Example 1:

If you enter a LOCATE RPCI 18 command, you may see something like this:

```
PCIF      RPCI      VPCI
00000018 02E36288 -----
```

Example 2:

## LOCATE RPCI

If you enter a LOCATE RPCI 18 command and PCIF 18 has been attached to a user, you may see something like this:

```
PCIF      RPCI      VPCI
00000018 02E36288 012E8708
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP009E Invalid range - *range*
- HCP021E A real PCI function ID was not supplied or it is invalid.
- HCP5780E Adjunct does not support the *command subcommand* command
- HCP6000E The range of PCI function ids cannot exceed 256.
- HCP6720I No items found to satisfy selection criteria

## LOCATE SHPBK

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE SHPBK to display the address of the shared system name table control block (SHPBK).

### Operands

#### *system*

tells CP to locate the control blocks for only those system names that match this pattern. For more information on system patterns, see Usage Note “1” on page 623.

If the system names do not match, the system alias is also checked for a match.

If you do not specify a system name, CP locates all SHPBKs.

\*

tells CP to locate the SHPBK for the current system.

### Usage Notes

1. Pattern matching follows the rules used by the CMS LISTFILE command. Use an asterisk (\*) to match any number of characters; use a percent symbol (%) to match any single character.

### Responses

Response 1:

```

Slot  System  SHPBK   ISFSYSTB
   n  system  nnnnnnnn nnnnnnnn [RESERVED]
:
  
```

#### **System**

shows the system name.

#### **SHPBK**

shows the host logical storage address of the shared system name table control block for that system.

#### **ISFSYSTB**

shows the host logical storage address of the CSE/SSI system table.

#### **RESERVED**

indicates there is a "reserved" system. In an SSI cluster, this indicates an available slot in the SSI member list.

### Examples

Example 1:

## LOCATE SHPBK

If you enter a LOCATE SHPBK command with no other operands, you may see something like this:

```
locate shpbk
Slot System  SHPBK    ISFSYSTB
  1  -----  0001CAF8 0001CEB0 RESERVED
  2  BOSTON2  0001CBF8 0001CEB0
  3  BOSTON3  0001CB78 0001CEB0
Ready;
```

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid
- HCP6720I No items found to satisfy selection criteria.

## LOCATE SNABK

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE SNABK to display the address of the system SNA control block (SNABK).

### Operands

#### *netname.*

is the network qualifier of the fully qualified logical unit name (*netname.luname*). The period is used to delimit the network name from the LU name. This tells CP to locate the control blocks for only those terminal names that match this pattern.

#### *luname*

tells CP to locate the control blocks for only those terminal names that match this pattern.

#### VSM

tells CP to display the addresses for those SNA control blocks under the control of any VTAM Service Machine whose user ID matches the pattern *userid*.

#### *userid*

tells CP to locate the SNABK entries for the user ID or user ID pattern specified. For more information on user ID patterns, see Usage Note [“1” on page 625](#).

#### \*

tells CP to locate the SNABK entries for your user ID.

### Usage Notes

1. Pattern matching follows the rules used by the CMS LISTFILE command. Use an asterisk (\*) to match any number of characters; use a percent symbol (%) to match any single character.
2. Blanks are not permitted between the *netname*, ., and *luname*.
3. Network qualifiers, if they exist will be displayed only if a *netname* is specified.
4. Multiple responses can occur with the same *luname* when a *netname* is not specified and one or more VSMs support network qualified names.

### Responses

Response 1:

```
LU Name  RDEV    SNABK    VSM
luname  nnnnnnnn nnnnnnnn userid
:
```

#### LU Name

shows the name of the logical unit.

## LOCATE SNABK

### RDEV

shows the host logical storage address of the real device block.

### SNABK

shows the host logical storage address of the SNA control block.

### VSM

shows the user ID of the VTAM service machine (VSM) controlling the SNABK.

## Examples

Example 1:

If you enter a LOCATE SNABK command without the VSM operand, you may see something like this:

```
locate snabk wgu*
LU Name  RDEV      SNABK      VSM
WGU00315 044D9060 044D9008  VTAM
Ready;
```

Example 2:

If you add the *netname* to the request the response shows the fully qualified network name and might look like this:

```
locate snabk *.*
LU Name  RDEV      SNABK      VSM
VTAM1.LU3E0 0667DCD0 0667DC68  VTAM
VTAM1.LU3E1 07077D88 07077D20  VTAM
Ready;
```

The same request without the *netname* might look like this:

```
locate snabk *
LU Name  RDEV      SNABK      VSM
LU3E0    0667DCD0 0667DC68  VTAM
LU3E1    07077D88 07077D20  VTAM
Ready;
```

Example 3:

You can request the addresses of the SNA control blocks for all the logical devices under the control of a specific VSM. For example, to show the relevant information for all the terminals whose names start with the characters TN6 that are logged on under VTAM2, enter:

```
locate snabk tn6* vsm vtam*
LU Name  RDEV      SNABK      VSM
TN6PV095 044D92A0 044D9248  VTAM2
Ready;
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP6720I No items found to satisfy selection criteria

## LOCATE SPFBK

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE SPFBK to find the addresses of the spool file control blocks (SPFBKs) for specified user IDs, pseudo-user IDs, or user ID patterns.

### Operands

#### *userid*

tells CP to locate the SPFBK entries for the user ID, user ID pattern, or pseudo-user ID (`*IMG`, `*NLS`, `*NSS`, `*UCR`, and `*SDF`) specified. For more information on user ID patterns, see Usage Note “1” on page 628.

#### **SYSTEM**

tells CP to locate the SPFBK entries for all user IDs. In this case, any spool file numbers are system spool file numbers, not user spool file numbers.

**\***

tells CP to locate the SPFBK entry for your user ID.

#### **\*IMG**

tells CP to locate the SPFBK entry for all printer image library files owned by the system.

#### **\*NLS**

tells CP to locate the SPFBK entry for all National Language Support files owned by the system.

#### **\*NSS**

tells CP to locate the SPFBK entry for all named saved system files owned by the system.

## LOCATE SPFBK

### **\*SDF**

tells CP to locate the SPFBK entries for all the system data files owned by the pseudo-user IDs (\*IMG, \*NLS, \*NSS, and \*UCR).

### **\*UCR**

tells CP to locate the SPFBK entry for all user class restructure files owned by the system.

### **Printer**

#### **PRT**

specifies printer spool files.

### **PUnch**

#### **PCH**

specifies punch spool files.

### **Reader**

#### **RDR**

specifies reader spool files.

### **systemdatafile**

specifies a system data file. System data files can be any of the following: IMG, NLS, NSS, TRF or UCR. SDF means all of these. If you do not specify a spool file type, all spool file types are eligible.

### **spid**

#### **spid1-spid2**

specifies a spool file number, range of spool file numbers, or a combination of spool file numbers and range of spool file numbers for the spool files desired. If you do not specify a spool file number, all spool files are eligible.

## Usage Notes

1. Pattern matching follows the rules used by the CMS LISTFILE command. Use an asterisk (\*) to match any number of characters; use a percent symbol (%) to match any single character. Because there are operands for pseudo-user IDs (\*IMG, \*NLS, \*NSS, \*UCR, and \*SDF) and because a single asterisk (\*) indicates your user ID, there are exceptions to the asterisk rule.

To specify a pattern that you would normally specify as one of these special cases, use an additional asterisk. For example, specify \*\*NSS to match all user IDs that end with the 3 characters NSS, including the pseudo-user ID \*NSS.

## Responses

Response 1:

```
OwnerID  SpID Type SPFBK   System  System-SpID
ownerid  spid type nnnnnnnn system  system_spid
:
```

### **OwnerID**

shows the user ID that owns the spool file.

### **SpID**

shows the spool file identification number.

### **Type**

shows the type of spool file.

### **SPFBK**

shows the host logical storage address of the spool file control block.

### **System**

shows the name of the system that controls the spool file.

### **System-SpID**

shows the system spool file identification number for the specified file. This number uniquely identifies each spool file on the system.

## Examples

Example 1:

If you enter LOCATE SPFBK with the SYSTEM operand, you may see something like this:

```
locate spfbk system
OwnerID SpID Type SPFBK System System-SpID
OLIVER 7369 RDR 0763A1C8 BOSTON 31260
DAVID 6951 RDR 07647A88 BOSTON 45996

*IMG 0001 IMG 0763B388 BOSTON 32055
*NSS 0016 NSS 075F40E8 BOSTON 20
Ready;
```

Example 2:

If you use the \*SDF operand, you may see this:

```
locate spfbk *sdf
OwnerID SpID Type SPFBK System System-SpID
*IMG 0001 IMG 0763B388 BOSTON 32055
*NSS 0064 NSS 07647E08 BOSTON 44739
*NSS 0090 NSS 075FDA88 BOSTON 2524
*NSS 0055 NSS 07B6CAB8 BOSTON 97316
Ready;
```

Example 3:

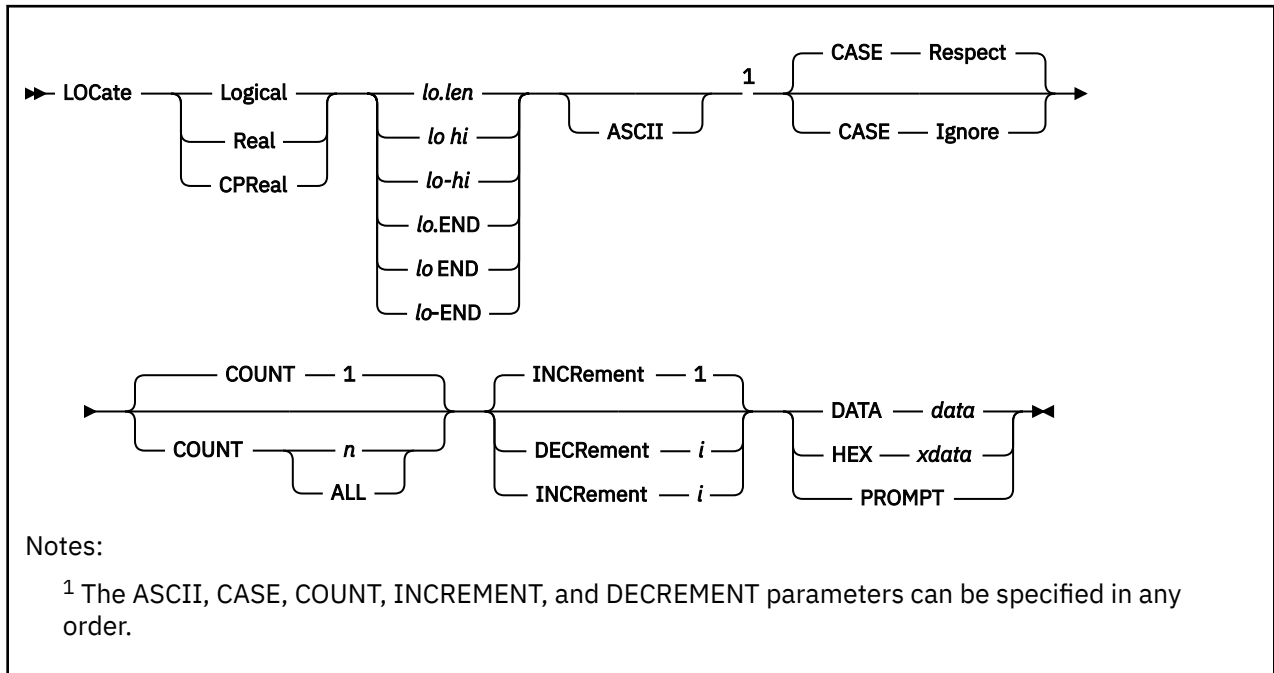

If you use the asterisk (\*) operand, you may see this:

```
locate spfbk *
OwnerID SpID Type SPFBK System System-SpID
EMILY 0242 RDR 0762DEE8 BOSTON 26419
EMILY 0257 RDR 0763E0E8 BOSTON 27056
EMILY 0260 PRT 0424DD08 BOSTON 27462
Ready;
```

## LOCATE (Storage)

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE (Storage) to display the location of data in host logical storage or host real storage.

### Operands

#### Logical

searches host logical storage (the system execution space).

#### Real

#### CPReal

searches host real storage.

#### *lo.len*

specifies the address of the beginning of the search area and the number of bytes to its end. *lo* and *len* must both be hexadecimal numbers. You must enter a period between these two values.

#### *lo hi*

#### *lo-hi*

specifies the addresses for the beginning and end of the search area. *lo* and *hi* must both be hexadecimal.

*lo*, *len*, and *hi* can be a 1 to 16 hexadecimal digit 64-bit address, separated with an optional underscore for readability.

#### *lo.END*

#### *lo END*

#### *lo-ND*

specifies the address of the beginning of the search area and tells CP to continue to search through to the end of the available storage. *lo* is a hexadecimal number. You can use any of the above formats.

**ASCII**

tells CP to convert the data you enter to ASCII before it is compared to the data in storage.

**CASE**

tells CP to convert the data you enter to upper case before it compares it to the data in storage.

**Note:** Unless you are using DIAGNOSE code X'08' to send commands to CP in mixed case, CP converts commands entered from the terminal to upper case before it processes them. If you specify the HEX operand, CASE is ignored. The default is CASE RESPECT.

**Respect**

tells CP not to convert the data from the command and the data from storage before comparing them.

**Ignore**

tells CP to convert the data from the command and the data from storage before comparing them so the upper and lower case characters are considered equal.

**COUNT *n*****COUNT ALL**

specifies how many matches to report. ALL reports all matches. If COUNT is not specified, the default is COUNT 1.

**DECRement *i***

tells CP to go *i* number of bytes backward through storage to search for the data. *i* must be a hexadecimal number. CP begins at the address you have specified as the end of the search area and compares the data you enter with what is at that address. If it does not find a match, it goes back *i* bytes and tries again. When it reaches the beginning of the search area or finds as many matches as you have specified with the COUNT keyword, CP displays the addresses of the fields within the search area that contain the data you are looking for.

*i* can be a 1 to 16 hexadecimal digit 64-bit address, separated with an optional underscore for readability. If the underscore is used there must be 8 hexadecimal digits to the right of it.

**INCRement *i***

tells CP to go *i* number of bytes forward through storage to search for the data. *i* must be a hexadecimal number. CP begins at the address you have specified as the start of the search area and compares the data you enter with what is at that address. If it does not find a match, it advances *i* bytes and tries again. When it reaches the end of the search area or finds as many matches as you have specified with the COUNT keyword, CP displays the addresses of the fields within the search area that contain the data you are looking for.

If you do not specify INCREMENT or DECREMENT, INCREMENT 1 is assumed.

*i* can be a 1 to 16 hexadecimal digit 64-bit address, separated with an optional underscore for readability. If the underscore is used there must be 8 hexadecimal digits to the right of it.

**DATA *data***

specifies the data to search for. The data to be compared starts after the first blank following the keyword DATA. Leading, imbedded, and trailing blanks are included in the comparison.

**HEX *xdata***

specifies the hexadecimal data to search for. The data may be specified as any number of strings of hexadecimal digits. If necessary, each string will be padded on the left with a single leading zero (0) to generate a string of an even number of hexadecimal digits. CP ignores blanks between the hexadecimal strings as it converts the strings for comparison. The length of the data to search for must be less than 254 hexadecimal digits.

**PROMPT**

tells CP to prompt you to enter the data to be searched for. The length of the data to search for must be less than 255 bytes.

### Usage Notes

1. CP searches only addresses for pages assigned. CP skips a page for an address not assigned (for example, an unreferenced page). If CP skips a page for any reason, the next comparison is in the next acceptable page at the address that would have been reached had the page or pages not been skipped and had all comparisons failed.
2. If you specify the search area as *lo hi* or *lo-hi*, CP searches and compares the byte at address *hi*. For example,

```
locate logical 0 1 hex 00
```

causes CP to compare the two bytes (address 0 and address 1) to the specified data (00).

3. Specifying the search area as *lo hi* or *lo-hi* is the same as specifying *lo.len* if  $len = hi - lo + 1$ .
4. If CP finds a match, the address of the next comparison attempt is the address of the match plus the increment amount (or minus the decrement amount).
5. If you specify DECREMENT, CP displays the addresses of matches with the highest address first.
6. Whether you specify INCREMENT or DECREMENT, the set of addresses eligible for the search are the same. The difference is that INCREMENT causes the search to start from the *lo* address and progress upward, while DECREMENT causes the search to start at the *hi* address and progress downward ending at the *lo* address. For example, in the following command:

```
locate logical 0 1000 decr c data 123456
```

the first comparison address is X'FF0'.

7. CP skips pages that contain CP directory data.
8. If a large search range is specified, the LOCATE command will take a large amount of CPU cycles and therefore can impact overall system performance.

### Responses

Response 1:

```
The data is located at address.  
:
```

**Note:** A host logical storage address is 8 hexadecimal digits. A host real storage address can be up to 16 hexadecimal digits, separated by an underscore if SET UNDERSCORE ON has been specified.

Response 2:

If you specify the PROMPT operand, you see the following:

```
Enter data now. To abort the command,  
press ENTER with no data or press PA1.
```

### Examples

Example 1:

If you enter a LOCATE REAL command, you might see something like this:

```
locate real 1_00000000-2_00000000 data david  
The data is located at 1_0001B8C8.  
Ready;
```

Example 2:

The following commands are equivalent:

```
locate real 0-400 hex 00010203
The data is located at 00000045.
Ready;
```

```
locate cpreal 0-400 hex 0 1 203
The data is located at 00000045.
Ready;
```

### Example 3:

If you enter a LOCATE REAL command with the COUNT operand for data you know is in the CP nucleus, you might see something like this:

```
locate real 2e8000-2eb000 count 3 data hcp
The data is located at 002E800C.
The data is located at 002E900C.
The data is located at 002EA00C.
Ready;
```

### Example 4:

If you enter a LOCATE LOGICAL command for the same data as in Example 3, you might see something like this:

```
locate logical 2e8000-2eb000 count 3 data hcp
The data is located at 002E800C.
The data is located at 002E900C.
The data is located at 002EA00C.
Ready;
```

Because the CP nucleus is identity mapped, the host logical storage addresses of the data are identical to the host real storage addresses. For data outside the CP nucleus, the host real storage addresses and host logical storage addresses would be different.

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *option*
- HCP004E Invalid hexloc - *hexloc*
- HCP005E Invalid hexdata - *data*
- HCP009E Invalid range - *range*An invalid address range was specified
- HCP026E Operand missing or invalid
- HCP6704E Missing token at end of line
- HCP6720I No items found to satisfy selection criteria
- HCP6896E The data field exceeds the maximum length of *nnn* characters.

## LOCATE SXSTE

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE SXSTE to display the address of the system execution space page management table entry (SXSTE) for a specific system execution space page, or the address of the system execution space page for a specific SXSTE.

### Operands

#### *addr1*

is the host logical storage address of the system execution space page whose SXSTE you want CP to locate. This address does not need to be page-aligned; CP will adjust it.

#### **ENTRY** *addr2*

tells CP to locate the system execution space page whose SXSTE address is *addr2*. Because SXSTEs reside above 2 GB in the system execution space, *addr2* must be a host logical storage address above 2 GB. This address does not need to be aligned with the boundary of a SXSTE; CP will adjust it.

### Responses

**Note:** If SET UNDERSCORE ON has been specified, an underscore is used to separate 16-digit addresses for readability.

Response 1:

```
Page Address SXSTE
nnnnnnnn  nnnnnnnnnnnnnnnnn
```

#### **Page Address**

shows the host logical storage address of the system execution space page.

#### **SXSTE**

shows the host logical storage address of the system execution space page management table entry.

### Examples

Example 1:

To find the SXSTE address for page 19FE400, enter:

```
locate sxste 19FE400
Page Address SXSTE
019FE000    0000020028033FC0
Ready;
```

The response shows that the SXSTE is located at host logical storage address 20028033FC0.

Example 2:

To find the page whose SXSTE is located at host logical storage address 2003E011020, enter:

```
locate sxste entry 2003E011020
Page Address SXSTE
00881000      00000200_3E011020
Ready;
```

The response shows that the page is located at host logical storage address 881000. Note that SET UNDERSCORE ON is in effect.

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP004E Invalid hexloc - *hexloc*
- HCP025E Storage missing or invalid
- HCP094E Storage exceeds allowed maximum of *maximum* {M|K}
- HCP6875E System execution space page management table entry is outside the extents of the SXSTE table: *addr1-addr2*

## LOCATE SYMBOL

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE SYMBOL to display the address of an external symbol.

### Operands

#### *symbol*

is the name of an external symbol. If you specify the SYMBOL keyword, CP supports pattern matching as described below in Usage Note “2” on page 636. Specifying a single asterisk (\*) with the SYMBOL keyword tells CP to list every CP external symbol and its location.

### Usage Notes

1. Because there are several LOCATE commands that treat the qualifying keyword as optional (LOCATE RDEV, LOCATE SYMBOL, LOCATE VDEV, LOCATE VMDBK), specifying the SYMBOL keyword is recommended to avoid undesired results. Specifying the SYMBOL keyword also allows you to use pattern matching in the symbol name, as described in Usage Note “2” on page 636, and provides additional information in the response.
2. Pattern matching generally follows the rules used by the CMS LISTFILE command. Use an asterisk (\*) to match any number of characters; use a percent symbol (%) to match any single character.

### Responses

Response 1:

If you specify the SYMBOL keyword, the response format is:

```
symbol = nnnnnnnn Resident nnnnnn Bytes
:
```

#### *symbol*

is the symbol name you specified, or a symbol name that matches the pattern you specified.

#### *nnnnnnnn Resident*

is the host logical storage address of the external symbol. All external symbols are resident.

#### *nnnnnn Bytes*

is the length of the CSECT, and is shown if the entry in the map contains a nonzero length for the external label:

- For normal assembler routines, the CSECT is longer than 0 bytes. Therefore, when you enter a LOCATE command for an assembler module, CP shows you the length of the entire module. If you enter a LOCATE command for an entry point within an assembler module, CP does not display any information about the module's length, because entry points are not defined to have length.

- For PLX routines, the first CSECT is 0 bytes long. If you enter a LOCATE command for a PLX module, CP does not display any information about the length of the entire module. Entry points within a PLX module are actually independent CSECTs and are longer than 0 bytes. When you enter a LOCATE command for an entry point within a PLX module, CP shows you the length of the CSECT indicated by that entry point.

See Examples 2, 3, and 4.

Response 2:

If you do not specify the SYMBOL keyword, the response format is:

```
symbol = nnnnnnnn Resident
```

## Examples

Example 1:

If you use LOCATE SYMBOL without the SYMBOL keyword, you may see the following:

```
locate hcpabc
HCPABC = 00868000 Resident
Ready;
```

This response indicates HCPABC is at host logical storage address 00868000.

Example 2:

If you use LOCATE SYMBOL with the SYMBOL keyword to find the address of the same external symbol, you may get the following response:

```
locate symbol hcpabc
HCPABC = 00868000 Resident      000858 Bytes
Ready;
```

Example 3:

If you use pattern matching to find the addresses of all the external symbols that start with the letters HCPZSP, you may see the following:

```
locate symbol hcpzsp*
HCPZSP = 003D1CB0 Resident      0000A8 Bytes
HCPZSPPP = 003D1D30 Resident
HCPZSPRD = 003D1D10 Resident
Ready;
```

This response shows that HCPZSP is an Assembler module, and the other two items listed are entry points within it.

Example 4:

If you use pattern matching to find the addresses of all the external symbols that start with the letters HCPCFC, you may see the following:

```
locate symbol hcpcfc*
HCPCFC = 0087BAD0 Resident
HCPCFCMD = 0087BAD0 Resident      000900 Bytes
HCPCFCSD = 0087C3D0 Resident      0003A8 Bytes
Ready;
```

This response shows that HCPCFC is a PLX module, and the other two items are entry points within it.

## LOCATE VDEV

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE VDEV to display the addresses of the CP control blocks associated with a user or a user's virtual device.

### Operands

#### *userid*

\*

identifies the virtual machine whose control blocks you want to locate. To display the addresses of control blocks associated with your own virtual machine, specify *userid* as an asterisk (\*).

\*\*

indicates this is for all users logged onto the system.

#### *vdev*

#### *vdev1-vdev2*

identifies a virtual device number or range of virtual device numbers.

### Usage Notes

1. Because there are several LOCATE commands that treat the qualifying keyword as optional (LOCATE RDEV, LOCATE SYMBOL, LOCATE VDEV, LOCATE VMDBK), specifying the VDEV keyword is recommended to avoid undesired results. Using the VDEV keyword also allows you to specify more than one virtual device number and returns more information in the response.
2. You can use the LOCATE VDEV *userid vdev* command to find the RDEV control block for SNA/CCS terminals. This command returns the address of the VDEV control block, which contains a pointer to the RDEV.

### Responses

Response 1:

If you specify the VDEV keyword, the response format is:

```
Userid  Dev  VDEV   VDSBK   VPXBK   VSPBK   Rdev
userid  nnnn  nnnnnnnn  nnnnnnnn  nnnnnnnn  nnnnnnnn  nnnn
:
```

## LOCATE VDEV

### Userid

shows the user ID you specified.

### Dev

shows the virtual device number you specified, or a device number included in a range you specified.

### VDEV

shows the host logical storage address of the virtual device block associated with that device number.

### VDSBK

shows the host logical storage address of the virtual device simulation block associated with that device number, if the device is a spooled device.

### VPXBK

shows the host logical storage address of the virtual printer extension block.

### VSPBK

shows the host logical storage address of the virtual spooling device block.

### Rdev

shows the real device number of the device you specified.

**Note:** An asterisk in a response field indicates there is no information for that field.

Response 2:

If you do not specify the VDEV keyword, the response format is:

```
VMDBK      VDEV
nnnnnnnn  nnnnnnnn
```

### VMDBK

shows the host logical storage address of the virtual machine definition block.

### VDEV

shows the host logical storage address of the virtual device block.

## Examples

Example 1:

If you use the LOCATE VDEV command to display the addresses of control blocks for a range of virtual devices for the DAVID user ID, you may see something like this:

```
locate vdev david 0100-0150
Userid  Dev  VDEV  VDSBK  VPXBK  VSPBK  Rdev
DAVID   0120 04829998 *      *      *      0287
DAVID   0121 04829A70 *      *      *      0288
DAVID   0122 04829E28 *      *      *      0285
DAVID   0123 04829F00 *      *      *      0284
DAVID   0124 044D3008 *      *      *      0289
DAVID   0125 044D30E0 *      *      *      0283
DAVID   0126 044D31B8 *      *      *      0284
Ready;
```

Example 2:

If you enter the LOCATE LDEV command to display all user IDs (using the pattern \*\*) that have a virtual device defined at 0009 (the typical virtual device for the virtual machine console), you may see something like this:

```
locate vdev ** 9
Userid  Dev  VDEV  VDSBK  VPXBK  VSPBK  Rdev
CORAK   0009 01FD7B10 018B1F48 *      02A2AF38 TN6PV013
OPERATOR 0009 06E6C008 01AA8F48 *      06E6C0E0 *
DAWN    0009 072F8590 01EF6F48 *      072F8668 WGU00315
RSCS6   0009 0201E560 02030F48 *      0201E638 *
RSCS5   0009 022D0858 02024F48 *      022D0930 *
VTAM    0009 027974F0 0260BF48 *      027975C8 *
MURPHY  0009 02A1B1B8 028CBF48 *      02A1B290 L0002
```

```

OLIVER  0009 0497CBA8 04979F48 *      0497CC80 L0000
DAVID   0009 04981478 0497FF48 *      04981550 L0001
PUBSAUTH 0009 04982A28 04984F48 *      04982B00 *
SVCDIR  0009 056BAAC0 04A6EF48 *      056BAB98 08E0

```

Example 3:

If you do not use the VDEV keyword, you may see something like this:

```

locate david 120
VMDBK      VDEV
04A78000   04829998
Ready;

```

## Messages

## LOCATE VMDBK

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE VMDBK to display the logical and real addresses of a user's virtual machine definition block (VMDBK).

### Operands

#### *userid*

specifies the user ID (or user ID pattern) whose VMDBK entries CP should locate. If you use the VMDBK keyword, CP supports pattern matching as described below in Usage Note “2” on page 642.

\*

tells CP to locate the VMDBK entry for your user ID.

\*\*

tells CP to locate all VMDBKs on the system.

### Usage Notes

1. Because there are several LOCATE commands that treat the qualifying keyword as optional (LOCATE RDEV, LOCATE SYMBOL, LOCATE VDEV, LOCATE VMDBK), specifying the VMDBK keyword is recommended to avoid undesired results. It also allows you to use pattern matching in specifying the user ID, as described in Usage Note “2” on page 642, and to see information about multiple virtual processors in the response.
2. Pattern matching follows the rules used by the CMS LISTFILE command. Use an asterisk (\*) to match any number of characters; use a percent symbol (%) to match any single character.
3. If a large virtual machine is logged off multiple times and two or more logged-off instances are still going through memory reset, the user ID (transformed from uppercase to lowercase) will appear multiple times in the responses to this command. Eventually, each instance will finish memory reset and will disappear from the responses.

The following sequence of events is an example of this type of situation:

- a. A user logs on virtual machine "LARGEONE" and runs a workload that instantiates a large amount of memory.
- b. The user logs off the virtual machine. This instance of virtual machine "LARGEONE" becomes known as instance "largeone."
- c. Responses to LOCATE VMDBK include "largeone nnnnnnnn LOGOFF nnnnnnnnnnnnnnnnn."
- d. The user logs back on to virtual machine "LARGEONE" and runs a workload that instantiates a large amount of memory.

- e. The user logs off. This instance of virtual machine "LARGEONE" also becomes known as instance "largeone."
- f. Responses to LOCATE VMDBK now include two occurrences of "largeone nnnnnnnn LOGOFF nnnnnnnnnnnnnnnn."
- g. Eventually instance "largeone" from Step "3.b" on page 642 completes reset and disappears.
- h. Responses to LOCATE VMDBK now include only one occurrence of "largeone nnnnnnnn LOGOFF nnnnnnnnnnnnnnnn."
- i. Eventually instance "largeone" from Step "3.e" on page 643 completes reset and disappears.

## Responses

**Note:** If SET UNDERSCORE ON has been specified, an underscore is used to separate 16-digit addresses for readability.

Response 1:

If you specify the VMDBK keyword, the response format is:

```
Userid    VMDBK    Type      VMDBK-Real
userid    nnnnnnnn type      nnnnnnnnnnnnnnnn
:
```

### Userid

shows the user ID you specified, or a user ID that matches the pattern you specified.

### VMDBK

shows the host logical memory address of the virtual machine definition block.

### Type

shows the type of VMDBK. The possible values are:

#### SYSTEM

is a special global VMDBK for CP.

#### ORIGIN

is a VMDBK associated with a user when that user logs on.

#### MP

is a VMDBK for an additional virtual processor defined by a user or the user's directory entry.

#### PROTOTYPE

is a VMDBK associated with a user in the process of logging off.

#### LOGOFF

indicates that the user has logged off but its memory is still in the process of being released.

### VMDBK-Real

shows the host real memory address of the virtual machine definition block.

Response 2:

If you do not specify the VMDBK keyword, the response format is:

```
VMDBK = nnnnnnnn VMDBK-Real = nnnnnnnnnnnnnnnn
```

## Examples

Example 1:

If you enter a LOCATE VMDBK command with the VMDBK keyword and specify a user ID pattern, you may see something like this:

```
locate vmdbk cptest*
Userid  VMDBK  Type      VMDBK-Real
CPTST1  05ADD000 ORIGIN    000000AA01899000
```

## LOCATE VMDBK

```
CPTTEST1 06BCF000 MP          00000208B6894000
CPTTEST2 07BDF000 ORIGIN     000000FC9CE33000
CPTTEST3 03BCE000 ORIGIN     0000009B7B527000
Ready;
```

This response shows that user ID CPTTEST1 is using two virtual processors.

Example 2:

If you enter LOCATE without the VMDBK keyword, you may see something like this:

```
locate tools
VMDBK = 05ADD000 VMDBK-Real = 00000000_05ADD000
Ready;
```

Note that this response does not tell you if the TOOLS virtual machine is using multiple virtual processors. Note also that SET UNDERSCORE ON is in effect.

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on

## LOCATE VPCI

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE VPCI to display the address of a user's virtual PCI function block and its associated control blocks.

### Operands

#### *userid*

\*

identifies the virtual machine to which the function or functions are currently attached. The specified user must be logged onto the system. If you are locating a VPCI for your own virtual machine, you may specify your user ID as an asterisk (\*).

#### *vpfid*

#### *vpfid1-vpfid2*

specifies a virtual PCI function ID or a range of PCI function IDs whose control block addresses are to be displayed. Specify a PCI function ID as 8 hexadecimal digits. You may omit leading zeros. The total number of PCI functions specified cannot exceed 256.

### Responses

Response 1:

```
PCIF      VPCI      RPCI
xxxxxxxx  xxxxxxxx  xxxxxxxx
```

Where:

#### **PCIF**

shows the virtual PCI function ID

#### **VPCI**

shows the host logical storage address of the corresponding virtual PCI block.

#### **RPCI**

shows the real PCI function block address of the real PCI function associated with this virtual PCI function.

### Examples

Example 1:

If you enter a LOCATE VPCI \* 17 command, you may see something like this:

```
PCIF      VPCI      RPCI
00000017  012E8708  02E36288
```

### Messages

- HCP002E Invalid operand - *operand*

- HCP6720I No items found to satisfy selection criteria

## LOCATE VSMBK

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE VSMBK to display the address of a system VTAM service machine block (VSMBK).

### Operands

#### *userid*

specifies the user ID (or user ID pattern) whose VSMBK entries CP should locate. For more information about user ID patterns, see Usage Note “1” on page 647.

\*

tells CP to locate the VSMBK entry for your user ID.

### Usage Notes

1. Pattern matching follows the rules used by the CMS LISTFILE command. Use an asterisk (\*) to match any number of characters; use a percent symbol (%) to match any single character.

### Responses

Response 1:

```
Userid  VSMBK
userid  nnnnnnnn
:
```

#### **Userid**

shows the user ID you specified, or a user ID that matches the pattern you specified.

#### **VSMBK**

shows the host logical storage address of the VSMBK for that user ID.

### Examples

Example 1:

If you enter a LOCATE VSMBK command, you may see something like this:

```
locate vsmbk vtam
Userid  VSMBK
VTAM    0762B1C8
Ready;
```

### Messages

- HCP002E Invalid operand - *operand*

## LOCATE VSMBK

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP6720I No items found to satisfy selection criteria

## LOCATE XITBK

### Authorization

Privilege Class: C, E

### Purpose

Use LOCATE XITBK to display the address of the CP exit block for a specific exit point.

### Operands

*exit*

*exit1-exit2*

is the number of the CP exit block whose address you want to display. The exit number must be a hexadecimal number between X'0000' and X'FFFF'. You can specify a single exit number, a range of exit numbers, or any combination thereof.

### Usage Notes

1. CP creates CP exit blocks for exit points when you issue the ASSOCIATE EXIT command (see [“ASSOCIATE EXIT”](#) on page 20) to associate one or more entry point names or external symbols with that exit point. If no one issued the ASSOCIATE EXIT command, there is no CP exit block for CP to locate and CP issues error message HCP2752E.

After creating a CP exit block, CP will not erase that CP exit block until the next IPL. Disabling the exit point affects certain fields in the CP exit block, but does not erase it. Disassociating the entry point names and external symbols erases those fields in the CP exit block, but does not erase the CP exit block itself.

2. To display status and usage statistics information about a specific exit point, use the QUERY EXITS command (see [“QUERY EXITS”](#) on page 907).
3. To display the address of the CP indirect call locator block for a specific exit point, use the LOCATE ICLBK command (see [“LOCATE ICLBK”](#) on page 614).
4. For more information about user-defined exit points, see [z/VM: CP Exit Customization](#).

### Responses

Response 1:

```
Exit XITBK
nnnn nnnnnnnn
:
```

#### Exit

shows the exit number (exit point) you specified, or an exit number included in a range you specified.

#### XITBK

shows the host logical storage address of the CP exit block for that exit number.

### Examples

Example 1:

To display the address of the CP exit block for exit point X'070C', enter the following:

```
locate xitbk 70c
Exit XITBK
070C 005234C8
Ready;
```

Example 2:

To display the addresses of the CP exit blocks for exit points X'0005' and X'F000', enter the following:

```
locate xitbk f000 5
Exit XITBK
F000 01F101C8
0005 061E19C8
Ready;
```

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid
- HCP2752E Exit number *exit* does not exist
- HCP2752E Exit numbers *exit1-exit2* do not exist
- HCP6706E Invalid CP Exit number - *exit*

## LOCATEVM

### Authorization

Privilege Class: G

### Purpose

Use LOCATEVM to search for certain data in your virtual machine's storage.

### Operands

#### *lo.len*

specifies the address of the beginning of the search area and the number of bytes to its end. *lo* and *len* must both be hexadecimal numbers. You must enter a period between these two values.

#### *lo hi*

#### *lo-hi*

specifies the addresses for the beginning and end of the search area. *lo* and *hi* must both be hexadecimal numbers.

*lo*, *len*, and *hi* can be a 1-digit to 16-digit hexadecimal 64-bit address, separated with an optional underscore for readability.

#### *lo.END*

#### *lo END*

#### *lo-END*

specifies the address of the beginning of the search area and tells CP to search through to the end of the available storage. *lo* is a hexadecimal number. You may use any of the above formats.

#### CASE

tells CP to convert the data you enter to upper case before it is compared to the data in storage.

**Note:** Unless you are using DIAGNOSE code X'08' to send commands to CP in mixed case, CP converts commands entered from the terminal to upper case before it processes them. If you specify the HEX operand, CASE is ignored. The default is CASE RESPECT.

**Respect**

tells CP not to convert the data from the command and the data from storage before comparing them. RESPECT is the default.

**Ignore**

tells CP to convert the data from the command and the data from storage before comparing them so that the upper and lower case characters are considered equal.

**ASCII**

tells CP to convert the data you enter to ASCII before it is compared to the data in storage.

**COUNT *n*****COUNT ALL**

specifies how many matches to report. ALL reports all matches. The default is COUNT 1.

**DECRement *i***

tells CP to go *i* number of bytes backward through storage to search for the data. *i* must be a hexadecimal number. CP begins at the address you have specified as the end of the search area and compares the data you enter with what is at that address. If it does not find a match, it goes back *i* bytes and tries again. When it reaches the beginning of the search area or finds as many matches as you have specified with the COUNT keyword, CP displays the addresses of the fields within the search area that contain the data that you are looking for.

*i* can be a 1-digit to 16-digit hexadecimal 64-bit address, separated with an optional underscore for readability. If the underscore is used there must be 8 hexadecimal digits to the right of it.

**INCRement *i***

tells CP to go *i* number of bytes forward through storage to search for the data. *i* must be a hexadecimal number. CP begins at the address you have specified as the start of the search area and compares the data you enter with what is at that address. If it does not find a match, it advances *i* bytes and tries again. When it reaches the end of the search area or finds as many matches as you have specified with the COUNT keyword, CP displays the addresses of the fields within the search area that contain the data you are looking for.

*i* can be a 1-digit to 16-digit hexadecimal 64-bit address, separated with an optional underscore for readability. If the underscore is used there must be 8 hexadecimal digits to the right of it.

If you do not specify INCREMENT or DECREMENT, INCREMENT 1 is assumed.

**DATA *data***

specifies the data to search for. The data to be compared starts after the first blank following the keyword DATA. Leading, imbedded, and trailing blanks are included in the comparison. The length of the data to search for must be less than 254 bytes.

**HEX *xdata***

specifies the hexadecimal data to search for. You can specify the data as any number of strings of hexadecimal digits. If necessary, each string will be padded on the left with a single leading zero (0) to generate a string of an even number of hexadecimal digits. CP ignores blanks between the hexadecimal strings as it converts the strings for comparison. The length of the data to search for must be less than 254 hexadecimal digits.

If you specify the HEX operand, the CASE operand is ignored.

**PROMPT**

tells CP to prompt you to enter the data to be searched for. The length of the data to search for must be less than 254 bytes.

**Usage Notes**

1. CP only searches addresses for pages assigned. CP skips a page for an address not assigned (for example, an unreferenced page). If CP skips a page for any reason, the next comparison is in the next acceptable page at the address that would have been reached had the page or pages not been skipped and had all comparisons failed.

- If you specify the search area as *lo hi* or *lo-hi*, CP searches and compares the byte at address *hi*. For example,

```
locatevm 0 1 hex 00
```

causes CP to compare the two bytes (address 0 and address 1) to the specified data (00).

- Specifying the search area as *lo hi* or *lo-hi* is the same as specifying *lo.len* if  $len = hi - lo + 1$ .
- If CP finds a match, the address of the next comparison attempt is the address of the match plus the increment amount (or minus the decrement amount).
- If you specify DECREMENT, CP displays the addresses of matches with the highest address first.
- Whether you specify INCREMENT or DECREMENT, the set of addresses eligible for the search are the same. The difference is that INCREMENT causes the search to start from the *lo* address and progress upward, while DECREMENT causes the search to begin at the *hi* address and progress downward ending at the *lo* address. For example, in the following command,

```
locatevm 0 1000 decr c data 123456
```

the first comparison address is X'FF0'.

- If you specify PROMPT, you see the following:

```
Enter data now. To abort the command,
press ENTER with no data or press PA1.
```

- If a large search range is specified, the LOCATEVM command will take a large amount of CPU cycles and therefore can impact the overall system performance.

## Responses

Addresses in responses can be up to 16 hexadecimal digits, separated by an underscore if SET UNDERSCORE ON has been specified.

Response 1:

If you enter a LOCATEVM command, you might see something like this:

```
locatevm 1000-2000 hex 0
The data is located at 00001000.
Ready;
```

```
locatevm 4_00001000-4_00002000 hex 0
The data is located at 4_00001000.
Ready;
```

This response displays the address, in hexadecimal, of the information associated with your LOCATEVM request.

## Messages

# LOCK

## Authorization

Privilege Class: A

## Purpose

Use LOCK to keep selected guest pages in host storage.

## Operands

### ASIT *asit*

locks pages in the address space identified by the address-space-identification token, *asit*. The *asit* must be padded to 16 hexadecimal digits with leading zeros.

### SPACE *owner:space\_name*

locks pages in the address space identified by the space ID, *owner:space\_name*, where *owner* is the user ID of the virtual machine that owns the address space and *space\_name* is the name assigned to the address space.

If *owner:* is not specified, your virtual machine is assumed to be the owner of the address space.

The space name is a string of alphanumeric and national characters, 1 to 24 characters long. The space name "BASE" is preassigned by CP to be the name of the issuer's host-primary address space.

### Userid *userid*

#### *userid*

locks pages in the primary address space of the virtual machine identified by *userid*. The virtual machine must be logged on. If you are locking pages of your own virtual machine's storage, you can specify *userid* as an asterisk (\*).

### *firstpage*

is the hexadecimal number of the first user or address space page to be locked to host storage. Page numbers are assigned beginning with zero; each page is X'1000':

Storage Location	Page Number
0000-0FFF	0

<i>Table 29. Page Number Derivation (continued)</i>	
<b>Storage Location</b>	<b>Page Number</b>
1000-1FFF	1
2000-2FFF	2
⋮	⋮
1A000-1AFFF	1A
⋮	⋮

***lastpage***

is the hexadecimal number value of the last user or address space page to be locked to host storage. If only one page is to be locked, *firstpage* must be the same as *lastpage*.

**Logical**

locks the guest pages to host logical storage pages.

**Real**

locks the guest pages to real storage frames.

**MAP**

specifies that a map of the locked host storage should be displayed.

**SYMBOL *symbol***

has no effect and is retained only for compatibility purposes. All symbols are considered resident, which means they cannot be locked or unlocked.

**Usage Notes**

- In the primary address space, the first and last page numbers are treated as guest real addresses. They are prefixed with the prefix register value of the base virtual CPU of the target virtual machine. In other address spaces, the first and last page numbers are treated as *guest absolute* addresses. Prefixing is not applied to these addresses.
- If you are using LOCK for debugging purposes, use the LOGICAL operand to lock the guest pages to host logical storage. If you are using LOCK for performance reasons, use the REAL operand to lock the guest pages to real storage.
- If the SET RESERVED command has been issued by another virtual machine, you can use the LOCK command to enhance the efficiency of a particular virtual machine by keeping pages that are frequently referred to (such as page zero of the virtual machine's primary address space) in host storage. However, if the number of real storage frames available for paging is limited, you should not enter the LOCK command without the approval of your system programmer.
- If too many pages or frames of host storage are locked, there might not be enough resources available for the remaining virtual machines or for CP to operate efficiently. The performance of the system might be severely degraded because of the excessive contention for the available resources. Particular caution is warranted when locking pages in logical. Regardless of the real storage size, logical storage, also known as the system execution space, is limited to 2G and contains the CP nucleus, the prefix pages, dynamically allocated free storage, and other CP-use pages. Exhausting logical storage results in an SXA004 abend.
- Once a guest page is locked to host storage, it remains locked until one of these events occurs:
  - The CP UNLOCK command is issued for the page.
  - A SYSTEM CLEAR command is issued.
  - The page is released by a DIAGNOSE X'10' instruction or a TEST BLOCK instruction.
  - A MAPMDISK DEFINE operation is issued for the page.
  - A CP command causes an implicit system-reset-clear operation (for example, DEFINE STORAGE, LOGOFF, and some forms of the IPL command).

## LOCK

A locked page from an address space created by the ADRSPACE macro is unlocked when the address space is destroyed by the ADRSPACE macro.

6. Guest pages that are locked by this command are not unlocked by the operation of the [ADRSPACE ISOLATE](#) and [ADRSPACE PERMIT](#) macros. The ADRSPACE macros are described in *z/VM: CP Programming Services*.
7. The CP SYSTEM CLEAR command unlocks any locked pages and sets them to binary zeros.
8. The guest pages locked to host storage are 4 KB (4096-byte) blocks. This block of storage need not represent all of the user's virtual storage. The LOCK command may be issued as many times as required for one virtual machine to lock noncontiguous pages of storage. The remaining virtual machine storage blocks remain pageable.
9. If you omit the MAP operand from a LOCK command and you later want to find the address of the locked host logical storage page or real storage frame, reissue the same LOCK command with the MAP operand. No intervening UNLOCK command is required. Note that reissuing the same LOCK command does not put another lock on the guest page. Only one UNLOCK command is required to release the lock.
10. The LOCK and UNLOCK commands operate independently of the DIAGNOSE code X'98' page locking facility. Pages locked by the LOCK command cannot be unlocked by DIAGNOSE code X'98', nor can real I/O pages locked by DIAGNOSE code X'98' be unlocked by the UNLOCK command.
11. Some CP functions, such as DIAGNOSE code X'98' or X'214', may indirectly cause pages or frames of host storage to be unlocked.
12. If you specify the LOGICAL operand to lock a guest page to a host logical storage page, the corresponding real storage frame is also locked by CP. This makes it unnecessary to issue the LOCK command twice to lock the same guest page to both host logical storage and host real storage.  
  
Host storage must be unlocked in the same way it was locked. If you issued the LOCK command with the LOGICAL operand, you must also specify the LOGICAL operand on the UNLOCK command. That will release both the host logical storage page and the real storage frame.
13. The VMRELOCATE MOVE command is issued to relocate the guest to another system. Once a relocation unlocks pages, they remain unlocked even if the relocation is subsequently terminated or canceled prior to completion.
14. If you issue LOCK with the ASIT operand and specify the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the LOCK command is rejected and error message HCPCPW033E is issued. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value by using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:
  - SYSTEM CLEAR
  - IPL by NSS name
  - IPL by device with the CLeAr option
  - SET MACHine (to a different machine architecture)

## Responses

**Note:** If SET UNDERSCORE ON has been specified, an underscore is used to separate 16-digit addresses for readability.

Response 1:

If you specify the LOGICAL and MAP operands, the response format is:

```
      VIRTPAGE  HOST LOGICAL  HOST REAL
userid  nnnnnnnn  nnnnnnnn  nnnnnnnnnnnnnnnn
:
Command complete
```

**userid**

is the user ID you specified. If you did not specify a user ID, this field is omitted.

**VIRTPAGE**

shows the number of the locked guest page.

**HOST LOGICAL**

shows the host logical storage address of the locked host page.

**HOST REAL**

shows the host real storage address of the locked frame.

Response 2:

If you specify the REAL and MAP operands, the response format is:

```

      VIRTPAGE  HOST REAL
userid  nnnnnnnn  nnnnnnnnnnnnnnnnn
:
Command complete

```

**userid**

is the user ID you specified. If you did not specify a user ID, this field is omitted.

**VIRTPAGE**

shows the number of the locked guest page.

**HOST REAL**

shows the host real storage address of the locked frame.

Response 3:

If you do not specify the MAP operand, the response is:

```

Command complete

```

**Examples**

Example 1:

For *firstpage* and *lastpage*, only the page numbers are specified. For example, to lock the first three pages of USERA's primary address space into host logical storage, enter:

```

lock userid usera 0 2 to logical
Command complete
Ready;

```

To get the MAP information while these pages are still locked, reissue the command with the MAP operand:

```

lock userid usera 0 2 to logical map

```

The response format will be similar to Example 4. This does not put an additional lock on these pages.

Example 2:

To lock the first three pages of USERA's address space named MYSPACE into host logical storage, enter:

```

lock space usera:myspace 0 2 to logical
Command complete
Ready;

```

Example 3:

## LOCK

To lock storage locations X'12000' through X'14FFF' of USERA's primary address space into real storage and display the addresses of the locked real storage frames, enter:

```
lock userid usera 12 14 to real map
      VIRTPAGE  HOST REAL
USERA  00012000  00000000078F8000
USERA  00013000  0000000006B7C000
USERA  00014000  0000000002A77000
Command complete
Ready;
```

Example 4:

To lock pages above 2 GB for USERA into host logical storage and display the addresses, enter:

```
lock userid usera 123456 123457 to logical map
      VIRTPAGE          HOST LOGICAL  HOST REAL
USERA  00000001_23456000  078F8000      00000000_71A7F000
USERA  00000001_23457000  06B7C000      00000000_46B41000
Command complete
Ready;
```

Note that this example shows that SET UNDERSCORE ON is in effect.

## LOGOFF

### Authorization

Privilege Class: Any

### Purpose

Use LOGOFF or LOGOUT to end a virtual machine session.

### Operands

#### HOLD

causes the non-SNA TTY terminal telecommunication connection to remain in effect after your session is disconnected. If you specify the HOLD option from a logical device, you log off from the logical device without losing the connection between the logical device and the system.

### Usage Notes

1. When the LOGOFF command is entered from the virtual machine console as the first or only command on a CP command line (that is, while TERMINAL MODE is CP, or CP READ is displayed or the command line begins with #CP), z/VM attempts to break out of certain wait conditions that might exist. Thus the LOGOFF command may be entered to cause breakout of certain virtual machine wait conditions.

The breakout attempt occurs when the LOGOFF command is entered, not when the command is processed. Command errors do not prevent the breakout attempt. In some cases, a breakout resets the virtual machine.

2. When you log off, all active spool files are closed, all virtual devices (including temporary minidisks and virtual disks in storage) are detached (virtual disks in storage are also destroyed if you are the last user), dedicated devices are detached, all Concurrent Copy (CONCOPY) sessions on your virtual machine are terminated, and an accounting record is created for your session.
3. The LOGOFF command performs a system-reset-clear function on your virtual machine as if the SYSTEM CLEAR command had been processed. The effects of this system-reset-clear function are described in detail in the description for the SYSTEM CLEAR command.
4. Always log off your display in addition to turning off the power; turning off your display is not the same as logging off.

If you turn off the power at your display without logging off, your virtual machine is logged off at some installation-defined grace period (usually 15 minutes) after the host system determines that your display has been turned off. If you again turn on the display, your virtual machine is disconnected. You can reconnect the display to your virtual machine by logging on within the grace period; if you do not log on within the interval, your virtual machine is automatically logged off.

5. If you specify the HOLD option on an SNA/CCS terminal, the command is not valid, and an error message is issued. If you specify the HOLD option on a non-SNA TTY display terminal, or a logical terminal, it is accepted and processed. The HOLD option is accepted but ignored on all other terminals.
6. If your installation has coded the E3270HLD feature in the system real I/O configuration file for your TTY display terminal connected to your DACU control unit 7171, the telecommunication connection always remains in effect, regardless of the HOLD option.

## LOGOFF

7. Users who are being logged off from the system will be given QUICKDSP designation to expedite the logoff of the user.
8. The LOGOFF command will fail if issued when VMRELOCATE is in progress.
9. When the LOGOFF process begins to release guest memory, the user becomes unknown to most of the Control Program and can be logged on again as a new instance while the release of memory continues. For a guest with a large amount of memory instantiated, the release process can take a considerable amount of time. Accordingly, unless there are sufficient additional resources available, it is advisable to avoid restarting a workload on the new instance that consumes substantial memory and instead to perform maintenance or other activities that occasioned the LOGOFF.

Several commands will identify a guest that is in the memory release phase of LOGOFF. For all these command responses, alphabetic characters in the guest user identifier will have been translated to lower case. QUERY NAMES will show the guest as LOF; LOCATE VMDBK with an operand that matches the lower case guest user ID will show the VMDBK type as LOGOFF; and INDICATE PAGING will show LOGOFF in a new STATUS column for the guest.

## Responses

Response 1:

```
CONNECT= hh:mm:ss VIRTCPU= mmm:ss.hs TOTCPU= mmm:ss.hs
LOGOFF AT hh:mm:ss zone weekday mm/dd/yy
```

### **CONNECT= hh:mm:ss**

is the actual clock time in hours, minutes, and seconds spent in the current session. The maximum value for this field is 99:59.59. A time value larger than the maximum will be indicated by this value.

### **VIRTCPU= mmm:ss.hs**

is the virtual processor time in minutes, seconds, and hundredths of seconds used in the current session. The maximum value for this field is 999:59.99. A time value larger than the maximum will be indicated by this value. If multithreading is enabled, this is reported as MT-1 equivalent time.

### **TOTCPU= mmm:ss.hs**

is the total processor time in minutes, seconds, and hundredths of seconds (including virtual and overhead) used in the current session. The maximum value for this field is 999:59.99. A time value larger than the maximum will be indicated by this value. If multithreading is enabled, this is reported as MT-1 equivalent time.

These times are either the elapsed time for the entire session or the elapsed time since the ACNT command was entered for this user.

### **LOGOFF AT hh:mm:ss**

is the current time in hours, minutes, and seconds of your logoff.

### **zone**

is the time zone.

### **weekday**

is the current day of the week.

### **mm/dd/yy**

is the date in month/day-of-month/year format.

The system also responds with one of the following, depending on the type of terminal being used:

<b><u>Type of Terminal</u></b>	<b><u>Message</u></b>
3270 family	Press ENTER or CLEAR key to continue
SNA/CCS terminal	Press ENTER key to continue

Pressing the appropriate key on your terminal causes the logo to appear on the terminal, which readies the terminal for the next session. For terminals not listed above, control automatically returns to CP, and the logo is displayed.

Response 2:

```
{type {rdev} } LOGOFF AS userid     USERS = nnnnn
  {      {ldev} }
  {luname}
  {SYSC }
```

is the response sent to the primary system operator when you log off. If your virtual machine was logged on using the AUTOLOG command, this response is sent to both the primary system operator and the user who issued AUTOLOG.

**type**

is the user's display type.

**rdev**

**ldev**

is the real or logical device number of the user's display.

**luname**

identifies an SNA/CCS terminal controlled by a VTAM service machine. It is the name from the VTAM definition of the terminal as an SNA logical unit.

**SYSC**

identifies the system console.

**userid**

identifies the user who is logging off.

**USERS = *nnnnn***

is the number of users still on the system.

**Messages**

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP6061I APPC wait canceled; virtual machine has been reset.

## LOGON

## Authorization

Privilege Class: Any

## Purpose

Use LOGON or LOGIN to access the virtual console of the specified virtual machine (*userid*).

## Operands

### *userid*

is the identifier assigned to you in the system directory.

### *password*

is the word or phrase that proves your identity to the system. If you omit *password*, the system will prompt you for it.

Passwords longer than 8 characters or that contain special characters such as blanks, called password phrases, are permitted only when an external security manager (ESM), such as RACF<sup>®</sup>, is used. Check with your system administrator to find out if an ESM is in use and if it is configured to allow password phrases. Refer to [“Usage Notes” on page 664](#) for more information about passwords.

### **ACcount** *nnnnnnnn*

specifies an alternate account number to be assigned to your virtual machine at logon time. This account number must be valid in order for the LOGON command to be completed successfully. If you do not specify this option, the primary (or first) account number specified in your entry in the system directory is used.

**APL**

specifies that upon successful completion of the user logon, the control program is to use an APL or TEXT translation table for translating console input and output rather than the standard translation table. This option of the LOGON command provides the same function as the TERMINAL APL ON or the TERMINAL TEXT ON commands.

**BY *byuserid***

specifies a BYUSER for the user ID. The password of the BYUSER is used for LOGON authorization checking for the user ID. The BYUSER must be listed on a LOGONBY statement in the directory entry for the user ID to use the BY operand. Refer to usage note [“11” on page 665](#) for information on ESM considerations.

**CHANGE**

specifies the user wishes to change their password. If your system is configured with an ESM, you may be able to use the CHANGE operand to enter into a change password dialog. If your system does not use an ESM or if the ESM does not support the CHANGE operand, the operand is ignored.

**HERE**

specifies that if this user ID is already logged on, it should be disconnected from its current terminal and reconnected at the terminal where this logon is requested.

**Ipl *vdev*****Ipl *sysname***

specifies the virtual device number or named saved system that you want IPLed upon completion of your logon processing. This option overrides the IPL statement (if any) specified in your entry in the system directory. The validity of the IPL operand you specify is determined by the IPL command processor after your logon is completed; it is not verified as part of the LOGON command processing.

**NOipl**

specifies that the IPL device specified in your entry in the system directory should not be used for an automatic IPL.

**MACHine ESA****MACHine XA****MACHine XC****MACHine Z**

specifies the mode (architecture) of the virtual machine. This option overrides the MACHINE statement (if any) that is specified in your entry in the system directory. For further information on the MACHINE directory statement, see [z/VM: CP Planning and Administration](#).

**ESA** designates ESA/390 (31-bit) architecture. An ESA virtual machine initially operates in ESA/390 architecture; the guest can switch the virtual machine between ESA/390 and z/Architecture.

**XA** is supported for compatibility and is functionally equivalent to ESA.

**XC** designates ESA/XC architecture. An XC virtual machine initially operates in ESA/XC architecture; the guest can switch the virtual machine between ESA/XC and z/XC.

**Z** designates a guest that executes only in z/Architecture mode.

See usage note [“22” on page 666](#).

**NORUN**

specifies that upon successful completion of the user logon, the virtual machine is placed in a terminal CP READ state, and RUN is set OFF.

**QUIET**

suppresses the display of all informational LINK messages, system log messages, and information regarding spooled virtual reader, printer, and punch files.

**SEClabel *sssss***

specifies that the user is requesting to logon with a specific security label, identified by *sssss*. *sssss* is specified as a 1- to 8-character alphanumeric value. This operand is valid only when an ESM is installed and security label checking is enabled. For additional information, contact your security administrator.

**Storage nu**

specifies an alternate storage size to be assigned to your virtual machine. The storage size is specified in the form *nu*, where *n* is a 1- to 8-digit decimal number and *u* is the 1-character storage unit suffix:

*Table 30. Maximum Input Values for Storage Units*

Storage unit	Suffix ( <i>u</i> )	Maximum input value ( <i>n</i> )
Kilobytes	K	99999999
Megabytes	M	99999999
Gigabytes	G	99999999
Terabytes	T	16777216
Petabytes	P	16384
Exabytes	E	16

**Notes:**

1. A K specification is rounded up to a MB value.
2. The maximum input value of 99999999 for the K, M, or G suffix is not a size limit but the physical limit of the operand (8 digits plus suffix). If the maximum input value for one of these suffixes does not allow you to define the amount of storage you want, you need to use a larger storage unit.
3. An ESA/XC virtual machine can address up to 2 GB of storage in its base address space.
4. The value you specify for this option must be valid in order for the logon to be completed successfully. If you do not specify a value, the storage size defined in the user directory entry for your virtual machine is used. The maximum allowed value is the maximum storage size defined in the user directory entry for your virtual machine. The maximum cannot exceed a processor-specific limit imposed at run time.

**TEXT**

specifies that upon successful completion of the user logon, the control program is to use an APL or TEXT translation table for translating console input and output rather than the standard translation table. This option of the LOGON command provides the same function as the TERMINAL APL ON or the TERMINAL TEXT ON commands.

**FALLBack**

specifies that the user wants to perform a fallback logon.

This parameter is only relevant if an external security manager (ESM) is installed and the ESM supports this operand. Further processing may depend on ESM configuration, user authorization, or other factors. Refer to your ESM documentation for further information.

**#console\_input\_data**

is data that you want used as virtual console input in response to the first read your virtual machine issues. You may use the remainder of the command line to enter console data. The entire line, including any logical-line-end characters (#), is passed to your virtual machine.

**Note:** # refers to whatever logical-line-end character is the current system default.

**Usage Notes**

1. Upon a successful logon, CP creates your virtual machine configuration based upon information contained in the system directory.
2. Except for recognizing the system default logical-line-end character as the delimiter preceding a console\_input\_data operand, line-editing is not performed on any of the fields of the system logon screen or on responses to prompts before logon completes successfully.
3. A virtual machine is allowed to log on even though the number of users already logged on is equal to or greater than the maximum allowed by the MAXUSERS operand of the FEATURES system

configuration statement or by the SET MAXUSERS command if the user directory for the virtual machine was created using the IGNMAXU operand of the OPTION directory statement.

4. For compatibility, z/VM continues to accept the XA virtual machine designation. However, whether the virtual machine is defined as XA or ESA makes no difference when running on z/VM. A virtual machine defined as XA has the capabilities of an ESA virtual machine and is considered to be an ESA virtual machine simulating the ESA/390 architecture (or z/Architecture, if a guest has issued the instruction to change the architecture of the virtual machine).
5. CP does not support System/370 architecture (370 mode) virtual machines. If a LOGON is attempted for a virtual machine whose directory entry specifies 370 mode, the LOGON command is completed, but the virtual machine is set to XA mode instead of 370 mode. Message HCP1512E is issued to inform the user.
6. If a LOGON is attempted for a virtual machine whose directory entry specifies z/Architecture-only mode, but the relocation domain does not support that mode, the LOGON command is completed, the virtual machine is set to ESA mode instead, and message HCP1512E is issued to inform the user.
7. If you were disconnected from your virtual machine because of a console error, you have an installation-defined grace period (usually up to 15 minutes) to log on again. If you do not log on within the grace period, your virtual machine is automatically logged off. If this happens, you may have to reconstruct files and restart jobs that were interrupted by the error.
8. When you enter the LOGON command to reconnect to your virtual machine, the options NOIPL, IPL, ACCOUNT, MACHINE, SECLABEL, and STORAGE are ignored. If you enter any of these options, you receive an informational message and the value is not changed. The console-input data line is also ignored.
9. If your virtual machine is running in disconnected mode, and you enter the LOGON command to reconnect your console, certain SET and TERMINAL command operands are forced OFF. You can enter the QUERY SET and QUERY TERMINAL commands to check which functions are currently active.
10. If you or a system administrator has used the COMMAND directory statement to specify commands that will be automatically issued when a virtual machine is logged on, be aware that you may receive additional responses as a result of those commands whenever you log on. See the [COMMAND directory statement](#) in *z/VM: CP Planning and Administration* for more information.
11. When an ESM such as RACF is installed, it may have other authorization criteria defined that completely replace those provided by the LOGONBY directory statement. Refer to the documentation provided with your ESM for more information.
12. Users defined with the LBYONLY operand in the password field of their USER or IDENTITY statement in the system directory may be restricted from performing functions that require password validation. If an ESM is not installed, a LOGON of a user defined with the LBYONLY operand can be done only by an authorized user using the BY option of the LOGON command. A user defined with the LBYONLY operand is not allowed to log on to any user ID using the LOGON command with the BY option. If an ESM is installed, refer to the documentation provided with your ESM for more information.  
  
Refer to the [USER Directory Statement](#) or [IDENTITY Directory Statement](#) in *z/VM: CP Planning and Administration* for more details on the LBYONLY operand.
13. If your installation is using the password suppression facility for the LOGON command (controlled by the PASSWORDS\_ON\_CMDs operand of the FEATURES system configuration statement or by the SET PASSWORD command), you cannot specify your password on the command line. You must wait for the ENTER PASSWORD prompt before you type in the password. The password is automatically masked, thus improving system security. If your installation is not using the password suppression facility for the LOGON command, you can specify your password on the command line, or you can wait for the ENTER PASSWORD prompt before you type in the password.
14. If the password suppression facility is not active for the LOGON command, allowing passwords to be specified on the command, user logon passwords defined in the system directory cannot be identical to any of the LOGON command options.
15. User IDs that are defined with the NOPASS operand are able to logon without password authorization, unless an ESM is installed. When an ESM is installed, password authorization may

be required despite the NOPASS operand. Refer to the documentation provided with your ESM for more information.

16. Passwords are restricted to a maximum of 8 characters in length unless an ESM is used. In that case, the ESM may permit passwords up to 200 characters in length. The RACF Security Server for z/VM supports passwords up to 100 characters in length. Refer to the documentation provided with your ESM to determine the maximum.
17. You must surround the password with single quotation marks or omit it entirely when it begins with a single quotation mark, begins or ends with a blank, or is entered on the command line and contains one or more blanks. You must use double quotation marks that are part of the password when the password is quoted. See [“Examples” on page 669](#).
18. Long passwords and password phrases can contain any character between X'00' and X'FF'. This range includes all upper and lower case characters, blanks, and special characters. Using characters less than X'40' is not recommended. Even though CP supports all characters, your ESM may restrict the use of some characters.
19. The disconnect performed when the HERE option is specified may take significant time to complete because of the attempt made to process the disconnect even in the case of a hung terminal.
20. The NORUN option is intended when RUN is set ON for users who wish to reconnect and get into CP READ. However, the option is always accepted with no effect in cases other than when RUN is set ON. The option is particularly helpful for users who need to enter CP commands and who are in full-screen mode with no break-key and with RUN set ON. These users can power-off their terminals to be disconnected and then reconnect using LOGON with NORUN.
21. When a z/VM system is running in a Single System Image (SSI) configuration, and an External Security Manager (ESM) has enabled checking of Mandatory Access Controls (MAC), the SECLABEL operand is not allowed for virtual machines defined by an IDENTITY statement in the z/VM User Directory.
22. An ESA (or XA) virtual machine will be put into either full ESA/390 mode or ESA/390 compatibility mode, depending on the level of ESA/390 capability available in the machine where the virtual machine is logged on or in the virtual machine's relocation domain. ESA/390 compatibility mode allows a subset of ESA/390 functionality sufficient for CMS and GCS, but lacks advanced functions like dynamic address translation (DAT). For details on ESA/390 compatibility mode, see [z/Architecture Principles of Operation](#).

## Responses

Response 1:

- 3270 Display Version:

```
ENTER PASSWORD (It will not appear when typed):
```

This version of the password prompt is used for 3270 family displays. It indicates that your user ID has been accepted. Enter your password.

- Line-Mode ASCII Version:

```
ENTER PASSWORD:
```

This version of the password prompt is used for line-mode ASCII terminals. It also indicates that your user ID has been accepted. Enter your password.

Response 2:

```
z/VM Version v Release r.m, Service Level yynn (64-bit),  
built on IBM Virtualization Technology
```

**v**

is the software version level.

**r.m**

is the release and modification level.

**yynn**

is the service level which identifies the most recent RSU service tape that has been applied, where *yy* is the last two digits of the year and *nn* is the sequential number of the RSU tape for that year.

Response 3:

```
LOGMSG - hh:mm:ss zone day-of-week mm/dd/yy
```

indicates the time and date at which the system log message was recently revised and is displayed only when there are log messages to be displayed. All lines of the log message for which the first character is an asterisk are displayed. If you wish to see all of the system log messages, enter the QUERY LOGMSG command.

**hh:mm:ss**

is the time when the log message was last updated.

**zone**

is the time zone.

**day-of-week**

is the day when the log message was last updated.

**mm/dd/yy**

is the month/day/year when the log message was last updated.

Response 4:

```
FILES: nnnn RDR, nnnn PRT, nnnn PUN
       NO   NO   NO
```

where *nnnn* is the number of spool files of each type.

Response 5:

One of the following appears, indicating the time, day of the week, and date at which the logon or reconnect is complete.

```
LOGON AT hh:mm:ss zone weekday mm/dd/yy
```

```
RECONNECTED AT hh:mm:ss zone weekday mm/dd/yy
```

For the value of the variable fields, see Response 2.

Response 6:

One of the following is the response to the primary system operator.

```
{type {rdev}} LOGON AS userid USERS = nnnn [FROM ipadr]
{
  {ldev}}
  {lname}
  {SYSC}
```

```
{type {rdev}} RECONNECT userid USERS = nnnn [FROM ipadr]
{
  {ldev}}
  {lname}
  {SYSC}
```

```
{type {rdev}} LOGON AS userid USERS = nnnn BY byuserid [FROM ipadr]
{
  {ldev}}
  {lname}
  {SYSC}
```

```
{type {rdev}} RECONNECT userid USERS = nnnn BY byuserid
{
  {ldev}}
  {lname}
  {SYSC}
```

## LOGON

**type**

is the display type.

**rdev****ldev**

is the real or logical device number of the user's display.

**luname**

identifies an SNA/CCS terminal controlled by a VTAM service machine. It is the name from the VTAM definition of the terminal as an SNA logical unit.

**SYSC**

identifies the system console.

**userid**

identifies the user ID of the virtual machine that just completed logging on to the system.

**USERS = nnnnn**

is the number of users on the system.

**FROM ipadr**

is the IP address.

An IPv4 address is displayed in dotted-decimal format.

**Example:** 9 . 130 . 44 . 144

An IPv6 address is displayed in compressed format ("::" designates multiple 16-bit groups of zeros).

**Example:** The following is an IPv6 address:

```
F802:0000:0000:0000:0000:0000:0A00:0001
```

This address is displayed in compressed format as:

```
F802::A00:1
```

**BY byuserid**

identifies the user ID that logged on the virtual machine. This information is only provided when the LOGON command is entered with the BY operand.

Response 7:

```
DISCONNECT AT hh:mm:ss zone weekday mm/dd/yy BY LOGON FROM {type}{rdev}}
                                                              {
                                                              {ldev}}
                                                              {luname}
                                                              {SYSC}
                                                              }
```

is the response sent to the terminal from where your user ID is disconnected prior to processing a reconnect.

**type**

is the display type.

**rdev****ldev**

is the real or logical device number of the terminal from where the LOGON was entered with the HERE option.

**luname**

identifies an SNA/CCS terminal controlled by a VTAM service machine. It is the name from the VTAM definition of the terminal as an SNA logical unit.

**SYSC**

identifies the system console.

Response 8:

```
DISCONNECTED FROM {type} {rdev}}
                   {
                   {ldev}}}
```

```
{luname }
{SYSC }
```

is the response you receive when your user ID is disconnected from another terminal prior to reconnecting.

**type**

is the display type.

**rdev****ldev**

is the real or logical device number of the terminal from where the user was disconnected.

**luname**

identifies an SNA/CCS terminal controlled by a VTAM service machine. It is the name from the VTAM definition of the terminal as an SNA logical unit.

**SYSC**

identifies the system console.

Response 9:

```
{type{rdev}} DISCONNECT userid USERS=nnnnn BY LOGON FROM {type{rdev}}
{ {ldev}} { {ldev}}
{luname } {luname }
{SYSC } {SYSC }
```

is the response sent to the primary system operator when a disconnect for your user ID is performed prior to a reconnect.

**type**

is the display type from where the user was disconnected.

**rdev****ldev**

is the real or logical device number of the terminal from where the user was disconnected.

**luname**

identifies an SNA/CCS terminal controlled by a VTAM service machine. It is the name from the VTAM definition of the terminal as an SNA logical unit.

**userid**

is the user ID of the virtual machine for which the disconnect and log on was requested.

**USERS = nnnnn**

is the number of users remaining on the system after the disconnect is performed

**FROM type**

is the display type from where the LOGON command was issued.

**rdev****ldev**

is the real or logical device number of the terminal from where the LOGON command was entered.

**luname**

identifies an SNA/CCS terminal controlled by a VTAM service machine. It is the name from the VTAM definition of the terminal as an SNA logical unit.

**SYSC**

identifies the system console.

**Examples**

Example 1:

If you enter LOGON with a password that contains one or more blanks, you must surround it in single quotation marks to preserve any mixed-case characters and imbedded blanks.

```
logon alan 'now is the time for all good men' noip1
```

Example 2:

When you attempt to enter a password containing one or more single quotation marks, they must be entered as 2 single quotation marks.

```
logon mike 'That' 's Great!'
```

## Messages

- HCP107E *userid vdev* not linked; not in CP directory
- HCP108E *userid vdev* not linked; valid *valid* not mounted
- HCP109E *userid vdev* not linked; {Excessive link indirections|invalid link device}
- HCP110E *userid vdev* not linked; *type vdev* already defined
- HCP117E Userid *userid* not linked; valid *valid* conflict
- HCP174E Paging I/O error; IPL failed
- HCP196I Secondary user not in CP directory
- HCP205I The virtual=real area is not available because it was not generated.
- HCP264I One or more options are ignored during reconnect processing – *option(s)*
- HCP266E An account number was not supplied or is invalid.
- HCP288E LOGON from the initial screen was unsuccessful
- HCP298E *userid vdev* not linked; request denied
- HCP361E LOGOFF/FORCE pending for user *userid*
- HCP365I Requested language *langid* is unavailable. Language *langid* set. RC=*rc*
- HCP413E Command processing cannot complete due to a spool paging error.
- HCP475I Fatal I/O error trying to read directory from *valid* { for user *userid*}
- HCP799E IPL failed due to insufficient or faulty storage
- HCP844E The device is not defined due to an invalid control unit type.
- HCP849E A *userid* must be specified with the spoolid
- HCP1015E Insufficient storage is available to satisfy your request.
- HCP1128E FCP *vdev* not attached; USERACCESSID not supported on this device.
- HCP1150E DASD {*rdev|vdev*} is not a valid base exposure.
- HCP1151E *userid vdev* has not been linked because it is not within CP volume cylinder extents.
- HCP1152E *userid vdev* has not been linked because it would overlap system {spool|paging|temporary disk} space
- HCP1401I Expanded storage is not supported.
- HCP1454E CPU *nn* does not exist.
- HCP1501E An accounting error was encountered.
- HCP1502E The directory entry for this *userid* is in use.
- HCP1505I The device being used for LOGON conflicts with the console definition in the directory.
- HCP1510I Device *vdev* not defined; *device vdev* already defined
- HCP1512E The System/370 machine mode was requested, but CP does not support System/370 mode virtual machines; the machine mode will be set to XA instead.
- HCP1512E The z/Architecture-only machine mode was requested, but is not supported in this relocation domain. The machine mode will be set to ESA instead.
- HCP1513E Log on already in progress on {GRAF *rdev*|GRAF *ldev*|*luname*|SYSC}
- HCP1558E Command processing cannot complete.
- HCP1615E IPL LOADDEV|DUMPDEV failed because not all necessary parameters have been set.
- HCP1700I One or more virtual CPUs are not defined due to an error in the CP directory.
- HCP1830I Virtual architecture has been adjusted to permit AP Dedicated Crypto facilities not allowed in the assigned or default relocation domain.

## LOGON

- HCP2094I Requested ABSOLUTE I/O priority range falls outside range currently allowed by CP and has been changed to fit within CP's range.
- HCP2550I The console has been defined as a 3215 because a console mode of 3270 is not supported by the VTAM Service Machine controlling the real terminal.
- HCP2551E The console has been defined as a 3215 because the real device is not a 3270 display.
- HCP2553E TERMINAL BRKKEY *name* is not allowed during this session; it has been changed to PA1.
- HCP2554E TERMINAL BREAKIN GUESTCTL is not allowed during this session; it has been changed to IMMED.
- HCP2808E User ID is a CF Service Machine and may not be started by the LOGON command.
- HCP2880E *userid vaddr* is not linked, CSE LINK I/O error, code *cc*.
- HCP3224I NICDEF network configuration is ignored due to the current setting of VMLAN DNA.
- HCP6050E Your *userid* is not authorized to logon *userid userid*.
- HCP6053E You cannot issue the {LOGON|AUTOLOG|XAUTOLOG} command because the maximum number of users allowed is already logged on.
- HCP6059I One or more devices were not defined because an error occurred while reading the CP directory.
- HCP6525E External Security Manager is unavailable.
- HCP6704E Missing token at end of line

## MESSAGE

---

### Purpose

Use the MESSAGE commands to transmit message text to the virtual consoles of other active users.

### Usage Notes

(General for MESSAGE)

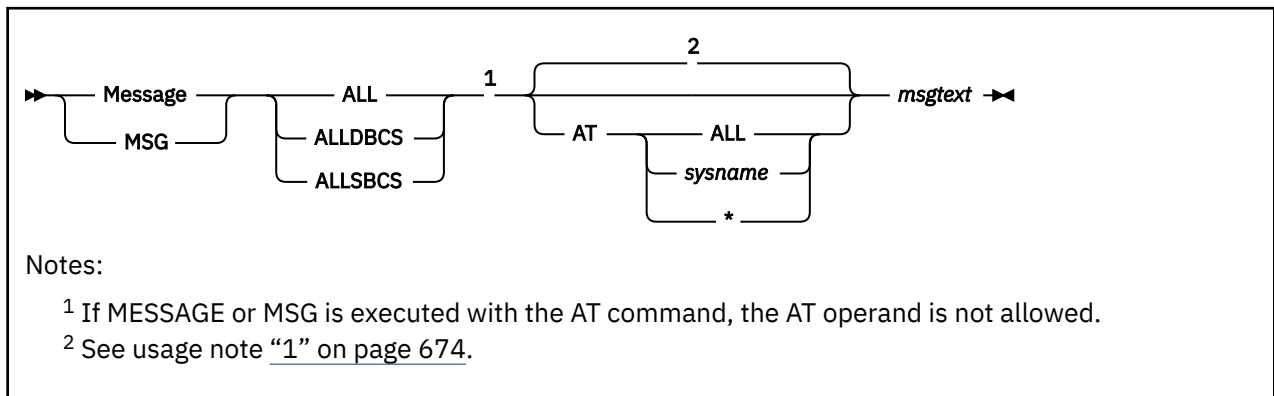

1. If a message is issued from a CMS environment, the command and the message text cannot be longer than 240 characters.  
If a message is issued from a CP environment, the command and message length is limited by the input area of the terminal.
2. If you send a message to a user who is not logged on and has not defined a secondary user, or to a user who has suppressed the receiving of messages (that is, a user who has issued the SET MSG OFF command), your message is not transmitted, and you receive an informational message. The message that was transmitted is not saved. You must send it again when the user is receiving messages.
3. The MESSAGE command routes the message to the secondary user of a disconnected virtual machine. If the secondary user is connected or the secondary user is disconnected but has a valid path to a \*MSG or \*MSGALL CP system service, the secondary user receives the message.  
If the secondary user is disconnected and there is no valid path to a \*MSG or \*MSGALL CP system service, *userid* not receiving; disconnected. is returned to the command issuer.
4. Messages are displayed only when the display device is ready to receive output. If you have a CP READ or a VM READ, messages are held until you end the read. Note, however, that if you are using an SNA/CCS terminal, messages are displayed when in CP READ or VM READ.
5. If you receive a message on a 3270 virtual console that has the alarm feature, the alarm sounds.
6. DBCS text is supported as message text for the MESSAGE commands.

### Messages

(General for MESSAGE)

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on
- HCP057I *userid* not receiving; *text*
- HCP1142E The AT option is not allowed if this command is initiated with an AT command from another system.
- HCP2970E The SSI cluster member name is missing or invalid.
- HCP2971I Specified SSI cluster member is not joined.
- HCP6600E An error was detected by installation-wide {*CP module name*|exit point 1210} - return code *nnnn*

## MESSAGE ALL

### Authorization

Privilege Class: A, B

### Purpose

Use MESSAGE ALL or MSG ALL to transmit message text to all active users and disconnected users.

### Operands

#### ALL

transmits the message to all users.

#### ALLDBCS

transmits the message to all users logged on to DBCS (double-byte character set) terminals.

#### ALLSBCS

transmits the message to all users and all disconnected users logged on to SBCS (single-byte character set) terminals.

#### AT ALL

transmits the message to all systems in the SSI cluster to which this system belongs. The lowest return code is returned to the command issuer.

#### AT *sysname*

transmits the message to a specific system in the SSI cluster to which this system belongs. The return code is returned to the command issuer.

#### AT \*

transmits the message only to the system where the command is issued. This is the default if the system is not a member of an SSI cluster.

#### *msgtext*

is the text of the message you are sending. The length of the message is limited by the number of characters remaining on the input line after the command and appropriate operand are entered. You must include at least one blank between the ALL operand and the message text. DBCS text is supported as message text.

### Usage Notes

- If the AT operand is not specified:
  - If MESSAGE or MSG is not executed with the AT command:
    - If the sender's system is not a member of an SSI cluster, the default is AT \*.

- If the sender's system is a member of an SSI cluster, the default is AT ALL, except in the following cases:
    - If the sender is defined by a multiconfiguration virtual machine definition, the default is AT \*.
    - If a potential recipient user ID is defined by a multiconfiguration virtual machine definition, the default for that user ID is AT \*.
  - If MESSAGE or MSG is executed with the AT command, the AT operand function is bypassed (there is no default), and the message is sent to the system specified on the AT command.
2. The total number of logged-on users significantly affects command processing. The command might take a long time to process and might tie up user terminals.
  3. For additional information, see [“MESSAGE” on page 673](#).

## Responses

```
hh:mm:ss * MSG FROM userid : msgtext
```

### ***hh:mm:ss***

identifies the time the message was sent to the user, in hours, minutes, and seconds.

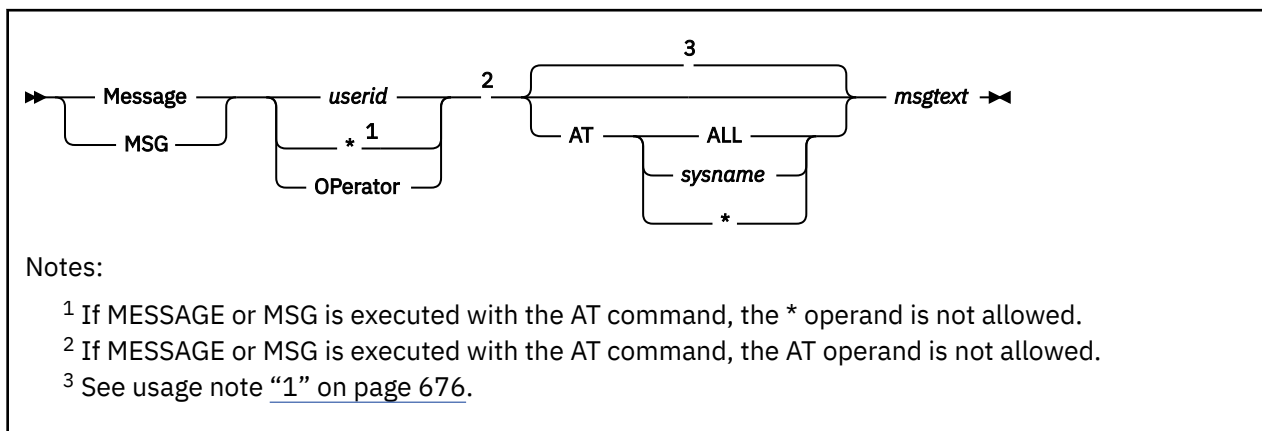

### ***userid***

identifies the user sending the message.

### ***msgtext***

identifies the message text.

## MESSAGE (User)

### Authorization

Privilege Class: Any

### Purpose

Use MESSAGE (User) or MSG (User) to send message text to a specified user ID or to the primary system operator.

### Operands

*userid*

\*

**OPerator**

identifies the user to whom you are sending a message. To send a message to yourself, specify an asterisk (\*).

Specify OPERATOR if you want to send a message to the primary system operator, regardless of the operator's user ID.

**AT ALL**

transmits the message to all systems in the SSI cluster to which this system belongs. The lowest return code is returned to the command issuer.

**AT *sysname***

transmits the message to a specific system in the SSI cluster to which this system belongs. The return code is returned to the command issuer.

**AT \***

transmits the message only to the system where the command is issued. This is the default if the system is not a member of an SSI cluster.

*msgtext*

is the text of the message you are sending. The length of the message is limited by the number of characters remaining on the input line after the command and appropriate operand are entered. DBCS text is supported as message text.

### Usage Notes

1. If the AT operand is not specified:
  - If MESSAGE or MSG is not executed with the AT command:

- If the sender's system is not a member of an SSI cluster, the default is AT \*.
  - If the sender's system is a member of an SSI cluster, the default is AT ALL, except in the following cases, when the default is AT \*:
    - If the specified user ID is OPERATOR.
    - If the specified user ID is logged on to the same system as the sender.
    - If the specified user ID or the sender is defined by a multiconfiguration virtual machine definition.
  - If MESSAGE or MSG is executed with the AT command, the AT operand function is bypassed (there is no default), and the message is sent to the system specified on the AT command.
2. You do not have to be logged on to issue the MESSAGE (User) command. However, if an external security manager (ESM) is installed on your system, the ability to send pre-logon messages might be disabled.
  3. If an ESM is installed on your system, you might not be authorized to use this command even after you have logged on. However, messages sent to or from the system operator and messages sent with the ALL option are not subject to authorization checking by the ESM. For additional information, contact your security administrator.
  4. The expression msg \* followed by text can be used to identify the current user ID of an abandoned display.
  5. For additional information, see [“MESSAGE” on page 673](#).

## Responses

Response 1:

```
hh:mm:ss * MSG FROM OPERATOR: msgtext
```

is the response received by the user when the system operator sends a message. For the contents of the variable fields, see under Response 2.

Response 2:

```
hh:mm:ss * MSG FROM
{userid }: msgtext
      {LOGNxxxx}
      {LOGLxxxx}
      {LOGVxxxx}
      {LOGMxxxx}
```

is the response received by the user when another user sends a message.

**hh:mm:ss**

identifies the time the message was sent to the user in hours, minutes, and seconds.

**userid**

**LOGNxxxx**

**LOGLxxxx**

**LOGVxxxx**

**LOGMxxx**

identifies the user sending the message. LOGNxxxx identifies the user in the process of logging on to a real device. LOGLxxxx identifies the user in the process of logging on to a logical device. LOGVxxxx identifies the logical unit name of the SNA/CCS terminal to which a user is in the process of logging on; it is the name from the VTAM definition of the terminal as an SNA logical unit. If the user is not logged on, LOGNxxxx or LOGLxxxx identifies the line number of the device from which the message originated. LOGMxxx identifies the user in the process of being relocated on to this system from another member of the SSI cluster. Userids starting with LOGN, LOGL, and LOGV are restricted.

**xxx or xxxx**

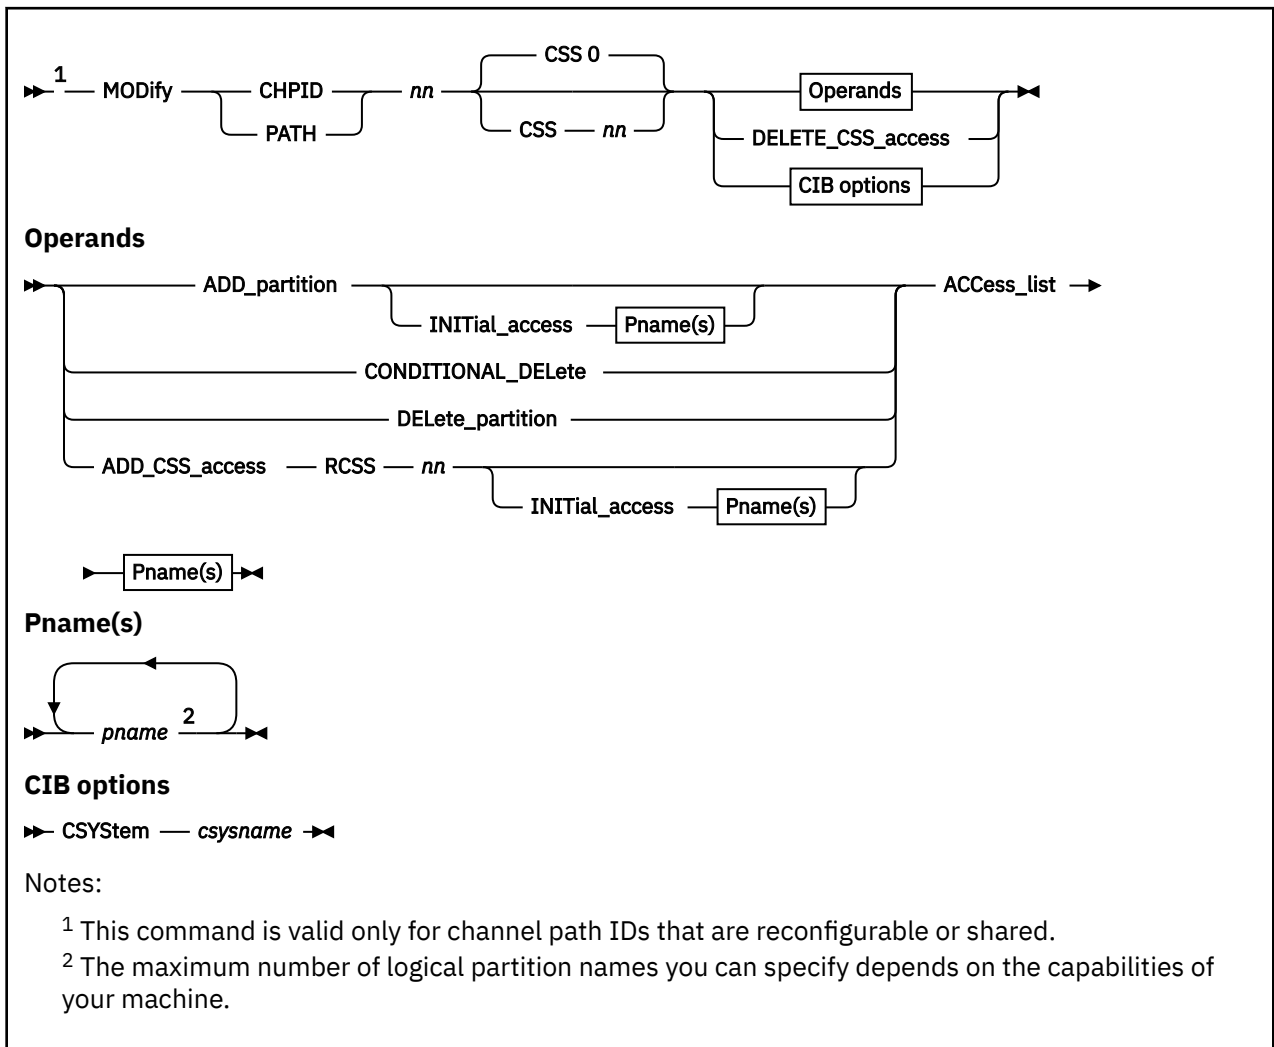

can be any character, number, or symbol.

## MESSAGE (User)

***msgtext***

identifies the message text.

# MODIFY CHPID / PATH

## Authorization

Privilege Class: B

## Purpose

Use MODIFY CHPID or PATH to change the definition of an existing reconfigurable or shared channel path identifier (CHPID) in the I/O configuration.

## Operands

**nn**

is the number of the channel path ID that you are changing. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

**CSS nn**

is the channel-subsystem ID where the channel path is to be modified. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'. Your machine might support a lower maximum value.

**Note:** This parameter and other parameters that identify different channel-subsystem IDs require that the logical channel-subsystem facility be installed.

**ADD\_partition**

tells CP that you want to add one or more logical partitions to the list of logical partitions that have access to this channel path in the specified or implied channel-subsystem image.

**CONDITIONAL\_DELeTe**

tells CP that you want to delete one or more logical partitions from the list of logical partitions that have access to this channel path in the specified or implied channel-subsystem image, but only if the channel path is not presently in use and configured to the logical partition.

**DELeTe\_partition**

tells CP that you want to delete one or more logical partitions from the list of logical partitions that have access to this channel path in the specified or implied channel-subsystem image, regardless of whether the channel path is in use or configured to one or more logical partitions.

**ADD\_CSS\_access**

tells CP that you want to add the channel path to the specified channel-subsystem image. See Usage Note “1” on page 680.

**RCSS nn**

is the reference channel-subsystem image from which the channel-path characteristics are to be copied. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'. Your machine might support a lower maximum value.

**INITIAL\_access pname**

specifies the name(s) of the logical partition(s) that will have initial access to this channel path in the specified or implied channel-subsystem image. The maximum number of logical partition names you can specify depends on the capabilities of your processor. Each *pname* must be a 1- to 8-digit character alphanumeric string.

**ACCess\_list pname**

specifies the name(s) of the logical partition(s) for which access to this channel path is being added or deleted in the specified or implied channel-subsystem image. The maximum number of logical partition names you can specify depends on the capabilities of your processor. If you are deleting the logical partitions from the access list, those logical partitions must already be in the access list for this channel path in the specified or implied channel-subsystem image. Each *pname* must be a 1- to 8-digit character alphanumeric string.

**DELETE\_CSS\_access**

tells CP that you want to delete the channel path from the specified the channel-subsystem image. See Usage Note “2” on page 680.

**CSYSstem csysname**

is the name of the target system to which the CIB CHPID connects. It is the name you would see after issuing the QUERY LSYSTEM command in a z/VM system running on that target machine. The name is established via an IOCP configuration definition, HCD configuration definition (in z/OS or z/VM), or the z/VM SET LSYSTEM operator command on the target machine. The variable *csysname* must be a 1- to 8-character alphanumeric string.

**Usage Notes**

1. On a machine with multiple logical channel-subsystem images, the DEFINE PATH and DEFINE CHPID commands first define the channel path in the single specified channel-subsystem image. If the channel path is a type that can span multiple logical channel-subsystem images, then MODIFY PATH or MODIFY CHPID commands must be entered for each additional channel-subsystem image in which you want to define the channel path.
2. On a machine with multiple logical channel-subsystem images, the DELETE CHPID and DELETE PATH commands are effective only for channel paths in a single channel-subsystem image. To delete channel paths that are in more than one channel-subsystem image, you must first enter MODIFY CHPID or MODIFY PATH commands to remove all but one channel-subsystem image. Then a DELETE CHPID or DELETE PATH command can be entered.

3. After successfully entering this command, you will have changed the software's view of the I/O configuration and part of the hardware's view: the active I/O configuration in the hardware system area (HSA). You should also change the other part of the hardware's view: the machine's active I/O configuration data set (IOCDS) file.

To change the machine's IOCDS file, you must:

- a. Update the IOCP source file.
  - b. Run the IOCP utility (see [“IOCP” on page 2203](#)) against the updated IOCP file. If the IOCP utility runs without errors, it downloads the new IOCDS file to the SE hard disk.
  - c. Issue the SET IOCDS\_ACTIVE command (see [“SET IOCDS\\_ACTIVE” on page 1525](#)) to make the new IOCDS file the active file that the processor will use during the next power-on reset (POR).
4. For more information about [Dynamically Changing Channel Paths \(CHPIDs\)](#) definitions in your I/O configuration, see *z/VM: I/O Configuration*.
  5. To define a new channel path ID on the system, use the DEFINE CHPID or PATH command. (See [“DEFINE CHPID / PATH” on page 132](#).)
  6. To delete an existing channel path ID on the system, use the DELETE CHPID or PATH command. (See [“DELETE CHPID / PATH” on page 259](#).)
  7. To change the definition of an existing nonreconfigurable channel path ID on the system, you must:
    - a. Delete the existing channel path definition, using the DELETE CHPID or PATH command.
    - b. Redefine the channel path definition, using the DEFINE CHPID or PATH command.
  8. To display the status of a specific logical channel path and the devices with that logical channel path installed or to display the type of a specific logical channel path, use the QUERY CHPID command. (See [“QUERY CHPID” on page 791](#).)
  9. To display the physical status of all 256 of the machine's channel paths, use the QUERY CHPIDS command. (See [“QUERY CHPIDS” on page 796](#).)
- Note:** If the channel path is in single channel service (SCS) mode, it will appear as "not configured" in the display.
10. To display the logical and physical status of the channel paths installed on one or more devices, use the QUERY PATHS command. (See [“QUERY PATHS” on page 1064](#).)

## Responses

Response 1:

To add 2 partitions to a reconfigurable channel path, enter the following:

```
modify chpid 1f add access_list vm6 vm9
Channel path configuration change completed successfully
Ready;
```

Response 2:

To delete 2 logical partitions from a reconfigurable channel path, enter the following:

```
modify chpid 1f conditional_delete access_list vm1 vm5
Channel path configuration change completed successfully
Ready;
```

Response 3:

To add access for an existing channel path to an additional channel-subsystem image, enter the following:

```
mod chpid 43 css 2 add_css rcss 1 init vm1 acc vm1 vm2 vm3
Channel path configuration change completed successfully
Ready;
```

Response 4:

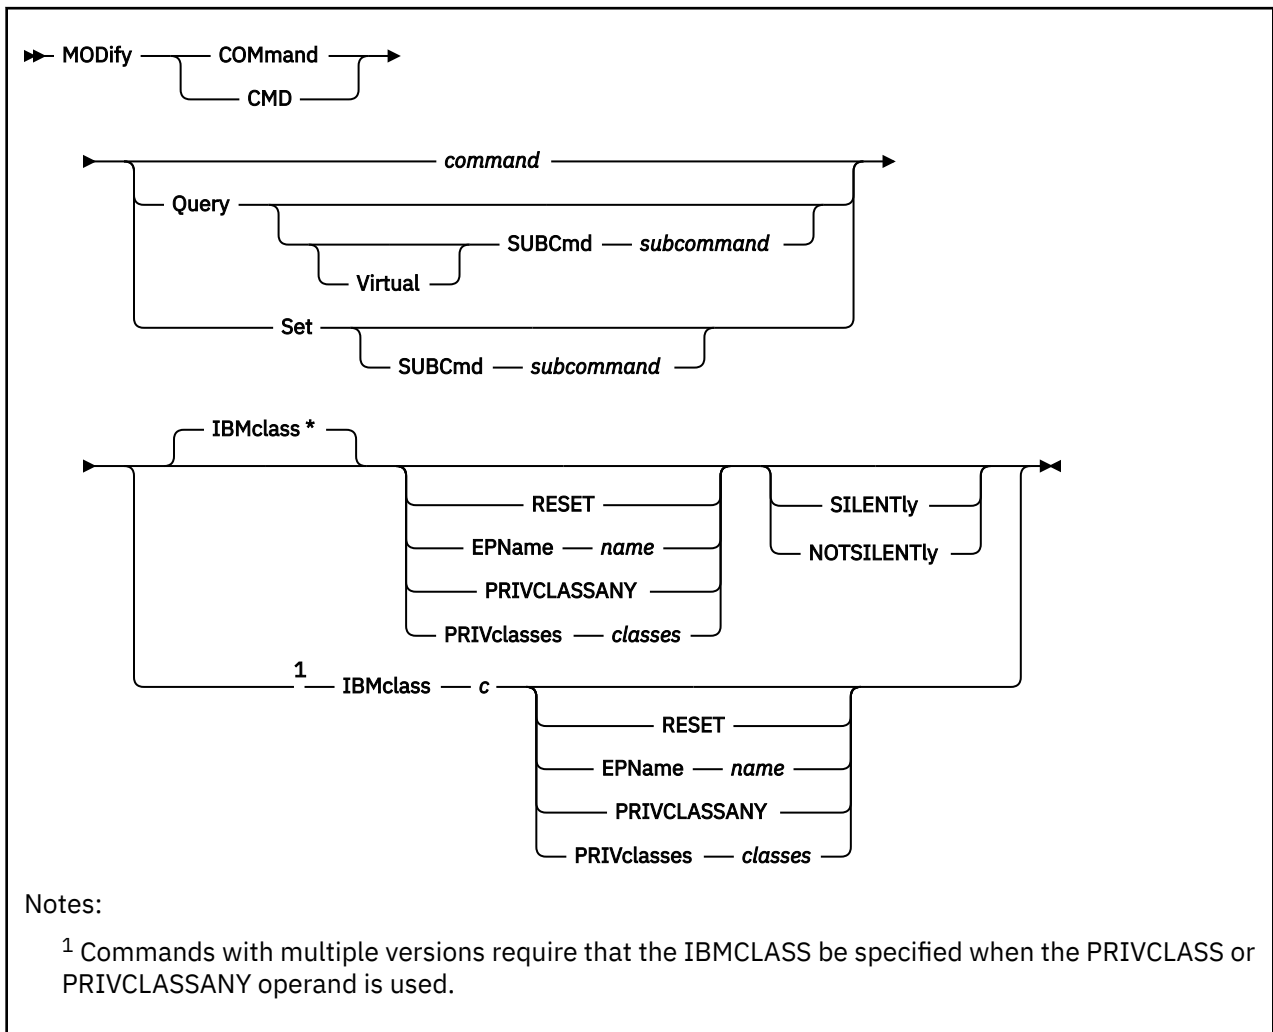

To change the name of the target system to which a CIB channel path connects, enter the following:

```
mod chpid 81 css 2 csystem machnum1
Channel path configuration change completed successfully
Ready;
```

### Messages

- HCP864E Partition *pname* does not have access to CSS *nn*

- HCP6819E A dynamic I/O command is currently executing for user *userid*

## MODIFY COMMAND / CMD

### Authorization

Privilege Class: A

### Purpose

Use `MODIFY COMMAND` or `MODIFY CMD` to redefine an existing CP command on the system. For more information about specifying generic command names, see Usage Note “1” on page 685.

You can also redefine an existing CP command during initialization using the `MODIFY COMMAND` or `MODIFY CMD` configuration file statements. For more information, see [MODIFY COMMAND / CMD Statement](#) in *z/VM: CP Planning and Administration*.

### Operands

#### *command*

is the name of the existing CP command that you are overriding. The variable *command* is a 1-character to 12-character alphanumeric string.

#### Query

tells CP that you are overriding a `QUERY` command.

**Virtual**

tells CP that you are overriding a QUERY VIRTUAL subcommand.

**SUBCmd *subcommand***

is the name of the QUERY subcommand that you are overriding. The variable *subcommand* is a 1- to 12-character alphanumeric string. For more information about specifying generic subcommand names, see Usage Note [“1” on page 685](#).

**Set**

tells CP that you are overriding a SET command.

**SUBCmd *subcommand***

is the name of the SET subcommand that you are overriding. The variable *subcommand* is a 1-character to 12-character alphanumeric string. For more information about specifying generic subcommand names, see Usage Note [“1” on page 685](#).

**IBMclass \***

tells CP to redefine all versions of the specified command or subcommand. If omitted, IBMCLASS \* is the default.

**IBMclass c**

tells CP to redefine a specific version of the specified command or subcommand. The variable *c* can be any 1 of the following:

**A**

this is a system-control command to be used by the primary system operator.

**B**

this is a command for operational control of real devices.

**C**

this is a command to alter system storage.

**D**

this is a command for system-wide control of spool files.

**E**

this is a command to examine system storage.

**F**

this is a command for service control of real devices.

**G**

this is a general-use command used to control the functions of a virtual machine.

**O**

(zero) this command has no specific IBM class assigned.

**RESET**

tells CP to restore the command to the originally defined settings.

**EPName *name***

tells CP the name of the entry point that contains the code to process the command. The variable *name* must be a 1-character to 8-character string. The first character must be alphabetic or one of the following special characters: dollar sign (\$), number sign (#), underscore (\_), or at sign (@). The rest of the string can be alphanumeric characters, the 4 special characters (\$, #, \_, and @), or any combination thereof.

**PRIVCLASSANY**

tells CP that users with any privilege class can issue the command that you are redefining.

**PRIVclasses *classes***

tells CP that only users with one or more of the specified privilege classes can issue the command that you are redefining. Whatever you specify on this operand will replace the current privilege classes. The variable *classes* is 1 or more privilege classes in the range A through Z, 1 through 6, or an asterisk (\*). Privilege class \* indicates all privilege classes (A-Z and 1-6).

**Note:** If you want more than one privilege class, specify your classes in one string of characters. Do not separate the classes with blank spaces. For example, specify "privclasses abc123", not "privclasses a b c 1 2 3".

### SILENTly

tells CP that the responses from the command you are redefining can be suppressed by invoking it using the SILENTly command. For more information, see [“SILENTly” on page 1798](#).

**Note:** Response suppression is supported only for the ATTACH, DETACH, and GIVE commands.

### NOTSILENTly

tells CP that the responses from the command you are redefining cannot be suppressed.

## Usage Notes

1. If you are making similar changes to several QUERY (or SET) subcommands that share common characters, you can use a generic name rather than issuing multiple MODIFY COMMAND or CMD commands. A generic name is a 1- to 12-character alphanumeric string with asterisks (\*) in place of one or more characters and percent signs (%) in place of exactly one character. For example:

```
modify command query subcmd tr*c% ...
```

redefines all QUERY subcommands that start with TR and have C as their next-to-last character.

2. The subcommands that make up the set of QUERY subcommands are divided into two groups and are controlled by two separate MODIFY commands. For example, QUERY DASD is a subcommand and QUERY VIRTUAL DASD is a separate subcommand. You must specify the VIRTUAL operand on the MODIFY command if you wish to change the QUERY VIRTUAL DASD subcommand. Because of the additional granularity that is provided by the MODIFY command, you must issue two MODIFY commands if you wish to change both the virtual and non-virtual subcommands of QUERY. For example, to change all versions of the QUERY DASD and QUERY VIRTUAL DASD subcommands so that only user privilege class "X" can issue them, enter the following:

```
modify cmd query virtual subcmd DASD ibmc * priv x
modify cmd query subcmd DASD ibmc * priv x
```

The first MODIFY command changes the QUERY VIRTUAL subcommands while the second changes the QUERY subcommands.

3. Several commands in the system share generic command control blocks. For example, QUERY 000E (Class B version) shares the same generic command control block with QUERY L00E (Class B version). The determination of the actual command being issued is not made until the command handler gets control. The generic command blocks exist only for Class B and G commands. In addition, they exist on the virtual subcommand chain. In order to change these commands, you must specify the "VIRTUAL SUBCMD \*" and the appropriate IBMCLASS. For example, to add a user privilege Class X to the Class B version, you would enter the following:

```
modify cmd query virtual subcmd * ibmc b priv bx
```

For more information, refer to [Modifying a Command in z/VM: CP Planning and Administration](#).

4. To define a new CP command or a new version (by IBM class) of an existing CP command, use the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD” on page 143](#)).
5. To define a new alias for an existing CP command, use the DEFINE ALIAS command (see [“DEFINE ALIAS” on page 127](#)).
6. Once defined, an alias name cannot be used again. An alias cannot be modified or eliminated; it can only be disabled.
7. To load the command processing code into the system execution space, use the CPXLOAD command (see [“CPXLOAD” on page 111](#)).
8. To activate a CP command:

## MODIFY COMMAND / CMD

- While defining it, use the ENABLE operand of the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD” on page 143](#)).
  - After defining it, use the ENABLE COMMAND or CMD command (see [“ENABLE COMMAND / CMD” on page 460](#)).
9. To display the address of the CP command table entry block, the current IBM class, and the current privilege class for a specified CP command, use the LOCATE CMDBK command (see [“LOCATE CMDBK” on page 603](#)).
  10. To deactivate a CP command:
    - While defining it, use the DISABLE operand of the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD” on page 143](#)).
    - After defining it, use the DISABLE COMMAND or CMD command (see [“DISABLE COMMAND / CMD” on page 313](#)).
  11. To remove the command processing code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD” on page 117](#)).
  12. MODIFY COMMAND RESET will not allow a RESET to occur if the resulting command versions would have different EPNAMEs. This can occur if you change the EPNAME for a command then add a new version for that command. To avoid this restriction, you should add new versions of a command before changing the EPNAMEs associated with the command.
  13. The SILENTly and NOTSILENTly option must be applied to all versions of a command.
  14. For more information about user-defined commands, see [z/VM: CP Exit Customization](#).

## Responses

### Response 1:

To change the CP SHUTDOWN command from privilege class A to privilege class S, enter the following:

```
modify command shutdown privclasses s
Ready;
```

### Response 2:

To change the version of the CP SET PRIVCLASS command that allows users with any privilege class to issue the command to a version that allows only users with privilege class G and Z to issue the command, enter the following:

```
locate cmdbk set subcmd privc
Subcommand  CMDBK      Alias      IBMCLASS  Privilege
PRIVCLASS   12345678 *          C          C
PRIVCLASS   76543218 *          0          <ANY>
Ready;

modify cmd set subcmd privc ibmclass 0 privclasses gz
Ready;

locate cmdbk set subcmd privc
Subcommand  CMDBK      Alias      IBMCLASS  Privilege
PRIVCLASS   12345678 *          C          C
PRIVCLASS   76543218 *          0          GZ
----- 58281098 *          0          <ANY>
Ready;
```

Issuing the LOCATE CMDBK commands before and after your MODIFY COMMAND command is not necessary, but it shows you how the command definition has changed.

### Response 3:

To change all IBM class E QUERY subcommands to privilege class G, enter the following:

```
modify cmd query subcmd * ibmclass e privclasses g
Ready;
```

The preceding command does not change any QUERY VIRTUAL subcommands. To change them, enter the following:

```
modify cmd query virtual subcmd * ibmc e priv g
Ready;
```

## MODIFY CU / CNTLUNIT

### Authorization

Privilege Class: B

### Purpose

Use **MODIFY CU** or **CNTLUNIT** to change the definition of an existing control unit in the I/O configuration.

## Operands

### *nnnn*

is the number of the control unit that you are changing. The variable *nnnn* must be a 1- to 4-digit hexadecimal number between X'0000' and X'FFFE'.

### **CSS** *nn*

is the channel-subsystem image in which the control unit is to be modified. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'.

**Note:** This parameter and other parameters that identify different channel-subsystem IDs require that the logical channel-subsystem facility be installed.

### **ADD**

tells CP that you want to add one or more channel paths or unit addresses to this control unit.

### **DELeTe**

tells CP that you want to delete one or more existing channel paths or unit addresses from this control unit.

**Note:** You cannot use the DELETE operand to delete all of the existing channel paths or unit addresses from this control unit. To delete all of the existing channel paths, use the DELETE CHPID or PATH command. (See [“DELETE CHPID / PATH”](#) on page 259.) To delete all of the existing unit addresses, use the DELETE CU or CNTLUNIT command. (See [“DELETE CU / CNTLUNIT”](#) on page 263.)

### **ADD\_CSS\_access**

tells CP that you want to add the control unit to the specified channel-subsystem image. See Usage Note [“1”](#) on page 691.

### **DELETE\_CSS\_access**

tells CP that you want to delete the control unit from the specified the channel-subsystem image. See Usage Note [“2”](#) on page 691.

### **MANAged\_paths** *n*

tells CP that you want to modify the maximum number of managed channel paths which can be attached to the specified control unit or, for an ADD\_CSS\_access request, is the maximum number of managed channel paths in the specified channel-subsystem image that can be attached to the specified control unit. The variable *n* must be a 1-digit decimal number from 0 to 7.

**Note:** The number of MANAged\_paths plus the number of static paths attached to the specified control unit cannot exceed 8.

### **CHPID** *nn*

### **PATH** *nn*

tells CP which channel paths you want to add to or delete from this control unit or, for an ADD\_CSS\_access request, identifies the channel paths in the specified channel-subsystem image associated with this control unit. You can specify up to 8 channel path IDs. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

**Note:** You cannot specify managed channel paths.

### **UNIT\_Address** *nn*

### **UNIT\_Address** *nn-nn*

### **UNITADD** *nn*

### **UNITADD** *nn-nn*

tells CP which unit addresses you want to add to or delete from this control unit. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

### **ESCON**

tells CP that this control unit uses the Enterprise Systems Connection (ESCON) channel to control unit interface to transmit data through optical cables. Also, specify ESCON for a control unit that connects to ESCON unswitched channels.

**LINK\_address aa**

**LINK\_address ddaa**

**LINK\_address \***

Each link-address value you specify identifies a port on a destination switch (ESCON or FICON director) to which the control unit is connected.

The LINK\_address operand must be specified when one or more of the channel paths to the control unit are switched paths; that is, when any of the paths traverse an ESCON or FICON director and for an ESCON director the path through the director is not dedicated. When all of the channel paths are unswitched (including dedicated paths through an ESCON director), the LINK\_address operand is optional.

For an unswitched FICON channel path, the end nodes determine the link addresses used at each end. Thus you cannot specify a numeric link address to be used. If you specify a LINK\_address operand value for an unswitched FICON channel path (for example, because other paths to the control unit are switched and a "placeholder" value is required), you must specify an asterisk (\*) as the link-address value.

When any link addresses are required to be specified (for example, when one or more of the channel paths is a switched path), you must provide a link address for each channel-path identifier (PATH or CHPID) that you specified, in the same order. When no link addresses are required to be specified (for example, when all of the channel paths are unswitched paths), the link address for each ESCON channel path is determined by the hardware processor, and the link address for each FICON channel path is negotiated between the hardware endpoints.

The link address is a one or two digit hexadecimal value for control units connected to an ESCON channel. The link address is a one, two, three, or four digit hexadecimal value for control units connected to a FICON channel. Leading zeroes can be omitted, except that an actual *dd* value of zero (see below) must be specified with at least one digit.

*aa* is the one-byte port-area address in an ESCON or FICON director to which the control unit is connected. This address must be a one or two digit hexadecimal number between X'01' and X'FE' for ESCON directors, and between X'00' and X'FF' for FICON directors.

Link addresses for channel paths having dedicated (unswitched) connections through an ESCON director can be arbitrary within the above-specified range, but it is recommended that the actual port-area address be used.

*ddaa* is the first two bytes of a standard three-byte fibre-channel port address. The third byte of a standard port address is used for fibre-channel arbitrated loops, which are not supported for FICON channels and therefore you do not specify. This two-byte form of the link address is required when the channel path is a FICON channel path that traverses more than one FICON director to reach any of the channel-path's destination control units.

This means that if the channel path traverses more than one FICON director to reach this control unit, a two-byte link address is required. In addition, if the channel path traverses only one FICON director to reach this control unit, but the same channel path traverses more than one FICON director to reach some other control unit, a two-byte link address is required for that channel path in all control-unit definitions in which the channel path appears. That is, once a two-byte link address is required for any control unit on a channel path, a two-byte link address is required for all control units on that channel path.

*dd* is the switch address (or domain identifier) of the destination FICON director (for example., the switch to which the control unit is directly connected), and *aa* is the port-area address within that FICON director. The link address must be a three to four digit hexadecimal number between X'0000' and X'FFFF'.

One-byte and two-byte link addresses can be mixed within the LINK\_address operand, according to the requirements for each channel path. You can choose to use a two byte link address when only a one byte address is required as long as the FICON director is configured with the high-integrity attributes (see the *IOCP User's Guide* for more information).

**CU\_LOGICAL\_address nn****CUADD**

is the logical address of the control unit that you are changing. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FE'. If omitted, the default is X'00'.

**Type CF**

tells CP that this control unit is connected to coupling facility channel paths. Coupling facility channel paths include coupling facility sender (CFS), coupling facility receiver (CFR), coupling facility peer (CFP), cluster bus sender (CBS), cluster bus receiver (CBR), cluster bus peer (CBP), or internal coupling peer (ICP) channel paths.

**RCSS nn**

is the reference channel-subsystem image from which the control unit attributes are to be copied for the specified coupling-facility control unit that is being added to the additional channel-subsystem image specified by the *CSS nn* parameter. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'.

**Usage Notes**

1. On a machine with multiple logical channel-subsystem images, the DEFINE CU and DEFINE CNTLUNIT commands first define the control unit on channel paths within the single specified channel-subsystem image. If the control unit is connected to channel paths in more than one channel-subsystem image, then MODIFY CU or MODIFY CNTLUNIT commands must be entered to define the control unit's connections to each group of channel paths in the additional channel-subsystem images.
2. On a machine with multiple logical channel-subsystem images, the DELETE CU and DELETE CNTLUNIT commands are effective only for control units in a single channel-subsystem image. To delete control units that are in more than one channel subsystem image, you must first enter MODIFY CU or MODIFY CNTLUNIT commands to remove all but one channel-subsystem image. Then a DELETE CU or DELETE CNTLUNIT command can be entered.
3. After successfully entering this command, you will have changed the software's view of the I/O configuration and part of the hardware's view: the active I/O configuration in the hardware system area (HSA). You should also change the other part of the hardware's view: the active I/O configuration data set (IOCDS) file on the support element (SE) hard disk.  
To change the IOCDS file on the SE hard disk, you must:
  - a. Update the IOCP source file.
  - b. Run the IOCP utility (see “IOCP” on page 2203) against the updated IOCP file. If the IOCP utility runs without errors, it downloads the new IOCDS file to the SE hard disk.
  - c. Issue the SET IOCDS\_ACTIVE command (see “SET IOCDS\_ACTIVE” on page 1525) to make the new IOCDS file the active file that the processor will use during the next power-on reset (POR).
4. For more information about changing control unit definitions in your I/O configuration, see [Dynamically Changing Channel Paths \(CHPIDs\)](#) in *z/VM: I/O Configuration*.
5. To define a new control unit on the system, use the DEFINE CU or CNTLUNIT command. (See “DEFINE CU / CNTLUNIT” on page 161.)
6. To delete an existing control unit on the system, use the DELETE CU or CNTLUNIT command. (See “DELETE CU / CNTLUNIT” on page 263.)

**Responses**

Response 1:

To add unit addresses X'01' through X'1F' to existing control unit 1200, enter the following:

```
modify cu 1200 add unit_address 01-1f
Control unit configuration change completed successfully
Ready;
```

Response 2:

To add a link address of X'F4' and a control unit logical address of X'00' to channel path 19 on control unit 2F00, enter the following:

```
mod cu 2f00 add chpid 19 escon link_addr f4 cu_logical_addr 00
Control unit configuration change completed successfully
Ready;
```

Response 3:

To add access to existing control unit 1210 from an additional channel-subsystem image, enter the following:

```
mod cu 1210 css 3 add_css chpid 9 link 43 cuadd 81 man 2
Control unit configuration change completed successfully
Ready;
```

### Messages

## MODIFY DEVICE / IODEVICE

### Authorization

Privilege Class: B

### Purpose

Use **MODIFY DEVICE** or **IODEVICE** to change the definition of one or more existing real devices in the I/O configuration.

**Note:** You cannot modify an open systems adapter (OSA) device. If you need to change the definition of an OSA device, you must delete the device and define it again with the new information.

### Operands

*rdev*

*rdev1-rdev2*

is the real device number (or range of real device numbers) of the device that you are changing.

**UNIT\_Address *nn*****UNITADD *nn***

is the last 2 digits of the device address or number. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

**Note:**

1. If you are specifying a range of devices (*rdev1-rdev2*), the unit address that you specify is the starting address associated with the first device in the range.

**CU\_number *nnnn*****CUNUMBR *nnnn***

is the number of one of the control units associated with the device that you are changing. The variable *nnnn* must be a 1- to 4-digit hexadecimal number between X'0000' and X'FFFE'.

**CSS *nn***

is the channel-subsystem image in which the devices are to be modified. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'.

**Note:** This parameter and other parameters that identify different channel-subsystem IDs require that the logical channel-subsystem facility be installed.

**SS *nn***

is the subchannel set with which this device is associated. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'03'.

**Note:** This parameter requires that the multiple-subchannel-set facility be installed.

**ADD**

tells CP that you are adding one or more control units or logical partition accesses to this device.

**DELeTe**

tells CP that you are deleting one or more control units or logical partition accesses from this device.

**CU\_number *mmmm*****CUNUMBR *mmmm***

tells CP which control units you are adding to or deleting from this device. You can specify up to 8 control unit numbers. Each *mmmm* must be a 1- to 4-digit hexadecimal number between X'0000' and X'FFFE'.

**PARTition *pname***

tells CP the logical partitions whose access you are adding to or deleting from this device. The maximum number of logical partition names you can specify depends on the capabilities of your machine. Each *pname* must be a 1- to 8-character alphanumeric string.

**STATus\_verification**

tells CP that the status verification facility is active for this device, causing the channel subsystem to check the device's status every time this device announces its status.

**NOSTATus\_verification**

tells CP that the status verification facility is not active for this device, and so the channel subsystem will not check the device's status.

**DASD**

tells CP that this device is a direct access storage device (DASD).

**NOTDASD**

tells CP that this device is not a direct access storage device (DASD).

**TIME\_Out**

tells CP that the I/O interface time out function is active for the following I/O interfaces between the channel and I/O device:

- 4 second time out for initial selection
- 30 second time out for data transfer.

**NOTIME\_Out**

tells CP that the I/O interface time out function is not active for this device.

**PREFerred\_channel\_path nn**

tells CP to use this channel path in the specified or implied channel-subsystem image to initiate I/O requests before trying any other channel paths from the device that you are changing. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

**Note:** A preferred path must not be specified for a device connected to a control unit for which z/OS-managed paths are being used. Although the command will not prevent you from doing so, the use of preferred paths in a managed-path environment will adversely affect z/OS's ability to manage channel-path workloads.

**NOPREFerred\_channel\_path**

tells CP that there is no preferred channel path.

**Usage Notes**

1. If you are using this command to modify I/O device characteristics, then you must specify one of each of the I/O device characteristics (IODC), because this command does not accept defaults and will not carry over any previous IODC characteristics definitions.

For example, suppose you used the following command to define a new DASD:

```
define device 16d9 unit_address a3 cu 501 dasd
```

In this command, you specified one IODC characteristic, DASD. You took the defaults for the other three: no preferred channel path, no status verification, and no time out function.

If you want to change the DASD to another device and retain the previous IODC characteristic definitions, you must specify exactly what you want:

```
mod dev 16d9 unit_addr a3 cu 501 nostat notdasd notime_out nopref
```

**Note:** This is especially true for DASD devices. If you are modifying the IODC characteristics of a DASD, you must specify DASD in your command. If you do not, the DASD will not work as expected.

2. After successfully entering this command, you will have changed the software's view of the I/O configuration and part of the hardware's view: the active I/O configuration in the hardware system area (HSA). You should also change the other part of the hardware's view: the active I/O configuration data set (IOCDS) file on the support element (SE) hard disk.

To change the IOCDS file on the SE hard disk, you must:

- a. Update the IOCP source file.
  - b. Run the IOCP utility (see [“IOCP” on page 2203](#)) against the updated IOCP file. If the IOCP utility runs without errors, it downloads the new IOCDS file to the SE hard disk.
  - c. Issue the SET IOCDS\_ACTIVE command (see [“SET IOCDS\\_ACTIVE” on page 1525](#)) to make the new IOCDS file the active file that the machine will use during the next power-on reset (POR).
3. For more information about changing real device definitions in your I/O configuration, see [I/O Configuration Definition Process in z/VM: I/O Configuration](#).
  4. To define a new device on the system, use the DEFINE DEVICE or IODEVICE command. (See [“DEFINE DEVICE / IODEVICE” on page 167](#).)
  5. To delete an existing device on the system, use the DELETE DEVICE or IODEVICE command. (See [“DELETE DEVICE / IODEVICE” on page 265](#).)
  6. To display the status of one or more real devices, use the QUERY (Real Device) command. (See [“QUERY \(Real Device\)” on page 1114](#).)

**Note:** The QUERY (Real Device) command displays the status of the device only if you issue the QUERY command in a logical partition (LPAR) that has been defined to have access to the device.

**Responses**

Response 1:

To change the IO DC characteristics of device 300, enter the following:

```
mod dev 300 unit_addr 0 cu 300 nostatus dasd notime_out nopreferred
Device configuration change completed successfully
Ready;
```

Response 2:

To add another control unit to the 32 devices at addresses X'3200' through X'321F', enter the following:

```
modify dev 3200-321f unit_addr 20 cu 1200 add cu 1300
Device configuration change completed successfully
Ready;
```

Response 3:

To delete a logical partition from the 64 devices at addresses X'4640' through X'467F', enter the following:

```
mod dev 4640-467F unit_addr 40 cu 4000 delete partition cambridg
Device configuration change completed successfully
Ready;
```

- HCP6819E A dynamic I/O command is currently executing for user *userid*.

## MODIFY DIAGNOSE

### Authorization

Privilege Class: A

### Purpose

Use MODIFY DIAGNOSE to redefine an existing DIAGNOSE code on the system.

You can also redefine an existing DIAGNOSE code during initialization using the `MODIFY DIAGNOSE` configuration file statement. For more information, see *z/VM: CP Planning and Administration*.

### Operands

#### *diag*

is the number of the DIAGNOSE code that you are redefining.

#### RESET

tells CP to stop using the customer-written DIAGNOSE code and return to using the existing DIAGNOSE code that was shipped with the z/VM product.

#### CHECKR15 YES

indicates that the diagnose router should check register 15 upon return from the diagnose handler.

#### CHECKR15 NO

indicates that the diagnose router should not check register 15 upon return from the diagnose handler.

#### EPName *name*

tells CP the name of the entry point that contains the code to process the DIAGNOSE code. The variable *name* must be a 1- to 8-character string. The first character must be alphabetic or one of the following special characters: dollar sign (\$), number sign (#), underscore (\_), or at sign (@). The rest of the string can be alphanumeric characters, the 4 special characters (\$, #, \_, and @), or any combination thereof.

#### PRIVCLASSANY

tells CP that users with any privilege class can issue the DIAGNOSE code that you are redefining.

**PRIVclasses classes**

tells CP that only users with 1 or more of the specified privilege classes can issue the DIAGNOSE code that you are redefining. Whatever you specify on this operand will replace the current privilege classes. The variable *classes* is 1 or more privilege classes in the range A through Z, 1 through 6, or an asterisk (\*). Privilege class \* indicates all privilege classes (A-Z and 1-6).

**Note:** If you want more than one privilege class, specify your classes in one string of characters. Do not separate the classes with blank spaces. For example, specify "privclasses abc123", not "privclasses a b c 1 2 3".

**Usage Notes**

1. To define a new DIAGNOSE code, use the DEFINE DIAGNOSE command (see [“DEFINE DIAGNOSE”](#) on page 172).
2. To load the DIAGNOSE processing code into the system execution space, use the CPXLOAD command (see [“CPXLOAD”](#) on page 111).
3. To activate a new DIAGNOSE code:
  - While defining it, use the ENABLE operand of the DEFINE DIAGNOSE command (see [“DEFINE DIAGNOSE”](#) on page 172).
  - After defining it, use the ENABLE DIAGNOSE command (see [“ENABLE DIAGNOSE”](#) on page 463).
4. To display information about a DIAGNOSE code (status, entry point name, and privilege class), use the QUERY DIAGNOSE command (see [“QUERY DIAGNOSE”](#) on page 885).
5. To display the address of the CP DIAGNOSE code table block for a DIAGNOSE code, use the LOCATE DGNBK command (see [“LOCATE DGNBK”](#) on page 608).
6. To deactivate a DIAGNOSE code:
  - While defining it, use the DISABLE operand of the DEFINE DIAGNOSE command (see [“DEFINE DIAGNOSE”](#) on page 172).
  - After defining it, use the DISABLE DIAGNOSE command (see [“DISABLE DIAGNOSE”](#) on page 316).
7. To remove the DIAGNOSE processing code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD”](#) on page 117).
8. Many external security managers (ESMs) do not support DIAGNOSE codes above X'03FC'. For this reason, CP does not support DIAGNOSE codes above X'03FC'. The DIAGNOSE codes between X'0000' and X'03FC' are divided as follows:
  - X'0000' to X'00FC'**  
Reserved for IBM use
  - X'0100' to X'01FC'**  
Reserved for customer use
  - X'0200' to X'03FC'**  
Reserved for IBM use.
9. When CHECKR15 YES is specified, the diagnose router will check register 15 on return from the diagnose handler. If register 15 contains:
  - RC = 0**  
Processing was successful. Complete the guest instruction.
  - RC = 4**  
Processing failed due to a condition which would cause a guest program check. Simulate guest program interruption passed in R0.
  - RC = 8**  
Nullify the instruction.
  - RC = 12**  
Present the machine check then nullify the instruction. R2 will contain the address of the MCRBK which will contain the machine check information.

**RC = 16**

Generate machine check for processing damage, then go to HCPENDOP to terminate the instruction.

**RC = 20**

Present the machine check, then go to HCPENDOP to terminate the instruction. R2 will contain the address of the MCRBK, which contains machine check information.

**RC = 24**

Issue error message or soft abend for paging I/O error, then nullify the instruction. R1 has the message or abend number.

If a return code is invalid (negative, not a multiple of 4 or too big ( RC > 24 )), then a soft abend will occur.

10. For more information about user-defined DIAGNOSE codes, see [Creating, Controlling, and Redefining CP Commands and Diagnose Codes in z/VM: CP Exit Customization](#).

## Responses

Response 1:

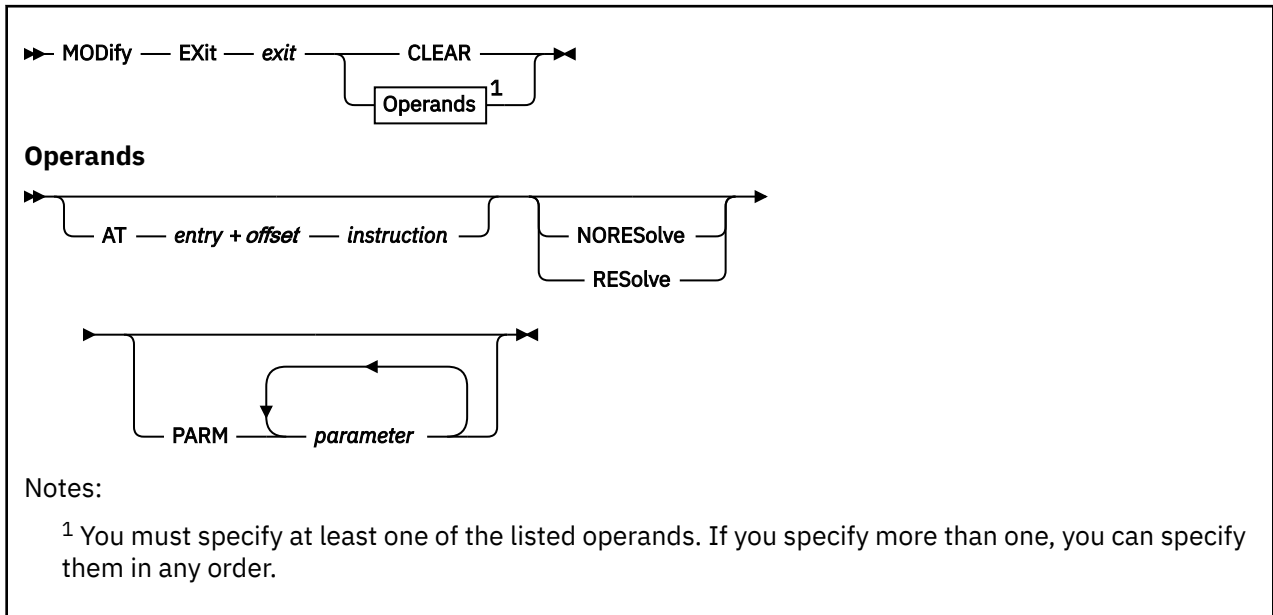

To change the privilege class for DIAGNOSE code X'7C' from "any" to R, enter the following:

```
modify diagnose 7c privclasses r
Ready;
```

## MODIFY EXIT

### Authorization

Privilege Class: A

### Purpose

Use MODIFY EXIT to redefine or remove an existing dynamic exit point.

You can also redefine or remove an existing dynamic exit point during system initialization using the MODIFY EXIT configuration file statement. For more information, see [MODIFY EXIT Statement](#) in *z/VM: CP Planning and Administration*.

### Operands

#### exit

is the number of the exit point you are redefining or removing. This value must be a hexadecimal number between X'0' and X'FFFF'. The recommended value is between X'F000' and X'FFFF', because that range is reserved for customer use. All other exit numbers are reserved for IBM, vendor, or general use.

#### CLEAR

tells CP to remove the exit.

#### AT entry + offset instruction

identifies the new location for the exit point you are redefining and the instruction that is located at the exit point. The variable *entry* must be a 1-to-8-character string. The first character must be alphabetic or one of the following special characters: \$ (dollar sign), # (number sign), \_ (underscore), or @ (at sign). The rest of the string can be alphabetic or numeric characters, the four special characters (\$, #, \_, or @), or any combination. The variable *offset* must be a 1-to-4-character even hexadecimal number between X'0' and X'FFFE'. The variable *instruction* must be a 2-, 4-, or 6-character hexadecimal number.

#### NORESolve

tells CP to resolve the entry points associated with this exit number the first time they are called.

**RESolve**

tells CP to resolve the entry points associated with this exit number when the association is first established. Any existing associated entry points are resolved immediately.

**PARM parameter**

is a list of one or more parameters to be supplied to the exit. Five kinds of tokens can be used to define a parameter:

1. Addresses: strings up to eight characters long, consisting of the hexadecimal digits 0 through 9 and A through F.
2. General Registers: strings beginning with G or R, followed by a decimal number between 0 and 15 or a hexadecimal digit, designating the contents of a general register.
3. Indirection: a percent sign (%), which causes the contents of an address or the contents of an address in a register to be used instead of the address or register contents itself.
4. Arithmetic: a plus sign (+) or minus sign (-).
5. Displacement: strings of up to four hexadecimal digits.

Each parameter string specifies how to combine these tokens to generate a parameter value to be passed to an exit routine. The following is a Backus-Naur definition of the syntax of a parameter:

```
<parameter> ::= <anchor> | <anchor><vector>
<anchor> ::= <reg> | 0..FFFFFFFF | <anchor>%
<vector> ::= <modifier> | <vector>% | <vector><modifier>
<modifier> ::= +<disp> | -<disp> | +<reg> | -<reg>
<reg> ::= G<digit> | R<digit>
<digit> ::= 0..15 | 0..9, A..F
<disp> ::= 0..7FFF
```

**Usage Notes**

1. To define a new dynamic exit point, use the DEFINE EXIT command (see [“DEFINE EXIT” on page 176](#)).
2. To load the exit processing code into the system execution space, use the CPXLOAD command (see [“CPXLOAD” on page 111](#)).
3. To activate a new exit point, use the ENABLE EXITS command (see [“ENABLE EXITS” on page 465](#)).
4. To display information about an exit point (status, entry point name, and parameters), use the QUERY EXITS command (see [“QUERY EXITS” on page 907](#)).
5. To deactivate an exit point, use the DISABLE EXITS command (see [“DISABLE EXITS” on page 319](#)).
6. To remove the exit processing code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD” on page 117](#)).
7. Exit numbers are allocated as follows:
  - X'0000' to X'7FFF' are reserved for IBM use.
  - X'8000' to X'FFFF' are reserved for vendor and general use.
  - X'F000' to X'FFFF' are reserved for private customer use.
8. The RESOLVE option ensures that the entry names associated with an exit point are defined.
9. Each exit is passed a parameter list that begins with three standard parameters, see [Usage Conventions in z/VM: CP Exit Customization](#). Additional parameters, specified by the PARM operand, are optional and follow the first three in the order in which they are specified.
10. Errors (for example, addressing exceptions) during evaluation of user-defined parameters when an exit is being invoked cause CP to abend.
11. For more information about user-defined exits, see [Dynamic Exit Points](#) in *z/VM: CP Exit Customization*.

### Examples

Example 1:

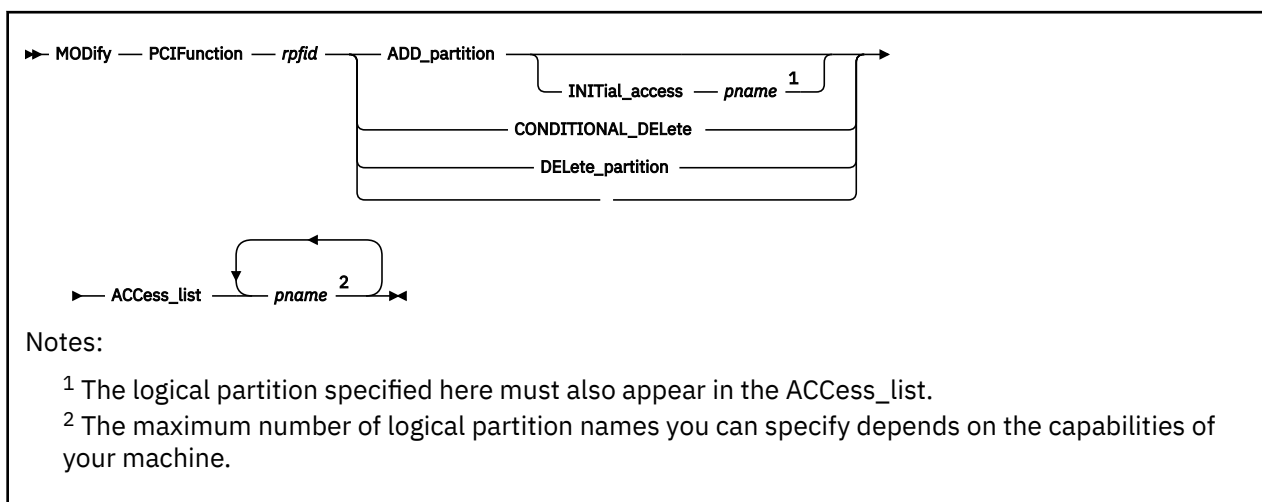

To change the location of exit point X'F422' to HCPXGMSM + 4, enter the following:

```
modify exit f422 at hcpxmgsM + 4 41700001  
Ready;
```

## MODIFY PCIFUNCTION

### Authorization

Privilege Class: B

### Purpose

Use MODIFY PCIFUNCTION to modify a real PCI function in the I/O configuration.

### Operands

#### *rpfid*

is the real function identifier of the PCI function you are modifying. The *rpfid* must be a 1- to 8-digit hexadecimal number between X'00000000' and X'7FFFFFFF'. The maximum value of the *rpfid* is model dependent and your machine likely supports a lower maximum value.

#### **ADD\_partition**

tells CP that you want to add one or more logical partitions to the list of logical partitions that have access to this PCI function.

#### **CONDITIONAL\_DELETE**

tells CP that you want to delete one or more logical partitions from the list of logical partitions that have access to this PCI function, but only if the PCI function is not presently configured to any logical partition in the I/O configuration.

#### **DELETE\_partition**

tells CP that you want to delete one or more logical partitions from the list of logical partitions that have access to this PCI function regardless of whether the PCI function is presently configured to any logical partition in the I/O configuration.

#### **ACCESS\_list pname**

specifies the name(s) of the logical partition(s) for which access to this PCI function is being added or deleted. The maximum number of logical partition names you can specify depends on the capabilities of your machine. Each *pname* must be a 1- to 8-digit character alphanumeric string.

#### **INITIAL\_access pname**

specifies the name of the logical partition that will have initial access to this PCI function.

**Note:** When a logical partition is specified with the INITIAL\_access parameter, it must also be specified as part of the ACCESS\_list.

### Usage Notes

1. After successfully entering this command, you will have changed the software's view of the I/O configuration and part of the hardware's view: the active I/O configuration in the hardware system area (HSA). You should also change the other part of the hardware's view: the active I/O configuration data set (IOCDS) file on the support element (SE) hard disk.

To change the IOCDS file on the SE hard disk, you must:

- a. Update the IOCP source file.
  - b. Run the IOCP utility against the updated IOCP file. If the IOCP utility runs without errors, it downloads the new IOCDS file to the SE hard disk.
  - c. Issue the SET IOCDS\_ACTIVE command to make the new IOCDS file the active file that the processor will use during the next power-on reset (POR).
2. For more information about changing real PCI functions in your I/O configuration, see [z/VM: I/O Configuration](#).
  3. To define a PCI function to the system, use the DEFINE PCIFUNCTION command.
  4. To delete an existing PCI function on the system, use the DELETE PCIFUNCTION command.
  5. To display the status of one or more real PCI functions, use the QUERY PCIFUNCTION command.

### Responses

Response 1:

To add access to a PCI function for two partitions, enter the following:

```
modify pcif 43 add init vm6 acc vm6 vm9
PCI function configuration change completed successfully
Ready;
```

Response 2:

To delete access from a PCI function for two partitions, enter the following:

```
modify pcif 43 del acc vm3 vm5
PCI function configuration change completed successfully
Ready;
```

### Messages

- HCP864E Partition *pname* not found

- HCP6805E Cannot find RDEV for TYPE 1 subchannel
- HCP6806E Dynamic I/O change request for PCI function failed with return code *nnnn*
- HCP6809E This processor does not support dynamic I/O changes
- HCP6815E Command failed in the channel subsystem
- HCP6818E Modify command failed. PCI function *rpfid* is not offline.
- HCP6819E A dynamic I/O command is currently executing for user *userid*

## MODIFY PRIV\_CLASSES

### Authorization

Privilege Class: A

### Purpose

Use MODIFY PRIV\_CLASSES to change the privilege classes authorizing the following CP functions:

- Logging on as the primary system operator
- Intensive error recording
- Using the read function of the CP IOCP utility
- Using the write function of the CP IOCP utility
- Specifying the default user class.

### Operands

#### HW\_Service

tells CP to change the privilege classes authorized to perform intensive error recording.

#### IOCP\_Read

tells CP to change the privilege classes authorized to use the read function of the IOCP utility. (For more information about the IOCP utility, see *z/VM: CP Planning and Administration*.)

#### IOCP\_Write

tells CP to change the privilege classes authorized to use the write function of the IOCP utility. (For more information about the IOCP utility, see *z/VM: CP Planning and Administration*.)

#### OPERator

tells CP to change the privilege classes which are for the primary system operator.

#### USER\_DEFault

tells CP to change the privilege classes that are defined for users who do not have a class specified in their directory entries.

#### RESET

tells CP to reset the privilege classes to their original default settings.

#### classes

tells CP which class or classes are to be set. The variable *classes* is a 1- to 8-character alphanumeric string from A through Z and from 0 to 6.

### Usage Notes

1. The configuration file statement PRIV\_CLASSES can be used to establish initial values.

### Responses

Response 1:

## MODIFY PRIV\_CLASSES

To authorize:

- The primary system operator for class A, C, and E commands
- Class C users to issue the IOCP READ and WRITE
- Class D users to perform intensive error recording
- All users without classes defined in their directory entries for class G commands

use the following MODIFY PRIV\_CLASSES commands:

```
MODify PRIV_CLASSES Operator ACE
Ready;
MODify PRIV_CLASSES IOCP_Write C
Ready;
MODify PRIV_CLASSES IOCP_Read C
Ready;
MODify PRIV_CLASSES HW_Service D
Ready;
MODify PRIV_CLASSES User_Default G
Ready;
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP770E Modify RESET is not valid for PRIV\_CLASSES *type*
- HCP6704E Missing token at end of line
- HCP6706E Invalid privilege classes - *class*

# MONITOR

## Purpose

Use the MONITOR commands to control the selection, collection, and reporting of data from the host system:

- MONITOR EVENT controls monitoring of event data
- MONITOR SAMPLE controls monitoring of sample data
- MONITOR START starts both event and sample monitoring
- MONITOR STOP stops all monitoring.

## Usage Notes

(General for MONITOR)

1. MONITOR commands can be run from virtual machines with the A/E privilege. In order to avoid conflict among the commands, the administrator should be aware of the virtual machines that have the privilege to run the monitor commands.
2. MONITOR START can be issued before or after a user connects to \*MONITOR. If the MONITOR START command is issued before any connection to \*MONITOR, monitor recording goes into a pending state until a user connects to \*MONITOR. The following must be done before the monitor recording gets activated:
  - A saved segment must be defined and saved for the monitor
  - An application program running in a virtual machine must load the monitor saved segment and connect to the \*MONITOR CP system service
  - A MONITOR START command must be issued.
3. Both the event and sample profiles can be changed after monitoring has started. Note that:
  - Partition size of the saved segment cannot be changed unless event monitoring is stopped.

New event domains are activated upon completion of the EVENT command, and new sample domains are activated when the next interval elapses.
4. For a detailed description of data collected, refer to the monitor records in [z/VM: Performance](#).
5. The valid classes and types for use with Seeks and I/O domains are listed in the following table:

CLASS	TYPE	Other TYPES Included	Valid for Seeks	Valid for I/O
	3480			X
	3490			X
	3590			X
	3380		X	X
	3390		X	X
	9336		X	X
	FB-512 <sup>1</sup>	9336	X	X
SPOOL	1403			X
	3203			X

Table 31. Valid Classes and Types for Seeks and I/O Domains (continued)				
CLASS	TYPE	Other TYPES Included	Valid for Seeks	Valid for I/O
	3262			X
	3505			X
	3525			X
	3800			X
	4245			X
	4248			X
GRAF	GPRT <sup>2</sup>			X
	GTERM <sup>2</sup>			X
PCIF				X

**Note:**

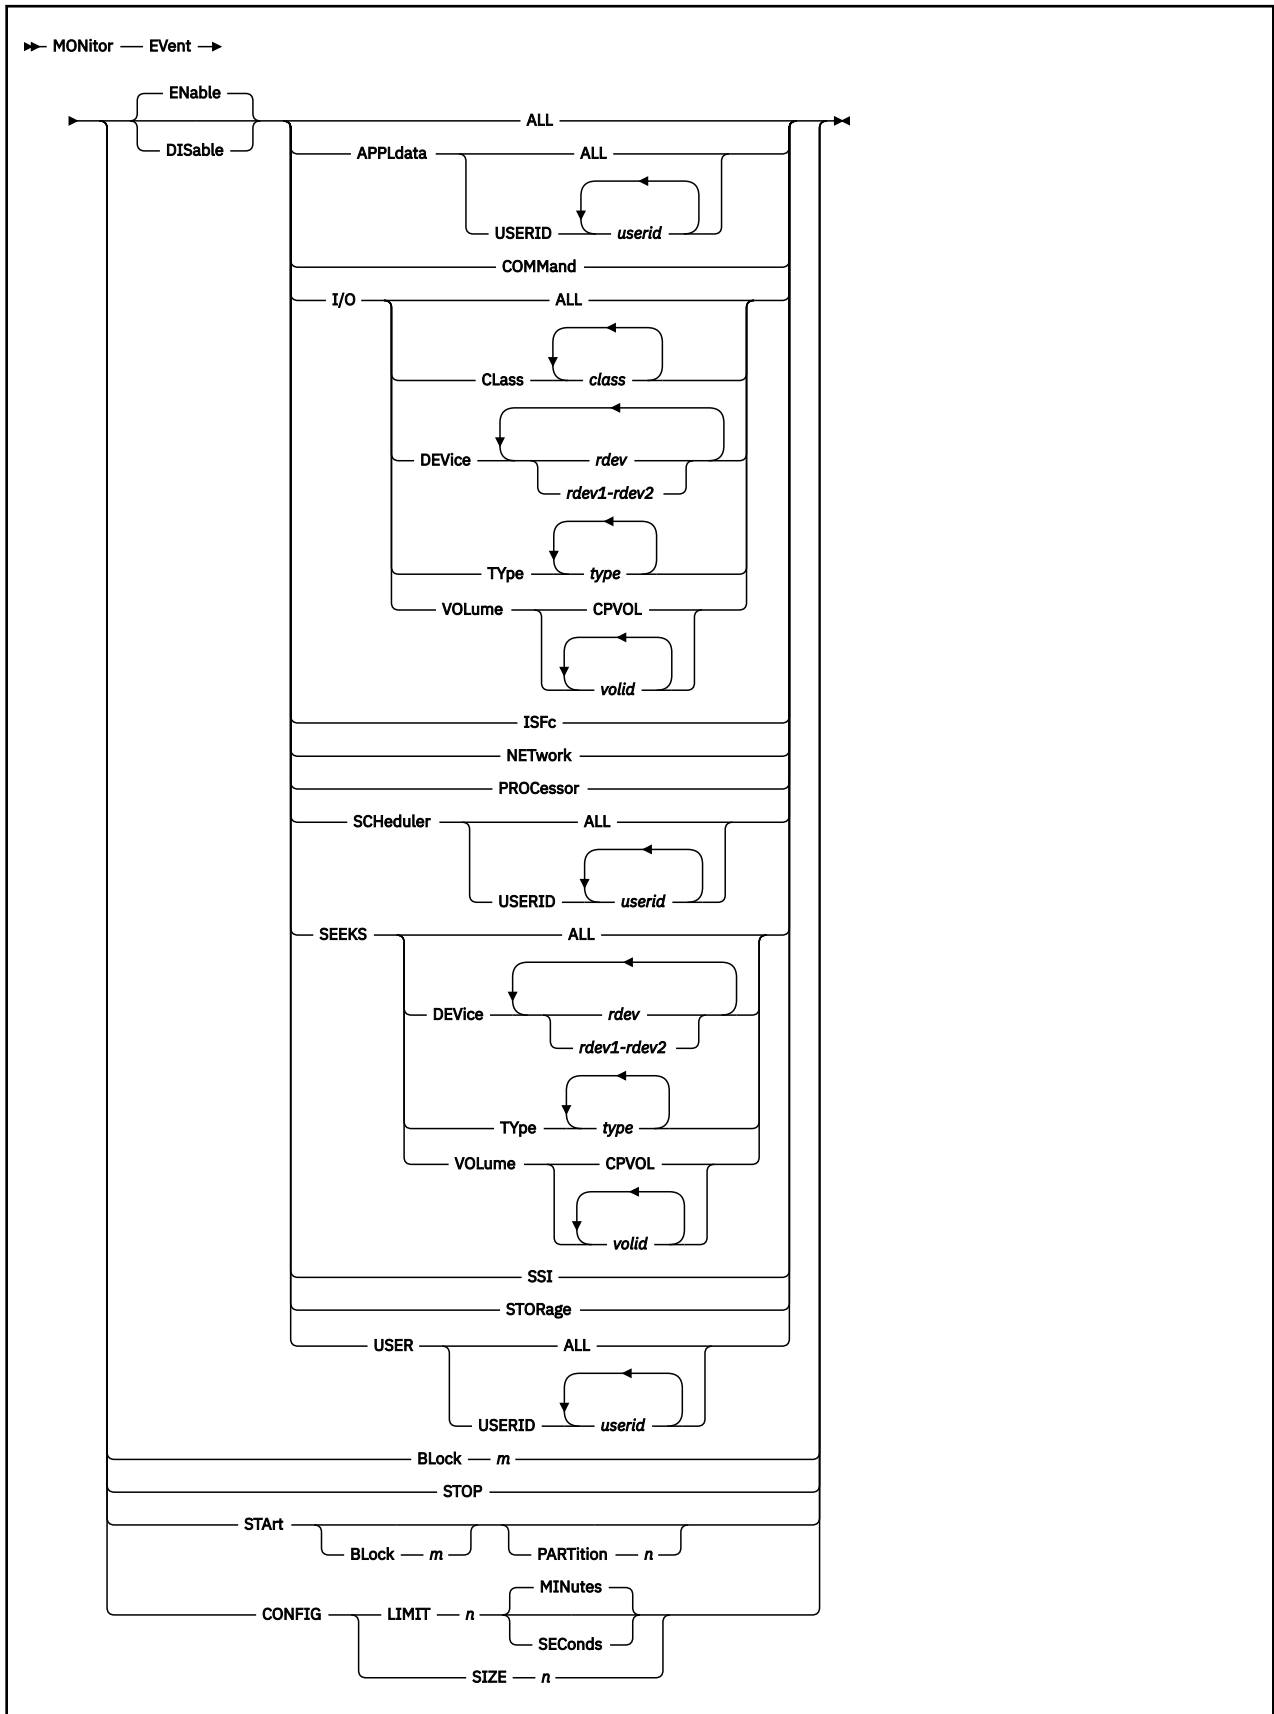

- a. FB-512 represents all FBA-type DASD devices.
  - b. GPRT represents all graphic display printers; GTERM represents all display terminals. For a list of graphic devices supported, see *z/VM: General Information*.
6. If while running monitor you experience missing or incomplete monitor records, the size of the sample configuration record area may not be large enough to record all the system configuration data, especially if there are a large number of devices available on your system. To increase the size of the sample configuration record area, see the MONITOR SAMPLE CONFIG command.

- HCP6246E Monitor has been terminated due to a soft abend.
- HCP6249I Device *rdev* is enabled for monitoring, but is offline
- HCP6250I A monitor sample interval has been skipped because the IUCV message limit of number to \*MONITOR has been reached.
- HCP6255I number monitor sample interval(s) have been skipped because data collection could not complete before the next sample interval.
- HCP6262E *value* is an invalid time limit for monitor {event|sample} CONFIG.
- HCP6274I The {sample|event} data messages and corresponding records have been purged.
- HCP6551I User *userid* will not be monitored for the APPLDATA domain because it is not authorized
- HCP6552E The size of the {event|sample} configuration area cannot be changed because {event|sample} monitoring has already been started.
- HCP6553E *value* is an invalid size for monitor {event|sample} CONFIG.
- HCP6554E The MONITOR EVENT START failed because the event partition size of *n* pages is not large enough. At least *n* pages are currently required.
- HCP6555E The MONITOR EVENT START failed because even with the largest possible DCSS, the default partition size will not be large enough. At least *n* pages are currently needed.
- HCP6556E {Sample|Event} monitoring cannot start because there are not enough pages available in the DCSS *dcssname*. *n* pages are available.
- HCP6557E {Sample|Event} monitoring cannot start because even the largest possible DCSS won't have enough pages. At most, *n* pages will be available.
- HCP6558E The MONITOR EVENT START failed because the default partition size cannot be allocated. Only *n* pages are available.
- HCP6559E The MONITOR EVENT START failed because even with the largest possible DCSS, the default partition size could not be allocated. At most, *n* pages are available.

# MONITOR EVENT

## Authorization

Privilege Class: A, E

## Purpose

Use MONITOR EVENT to establish or modify a profile for event data collection. You can also use this command to begin or end event monitoring. An event data profile lists:

- Data domains and domain elements to be monitored
- The number of pages reserved for event configuration records
- The block and partition values the shared segments.

**Note:** MONITOR EVENT START/STOP does *not* affect the profile and is *not* a subset of MONITOR EVENT ENABLE/DISABLE.

## Operands

### ENable

enables the specified domains and their elements for event data collection. Event data is collected only from those domains that have been enabled. ENABLE is the default.

**Note:** The MONITOR domain is always enabled for event monitoring.

### DISable

disables the specified domains or their elements from event data collection.

**Note:** The MONITOR domain cannot be disabled from monitoring.

### ALL

specifies that all domains and all their elements will be enabled or disabled for event data collection, including:

- APPLDATA (all authorized users)
- I/O (all devices)
- ISFC
- NETWORK
- PROCESSOR
- SCHEDULER (all users)
- SEEKS (all DASD devices)
- SSI
- STORAGE
- USER (all users)
- COMMAND

**Note:** The MONITOR domain is enabled for event data collection at all times.

### APPLdata

specifies that the APPLDATA domain will be enabled or disabled for event data collection. APPLDATA domain is where CP collects data generated by an application program in a virtual machine. The virtual machine issues DIAGNOSE X'DC' START to declare a buffer from which CP can collect the information. For information on DIAGNOSE Code X'DC' – Control Application Monitor Record Collection in *z/VM: CP Programming Services*.

### APPLDATA ALL

specifies that all authorized users will be enabled or disabled for event monitoring in the APPLDATA domain. To be authorized for monitoring in the APPLDATA domain, the user's directory entry must contain an OPTION APPLMON statement.

**APPLdata USERID *userid***

specifies a list of users to be enabled or disabled for event monitoring in the APPLDATA domain. The *userid* is a list of one or more user IDs, separated by blanks, from whom data is collected. Each user specified in this list must have the OPTION APPLMON statement in their directory entry. Users that do not have this statement in their directory entries will not be enabled for this domain.

**COMMANd**

specifies that the COMMAND synthetic domain will be enabled or disabled for event data collection. The COMMAND synthetic domain comprises the events in other domains that are produced by commands such as VARY ON and OFF, SET SHARE, and LOGOFF. This domain can be enabled to allow these records to be collected without also having to collect records that are generated at much higher frequency and produce substantial amounts of data.

**I/O**

specifies that the I/O domain will be enabled or disabled for event data collection. An I/O domain is comprised of all real I/O devices. Events in this domain include such activities as VARY ON and OFF, and attachment and detachment of devices. You may enable or disable all or selected I/O devices for the I/O domain. You can restrict them by device number, class type, or volume.

**I/O ALL**

specifies that all real devices will be enabled or disabled for event monitoring in the I/O domain.

**I/O CLass *class***

specifies a list of device classes that will be enabled or disabled for event monitoring in the I/O domain. *class* is a list of one or more device classes, separated by blanks. All real devices of the specified class or classes are monitored. For a list of classes that can be specified in this command, see [Table 31 on page 707](#).

**I/O DEVIce *rdev*****I/O DEVIce *rdev1-rdev2***

specifies the real devices to be enabled or disabled for event data collection in the I/O domain. You may specify the device number of a single device; you can also specify a list, a range of devices, or a combination of both. If you specify a range, all valid devices in the range, inclusively, are enabled or disabled. For additional information, see the specific usage notes for I/O.

**I/O TYpe *type***

specifies a list of device types to be enabled or disabled for event monitoring in the I/O domain. *type* is a list of one or more device types (such as 3380), separated by blanks. For valid device types, see [Table 31 on page 707](#). All real devices of the specified type or types are monitored.

**I/O VOLume *valid*****I/O VOLume CPVOL**

specifies a list of volumes that are to be enabled or disabled for event monitoring in the I/O domain. *valid* is a list of one or more volume identifiers, separated by blanks. If CPVOL is specified, all CP-owned volumes will be enabled or disabled for monitoring. A CP-owned volume is any volume specified on the CP\_OWNED statement in the system configuration file. For devices identified by DEVNO, you cannot use the volume option of Monitor. The volume option can only be used for devices identified by VOLSER.

**IFSc**

specifies that the ISFC domain is to be enabled or disabled for event data collection. Data such as ISFC Transport end point status change or ISFC Logical Link Definition changes are recorded.

**NETwork**

specifies that the NETWORK domain is to be enabled or disabled for event data collection. Data such as a virtual guest adapter initialization or termination is recorded.

**PROCeSSor**

specifies that the PROCESSOR domain will be enabled or disabled for event data collection. Events such as VARY ON or OFF of a processor are monitored.

**SCHeduler**

specifies that the SCHEDULER domain will be enabled or disabled for event data collection. Event data include such statistics as scheduler queue manipulation, flow of work through the system, and resource allocation strategies of the scheduler and the dispatcher.

**SCheduler ALL**

specifies that all users will be enabled or disabled for event data collection in the SCHEDULER domain.

**SCheduler USERID *userid***

specifies a list of users that will be enabled or disabled for event data collection in the SCHEDULER domain. *userid* is a list of 1 or more user IDs, separated by blanks.

**SEEKS**

specifies that the SEEKS domain will be enabled or disabled for event data collection. A SEEKS domain is comprised of all architected DASD devices. Event data, which include DASD positioning, are collected on every I/O request on such enabled DASD devices. You may enable or disable all or specified devices in the SEEKS domain. You can restrict them by their device numbers, types, or volumes. Event data are collected on every I/O request on such enabled DASDs.

**SEEKS ALL**

specifies that all real DASDs will be enabled or disabled for event data collection in the SEEKS domain.

**SEEKS DEvice *rdev*****SEEKS DEvice *rdev1-rdev2***

specifies the DASDs to be enabled or disabled for event data collection in the SEEKS domain. You may specify the device number of a single device; you can also specify a list, a range of devices, or a combination of both. If you specify a range, all valid DASD devices in the range, inclusively, are enabled or disabled. See the specific SEEKS usage notes for additional information.

**SEEKS Tpe *type***

specifies a list of DASD types that will be enabled or disabled for event data collection in the SEEKS domain. *type* is a list of one or more device types (such as a 3380), separated by blanks. All DASDs of the specified type or types are monitored. For valid device types, see [Table 31 on page 707](#).

**SEEKS VOLume *valid*****SEEKS VOLume CPVOL**

specifies a list of volumes that will be enabled or disabled for event data collection in the SEEKS domain. *valid* is a list of one or more volume identifiers, separated by blanks. If CPVOL is specified, all CP-owned volumes are enabled or disabled. A CP-owned volume is any volume specified on the CP\_OWNED statement in the system configuration file. For devices identified by DEVNO, you cannot use the volume option of Monitor. The volume option can only be used for devices identified by VOLSER.

**SSI**

specifies that the SSI domain will be enabled or disabled for event data collection. SSI domain events include z/VM Single System Image (SSI) cluster state changes and slot definition data. The SSI operand cannot be specified if the z/VM system is not part of the z/VM SSI cluster.

**STORAge**

specifies that the STORAGE domain will be enabled or disabled for event data collection. Events such as defining and purging of a named saved system or a saved segment, or attaching, or detaching a CP volume are monitored.

**USER**

specifies that the USER domain will be enabled or disabled for event data collection. A USER domain is comprised of all users. All or selected users may be specified for monitoring. USER domain events include such activities as logon and logoff, defining and detaching a virtual CPU, and an end of transaction.

**USER ALL**

specifies that all users will be enabled or disabled for event data collection in the USER domain.

**USER USERID *userid***

specifies a list of users to be enabled or disabled in the USER domain. *userid* is a list of one or more user IDs, separated by blanks.

**Event BLock *m***

specifies the maximum number of 4 KB pages, *m*, of the shared segment (saved segment), that are accumulated before the virtual machine is notified that the event data is available for data collection. You can modify *m* using the MONITOR EVENT BLOCK command while event monitoring is active.

### Event STOP

deactivates the event-driven data collection. The monitor event profile is not affected by this command, except for PARTITION, which is set to zero.

**Note:** Do not use this command to stop the MONWRITE utility. (See [“MONWRITE” on page 2212](#) for more information.)

### Event START

starts event monitoring for the domains and their elements listed in the event profile set by the preceding MONITOR EVENT commands.

If no virtual machine is connected for event data (or no virtual machine connected for event data has an active path to \*MONITOR) when the command is issued, event recording is held pending.

When recording is activated (that is, when there is a user connected with an active path for event data), event configuration records from the monitor domain are the first event records generated.

### BLOCK *m*

specifies the maximum number of 4 KB frames of the shared segment, that are accumulated before the virtual machine is notified that the event data is available for data collection.

The BLOCK value may be modified using the MONITOR EVENT BLOCK command while event monitoring is active.

### PARTITION *n*

specifies the number of 4 KB pages in the shared segment to be reserved for event records. The rest of the shared segment is used for sample data.

### EVENT CONFIG LIMIT *n* MINutes

### EVENT CONFIG LIMIT *n* SECOnds

specifies the time limit a user can refer to the event configuration area before the data is refreshed or zeroed.

### EVENT CONFIG SIZE *n*

specifies the size in 4 KB pages to be allocated in the saved segment for EVENT configuration records.

## Usage Notes

(General)

1. Both event and sample monitoring can be active at the same time. The MONITOR EVENT START command starts only event monitoring. To start both event and sample monitoring, see [“MONITOR START/STOP” on page 727](#). Similarly, MONITOR EVENT STOP, stops only event monitoring while MONITOR STOP stops both event and sample monitoring.
2. The following must be done to activate event recording:
  - A saved segment must be defined and saved for the monitor
  - A virtual machine must load the monitor saved segment and connect to \*MONITOR for event data
  - A MONITOR START or MONITOR EVENT START command must be issued.

If the START command is issued when no virtual machine is connected with an active path to \*MONITOR for event data, event recording is held pending until there is a connection with an active path.

3. The event configuration message may be delayed for a user who connects to \*MONITOR to collect event data and, in turn, the event data notification messages are also delayed for the user.
  - If another user has already connected to \*MONITOR to collect event data and has not replied to the event configuration message, the monitor regenerates the configuration records after the configuration area has been freed, and sends an event configuration message to the user who has just connected to \*MONITOR
  - If a user's path is quiesced (or at its IUCV message limit) when the event configuration notification is sent, the user receives notification for a refreshed set of configuration records when the user resumes the path to \*MONITOR (or responds to one or more previous messages).

4. The event profile can be changed after monitoring has started. The only exceptions are that the partition size and the event config size of the saved segment cannot be changed unless event monitoring is stopped. New event domains are activated upon completion of the event command.
5. Event monitoring can result in large volumes of data generated and an increased CP overhead, particularly in the SEEKS and SCHEDULER domains. For this reason, these two domains should be enabled only when needed and should be limited to specific devices or a specific set of devices.

#### Specific Usage Notes for I/O and SEEKS:

1. Any overlapping of I/O devices can exist in a series of MONITOR EVENT commands on the I/O domain and the SEEKS domain. For example, a command:

```
monitor event enable i/o type 3380
```

followed by:

```
monitor event enable i/o class dasd
```

would result in all DASD's enabled for monitoring. If this is then followed by:

```
monitor event disable i/o type 3380
```

monitoring ceases for all 3380 devices but continues for all other types of DASD devices.

2. A message is issued for any device that had been specified but does not exist. For the SEEKS domain, a message is issued for any specified device that is found not to be a DASD.
3. Devices that are enabled but are found to be offline are monitored after they are varied online. A summary message is issued indicating how many devices are enabled for monitoring, and how many are offline.
4. The VOLUME operand can be used only for volumes attached to the system, because CP associates a volume label to a device number only at the time it is attached. If you want to enable a DASD device that is not attached to the system, use the DEVICE option.
5. The volume to be monitored is maintained by its device address. Enabling or disabling a volume for monitoring remains valid as long as its device address does not change. For example, if a volume is detached and a volume with the same label at a different address is attached, the volume must be enabled again to be monitored and its previous device address disabled.

#### Specific Usage Notes for BLOCK:

1. If BLOCK is omitted, the default is four 4 KB pages.
2. The minimum value for BLOCK is four 4 KB pages.
3. The maximum value for BLOCK is half the number of pages to be used for event data (partition-event config size).
4. The value of BLOCK is preserved when monitoring is stopped.

#### Specific Usage Notes for CONFIG SIZE:

1. The default size reserved for event configuration records when event monitoring is started is 68 pages.
2. The MONITOR EVENT CONFIG SIZE can be issued only when event monitoring is not active. To change the size after event monitoring has been started, you must first stop event monitoring.
3. The minimum value for CONFIG SIZE is one 4 KB page.
4. The maximum value for CONFIG SIZE is equal to the maximum number of pages that can be specified as a type SC range with the DEFSEG command, minus 8 pages for event data records.

**Note:** The number of pages reserved must fit within the saved segment to be used by monitor. This check is made when monitoring is started (if someone is connected to \*MONITOR and the saved segment is known) or when the first user connects after monitoring has been started.

5. The value of CONFIG SIZE is preserved when monitoring is stopped.

#### Specific Usage Notes for CONFIG LIMIT:

## MONITOR EVENT

1. The CONFIG time limit is the amount of time a user can keep the configuration area in use.
2. The CONFIG time limit default is 1 minute.
3. The minimum value for CONFIG time limit is 1 second.
4. The maximum value for CONFIG time limit is 120 minutes.
5. The CONFIG time limit value must be specified as a whole number.
6. When the CONFIG time limit expires, CP:
  - In the EXCLUSIVE environment—stops monitoring and issues message HCP6239I
  - In the SHARED environment—purges the configuration message, releases the corresponding saved-segment pages, and issues message HCP6253I. Data recording continues.
7. Configuration records are created and the CONFIG time limit enforced whenever:
  - Recording has begun. (A MONITOR START command is issued and at least one user is connected, with an active path, for the type of monitoring being started.)
  - Recording is underway and:
    - A user connects (with an active path) for that type of monitor data
    - The path of a user connected for that type of data becomes active
    - The user, whose path to \*MONITOR was quiesced when \*MONITOR tried to send a configuration notification message, issues IUCV RESUME
    - The user, whose path to \*MONITOR was at its IUCV message limit when \*MONITOR tried to send a configuration notification message, issues IUCV REPLY or REJECT to one or more previous messages from \*MONITOR.
8. CONFIG time limit is preserved when monitoring is stopped.

### Specific Usage Notes for PARTITION:

1. The default value of PARTITION is half of the size of the saved segment.
2. The minimum PARTITION size is 8 pages plus the number of pages reserved for event configuration records. The absolute minimum partition size is 9 pages.

#### Note:

- a. To determine the number of pages currently designated for event configuration records, enter the QUERY MONITOR EVENT command.
  - b. To reserve a number of pages for the event configuration area, enter the MONITOR EVENT CONFIG SIZE command. If the MONITOR EVENT CONFIG SIZE command has not been issued when the MONITOR EVENT START command is issued, 68 pages are reserved for event configuration recording, and the PARTITION size must be at least 76 pages.
3. The maximum PARTITION size depends on whether sample monitoring has already been started, and on whether any user is connected to \*MONITOR when the command is issued to start event monitoring.

If sample monitoring has *not* started, and:

- If one or more users are connected, the maximum PARTITION value that can be entered is the number of pages in the first type SC range of the saved segment that is currently being used by monitor.
- If there are no users connected to \*MONITOR, the maximum value for PARTITION is equal to the maximum number of pages that can be specified as a type SC range with the DEFSEG command.

If sample monitoring *has* been started, the maximum number of pages that can be specified by PARTITION is reduced by one more than the number of pages reserved for sample configuration records. (QUERY MONITOR EVENT or QUERY MONITOR SAMPLE displays the number of pages currently reserved for the event and the sample configuration areas.)

4. When monitoring is stopped, the value of PARTITION reverts to the default value.

## Responses

The command MONITOR EVENT START can be issued before or after a user connects to \*MONITOR to collect event data.

Response 1:

```
MONITOR EVENT STARTED -- RECORDING IS ACTIVATED
```

- or -

```
MONITOR EVENT STARTED BY [userid] -- RECORDING IS ACTIVATED
```

As a result of the MONITOR EVENT START command, event monitoring has successfully started. There is at least one user with an active path connected to \*MONITOR for event data collection.

This response is sent to the user that issued the command. If this user is not the system operator, the response containing [userid] is also sent to the system operator.

Response 2:

```
MONITOR EVENT STARTED -- RECORDING IS PENDING
```

- or -

```
MONITOR EVENT STARTED BY [userid] -- RECORDING IS PENDING
```

MONITOR EVENT START has been issued. Because there is no user with an active path connected to \*MONITOR for event data collection, event monitoring is held pending. It shall remain pending until the first user is connected to \*MONITOR for event data collection.

This response is sent to the user that issued the command. If this user is not the system operator, the response containing [userid] is also sent to the system operator.

Response 3:

```
MONITOR EVENT STOPPED
```

- or -

```
MONITOR EVENT STOPPED BY [userid]
```

MONITOR EVENT STOP has been issued and event monitoring has been stopped.

This response is sent to the user that issued the command. If this user is not the system operator, the response containing [userid] is also sent to the system operator.

Response 4:

```
Command complete
```

The MONITOR command has completed successfully.

# MONITOR SAMPLE

## Authorization

Privilege Class: A, E

## Purpose

Use MONITOR SAMPLE to establish or modify a profile for collecting both single sample and high-frequency sample data. This command can also be used to begin or end sample monitoring.

Single sample data are a set of counters and data that characterize a system operation. High-frequency sample data are a set of counters and data that characterize the system at the moment the data is sampled.

The sample profile lists the following:

- Data domains and domain elements to be monitored
- Rate at which high-frequency sample data is collected
- Time interval at which sample data is reported
- Number of pages to be reserved for sample configuration records.

## Operands

### ENable

enables the specified domains and their elements for sample data collection. Sample data is collected only from those domains that have been enabled. ENABLE is the default.

**Note:** The MONITOR domain and the SYSTEM domain are always enabled for sample data monitoring.

### DISable

disables the specified domains or their elements from monitoring.

**Note:** The MONITOR domain and the SYSTEM domain cannot be disabled from sample data collection.

### ALL

specifies that all domains and all their elements are to be enabled or disabled for sample data collection. This includes the following domains:

- APPLDATA (all authorized users)
- I/O (all devices)
- ISFC
- NETWORK
- PROCESSOR
- SSI
- STORAGE
- USER (all users)

**Note:** SYSTEM and MONITOR domains are enabled for sample monitoring at all times.

### APPLdata

specifies that the APPLDATA domain is to be enabled or disabled for sample data collection. APPLDATA domain is where CP collects data generated by an application program in a virtual machine. The virtual machine issues DIAGNOSE X'DC' START to declare a buffer from which CP can collect the information. For information on [DIAGNOSE Code X'DC' – Control Application Monitor Record Collection](#) in *z/VM: CP Programming Services*.

### APPLdata ALL

specifies that all authorized users are to be enabled or disabled for sample monitoring in the APPLDATA domain. To be authorized for monitoring in the APPLDATA domain, the user's directory entry must contain an OPTION APPLMON statement.

### APPLdata USERID *userid*

specifies a list of users to be enabled or disabled for sample monitoring in the APPLDATA domain. The *userid* is a list of one or more user identifiers, separated by blanks, from whom data is collected.

Each user specified in this list must have the OPTION APPLMON statement in their directory entry. Users who do not have this statement in their directory entries are not enabled for this domain.

**I/O**

specifies that the I/O domain is to be enabled or disabled for sample data collection. An I/O domain is comprised of all real I/O devices. You may enable or disable all or selected I/O devices for the I/O domain. You can restrict them by device numbers, classes, types, or volumes.

**I/O ALL**

specifies that all real devices are to be enabled or disabled for sample data collection in the I/O domain.

**I/O CClass *class***

specifies a list of device classes that are to be enabled or disabled for sample data collection in the I/O domain. *class* is a list of one or more device classes, separated by blanks. All real devices of the specified class or classes are monitored.

For a list of classes that can be specified in this command, and for a list of device types that each class supports, see [Table 31 on page 707](#).

**I/O DEvIce *rdev*****I/O DEvIce *rdev1-rdev2***

specifies the real devices to be enabled or disabled for sample data collection in the I/O domain. You may specify the device number of a single device; you can also specify a list, a range of devices, or a combination of both. If you specify a range, all valid devices in the range, inclusively, are enabled or disabled. For additional information, see [Specific Usage Notes for I/O](#).

**I/O TYpe *type***

specifies a list of device types that are to be enabled or disabled for sample data collection. *type* is a list of one or more device types (such as the 3380), separated by blanks. For valid device types, see [Table 31 on page 707](#). All real devices of the specified type or types are monitored.

**I/O VOLume *valid*****I/O VOLume CPVOL**

specifies a list of volumes that are to be enabled or disabled for sample data collection. *valid* is a list of one or more volume identifiers, separated by blanks. If CPVOL is specified, all CP-owned volumes are to be enabled or disabled for monitoring. A CP-owned volume is any volume specified on the CP\_OWNED statement in the system configuration file. For devices identified by DEVNO, you cannot use the VOLUME option of MONITOR. The VOLUME option can only be used for devices identified by VOLSER.

**IFSc**

specifies that the ISFC domain is to be enabled or disabled for sample data collection. Data such as ISFC Transport end point status change or ISFC Logical Link Definition changes are recorded.

**NETwork**

specifies that the NETWORK domain is to be enabled or disabled for sample data collection. Data such as the number of packets sent by and delivered to a virtual guest adapter are recorded.

**PROcessor**

specifies that the PROCESSOR domain, including the CPU-Measurement Counter Facility, is to be enabled or disabled for sample data collection. Data related to CPU usage such as system locks, simulation, and interprocessor signaling are collected.

**PROcessor CPUMFC**

specifies that collection of CPU-Measurement Counter Facility counters is to be disabled for counter sets requiring activation by CP. Sample data collection of the rest of the PROCESSOR domain is unaffected.

Collection of CPU-Measurement Counter sets for the Multithreading (MT) Facility is unaffected. Those counter sets are collected when multithreading is enabled and collection of monitor sample records in the PROCESSOR domain is enabled.

**Note:** The CPUMFC keyword is valid only with the DISABLE keyword.

**SSI**

specifies that the SSI domain will be enabled or disabled for sample data collection. Data collected for this domain includes z/VM Single System Image (SSI) cluster state change synchronization activities and mode occupancy. The SSI operand cannot be specified if the z/VM system is not part of the z/VM SSI cluster.

**STORAge**

specifies that the STORAGE domain is to be enabled or disabled for sample data collection. Status and utilization data of real, virtual, shared, and auxiliary storage are collected.

**USER**

specifies that the USER domain is to be enabled or disabled for sample data collection. A USER domain is comprised of all users. Data collected for this domain consists of user resource utilization and status data for all or selected users.

**USER ALL**

specifies that all users are to be enabled or disabled for sample data collection in the USER domain.

**USER USERID *userid***

specifies a list of users that are to be enabled or disabled for sample data collection. *userid* is a list of one or more user identifiers, separated by blanks.

**SAMPlE INTerval *n* MINutes****SAMPlE INTerval *n* SECOnds**

specifies the time interval at which the sample data is to be reported. MINUTES is the default. For additional information, see [Specific Usage Notes for INTERVAL](#).

**SAMPlE RATE *n* SECONDS**

specifies the frequency at which the high-frequency sample data is to be sampled. The operand *n* is the length of time between high-frequency sampling. High-frequency sample data is a set of counters and data that represent the state of the system at the moment they are sampled.

High-frequency sampling is automatically activated whenever the MONITOR SAMPLE START command is issued, unless the RATE value has been previously set to STOP. For additional information, see [Specific Usage Notes for RATE](#).

**SAMPlE RATE STOP**

immediately terminates the sampling of high-frequency data. Data for the current interval is lost.

**SAMPlE CONFIG SIZE *n***

specifies the size in 4 KB pages to be allocated in the saved segment for SAMPLE configuration records.

**SAMPlE CONFIG LIMIT *n* MINutes****SAMPlE CONFIG LIMIT *n* SECOnds**

specifies the time limit that the configuration records remain in the CONFIG area of the saved segment before they are refreshed or zeroed.

**SAMPlE STArt**

starts sample monitoring for the domains and their elements specified in preceding MONITOR SAMPLE commands.

If no application is connected (with an active path) for sample data when the command is issued, sample recording is held pending. However, high-frequency sampling, if enabled, is started.

When recording is activated (that is, when there is a user connected with an active path for sample data), sample configuration records from the monitor domain are generated. Sample configuration records include information concerning the processor, storage, paging, real I/O configurations, and initial sample configuration settings.

**SAMPlE STOP**

deactivates sample monitoring. Collection of single sample data and high frequency data are stopped. All data collected for the current interval are purged. The monitor sample profile is not affected by this command.

**Note:** Do not use this command to stop the MONWRITE utility. (See [“MONWRITE” on page 2212](#) for more information.)

## Usage Notes

(General)

1. The following must be done to activate sample recording:
  - A saved segment must be defined and saved for the monitor
  - A virtual machine must load the monitor saved segment and connect to \*MONITOR for sample data
  - A MONITOR START or MONITOR SAMPLE START command must be issued.

If the START command is issued when no virtual machine is connected with an active path to \*MONITOR for sample data, sample recording is held pending until there is a connection with an active path.
2. The intervals for sample data collection start at the time the sample start command is issued. Monitor does not generate sample records unless there is at least one eligible monitor user for sample data. The following are two examples for the condition mentioned above:
  - Example 1
    - a. MONITOR SAMPLE START is issued at 10:00 A.M. with 10-minute intervals.
    - b. A user connects to \*MONITOR at 10:05 A.M. to collect sample data. The sample configuration records are generated at the connect time (10:05 A.M.), and the first data records are generated at 10:10 A.M.
  - Example 2
    - a. A user connects to \*MONITOR at 10:00 A.M. to collect sample data.
    - b. MONITOR SAMPLE START is issued at 10:05 A.M. with 10-minute intervals. The first sample data records are generated immediately after the sample configuration records are generated (at 10:05 A.M.). The next sample interval is at 10:15 A.M.
3. It is possible for a user who connects to \*MONITOR for sample data collection to receive two record notification messages—one for sample configuration followed by one for the sample data records. See [Example 2](#) above.
4. The sample configuration message might be delayed for a user who connects to \*MONITOR to collect sample data, and in turn the sample data notifications are also delayed for the user.
  - If another user has already connected to \*MONITOR to collect sample data and has not replied to the sample configuration message, the monitor regenerates the configuration records after the configuration area is free and sends a sample configuration message to the user who just connected to \*MONITOR.

**Note:** If the MONITOR SAMPLE START command is issued before any user is connected to \*MONITOR, the first user connected to \*MONITOR holds the configuration area. When that user issues an IUCV REPLY or the configuration time limit expires, the other users who are connected receive data notification for a new set of configuration records.

  - If a user's path to \*MONITOR is quiesced (or at its IUCV message limit) when the sample configuration notification is sent, the user receives notification for a refreshed set of configuration records when the user resumes the path (or responds to one or more previous messages).
5. Both event and sample monitoring can be active at the same time. The MONITOR SAMPLE START command only starts sample monitoring. To start both event and sample monitoring, use the MONITOR START command described in “MONITOR START/STOP” on page 727. Similarly, MONITOR SAMPLE STOP stops only sample monitoring while MONITOR STOP stops both event and sample monitoring.

Specific Usage Notes for I/O:

1. Any overlapping of I/O devices can exist on a series of MONITOR SAMPLE commands on the I/O domain. For example, if the command:

```
monitor sample enable i/o type 3380
```

is followed by:

```
monitor sample enable i/o class dasd
```

all DASD are enabled for monitoring. If the command is then followed by:

```
monitor sample disable i/o type 3380
```

monitoring ceases for all 3380 devices, but continues for all other types of DASD.

2. A message is issued for any specified device that does not exist.
3. Devices that are enabled but are found to be offline are monitored when varied online. A summary message is issued indicating how many devices are enabled for monitoring, and how many are offline.
4. The VOLUME operand can be used only for volumes attached to the system, because CP associates a volume label to a device number only at the time it is attached. If it is desired to enable a DASD not attached to the system, it can be done by using the DEVICE option.
5. The volume to be monitored is maintained by its device address. Enabling or disabling a volume for monitoring remains valid as long as its device address does not change. For example, if a volume is detached and a volume with the same label at a different address is attached, the volume must be enabled again to be monitored, and its previous device address disabled.
6. A cache data record will not be created for a secondary device of a duplex pair.

Specific Usage Notes for PROCESSOR:

1. The MONITOR SAMPLE ENABLE PROCESSOR command can be used to turn on collection of CPU-Measurement Counter Facility counters only if the machine supports the CPU-Measurement Counter Facility, the z/VM software recognizes and supports the counter first version number (CFVN) and counter second version number (CSVN) values reported by the hardware, and the partition is authorized for the basic counter set. Authorization is set either in the partition's activation profile or through the Change LPAR Security task on the Support Element. If one or more of these prerequisites is not met, z/VM does not activate the collection of CPU-Measurement Counter Facility counters. If all of these prerequisites are met, z/VM collects counters in the basic counter set, along with counters in the problem-state, crypto-activity, and extended counter sets, provided those counters are authorized. See the CPUMFC operand for an explanation of how the collection of these counter sets can be controlled.

The MT-Diagnostic counter set is not controlled by the CPUMFC operand. This counter set is authorized, enabled, and activated only if the Multithreading Facility is enabled. Therefore it is always collected if the Multithreading Facility is enabled and the PROCESSOR domain is enabled for sample data monitoring.

2. Message HCP6263I is displayed when CPU-Measurement Counter Facility counters are available on the machine but the basic counter set is not authorized for the partition.
3. The CPU-Measurement Counter Facility counters are part of the PROCESSOR sample domain. However, you might want to run with the PROCESSOR sample domain enabled but with the CPU-Measurement Counter Facility counters turned off. With respect to the PROCESSOR domain, the MONITOR SAMPLE command has the following behaviors:
  - a. MONITOR SAMPLE ENABLE PROCESSOR turns on the entire PROCESSOR sample domain including the CPU-Measurement Counter Facility counters.
  - b. MONITOR SAMPLE DISABLE PROCESSOR turns off the entire PROCESSOR sample domain, including the CPU-Measurement Counter Facility counters.
  - c. MONITOR SAMPLE DISABLE PROCESSOR CPUMFC turns off collection of CPU-Measurement Counter Facility counters but leaves the rest of the PROCESSOR sample domain enabled.
4. For more information about CPU-Measurement Counter Facility counters and the contents and formats of the various counter sets, refer to *Load-Program-Parameter and CPU-Measurement Facilities* and *CPU-Measurement Facility Extended Counters Definition* accompanying the machine on which you are running.

Specific Usage Notes for INTERVAL:

## MONITOR SAMPLE

1. The valid range of values for INTERVAL is 6 to 3600 for SECONDS, and 1 to 60 for MINUTES. INTERVAL values must be specified in whole numbers.
2. The default value of INTERVAL is one minute (60 seconds).
3. If an interval is currently in effect, the new interval does not take effect until the next sample data record is produced.
4. The SAMPLE INTERVAL value must be greater than or equal to the SAMPLE RATE value.
5. It is possible that data may not be reported by the time the interval expires. This happens when it takes longer than an interval to collect the data. If this happens, the interval time should be adjusted to allow sufficient time to collect and report the data.

### Specific Usage Notes for RATE:

1. The valid range of value for RATE is .01 to 30 seconds. As many as two digits may be specified after the decimal point. Leading zeros are not required, and trailing zeros are not required after the decimal point.
2. The default value of RATE is two seconds.
3. If a rate is currently in effect, the new rate does not take effect until the current high-frequency rate has elapsed.
4. The SAMPLE RATE value specified must be less than or equal to the SAMPLE INTERVAL value.
5. The frequency of doing high-frequency sampling is determined by the RATE setting, however the creation of monitor records containing high-frequency data is controlled by MONITOR SAMPLE INTERVAL.

### Specific Usage Notes for CONFIG SIZE:

1. The default size reserved for sample configuration records when sample monitoring is started is 4096 pages.
2. The MONITOR SAMPLE CONFIG SIZE can be issued only when sample monitoring is not active. To change the size after sample monitoring has been started, you must first stop sample monitoring.
3. The minimum value for CONFIG SIZE is one 4 KB page.
4. The maximum value for CONFIG SIZE is equal to the maximum number of pages that can be specified as a type SC range with the DEFSEG command, minus 1 page for sample data records.

**Note:** The number of pages reserved must fit within the saved segment to be used by monitor. This check is made when monitoring is started (if someone is connected to \*MONITOR and the saved segment is known) or when the first user connects after monitoring has been started.

5. The value of CONFIG SIZE is preserved when monitoring is stopped.
6. If while running monitor you experience missing or incomplete monitor records, the size of the sample configuration record area may not be large enough to record all of the system configuration data, especially if there are a large number of devices available on your system. To increase the size of the sample configuration record area, see the MONITOR SAMPLE CONFIG command.

### Specific Usage Notes for CONFIG LIMIT:

1. The CONFIG time limit is the amount of time a user can keep the configuration area in use.
2. The default value for the CONFIG time limit is one minute.
3. The minimum value for CONFIG time limit is one second.
4. The maximum value for CONFIG time limit is 120 minutes.
5. The CONFIG time limit value must be specified as a whole number.
6. When the CONFIG time limit expires, CP:
  - In the EXCLUSIVE environment—stops monitoring and issues message HCP6239I.
  - In the SHARED environment—purges the configuration message, releases the corresponding saved segment pages, and issues message HCP6253I. Data recording continues.
7. Configuration records are created and the CONFIG time limit enforced whenever:

- Recording begins. (A MONITOR START command is issued and at least one user is connected, with an active path, for the type of monitoring being started.)
  - Recording is underway, and:
    - A user connects (with an active path) for that type of monitor data
    - The path of a user connected for that type of data becomes active
    - The user, whose path to \*MONITOR was quiesced when \*MONITOR tried to send a configuration notification message, issues IUCV RESUME
    - The user, whose path to \*MONITOR was at its IUCV message limit when \*MONITOR tried to send a configuration notification message, issues IUCV REPLY or REJECT to one or more previous messages from \*MONITOR.
8. CONFIG TIME LIMIT is preserved when monitoring is stopped.

## Responses

The command, MONITOR SAMPLE START, can be issued before or after a user connects to \*MONITOR to collect sample data.

Response 1:

```
MONITOR SAMPLE STARTED -- RECORDING IS ACTIVATED
```

- or -

```
MONITOR SAMPLE STARTED BY [userid] -- RECORDING IS ACTIVATED
```

As a result of the MONITOR SAMPLE START command, sample monitoring has successfully started. There is at least one user with an active path connected to \*MONITOR for sample data collection.

This response is sent to the user that issued the command. If this user is not the system operator, the response containing [userid] is also sent to the system operator.

Response 2:

```
MONITOR SAMPLE STARTED -- RECORDING IS PENDING
```

- or -

```
MONITOR SAMPLE STARTED BY [userid] -- RECORDING IS PENDING
```

MONITOR SAMPLE START has been issued. Because there is no user with an active path connected to \*MONITOR for sample data collection, sample monitoring is held pending. It shall remain pending until the first user is connected to \*MONITOR for sample data collection.

This response is sent to the user that issued the command. If this user is not the system operator, the response containing [userid] is also sent to the system operator.

Response 3:

```
MONITOR SAMPLE STOPPED
```

- or -

```
MONITOR SAMPLE STOPPED BY [userid]
```

MONITOR SAMPLE STOP has been issued and sample monitoring has been stopped.

This response is sent to the user that issued the command. If this user is not the system operator, the response containing [userid] is also sent to the system operator.

Response 4:

## MONITOR SAMPLE

```
Command complete
```

The MONITOR command has completed successfully.

## MONITOR START/STOP

### Authorization

Privilege Class: A, E

### Purpose

Use the MONITOR START command to activate event and sample monitoring based on the profiles established by the preceding MONITOR EVENT and MONITOR SAMPLE commands or by either one of those commands.

Use the MONITOR STOP command to deactivate all monitoring.

### Operands

#### STArT

activates event and sample monitoring based on the profiles established by the MONITOR EVENT and MONITOR SAMPLE commands. Event monitoring is started first.

#### STOP

deactivates the event and sample monitoring. The profiles for event and sample monitoring are not affected by this command, except for PARTITION which is set to zero. Event monitoring is stopped first.

**Note:** Do not use this command to stop the MONWRITE utility. (See “MONWRITE” on page 2212 for more information.)

#### BLoCk *m*

specifies the number of 4 KB frames, *m*, of the shared segment that are accumulated before the virtual machine is notified that the event data is available for data collection. The BLOCK value may be modified using the MONITOR EVENT BLOCK command while event monitoring is active.

#### PARTition *n*

specifies the number of 4 KB frames, *n*, in the shared segment that are reserved for event records. The rest of the shared segment is then used for sample data.

### Usage Notes

1. The MONITOR START command can be issued before or after a user connects to \*MONITOR. If the MONITOR START command is issued and there is no connection to \*MONITOR through an active path, monitor recording goes into a pending state. Monitor recording is not activated until there is a user connected with an active path (a path that is not quiesced at its IUCV message limit).

The following must be done before monitor recording gets activated:

- A saved segment must be defined and saved for the monitor
- A virtual machine must load the monitor saved segment and connect to the \*MONITOR CP system service
- A MONITOR START command must be issued.

## MONITOR START/STOP

If the START command is issued when no virtual machine is connected with an active path to \*MONITOR for event data, event recording is held pending until there is a connection with an active path.

Specific Usage Note for BLOCK:

1. The default BLOCK value is four 4 KB pages.
2. The minimum value for BLOCK is four 4 KB pages.
3. The maximum value for BLOCK is half the number of pages to be used for the event data area (partition-event config size).
4. The value of BLOCK is saved when monitoring is stopped.

Specific Usage Notes for PARTITION:

1. The default PARTITION size is half the size of the saved segment. The minimum is nine pages.
2. The minimum PARTITION size is eight pages plus the number of pages reserved for event configuration records.

### Notes:

- a. The QUERY MONITOR EVENT command can be used to display the number of pages currently designated for event configuration records.
- b. The MONITOR EVENT CONFIG SIZE command can be used to specify the number of pages to be reserved for the event configuration area. If the MONITOR EVENT CONFIG command has not been issued before the MONITOR START is issued, 68 pages are reserved for event configuration recording, and the PARTITION size must be at least 76 pages.
- c. The maximum PARTITION size depends on whether sample monitoring has already been started, and on whether any user is connected to \*MONITOR when the command is issued to start event monitoring.

If sample monitoring has *not* started, and:

- If one or more users are connected, the maximum PARTITION value that can be entered is the number of pages in the first type SC range of the saved segment that is currently being used by the monitor.
- If there are no users connected to \*MONITOR, the maximum value for PARTITION is equal to the maximum number of pages that can be specified as a type SC range with the DEFSEG command.

If sample monitoring **has** started, the maximum number of pages that can be specified by PARTITION is reduced by one more than the number of pages reserved for sample configuration records. (QUERY MONITOR EVENT and QUERY MONITOR SAMPLE display the number of pages currently reserved for the event and the sample configuration areas.)

3. The maximum PARTITION size depends on whether sample monitoring has already been started, and on whether any user is connected to \*MONITOR when the command is issued to start event monitoring.
4. When monitoring is stopped, the value of PARTITION reverts to the default value.

## Responses

Response 1:

```
MONITOR SAMPLE STARTED -- RECORDING IS ACTIVATED.
```

- or -

```
MONITOR SAMPLE STARTED BY [userid] -- RECORDING IS ACTIVATED.
```

As a result of the MONITOR START command, sample monitoring has successfully started. There is at least one user with an active path connected to \*MONITOR for sample data collection.

```
MONITOR SAMPLE STARTED -- RECORDING IS PENDING.
```

- or -

```
MONITOR SAMPLE STARTED BY [userid] -- RECORDING IS PENDING.
```

MONITOR START has been issued. Because there is no user with an active path connected to \*MONITOR for sample data collection, sample monitoring is held pending. It shall remain pending until the first user is connected to \*MONITOR for sample data collection.

```
MONITOR EVENT STARTED -- RECORDING IS ACTIVATED.
```

- or -

```
MONITOR EVENT STARTED BY [userid] -- RECORDING IS ACTIVATED.
```

As a result of the MONITOR START command, event monitoring has successfully started. There is at least one user with an active path connected to \*MONITOR for event data collection.

```
MONITOR EVENT STARTED -- RECORDING IS PENDING.
```

- or -

```
MONITOR EVENT STARTED BY [userid] -- RECORDING IS PENDING.
```

MONITOR START has been issued. Because there is no user with an active path connected to \*MONITOR for event data collection, event monitoring is held pending. It shall remain pending until the first user is connected to \*MONITOR for event data collection.

#### Notes:

1. Only one of the above responses is displayed for sample monitoring; another is displayed for event monitoring. Depending on the profile set up for monitoring, one or the other, or both, will be displayed.
2. These responses are sent to the user that issued the command. If this user is not the system operator, the responses containing [userid] are also sent to the system operator.

Response 2:

```
MONITOR SAMPLE STOPPED
```

- or -

```
MONITOR SAMPLE STOPPED BY [userid]
```

As a result of the MONITOR STOP command, sample monitoring has been stopped.

```
MONITOR EVENT STOPPED
```

- or -

```
MONITOR EVENT STOPPED BY [userid]
```

As a result of the MONITOR STOP command, event monitoring has been stopped.

#### Note:

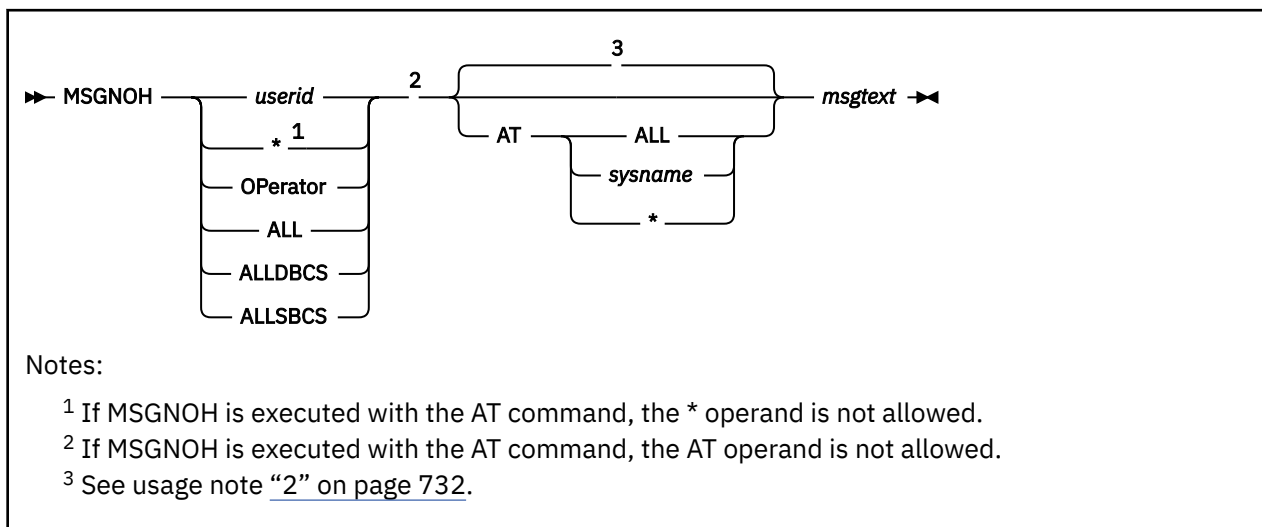

1. Only one of the above responses is displayed for sample monitoring; another is displayed for event monitoring. Depending on the profile set up for monitoring, one or the other, or both, will be displayed.
2. These responses are sent to the user that issued the command. If this user is not the system operator, the responses containing [userid] are also sent to the system operator.

## MONITOR START/STOP

### Messages

- HCP026E Operand missing or invalid
- HCP6227E Monitor {event|sample} collection is not active.

## MSGNOH

### Authorization

Privilege Class: B

### Purpose

Use MSGNOH to allow a service virtual machine to send messages without the standard MESSAGE command header.

### Operands

*userid*

\*

**OPERATOR**

**ALL**

identifies the user to whom you are sending the message. To send a message to yourself, specify an asterisk (\*).

Specify OPERATOR if you want to send a message to the primary system operator, regardless of the operator's user ID. If you specify ALL, you broadcast the message to all users receiving messages.

**ALLDBCS**

transmits the message to all users logged on to DBCS (double-byte character set) terminals.

**ALLSBCS**

transmits the message to all users logged on to SBCS (single-byte character set) terminals.

**AT ALL**

transmits the message to all systems in the SSI cluster to which this system belongs. The lowest return code is returned to the command issuer.

**AT *sysname***

transmits the message to a specific system in the SSI cluster to which this system belongs. The return code is returned to the command issuer.

**AT \***

transmits the message only to the system where the command is issued. This is the default if the system is not a member of an SSI cluster.

***msgtext***

is the text of the message you are sending. The length of the message is limited by the number of characters remaining on the input line after the command and appropriate operand are entered. DBCS text is supported as message text.

**Usage Notes**

1. If a message is issued from a CMS environment, the command and the message text cannot be longer than 240 characters.  
If the message is issued from a CP environment, the command and message length is limited by the input area of the terminal.
2. If the AT operand is not specified:
  - If MSGNOH is not executed with the AT command:
    - If the sender's system is not a member of an SSI cluster, the default is AT \*.
    - If the sender's system is a member of an SSI cluster, the default is AT ALL, except in the following cases, when the default is AT \*:
      - If the specified user ID is OPERATOR.
      - If the specified user ID is logged on to the same system as the sender.
      - If the specified user ID or the sender is defined by a multiconfiguration virtual machine definition.
      - If ALL, ALLDBCS, or ALLSBCS is specified, and a potential recipient user ID is defined by a multiconfiguration virtual machine definition, the default is AT \* for that user ID.
  - If MSGNOH is executed with the AT command, the AT operand function is bypassed (there is no default), and the message is sent to the system specified on the AT command.
3. If an external security manager (ESM) is installed on your system, you might not be authorized to enter this command. However, messages sent to or from the system operator and messages sent with the ALL option are not subject to authorization checking by the ESM. For additional information, contact your security administrator.
4. For additional information, see [“MESSAGE” on page 673](#).

**Responses**

Response 1:

```
msgtext
```

is the response received by the specified user or users.

***msgtext***

identifies the message text.

**Messages**

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on
- HCP057I *userid* not receiving; *text*
- HCP1142E The AT option is not allowed when this command is executed remotely with the AT command.
- HCP2970E The SSI cluster member name is missing or invalid.
- HCP2971I Specified SSI cluster member is not joined.

- HCP6600E An error was detected by installation-wide {*CP module name*|exit point 1210} - return code *nnnn*

## NOTREADY

---

▶ NOTReady — *vdev* ▶

### Authorization

Privilege Class: G

### Purpose

Use NOTREADY to change the apparent status of a virtual spool or console from ready to not ready.

### Operands

#### *vdev*

identifies the number of the virtual device to be made not ready.

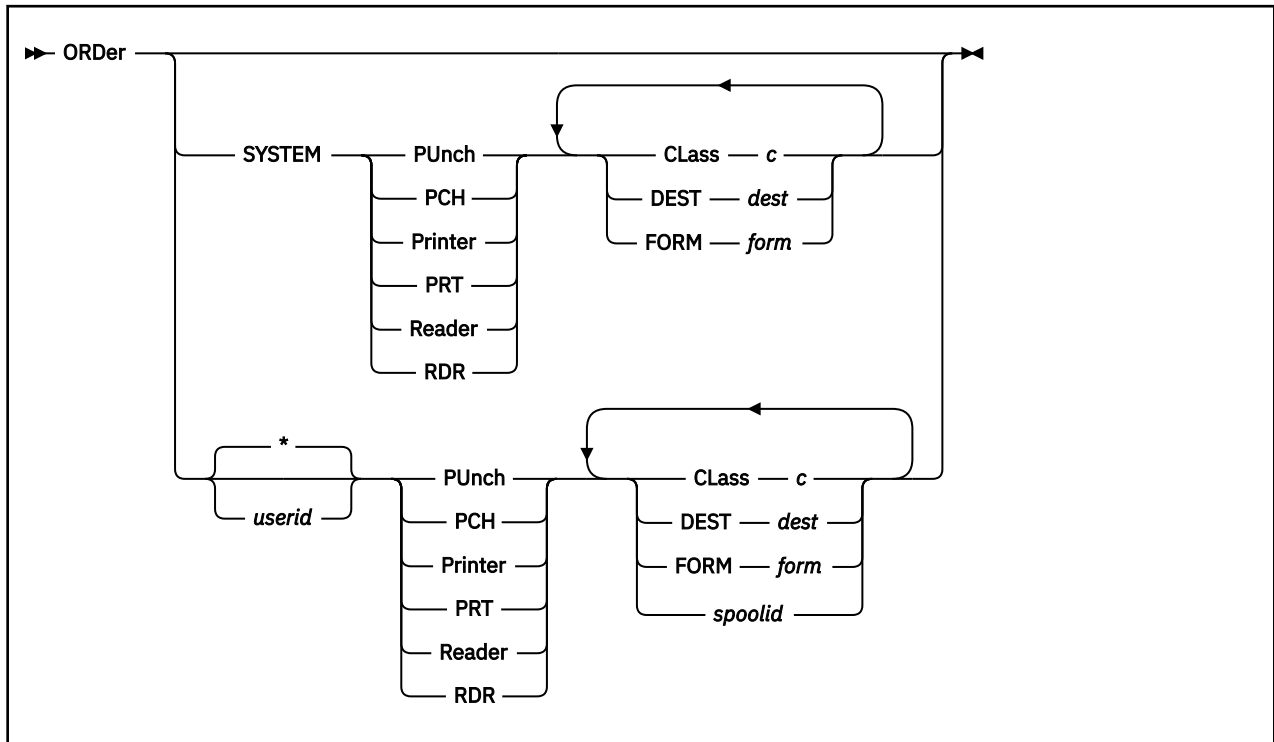

### Usage Notes

1. Use this command to change the status of spooled unit record devices and virtual consoles only.
2. Any I/O operation in progress to the specified device at the time the command is issued is completed; the not-ready condition is in effect for the next I/O operation.

### Messages

- HCP006E Invalid device type - {*rdev/vdev/ldev*}
- HCP022E A virtual device number was not supplied or it was invalid.
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP263E Too many operands were supplied for this command.

## ORDER

### Authorization

Privilege Class: D, G

### Purpose

Use ORDER to change the order of a specified output queue.

Class G users can use ORDER to arrange their own spool files. Class D users can use ORDER to arrange any spool files in the system, regardless of owner.

### Operands

#### SYSTEM

is restricted to class D users. Use the SYSTEM operand to order any file or group of files on the system queue that you specify without indicating the owner's user ID. This is not valid with the *spoolid* option.

\*

#### userid

identifies the user whose spool files are to be ordered. If you are ordering your own files, you may specify *userid* as an asterisk (\*).

The *userid* option allows a class D user to order any file, or group of files, owned by a particular user. Reader files are repositioned only with respect to other reader files owned by the user ID that you specified. Print or punch files are repositioned to the top of the system queue and to the specified user output queue.

The *userid* option allows a class G user to order any file originated by that user, and that is now owned by the user whose user ID is specified on the command line. The files are only in relation to any other files that the class G user originated which are owned by the user ID specified in the command line.

## ORDER

**PUnch**  
**PCH**  
**Printer**  
**PRT**  
**Reader**  
**RDR**

indicates the spool file queue you want to order.

### **Class *c***

are the file classes that you want to rearrange, and the sequence in which they are to be processed. You must enter the keyword **Class** for each class that you want to order. The operand *c* is a 1-character alphanumeric fields (from A to Z or from 0 to 9) that represent spooling classes.

### **FORM *form***

are the forms to be rearranged, and the sequences in which they are to be processed. The operand *form* is specified as one to eight characters in length. For the class G user, the form is the user form name. For the class D user, the form is the user form name when you specify asterisk (\*) or default to your user ID. Otherwise, the form is the operator form number.

### **DEST *dest***

are the file destination values to be rearranged, and the sequence in which they are to be processed. The operand *dest* is specified as 1- to 8-character names.

### ***spoolid***

identifies the files you want to order. This option is not valid with the **SYSTEM** keyword.

## Usage Notes

1. SET IMSG OFF suppresses informational messages for this command.
2. The order of closed spool files determines the sequence in which they are selected and processed.
3. Class G users can order only their own files and any files that they originated. The order that you specify does not affect the position of any other files that are in the same system queue as your files, but only repositions your files with respect to any other files you may own.

For example, suppose the system printer queue contains the following files:

<b><u>Spoolid</u></b>	<b><u>Owning User</u></b>
1	USER1
22	USER2
333	USER2
4444	USER2

Assume further that USER2 enters `order prt 4444`; the following queue order results:

<b><u>Spoolid</u></b>	<b><u>Owning User</u></b>
1	USER1
4444	USER2
22	USER2
333	USER2

The class G user may order files originated by that user and that another user ID now owns. If so, the user changes the order of the files only in relation to any other files that the user originated that are now owned by the other user ID. For example, assume there are two users, USER1 and USER2, and USER2's printer queue is as follows:

Spoolid	Owning User	Originator
123	USER2	USER2
456	USER2	USER1
789	USER2	USER1
9101	USER2	USER2

Assume further that USER1 enters `order user2 prt 789`; the following print queue order results for USER2:

Spoolid	Owning User	Originator
123	USER2	USER2
789	USER2	USER1
456	USER2	USER1
9101	USER2	USER2

4. The class D user can reorder any files in the system by specifying the SYSTEM or *userid* option.

For example, if you enter `order system printer class c`, all class C printer files are placed ahead of any other printer files in the system, regardless of who owns them or originated them.

The ORDER command is also useful to the class D user who wants to place files owned by a particular user ahead of all other files on a printer or punch queue. For example, if you enter `order user2 punch class b`, you place all of USER2's Class B punch files ahead of all other punch files on the system.

5. Use the QUERY READER/PRINTER/PUNCH command to determine spool file attributes, such as class and spool ID, for the files that you want to rearrange. The display produced by the command shows the current order of the spool files on the queue that you specify.
6. You can use a combination of CLASS, FORM, DEST and *spoolid* specifications to rearrange files. For example, `order printer class a 1963 class c form listing dest bldg2` orders the command issuer's printer queue as follows:
- All class A files
  - The file with spoolid 1963
  - All class C files
  - All files with the form LISTING
  - All files with the dest BLDG2.

They are followed by any other printer spool files not specified in the ORDER command line.

7. A file cannot be ordered more than once in a given command. For example, assume the following is a user's spool print queue.

Spoolid	Class
1234	A
4567	B
7890	A
5555	A
8888	B

If the user enters `order prt 8888 class a class b`, the following order results:

## ORDER

<u>Spoolid</u>	<u>Class</u>
8888	B
1234	A
7890	A
5555	A
4567	B

Note that *spoolid* 8888 was only ordered once.

8. Files that appear in PRINTED status when queried will not be selected for ORDER processing.

## Responses

Response 1:

```
{nnnnnn} FILE(S) ORDERED  
{      NO}
```

indicates the number of files ordered.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

## PER

---

### **Authorization**

Privilege Class: G

### **Purpose**

PER is a synonym for TRACE. Within z/VM, TRACE can monitor events that occur in your virtual machine. For more information, see [“TRACE” on page 1946](#).

## PURGE

### Authorization

Privilege Class: D, G

### Purpose

Use PURGE to remove closed spool files from the system before they are selected for output.

PURGE *spoolid* can be used to purge a file after it begins to be processed by a real device; output function ceases and the spool file is purged. Class G users can use PURGE to purge their own spool files. Class D users can use PURGE to purge any spool files in the system,

### Operands

#### Force

indicates that the files matching the selection criteria are purged immediately by CP, even files that have been converted by the print server. If FORCE is not specified, and a file has been converted, CP releases all of the file's resources, except for the file descriptor block, and marks the file as logically purged. When the print server selects a file for processing, it acknowledges that the file has been purged and tells CP to release the file descriptor. FORCE is valid for the Class D user only.

#### SYSTEM

allows the class D user to manipulate all files in the system, regardless of ownership. This is not allowed with *spoolid*.

\*

#### *userid*

identifies the user whose files are to be purged.

The operand *userid* allows the class D user to purge files that belong to any user on the system. If you are a class G user, you can purge your own files or files owned by another user ID that you originated.

Class D or class G users can purge their own files using the asterisk (\*) option. If you do not specify *userid* or \*, the default is to purge your own files.

**Reader****RDR****Printer****PRT****PUnch****PCH****UR**

indicates which spool file queue contains the files that you want to purge. UR indicates that all reader, printer, and punch files are to be purged.

**ALL**

specifies that all files on the queue of the device type specified (READER, PRINTER, PUNCH, UR) are to be purged.

**Class c**

designates a spool file class where *c* is a 1-character alphanumeric field from A to Z or 0 to 9. All the files of the specified class or classes for the specified device type or types are purged.

**DEST *dest***

purges all of the files with the specified destination value. The operand *dest* is specified as one to eight characters long.

**FORM *form***

purges all files with the specified form names or form numbers. The operand *form* is specified as one to eight characters long. For the class G user, the form is the user form name. For the class D user, the form is the user form name when you specify \* or default to your *userid*. Otherwise, the form is the operator form number.

***spoolid***

purges the files of the specified *spoolid*, for the specified device type.

**Usage Notes**

1. SET IMSG OFF suppresses informational messages for this command.
2. The class D user can use the PURGE command to purge any file in the system by specifying the SYSTEM or *userid* option. For example, if you enter `purge system printer class c`, you purge all class C printer files in the system, regardless of who owns them or who originated them.  
  
The class D user can use the *userid* option to purge any file or files that are owned by a particular user. For example, if you enter `purge genuser reader all`, you purge all reader files owned by the user ID GENUSER.
3. You can purge files using a combination of CLASS, FORM, DEST, and *spoolid* on the same command line. For example, `purge printer class a 1932 form document class d 619 dest bldg1` specifies that CP should purge all the command user's class A and class D printer files, all the command user's files with form DOCUMENT, all the command user's printer files with the destination BLDG1, and the command user's printer files having *spoolids* 1932 and 619.
4. If a command syntax error occurs when purging closed spool files from the system, only the files encountered prior to the error are processed.

**Responses**

Response 1:

```
{nnnnnn} FILE(S) PURGED
{
  NO}
```

## PURGE

indicates the number of files purged.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP008E Invalid spoolid - *spoolid*
- HCP026E Operand missing or invalid
- HCP028E Class missing or invalid
- HCP035E Device type missing or invalid

## PURGE IMG

### Authorization

Privilege Class: A, B, C, D, E

### Purpose

Use PURGE IMG to remove system data files containing image libraries.

### Operands

#### ALL

lets you purge all image library files.

#### *spoolid*

identifies the number used to identify the file or files to be purged.

#### NAME *fn*

identifies the file name of the file or files to be purged.

### Usage Notes

1. SET IMSG OFF suppresses informational messages for this command.
2. Any combination of *spoolid* and NAME may be specified on the PURGE IMG command line. For example, `purge img 1234 name imag3800 3421` purges IMG files 1234 and 3421, and any IMG files with the file name IMAG3800.
3. In response to the PURGE command, CP purges the designated files *unless* the files are currently in use. If a file is currently in use, CP places it in a pending purge state (class P) and purges it as soon as it is no longer being used or the system is shut down or re-IPLed.
4. To determine if a file is in a pending purge state, enter the QUERY IMG command. If the file *is* in a pending purge state, CP's response shows that the file is Class P.

### Responses

Response 1:

```
{nnnn} FILE(S) PURGED
{ NO }
```

displays the count of files purged.

#### *nnnn*

indicates the number of files purged.

Response 2:

```
{nnnn} FILE(S) PENDING PURGE
```

## PURGE IMG

displays the count of files pending purge.

### ***nnnn***

indicates the number of files to be purged when they are no longer in use.

For example, in the situation where five image files exist, of which two are in use, enter `purge img all`. The responses are:

```
0003 FILES PURGED
0002 FILES PENDING PURGE
```

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP008E Invalid spoolid - *spoolid*
- HCP026E Operand missing or invalid
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP1001E An operand is missing for *option*.
- HCP1013E An invalid operand was supplied for *option - operand*

## PURGE NLS

### Authorization

Privilege Class: E

### Purpose

Use PURGE NLS to purge message repository files.

### Operands

#### ALL

specifies that all message repository files are to be purged.

#### *spoolid*

identifies the file to be purged.

#### NAME *fn*

specifies the name of the file to be purged.

### Usage Notes

1. SET IMSG OFF suppresses informational messages for this command.
2. Any combination of *spoolid* and NAME may be specified on the PURGE NLS command line. For example, `purge nls 1234 name nls101 3421` purges message repository files 1234 and 3421, and any message repository files with the file name NLS101.

### Responses

Response 1:

```
{nnnn} FILE(S) PURGED
{ NO}
```

displays the count of files purged.

#### *nnnn*

indicates the number of files purged.

Response 2:

```
{nnnn} FILE(S) PENDING PURGE
```

displays the count of files waiting to be purged.

#### *nnnn*

indicates the number of files to be purged when they are no longer in use.

## PURGE NLS

For example, when five NLS files exist and two are in use, and you enter `purge nls all`, the responses are:

```
0003 FILES PURGED
0002 FILES PENDING PURGE
```

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP008E Invalid spoolid - *spoolid*
- HCP026E Operand missing or invalid
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP423E The function requested is not compatible with a previously specified operand.
- HCP1001E An operand is missing for *option*.
- HCP1013E An invalid operand was supplied for *option* - *operand*

## PURGE NSS

### Authorization

Privilege Class: E

### Purpose

Use PURGE NSS to remove system data files containing named saved systems (NSSs) and saved segments.

### Operands

#### ASSOCIates

specifies that the files associated with a segment space or member segment are to be purged. If you purge a segment space, its associated members are also purged or set to pending purge, or their segment space entries are compressed. If a segment space is purged with ASSOCIATES, then all the members in that space, that are not defined to another segment space (same ranged), are purged. If the member(s) belong to another segment space they will not be purged.

If you purge a member segment, it is purged or set to pending purge, and its associated segment spaces are purged or set to pending purge, or their member entries are compressed. If a member of a segment space is purged with ASSOCIATES, then the member will be purged when the use count=0, and the member will be removed from all of the segment spaces that it is defined to. Once the use count=0, and the member is purged, then the segment spaces it was previously defined to will complete and can be loaded from. If associates option is not used, the member will be purged when the use count=0, but the space will no longer be loadable.

#### ALL

lets you purge all NSS and saved segment files.

#### *spoolid*

is the number used to identify the file. It specifies the file to be purged. It can be an NSS, a saved segment, a segment space, or a member saved segment.

#### NAME *fn*

specifies the file name that identifies the file to be purged. The file can be an NSS, a saved segment, a segment space, or a member saved segment.

### Usage Notes

1. SET IMMSG OFF suppresses informational messages for this command.
2. Any combination of *spoolid* and NAME may be specified on the PURGE NSS command line. For example, `purge nss 1234 name cms 3421` purges NSS and saved segment files 1234 and 3421, and any NSS and saved segment files with the file name CMS.
3. The PURGE NSS command interrupts an in-process SAVESEG or SAVESYS operation to purge the saved segment or named saved system before the save completes. This will not leave a partially-saved

## PURGE NSS

system data file on the system. The skeleton system data file will be purged and must be redefined before the saved segment or named saved system can be resaved.

4. In response to the PURGE command, CP purges the designated files *unless* the files are currently in use. If a file is currently in use, CP places it in a pending purge state (class P), and purges it as soon as it is no longer being used or the system is shut down or re-IPLed. If the file being purged is a member of a segment space, the system places it in pending purge status if any user is accessing any member of the segment space. The system purges the member when the segment space is no longer in use.
5. If you do not specify ASSOCIATES and the target of the PURGE command is a member saved segment, CP purges only that member. It does not purge any other file, and it does not update any segment space descriptions. If the target of the PURGE command is a saved segment, CP purges only the saved segment. If the target of the PURGE command is a segment space, CP purges only that segment space. It does not purge any other file, and it does not update members of that segment space.
6. To determine if a file is in a pending purge state, enter the QUERY NSS command. If the file is in a pending purge state, the CP response shows that the file as class P.
7. Processing of a PURGE NSS command might be delayed if DIAGNOSE code X'64' is concurrently performing the initial load of a large DCSS.

## Responses

Response 1:

```
{nnnn} FILE(S) PURGED  
{ NO}
```

displays the count of files purged.

### **nnnn**

indicates the number of files purged.

Response 2:

```
{nnnn} FILE(S) PENDING PURGE
```

displays the count of files waiting to be purged.

### **nnnn**

indicates the number of files to be purged when they are no longer in use.

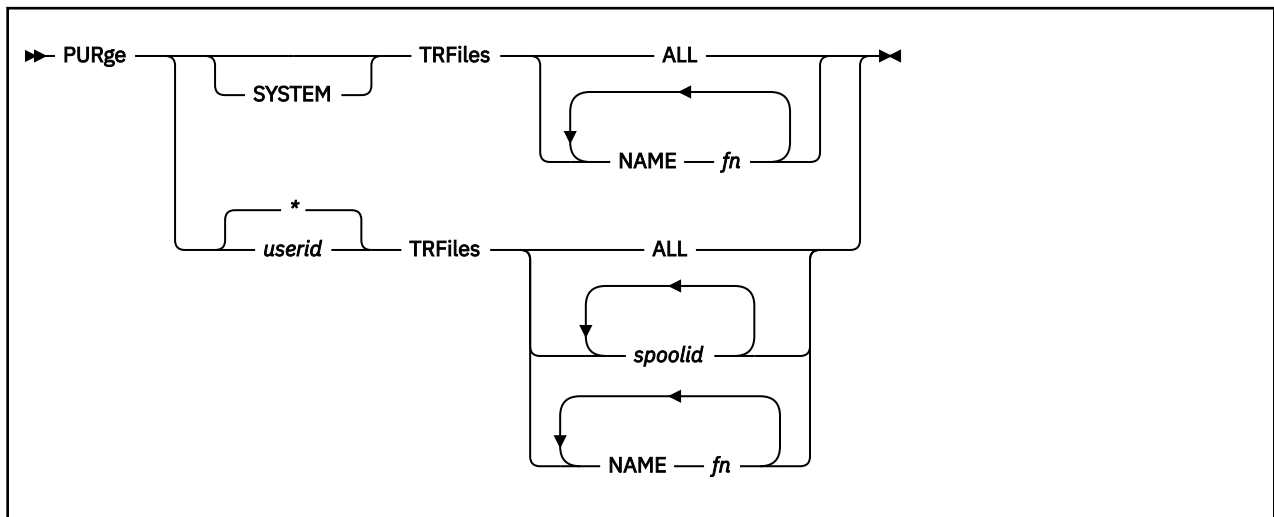

For example, when five NSS or saved segment files exist and two are in use, and you enter `purge nss all`, the responses are:

```
0003 FILES PURGED  
0002 FILES PENDING PURGE
```

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP008E Invalid spoolid - *spoolid*
- HCP026E Operand missing or invalid
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP1001E An operand is missing for *option*.
- HCP1013E An invalid operand was supplied for *option* - *operand*
- HCP1370E You cannot purge *name* using the ASSOCIATES option.

## PURGE TRFILES

### Authorization

Privilege Class: A, C, D, E, G

### Purpose

Use PURGE TRFILES to remove system trace files created by TRSAVE.

### Operands

#### SYSTEM

specifies that files are to be purged regardless of who owns or originates them. Class G users cannot use the SYSTEM option; it is not valid with the *spoolid* option.

\*

#### *userid*

specifies the owner of the files to be purged. System trace files cannot be purged while they are in use. Class G users can purge only files that they own or originate, and that are not in use. Class A, C, D, and E users can purge any system trace files that are not in use.

You can specify asterisk (\*) to purge your own system trace files. This is the default.

#### TRFiles

specifies that system trace files are to be purged.

#### ALL

specifies that all system trace files are to be purged.

#### NAME *fn*

specifies the name of the file to be purged. This is the file name specified on the command TRSAVE... ON DASD NAME *fname*... when the trace was started. More than one file can exist with the same file name for a given owner.

#### *spoolid*

specifies the spool file identification number of the file to be purged. This option is not valid with the SYSTEM option.

### Usage Notes

1. SET IMSG OFF suppresses informational messages for this command.

## PURGE TRFILES

2. Any combination of *spoolid* and NAME may be specified on the PURGE TRFILES command line. For example, `purge trf 1234 name gtrace 3421` purges system trace files 1234 and 3421, and any trace files with the file name GTRACE.
3. If you specify *spoolid* to purge files, the file you purge may be part of a group of files with the same file name as that created by the TRSAVE...ON DASD NAME *fname*... command. If this is the case, some system trace data information is purged.
4. If you specify the NAME option to purge files and there are multiple groups of trace files with the same name, you may accidentally purge files you do not want to purge. Use the QUERY TRFILES command to display all of the trace files and determine which files you want to discard. If more than one file exists with the same name, use *spoolid* to specify the correct file to be purged and to avoid losing data.
5. If you are authorized to use the SYSTEM option and you use it with the NAME option, you purge all trace files in the system with the file name specified.
6. If a system trace file has a class of W (meaning the file is being written to), it is not purged. You must enter the TRSAVE OFF, TRSAVE CANCEL, or TRSOURCE DISABLE command to purge the class W file.

## Responses

Response 1:

```
{nnnnnnn} FILE(S) PURGED  
{          NO}
```

indicates the number of files purged.

## Messages

- HCP003E Invalid option - *{option|command}* contains extra option(s) starting with *option*}
- HCP008E Invalid spoolid - *spoolid*
- HCP026E Operand missing or invalid
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP423E The function requested is incompatible with a previously specified operand.

- HCP1001E An operand is missing for *option*.
- HCP1013E An invalid operand was supplied for *option - operand*

## PURGE UCR

### Authorization

Privilege Class: A, B, C

### Purpose

Use PURGE UCR to purge a UCR file created by the system programmer.

### Operands

#### ALL

lets you purge all UCR files.

#### *spoolid*

is the number used to identify the files to be purged.

#### NAME *fn*

is the file name used to identify the files to be purged.

### Usage Notes

1. SET IMSG OFF suppresses informational messages for this command.
2. You may specify any combination of *spoolid* and NAME on the PURGE UCR command line. For example, `purge ucr 1234 name ucr101 3421` purges UCR files 1234 and 3421, and any UCR files with the file name UCR101.
3. UCR spool files and the OVERRIDE command are no longer supported. Once these files are purged, they cannot be rebuilt. Use the MODIFY statement or command to change command privilege classes. For information about MODIFY, see [Modifying a Command and Diagnose Code in z/VM: CP Exit Customization](#).

### Responses

Response 1:

```
{nnnn} FILE(S) PURGED
{ NO}
```

displays the count of files purged by the PURGE UCR command.

#### *nnnn*

indicates the number of files purged.

### Messages

- HCP003E Invalid option - *{option|command}* contains extra option(s) starting with *option*
- HCP008E Invalid spoolid - *spoolid*

## PURGE UCR

- HCP026E Operand missing or invalid
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP1001E An operand is missing for *option*.
- HCP1013E An invalid operand was supplied for *option - operand*

## QUERY ABEND

► Query — ABEND ◄

### Authorization

Privilege Class: B

### Purpose

Use QUERY ABEND to display the status of the soft abend function. Using this command, you can determine whether soft abends cause full system termination, full system snapdumps, or are processed normally.

### Responses

Response 1:

```

ABEND  {SOFT      }
       {SOFT aaannn}
       {HARD      }
       {HARD aaannn}
       {OFF       }
       {OFF aaannn}
       {SNAPDUMP  }
       {SNAPDUMP aaannn}

```

#### SOFT

indicates that soft abends do not force full system termination; normal system processing continues after recovery action is taken.

#### SOFT *aaannn*

specifies the soft abends that you have selected to be treated as soft abends; normal system processing continues after recovery action is taken. The code *aaannn* is made up of a 3-character module name and a 3-character abend code.

**Note:** ABEND SOFT *aaannn* can display up to five entries on a single output response line.

#### HARD

indicates that no soft abends are to attempt recovery action; all soft abends cause full system termination as if they were hard abends.

#### HARD *aaannn*

specifies the soft abends that you have selected to be treated as hard abends; they cause full system termination. The code *aaannn* is made up of a 3-character module name and a 3-character abend code.

**Note:** ABEND HARD *aaannn* can display up to five entries on a single output response line.

#### OFF

indicates that soft abends will not generate a soft abend dump; normal system processing continues after recovery action is taken.

#### OFF *aaannn*

specifies the soft abends that you have selected will not generate a soft abend dump; normal system processing continues after recovery action is taken. The code *aaannn* is made up of a 3-character module name and a 3-character abend code.

**Note:** ABEND OFF *aaannn* can display up to five entries on a single output response line.

#### SNAPDUMP

indicates that all soft abends cause full system snapdumps, as if they were specified as snapdumps.

## QUERY ABEND

### SNAPDUMP *aaannn*

specifies the soft abends that you have selected to be treated as snapdumps; they cause snapdump dumps to be created. The code *aaannn* is made up of a 3-character module name and a 3-character abend code.

**Note:** ABEND SNAPDUMP *aaannn* can display up to five entries on a single output response line.

### Examples

```
ABEND SOFT
ABEND HARD      ABC001 BCD002 CDE003
ABEND SNAPDUMP DEF004 EFG005 FGH006 GHI007 HIJ008
ABEND SNAPDUMP IJK009
```

This would indicate that there were three soft abends that had been set to hard (*ABC001*, *BCD002* and *CDE003*), and six soft abends that had been set to snapdump (*DEF004*, *EFG005*, *FGH006*, *GHI007*, *HIJ008* and *IJK009*). The global setting is soft, which is in effect for all of the remaining soft abend codes.

### Messages

## QUERY ADJUNCT

---

► Query — ADJunct ◄

### Authorization

Privilege Class: G

### Purpose

Use to display the status of an adjunct machine for the user.

### Responses

Response 1:

When the adjunct configuration of userid VTEST1 is active (and thus the principal configuration is suspended):

```
HCPYJT5777I VTEST1 Adjunct is currently active
```

In this state, commands prefixed with #CP are directed by default to the adjunct configuration.

Response 2:

When the adjunct configuration of userid VTEST1 is suspended (and thus the principal configuration is active):

```
HCPYJT5776I VTEST1 Adjunct is suspended
```

In this state, commands prefixed with #CP are directed by default to the principal configuration.

### Messages

- HCP5776I *userid* Adjunct is suspended
- HCP5777I *userid* Adjunct is currently active

# QUERY AGELIST

► Query — AGELIST ◄

## Authorization

Privilege Class: A, E

## Purpose

Use QUERY AGELIST to display the settings for the global aging list used by the system's frame replenishment algorithm.

To satisfy the system's need for real storage, the frame replenishment algorithm selects candidate frames from the user and system frame-owned lists. The pages associated with the selected frames are put in the invalid-but-resident (IBR) state. Any access to a page in the IBR state by the guest results in a re-validation. Otherwise, after a period of aging on the local frame-owned list, the frame associated with an IBR page is added to the global aging list.

If a page is referenced while its frame is on the aging list, the page is re-validated and the frame moves back to the appropriate frame-owned list. Before a frame can be reclaimed from the aging list, the page content must be backed in auxiliary storage.

## Responses

```
Target size      = nU (mU) x.x% of pageable storage
In use          = nU
Pending writes  = nU
Early writes    = Yes|No
Sizing          = Fixed|Variable
Keep slot       = Yes|No
```

where:

### Target size *nU*

identifies the maximum expected amount of pageable storage to be contained in the global aging list. The target size is displayed in a storage unit (K,M,G,T,P,E) suitable to represent the values displayed in the remaining lines of the command response.

### (*mU*)

the target size in a storage unit with a precision of no more than 7 significant digits. This value may be rounded if the aging list size is defined as a percentage of pageable storage. When the aging list is empty this value is omitted.

### *x.x%* of pageable storage

identifies the target size as a percentage of pageable storage. The value may be rounded to the nearest tenth of a percent if the aging list size is defined as a fixed storage size.

### In use *nU*

identifies the amount of storage currently within the global aging list in storage units (K,M,G,T,P,E). Usage of the aging list is at the discretion of CP based on storage constraints. The amount of storage currently within the aging list may be significantly less than the target size, or in some cases slightly higher.

### Pending writes *nU*

identifies the portion of the global aging list in storage units (K,M,G,T,P,E), that must be backed up in auxiliary before the associated frames can be reclaimed.

## QUERY AGELIST

### **Early writes = Yes**

indicates the frame replenishment algorithm backs up page content to auxiliary storage in advance of frame reclaim to maintain a pool of immediately reclaimable frames.

### **Early writes = No**

indicates the frame replenishment algorithm backs up page content to auxiliary storage only when the system is in need of frames.

### **Sizing = Fixed**

indicates the size of the aging list was specified on the SET AGELIST command as a fixed storage size.

### **Sizing = Variable**

indicates the size of the aging list was specified on the SET AGELIST command as a percentage of pageable storage. Since the number of real frames containing pageable content varies over time, so will the size of the aging list.

### **Keep slot = Yes**

indicates the auxiliary storage address (ASA) to which a page is written during frame replenishment will remain allocated to that page when it is read into real memory upon access by the guest.

### **Keep slot = No**

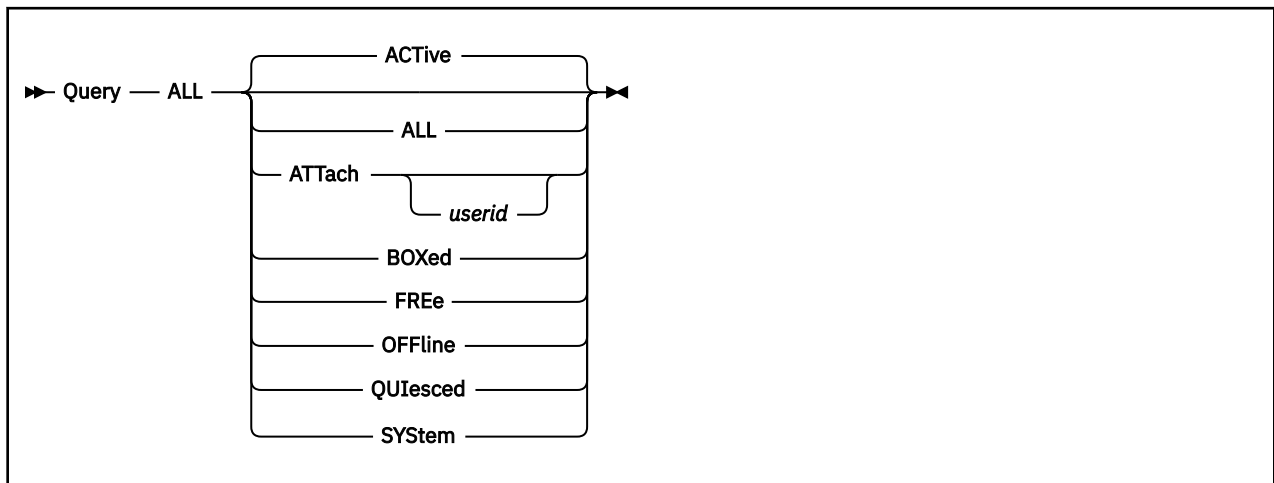

indicates the ASA to which a page is written during frame replenishment is unallocated during page fault processing.

When Keep slot is No, some resident pages might still have copies on auxiliary storage, unless Early writes is also No.

## **Messages**

- HCP003E Invalid option - *option*|command contains extra option(s) starting with *option*

## QUERY ALL

### Authorization

Privilege Class: B

### Purpose

Use `QUERY ALL` to display the status of all the real devices attached to the system. It also displays the size of real storage.

### Operands

#### ACTive

indicates all active devices. An active device is one that is in use by a user or the system and is specified as neither `FREE` nor `OFFLINE`.

#### ALL

indicates all devices attached to the system. The status is displayed in the order of `ACTIVE`, `FREE`, and `OFFLINE`. You receive the same response as you would receive if you entered all of the following commands:

```
query all active
query all free
query all offline
```

#### ATTach *userid*

indicates the devices that are dedicated to a user on the system. If you specify *userid*, only devices attached to that user's virtual machine are indicated. If you do not specify *userid*, you receive the status of all devices dedicated to any user on the system. Attached devices are always active.

#### BOXed

indicates the devices that are unavailable (usually because of a hardware condition). A boxed device may also be active, free, or offline.

#### FREe

indicates all free devices. A free device is one that is not currently in use by a user or the system and is specified as neither `ACTIVE` nor `OFFLINE`.

#### OFFline

indicates all offline devices. An offline device is specified as neither `ACTIVE` nor `FREE`. The offline response will also show offline devices which are quiesced.

## QUIesced

indicated all quiesced DASD. A quiesced device is an offline device which cannot be varied online until a resume request is received for the device.

## SYStem

indicates the devices in use by the system. A system device is always active.

## Usage Notes

1. When you enter a QUERY ALL command, you must make sure the command's options are valid for each virtual machine associated with one or more *prtids*. For example, if you enter a QUERY ALL command with the ALL parameter and a service virtual machine (SVM) controlling a printer does not accept that parameter, you get an error message from the service virtual machine.
2. A VIRTUAL version of this command, QUERY VIRTUAL ALL, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL ALL” on page 1273](#).

## Responses

The response to a QUERY ALL command is a mixture of all of the following responses. CP presents the information you request in ascending order of real device numbers.

Response about Real Storage:

At the beginning of the response to any QUERY ALL command, you receive a line like this:

```
STORAGE = 0128768K
```

This means the system's real storage is approximately 128 megabytes.

Response for Devices Needing Intervention:

If the system is using any device that is in an intervention-required state and you enter QUERY ALL, you receive a response like this:

```
DASD 1801 has intervention required.
```

The message indicates the real device type and device number. In this case, the real device type is DASD, which includes emulated DASD. The message can include the following device types:

<b>Type</b>	<b>Meaning</b>
FCP	SCSI device adapter
TAPE	Magnetic tape
RDR	Card reader
PRT	Printer
PUN	Card punch
GRAF	Display device
LINE	Communication line
CTCA	Channel-to-channel adapter
OSA	Open Systems Adapter
CTLR	3745 Communications Controller
MSC	Mass Storage Controller
SWCH	Dynamic Switching device
DEV	Any other device.

**Note:** This response will be preceded by a combination of messages that look like the following.

Responses from Real Channel-to-Channel Adapters:

If there are channel-to-channel adapters attached to the system, you see something like this:

```
CTCA 0480 ATTACHED TO PVM      0480
CTCA 0481 ATTACHED TO PVM      0481
CTCA 0482 ATTACHED TO RSCS     0482
CTCA 0483 ATTACHED TO RSCS     0483
CTCA 0484 ATTACHED TO PVM      0485
CTCA 0485 ATTACHED TO PVM      0484
CTCA 0486 ATTACHED TO VTAM     0486
CTCA 0700 ATTACHED TO TCPIP    0500
CTCA 0701 ATTACHED TO TCPIP    0501
```

The first number (for example, 0480) is the real device number of the channel-to-channel adapter. The ATTACHED operand might also read BOX/ATTC, which means that although the device is attached and dedicated to a user, it is unavailable. PVM, RSCS, TCPIP, and VMNET are user IDs to which the CTCAs are dedicated. The last number (for example, 0480) is the virtual device number that each virtual machine uses to refer to a CTCA.

If there are free channel-to-channel adapters attached to the system, you see something like this:

```
CTCA 0487 FREE      , CTCA 04A1 FREE      , CTCA 04A2 FREE      , CTCA 04A3 FREE
CTCA 04A4 FREE      , CTCA 04A5 FREE      , CTCA 04A9 FREE      , CTCA 04AA FREE
CTCA 04AB FREE      , CTCA 04BC FREE      , CTCA 04BD FREE      , CTCA 04BE FREE
CTCA 04BF FREE
```

This response shows the real device number for each free CTCA.

The responses for offline and boxed adapters are in the same format.

Responses from FCP Adapter Devices:

If there are FCP devices attached to the system, you see something like this:

```
FCP 0480 ATTACHED TO LINUX1    0480 CHPID F1
FCP 0481 ATTACHED TO LINUX1    0481 CHPID F1
FCP 0482 ATTACHED TO LINUX2    0482 CHPID F1
FCP 0483 ATTACHED TO LINUX3    0483 CHPID F1
FCP 0484 ATTACHED TO TEST1     0485 CHPID F1
FCP 0485 ATTACHED TO TEST1     0484 CHPID F1
```

The first number is the real device number of the FCP adapter device. The ATTACHED operand might also read BOX/ATTC, which means that although the device is attached and dedicated to a user, it is unavailable. LINUX1, LINUX2, LINUX3, and TEST1 are user IDs to which the FCP devices are dedicated. The next number is the virtual device number that each virtual machine uses to refer to an FCP device. The last number is the CHPID number (channel path) associated with the device number.

If there are free FCP devices attached to the system, you see something like this:

```
FCP 04A1 FREE      , FCP 04A2 FREE      , FCP 04A3 FREE      , FCP 04A4 FREE
FCP 04A5 FREE      , FCP 04A6 FREE      , FCP 04A9 FREE      , FCP 04AA FREE
FCP 04AB FREE      , FCP 04BC FREE      , FCP 04BD FREE      , FCP 04BE FREE
FCP 04BF FREE
```

This response shows the real device number for each free FCP device.

The responses for offline and boxed devices are in the same format.

Responses from Real DASD:

You see responses like the following if real DASDs are attached to the system for access as user minidisks or for system paging, spooling, or temporary disk space.

```
DASD 0280 CP SYSTEM XAUSR1    49
DASD 0281 CP SYSTEM XAUSR2    24
DASD 0282 CP SYSTEM XAUSR3    49
DASD 0283 CP SYSTEM XAUSR4    34
DASD 0284 CP SYSTEM XAUSR5    42
DASD 0285 CP SYSTEM XAUSR6    20
```

## QUERY ALL

```
DASD 0A01 CP OWNED ESAP01 3
DASD 0A02 CP OWNED ESAP02 1
DASD 0A03 CP OWNED ESAP03 1
DASD 0A04 CP OWNED ESAP04 1
DASD 0A05 CP OWNED ESAP05 1
DASD 0C08 CP SYSTEM ESAP7 1
DASD 0C09 CP SYSTEM ESAP6 1
DASD 1800 CP SYSTEM USP1 4
DASD 1801 CP SYSTEM USP2 2
```

The first number listed (for example, 0280) is the real device number of the DASD. SYSTEM indicates the device is allocated to the system for use as users' minidisks. OWNED indicates the device is used by the system for paging and spooling activity. XAUSR1, ESAP01, and the rest are volume labels of the devices. The last number (for example, 49) indicates the number of links to minidisks contained on the volume.

The following response is also displayed if real DASDs are attached to the system for access as user minidisks or for system paging, spooling, or temporary disk space. This response is longer than the response above because the device may be reserved (shared option is on), it may have a reserve pending, or it is currently reserved.

```
DASD 181A CP SYSTEM ESAP2C SHARED
DASD 181B CP OWNED ESAP2F RESERVE PENDING FOR USER DAVID
DASD 181C CP OWNED ESAP30 RESERVED BY SYSTEM
```

If a DASD is dedicated to a user, you see a message like this:

```
DASD 0820 ATTACHED TO OLIVER 01FC R/O XAUSR4
```

This means that the DASD at the real device number 0820 is attached to OLIVER's virtual machine as the virtual device 01FC. The DASD's volume identifier is XAUSR4. R/O means the user OLIVER has read-only access to the DASD. R/O might also read R/W, which means the user has read-write access. ATTACHED may be replaced with BOX/ATTC, which means that although the device is dedicated to a user, it is unavailable (usually because of a hardware condition).

Responses from Real Graphic Display Devices:

If a real graphic display is dedicated to a virtual machine, you see something like this:

```
GRAF 0BCD ATTACHED TO OLIVER 0010
```

This message means the graphic display device at the real device number 0BCD is attached to OLIVER's virtual machine as the virtual device 0010. ATTACHED may be replaced with BOX/ATTC, which means that although the device is dedicated to a user, it is unavailable (usually because of a hardware condition).

If a graphic display device has a user logged on or dialed through it, you see something like this:

```
GRAF 08E0 LOGON AS SVCDIR 0009
VTAM CONTROLS THE FOLLOWING LU'S
GRAF WGU9E316 LOGON AS DONNA 0009
GRAF TN6PV192 LOGON AS CORAK 0009
```

This response tells you the user SVCDIR is logged on through the graphic display device at 08E0. The number 0009 is SVCDIR's virtual console device number.

The second line of the response tells you the terminals are SNA terminals and the user ID VTAM controls them. VTAM is a VTAM service machine (VSM) recognized by z/VM CP. Any logical units controlled by this VTAM service machine that are logged onto or dialed into the system are described in the response lines following this line.

The numbers WGU9E316 and TN6PV192 identify SNA terminals controlled by a VTAM service machine. They are the names from the VTAM definition of the terminals as SNA logical units.

DONNA and CORAK are the users logged on through VTAM; each has 0009 as the virtual console device number.

If there are free graphic display devices, you see something like this:

```
LINE 00E5 FREE , LINE 00E6 FREE , LINE 00C0 FREE
GRAF 08E1 ENABLED , GRAF 08E2 ENABLED , GRAF 08E3 ENABLED , GRAF 08E4 ENABLED
GRAF 08E5 ENABLED , GRAF 08E6 ENABLED , PRT 08E7 ENABLED , GRAF 0BC0 ENABLED
GRAF 0BC1 ENABLED , GRAF 0BC2 ENABLED , GRAF 0BC3 ENABLED , GRAF 0BC4 ENABLED
GRAF 0BC5 ENABLED , GRAF 0BC6 ENABLED , GRAF 0BC7 ENABLED , GRAF 0BC8 ENABLED
```

The responses for offline and boxed displays are in the same format.

Responses from Real Communication Lines:

If a real communication line is dedicated to a user, you see something like this:

```
LINE 00F0 ATTACHED TO OLIVER 0010
```

This response means the communication line with the real device number 00F0 is attached to OLIVER's virtual machine as the virtual device 0010. ATTACHED may be replaced with BOX/ATTC, which means that although the device is dedicated to a user, it is unavailable (usually because of a hardware condition).

If there are communication lines that have users logged on at them or dialed through them, you see something like this:

```
LINE 00FA LOGON AS DAVID 0009
LINE 00FB DIALED TO PVM 00F9
```

This response tells you the user DAVID is logged on through the communication line at 00FA. The number 0009 is the virtual device number of the virtual console where DAVID is logged on. The second line tells you the terminal connected to communications line 00FB is dialed to PVM's virtual device number 00F9.

If there are free communication lines, you see something like this:

```
LINE 00C1 FREE , LINE 00C2 FREE , LINE 00C3 FREE , LINE 00C4 FREE
LINE 00C5 FREE , LINE 00C6 FREE , LINE 00C7 FREE , LINE 00C8 FREE
LINE 00E1 FREE , LINE 00E2 FREE , LINE 00E3 FREE , LINE 00E4 FREE
LINE 00E5 FREE , LINE 00E6 FREE , LINE 00C0 FREE
```

Responses for boxed and offline communication lines are in the same format.

Responses from Open Systems Adapter Devices:

If there are Open Systems Adapter devices attached to the system at the addresses specified, you see something like this:

```
q 480-486
OSA 0480 ATTACHED TO PVM 0480
OSA 0481 ATTACHED TO PVM 0481
OSA 0482 ATTACHED TO RSCS 0482
OSA 0483 ATTACHED TO RSCS 0483
OSA 0484 ATTACHED TO PVM 0485
OSA 0485 ATTACHED TO PVM 0484
OSA 0486 ATTACHED TO VTAM 0486
Ready;
```

The first number is the real device number of the Open Systems Adapter devices. The ATTACHED operand might also read BOX/ATTC, meaning that although the device is attached and dedicated to a user, it is unavailable. PVM, RSCS, TCP/IP, and VMNET are user IDs to which the OSA devices are dedicated. The last number is the virtual device number which each virtual machine uses to refer to an OSA device.

If there are free OSA devices attached to the system at the specified addresses, you see something like this:

```
q 4a1-4bf free
OSA 04A1 FREE , OSA 04A2 FREE , OSA 04A3 FREE , OSA 04A4 FREE
OSA 04A4 FREE , OSA 04A5 FREE , OSA 04A9 FREE , OSA 04AA FREE
OSA 04AB FREE , OSA 04BC FREE , OSA 04BD FREE , OSA 04BE FREE
OSA 04BF FREE
```

This response shows the real device number for each free OSA device.

The responses for offline and boxed devices are in the same format.

Responses from Real Dynamic Switching Devices:

If there is a dynamic switching device dedicated to a user, you see something like this:

```
SWCH 0CD5 ATTACHED TO EMILY 0012
```

This means the switching device at the real device number 0CD5 is attached to EMILY's virtual machine as the virtual device number 0012. ATTACHED may be replaced by BOX/ATTC, which indicates that the dedicated switching device is not available (usually because of a hardware condition).

If there are free switching devices attached to the system, you see something like this:

```
SWCH 0387 FREE , SWCH 03A1 FREE , SWCH 03A2 FREE , SWCH 03A3 FREE
SWCH 03A4 FREE , SWCH 03A5 FREE , SWCH 03A9 FREE , SWCH 03AA FREE
```

This response shows the real device number for each free switching device. Responses for boxed and offline switching devices are in the same format.

Responses from Real Magnetic Tape Drives:

If there is a tape drive dedicated to a user, you see something like this:

```
TAPE 0102 ATTACHED TO RALPH 0236 R/W
```

This means that the magnetic tape drive at the address 0102 is attached to RALPH's virtual machine as the virtual device number 0236. R/W means that the user RALPH has read-write access to the tape drive. R/W might also read R/O, which means the user has read-only access.

If the tape drive is currently being used by the TRSAVE command, you see something like this:

```
TAPE 0242 ASSIGNED SYSTEM TRSAVE
```

If a tape that is not dedicated to a user is not available (boxed), you see something like this:

```
TAPE 0244 BOXED
```

If a tape drive has been attached MULTIUSER to one or more users, you see something like this:

```
TAPE 2100 ATTACHED TO USER1 0181 R/W NOASSIGN MULTIUSER
TAPE 2100 ATTACHED TO USER2 0181 R/W NOASSIGN MULTIUSER
```

This means that the tape drive at real address 2100 is attached to USER1 and USER2 at virtual device address 0181. MULTIUSER indicates that the tape drive is shared by both users, and NOASSIGN states that the users must manage the assignment of the tape drive by using assign and unassign I/O.

Responses for free or offline tape drives will be in the same format.

Responses from Real Unit Record Devices:

If a unit record device is dedicated to a user, you see something like this:

```
RDR 000C ATTACHED TO JAMES 02F0
```

This response means that the real card reader at the device number 000C is dedicated to JAMES's virtual machine at the virtual device number 02F0. RDR might be replaced by PRT or PUN, depending on the kind of unit record device. ATTACHED might be replaced by BOX/ATTC, which indicates that the device is attached to the virtual machine but is unavailable (usually because of a hardware problem).

*Responses from Active Readers:*

If a reader is assigned to the system for spooling activity and it is currently active with a spool file, you see a message like this:

```
RDR 000C STARTED SYSTEM
RDR 000C READING PERCY FILE 0021
```

000C is the real device number of the card reader. STARTED indicates the device is available for spooling activity. SYSTEM means the device is available for input with user identification cards. STARTED might be replaced by any of the following:

- DRAINING, which means the device would be unavailable for spooling activity as soon as it finished processing the current file.
- DRAINED, which means the device was unavailable for spooling activity. You could enter the CP START command to restart it.
- INT REQ, which means the device is not ready and requires manual intervention before spool file processing could resume.

**Note:** If STARTED were replaced by any of the above options, except DRAINING, the second line of the response would not appear.

SYSTEM might be replaced by a user ID, which means the device was available for input without user identification cards. All input decks would be assigned to the user ID specified.

The second line of the response means the card reader is currently active with a spool file. In this example, the reader at the real device number 000C is reading a card deck and creating a file that will be the user PERCY's spool file 0021.

Responses from Active Printers:

If there is an impact printer in use as a system spooling device, you see a response like this:

```
PRT 0E0E STARTED      SYSTEM CLASS 1          SECLABEL
PRT 0E0E FORM STANDARD MANUAL  SEP   N03800 DEFFCB  LIMIT NONE
PRT 0E0E FOLD  IMAGE IMAG4248 CHARS      FCB FCB8      LPP 068
PRT 0E0E DEST OFF      DEST - NONE - DEST - NONE - DEST - NONE -
PRT 0E0E NOAFP
```

This response tells you the following about the impact printer at the real device number 0E0E. The first line tells you the printer will:

- Be available for spooling activity
- Process files for any user ID
- Select only class 1 spool files for processing.

The second line tells you it will:

- Select files requesting the STANDARD form
- Wait for the operator to schedule forms output
- Generate a separator page for output files
- Not accept spool files that contain 3800 load CCWs
- Use the default forms control buffer that was loaded into it
- Process spool files regardless of their length.

The third line tells you it will:

- Translate (fold) lower case characters into upper case
- Use the system image library file IMAG4248
- Not use a character set
- Use the forms control buffer FCB8.
- Print separator pages with 68 lines per page.

The fourth line tells you the printer will not use destination values as a criterion for selecting files.

The fifth line tells you the printer will not process files with advanced function printer (AFP) characteristics, that is, files that contain X'5A' CCWs or an extended attributes buffer (XAB). For more information about each line of the response, see the tables below.

If there is a 3800 printer in use as a system spooling device and that printer is currently active with a spool file, you see a response like this:

```
PRT 0F10 STARTED SYSTEM CLASS * SECLABEL
PRT 0F10 FORM STANDARD AUTO SEP ANY3800 LIMIT NONE
PRT 0F10 FLASH 0987 IMAGE IMAG3800 CHARS GF10 FCB 6 HOLD LPP 060
PRT 0F10 DEST OFF DEST - NONE - DEST - NONE - DEST - NONE -
PRT 0F10 AFP MARK
PRT 0F10 PRINTING DAVID FILE 0002 RECS 130K COPY 005 SEQ 001
```

This response tells you the following about the printer at the real device number 0F10. The first line means the printer will:

- Be available for spooling activity
- Process files for any user ID
- Select spool files regardless of class.

The second line tells you the printer will:

- Select files requesting the STANDARD form
- Automatically schedule forms output
- Generate a separator page for output files
- Accept spool files that contain 3800 load CCWs
- Process spool files regardless of their length.

The third line tells you the printer will:

- Use the forms overlay negative called 0987
- Use the system image library file IMAG3800
- Use the character set GF10
- Print six lines per inch
- Put spool files causing 3800 load checks into system HOLD status.
- Print separator pages with 60 lines per page.

The fourth line tells you that the printer will not use destination values as a criterion for selecting files.

The fifth line tells you that the printer will:

- Process files with advanced function printer (AFP) characteristics, that is, files that contain X'5A' CCWs or an extended attributes buffer (XAB).
- Mark separator trailer pages with separator bars.

The last line tells you:

- The printer is active with the spool file 0002, owned by the user DAVID.
- The number of records remaining for output in the file is 130K. K is the number of records in thousands rounded to the nearest 1000. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines in millions rounded to the nearest million.
- There are five copies remaining for output.
- The sequence for the file on the printer is 001.

The parts of the first line of the response for impact printers and 3800 printers might also be as follows:

Category	Possible Values	Meaning
Status	STARTED	Device is available for spooling activity.
	DRAINING	Device is processing a file, but will be drained after the file is finished.
	DRAINED	Device is not available for spooling activity. Issue the CP START command to activate the device.
	INT REQ	Device is not available, and needs manual intervention before it can continue to process spool files.
	SETUP REQ	Printer is ready to print an alignment page so that the operator can align the forms properly on an impact printer. The operator must press the STOP and START buttons to print another alignment page, or enter the START command to begin printing the entire file.
	MOUNT REQ	Printer is waiting for the operator to mount a new form.
User ID	SYSTEM	Device processes files for any user ID.
	<i>userid</i>	Device processes files only for the specified user ID.
Spool file class	CLASS <i>cl</i>	Device services spool files of the specified classes, in the specified order. An output device can service as many as 8 output classes.

The parts of the second line of the response can be:

Category	Possible Values	Meaning
Form	FORM <i>form</i>	Device services the specified 1- to 8-character operator form number.

Category	Possible Values	Meaning
Scheduling	MANUAL	Operator schedules forms output. Only spool files with the form currently active on the device are processed. When the last spool file with the current form is printed, the printer stops.
	AUTO	Operator wants CP to schedule forms output. The form that is currently active is processed first. When all files with the current form have been printed, CP selects a new form for the device.
	SETUP	<p>Operator wants CP to print a page for forms alignment verification. (Only valid for impact printers.) The operator receives a message to set up the form. After setting up the form, the operator must press the STOP button, then the START button. An alignment page prints with letters replaced by X's and numbers replaced by 9's on the first page of the file.</p> <p>Each time the operator presses STOP and START after a full alignment page is printed, another alignment page prints. After aligning the forms, the operator enters the START command for the device. The printer then returns to its previous mode (AUTO or MANUAL), and the file prints in its entirety.</p> <p><b>Note:</b> If neither MANUAL, AUTO, nor SETUP is specified and the printer is currently in SETUP mode, it returns to the previous mode, AUTO or MANUAL. The default forms output is MANUAL.</p>
File separator	SEP	File separator prints between output files.
	NOSEP	File separator does not print between output files.
3800 load CCWs	NO3800	Printer does not print any spool files containing 3800 load CCWs. This option ensures a fast output queue, because load CCWs issued to 3800 printers can take a lot of time.
	BEG3800	Only spool files without 3800 load CCWs, or spool files with 3800 load CCWs only at the beginning of the file, print on this device. This allows the user an initial setup with which the entire file can be printed.
	ANY3800	Output device will process spool files regardless of whether they contain 3800 load CCWs. This option may cause a slower output queue, based on the number of 3800 load CCWs issued by the spool files.
Default FCB	DEFFCB	Printer uses the default FCB with which it was loaded. CP does not send imbedded LOAD FCB CCWs to the printer. The LOADBUF command specifies the default FCB.
	FILEFCB	<p>CP sends FCBs to the real printer. File FCBs are LOAD FCB CCWs imbedded in the spool file. This is the default when you start the printer after a cold start.</p> <p><b>Note:</b> DEFFCB and FILEFCB only appear for non-1403 impact printers.</p>

Category	Possible Values	Meaning
Length limit	LIMIT NONE	CP selects files for printing regardless of the number of records.
	LIMIT <i>nnnnnnnnnn</i>	CP only selects spool files for printing that are less than or equal to the specified number of records. The spool file record number is the number of copies multiplied by the size of the file.

The parts of the third line of the response can be:

Category	Possible Values	Meaning
Folding into upper case	FOLD	CP translates (folds) lower case characters into upper case.
	NOFOLD	CP does not translate lower case characters into upper case. <b>Note:</b> FOLD and NOFOLD only appear for impact printers.
Forms overlay negative	FLASH <i>name</i>	Printer uses the specified forms overlay negative, which is from 1 to 4 characters long. <b>Note:</b> FLASH only appears for 3800 printers.
Image library	IMAGE <i>imagelib</i>	Printer uses the specified system image library file, which contains the load images (character sets, FCBs, graphic character modifications, or copy modifications) used for printing files and separator pages.
Character set	CHARS <i>chars</i>	Printer uses the specified character set, which is from 1 to 4 characters long, when printing the separator page.
FCB	FCB <i>name</i>	For impact printers: printer uses the specified FCB when printing the file or the separator page. For 3800 printers: the FCB is the number of lines per inch. <b>Note:</b> FCB does not appear for 1403-type printers.
3800 load checks	HOLD	Printer puts spool files causing 3800 load checks in system HOLD status.
	PURGE	Printer deletes spool files causing 3800 load checks. <b>Note:</b> HOLD and PURGE only appear for 3800 printers.
Lines per page	LPP	Defines the number of lines for file separator pages on the printer.

The parts of the next-to-last line of this response can be:

Category	Possible Values	Meaning
Destination	DEST	Printer services the specified destination values. The printer can service up to 4 destination values. The first value for the device is always OFF if it was not specifically set by either a START command, or at initialization with the RDEVICE statement in the system configuration file. If it was set, the specified destination is shown. If the remaining destination values were not specified, the values are null and are shown as – NONE –. If they were specified, the specified value is shown.
AFP characteristics	AFP	Printer processes files with advanced function printer (AFP) characteristics, that is, files that contain X'5A' CCWs or an extended attributes buffer (XAB).
	NOAFP	Printer does not process files with AFP characteristics.
Mark separator trailer pages	MARK	Printer marks 3800 trailer pages with separator bars.
	NOMARK	Printer does not mark 3800 trailer pages with separator bars.

**Note:** MARK and NOMARK only appear for 3800 printers.

*Responses from Active Card Punches*

If a punch is attached to a user and is currently active with a spool file, you see a message like:

```
q 1f30
PUN 1F30 STARTED SYSTEM CLASS 1
PUN 1F30 FORM STANDARD AUTO NOSEP LIMIT NONE
PUN 1F30 DEST OFF DEST - NONE - DEST - NONE - DEST - NONE -
PUN 1F30 PUNCHING JAMES FILE 0042 RECS 012K COPY 002 SEQ 001
Ready;
```

This response tells you the following about the card punch at the real device number 1F30. The first line means that the punch will:

- Be available for spooling activity
- Process files for any user ID
- Select class 1 spool files.

The second line tells you that the punch will:

- Select files requesting STANDARD form
- Automatically schedule forms output
- Not generate a separator page for output files.

The third line tells you that the punch will not use destination values as a criterion for selecting files.

The parts of the first line of the response can also be:

Category	Possible Values	Meaning
Status	STARTED	Device is available for spooling activity.
	DRAINING	Device is processing a file, but will be drained when the file is finished.
	DRAINED	Device is not available for spooling activity. Issue the CP START command to activate the device.
	INT REQ	Device is not available; it needs manual intervention before it can continue to process spool files.
	SETUP REQ	Punch is ready to generate an alignment page to let the operator align the forms properly on an impact printer. The operator must press the STOP and START buttons to print another alignment page, or enter the START command to begin printing the entire file.
	MOUNT REQ	Punch is waiting for the operator to mount a new form.
User ID	SYSTEM	Device processes files for any user ID.
	<i>userid</i>	Device processes files only for the specified user ID.
Spool file class	CLASS <i>cl</i>	Device services spool files of the specified classes, in the specified order. An output device can service as many as 8 output classes.

The options for the second line of the response can be:

Category	Possible Values	Meaning
Form	FORM <i>form</i>	Device services the specified 1- to 8-character operator form number.
Scheduling	MANUAL	Operator schedules forms output. Only spool files with the form currently active on the device are processed. When the last spool file with the current form is punched, the punch stops.
	AUTO	Operator wants CP to schedule forms output. The form that is currently active is processed first. After punching all files with the current form, CP selects a new form for the device.
File separator	SEP	File separator prints between output files.
	NOSEP	File separator does not print between output files.
Length limit	LIMIT NONE	CP selects files for punching regardless of the number of records.
	LIMIT <i>nnnnnnnnnn</i>	CP only selects spool files for punching that are less than or equal to the specified number of records. The spool file record number is the number of copies multiplied by the size of the file.

The options for the third line of the response can be:

Category	Possible Values	Meaning
Destination value	DEST	Printer services the specified destination values. The printer can service up to 4 destination values. The first value for the device is always OFF if it was not specifically set by either a START command, or at initialization with the RDEVICE statement in the system configuration file. If it was set, the specified destination is shown. If the remaining destination values were not specified, the values are null and are shown as – NONE –. If they were specified, the specified value is shown.

The last line of this response only appears if there is a file active on the card punch. The line in the example above tells you the punch at the real device number 1F30 is punching the spool file 0042, owned by the user JAMES. The number of records remaining for output in the file is 12K. K is the number of records in thousands rounded to the nearest 1000. If the number is greater than 999499, the number is shown as *nnnM*. M represents the number of lines in millions rounded to the nearest million. There are two copies remaining for output. The sequence for the file on the punch is 001.

Responses from Boxed Unit Record Devices:

If a unit record that is not dedicated to a user is unavailable, you see a message like the following:

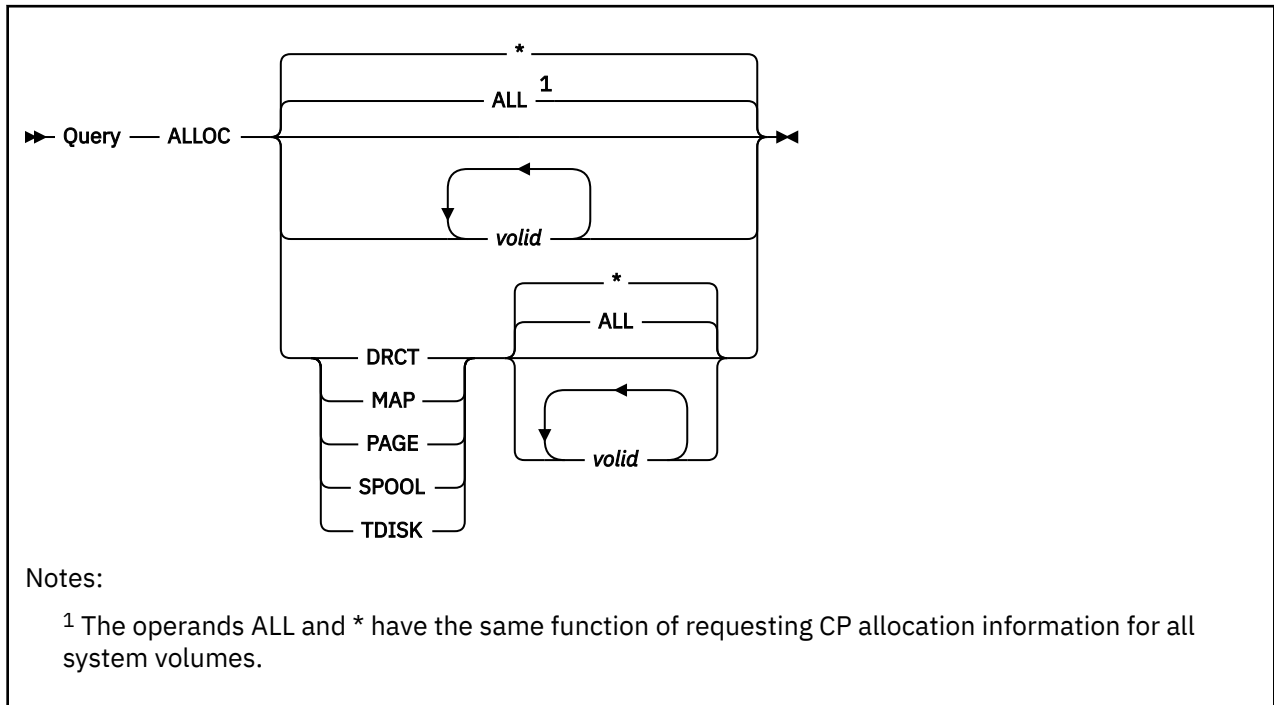

```
RDR 000F BOXED
```

000F is the real device number of the card reader that is unavailable. RDR might be replaced by PRT or PUN.

### Messages

- HCP003E Invalid option - *option*
- HCP020E Userid missing or invalid.
- HCP263E Too many operands were supplied for this command.

## QUERY ALLOC

### Authorization

Privilege Class: D

### Purpose

Use QUERY ALLOC to display the number of cylinders or pages that are allocated, in use, and available for DASD volumes attached to the system.

### Operands

#### ALL or \*

tells CP you want allocation information for all system volumes. This is the default.

#### valid

specifies one or more volume identifiers (volume IDs) for which you want information displayed. You can specify specific or generic volume IDs. To specify a generic volume ID, use the wildcard character (\*) as the last character of a string. CP compares the string with the beginning of all volume IDs on the system and gives you information about all volume IDs whose first few characters match the string.

#### DRCT

specifies that you want specific detailed information, including extent start and end cylinders or pages, and cylinder or page allocation, displayed for the DRCT extents on the specified volumes.

#### MAP

specifies that you want specific detailed information, including extent start and end cylinders or pages, and cylinder or page allocation, displayed for all CP use extents on the specified volumes.

#### PAGE

specifies that you want specific detailed information, including extent start and end cylinders or pages, and page allocation, displayed for the PAGE extents on the specified volumes.

### SPOOL

specifies that you want specific detailed information, including extent start and end cylinders or pages, and page allocation, displayed for the SPOOL extents on the specified volumes.

### TDISK

specifies that you want specific detailed information, including extent start and end cylinders or pages, and cylinder or page allocation, displayed for the TDISK extents on the specified volumes.

## Usage Notes

1. For options PAGE, SPOOL, TDISK, and DRCT, if *valid1* is not supplied, information is displayed for all CP-owned volumes that have space of that type allocated on them. For the MAP option, if *valid1* is not supplied, information is displayed for all CP use extents on all CP-owned volumes that have any CP use extents.
2. If QUERY ALLOC PAGE, QUERY ALLOC SPOOL, QUERY ALLOC TDISK, QUERY ALLOC DRCT, or QUERY ALLOC MAP commands are issued through DIAGNOSE code X'08' and the user requests the response returned in a buffer, complete volume information (*valid* and *rdev*) will be displayed for each extent displayed on the volume. This allows easier parsing of the command output by application execs or programs.
3. *Valid*s PAGE, SPOOL, TDISK, DRCT, MAP, and EXEC should be treated as restricted and should not be used for CP-owned volumes. If any of these *valid*s are used, the corresponding new option will not be available. For example QUERY ALLOC PAGE will default to the QUERY ALLOC *valid* syntax if *valid* PAGE is defined to CP.
4. Pattern wildcard characters (\*) are allowed only as the last character of the *valid*.
5. If space on a CP-owned volume is re-allocated while the volume is still attached to the system and a subsequent system IPL or the commands DETACH *rdev* FROM SYSTEM and ATTACH *rdev* TO SYSTEM do not occur, QUERY ALLOC may report incorrect information for that volume. This will occur until the system is IPLed or the device is DETACHED and re-ATTACHED to the system.
6. The *chnprg* field of the Query Alloc response in combination with other device/control unit hardware information can be used to determine if performance problems may be occurring. Severe performance degradation may occur on a device to which CP issues CKD channel programs (because of the presence of filler records) if the device is attached to an ECKD-capable control unit by way of an ESCON or non-synchronous interface. The problem can be corrected by formatting the DASD using the NO FILLER option of ICKDSF.

## Examples

Examples of QUERY ALLOC commands:

```
QUERY ALLOC
```

displays cylinder or page information about all system volumes.

```
QUERY ALLOC ALL
```

displays cylinder or page information about all system volumes.

```
QUERY ALLOC VOL001
```

displays cylinder or page information about a single system volume whose *valid* is VOL001.

```
QUERY ALLOC VOL001 DASD99
```

displays cylinder or page information about two system volumes whose *valid*s are VOL001 and DASD99.

```
QUERY ALLOC VOL*
```

displays cylinder or page information about all system volumes whose *valids* begin with the three characters VOL.

```
QUERY ALLOC VOL* DASD*
```

displays cylinder or page information about all system volumes whose *valids* begin with the three characters VOL or the four characters DASD.

```
QUERY ALLOC PAGE VOL001
```

displays detailed PAGE extent information for a single system volume whose *valid* is VOL001.

```
QUERY ALLOC PAGE VOL001 DASD99
```

displays detailed PAGE extent information for two system volumes whose *valids* are VOL001 and DASD99.

## Responses

Response 1:

```
DASD rdev valid type format{-chnprg} (UNITS IN units)
      TDISK TOTAL=nnnnnnnnnn INUSE=nnnnnnnnnn AVAIL=nnnnnnnnnn
      PAGE  TOTAL=nnnnnnnnnn INUSE=nnnnnnnnnn AVAIL=nnnnnnnnnn
      SPOOL TOTAL=nnnnnnnnnn INUSE=nnnnnnnnnn AVAIL=nnnnnnnnnn <,DR>
      DRCT  TOTAL=nnnnnnnnnn INUSE=nnnnnnnnnn AVAIL=nnnnnnnnnn <,<ACTIVE>
<IPL NUCLEUS ACTIVE ON VOLUME validn>
```

is displayed for each CP-owned volume.

### **rdev**

is the real device number of the CP-owned volume.

### **valid**

is the volume identification of the CP-owned volume.

### **type**

shows the DASD device type (for example, 3380).

### **format**

identifies the type of device (CKD or FBA).

### **<-chnprg>**

identifies the type of channel program that CP issues to the device (CKD or ECKD). This field is only displayed for CKD devices. The type of channel programs issued to a CKD device depends on the device type, the control unit to which it is attached, and if the device was formatted with filler records. CP will issue CKD channel programs to a 3380 attached to an ECKD capable control unit if it was formatted using the FILLER option of ICKDSF (filler records exist). CP will issue ECKD channel programs to the same device/control unit combination if it was formatted with the NO FILLER option of ICKDSF. For best performance, the type of channel programs that CP issues to the device should match the interface of the control unit to which it is attached. See the usage notes section for more details.

### **units**

identifies the units of *nnnnnnnnnn* in the response for this volume. *units* is set to CYLINDERS for CKD devices and PAGES for FBA devices.

### **nnnnnnnnnn**

shows the number of cylinders or pages allocated in each category. For PAGE and SPOOL, when *units* is set to CYLINDERS, a cylinder is considered "in use" when at least one page in it is in use. Calculating a percentage used -  $(INUSE * 100) / (INUSE + AVAIL)$  - will therefore usually yield a larger and less accurate result than the percentage used shown in the following responses.

### **<,<ACTIVE>**

appears on the DRCT response line if that volume contains the currently active user directory.

## QUERY ALLOC

### <DR>

appears on the TDISK, PAGE, or SPOOL response line if CP is currently not allocating space of that type on that volume.

### <IPL NUCLEUS ACTIVE ON VOLUME *valid*>

appears as the final response line if the volume containing the active IPL nucleus was one of those for which cylinder or page allocation information was displayed.

Response 2:

VOLID	RDEV	EXTENT START	EXTENT END	TOTAL PAGES	PAGES IN USE	HIGH PAGE	% USED	
<i>valid</i>	<i>rdev</i>	nnnnnnnnnn	nnnnnnnnnn	pppppp	pppppp	pppppp	ppp%	<DR>
		nnnnnnnnnn	nnnnnnnnnn	pppppp	pppppp	pppppp	ppp%	<DR>
		nnnnnnnnnn	nnnnnnnnnn	pppppp	pppppp	pppppp	ppp%	<DR>
<i>valid</i>	<i>rdev</i>	nnnnnnnnnn	nnnnnnnnnn	pppppp	pppppp	pppppp	ppp%	DUMP <DR>
		nnnnnnnnnn	nnnnnnnnnn	pppppp	pppppp	pppppp	ppp%	DUMP <DR>
<i>valid</i>	<i>rdev</i>	-	-	-	-	-	-	SHARED
<i>valid</i>	<i>rdev</i>	-	-	0	0	0	0%	NOT FOUND
SUMMARY				pppppp	pppppp		ppp%	
usable				pppppp	pppppp		ppp%	
DRAINING				pppppp	pppppp		ppp%	

is the response for QUERY ALLOC PAGE and QUERY ALLOC SPOOL.

### *valid*

is the volume identification of the CP-owned volume.

### *rdev*

is the real device number of the CP-owned volume.

### *nnnnnn*

is the starting or ending cylinder or page number of the extent. For CKD volumes, this number is in cylinders. For FBA volumes, this number is in pages. The abbreviations K, M, G, T and P are used to indicate Kilo, Mega, Giga, Tera and Peta, for example, nnnnnK.

### *pppppp*

is the total number of pages in the extent, the number of pages in use in the extent, or the highest page number in use in the extent. The abbreviations K, M, G, T and P are used to indicate Kilo, Mega, Giga, Tera and Peta, for example, pppppK.

### *ppp*

is the percentage of pages in use in the extent.

### DUMP

indicates that this SPOOL extent is reserved for DUMP use only.

### SHARED

indicates the volume is owned by another system in the same SSI cluster. This system cannot allocate or release space on the volume, but it can read spool data from areas previously allocated and written to by the owning system. No allocation data can be displayed for this volume.

### Notes:

1. The SHARED response line will be displayed only for QUERY ALLOC SPOOL or QUERY ALLOC MAP, unless that volume was specifically requested.
2. A zero (0) will be displayed in the TOTAL, IN USE, HIGH, and % USED fields of this line.

### <DR>

indicates the extent is draining. If DR is indicated, CP is currently not allocating space of that type on that volume. Draining applies only to TDISK, PAGE, and SPOOL space.

### NOT FOUND

indicates that no CP-owned extents of the requested allocation type (PAGE or SPOOL) were found on the specified *valid*. The *valid* is the *valid* operand specified on the QUERY ALLOC command that was issued. It can, therefore, be a wildcard *valid* specifier, in which case it indicates that no CP-owned

extents of the requested type were found on any volume with a *valid* matching the wildcard *valid* specifier. In this case, the *rdev* is displayed as *\**.

**Notes:**

1. Leading zeros are not displayed for *nnnnnn*, *pppppp* and *ppp*.
2. *Valid* and *rdev* are only displayed for the first extent on the volume, unless the command was issued using DIAGNOSE code X'08' and the response was requested in the user's buffer. In this case *valid* and *rdev* are displayed on every response line.
3. The summary response lines (including the footer line) are displayed only when information for all system volumes is displayed (the default ALL or \* was specified as the only operand) and some space of the requested type was found. The SUMMARY line gives system-wide total, in-use, and percent in-use values, including both usable and draining space. The usable line gives system-wide total, in-use, and percent in-use values, excluding any space not generally usable for the specified type (either draining for the specified type, or for the type SPOOL, reserved for dump use only). The DRAINING line is displayed only if draining space of the specified type (that would otherwise be generally usable) was found. The DRAINING line gives system-wide total, in-use, and percent in-use values for all draining volumes that are draining for the specified type (and for type SPOOL, not reserved for dump use only).

Response 3:

VOLID	RDEV	EXTENT START	EXTENT END	TOTAL	IN USE	HIGH	% USED	
<i>valid</i>	<i>rdev</i>	<i>nnnnnnnnnn</i>	<i>nnnnnnnnnn</i>	<i>nnnnnn</i>	<i>nnnnnn</i>	<i>nnnnnn</i>	<i>ppp%</i>	<DR>
		<i>nnnnnnnnnn</i>	<i>nnnnnnnnnn</i>	<i>nnnnnn</i>	<i>nnnnnn</i>	<i>nnnnnn</i>	<i>ppp%</i>	<DR>
<i>valid</i>	<i>rdev</i>	<i>nnnnnnnnnn</i>	<i>nnnnnnnnnn</i>	<i>nnnnnn</i>	<i>nnnnnn</i>	<i>nnnnnn</i>	<i>ppp%</i>	ACTIVE
<i>valid</i>	<i>rdev</i>	-	-	-	-	-	-	SHARED
<i>valid</i>	<i>rdev</i>	-	-	0	0	0	0%	NOT FOUND
SUMMARY				< <i>nnnnnn</i>	<i>nnnnnn</i>		<i>ppp%</i>	CKD>
usable				< <i>nnnnnn</i>	<i>nnnnnn</i>		<i>ppp%</i>	FBA>
DRAINING				< <i>nnnnnn</i>	<i>nnnnnn</i>		<i>ppp%</i>	CKD>
				< <i>nnnnnn</i>	<i>nnnnnn</i>		<i>ppp%</i>	FBA>

is the response for QUERY ALLOC DRCT and QUERY ALLOC TDISK.

***valid***

is the volume identification of the CP-owned volume.

***rdev***

is the real device number of the CP-owned volume.

***nnnnnn***

is the starting or ending cylinder or page number of the extent, the total number of cylinders or pages in the extent, the number of cylinders or pages in use in the extent, or the highest cylinder or page number in use in the extent. For CKD volumes, this number is in cylinders. For FBA volumes, this number is in pages. The abbreviations K, M, G, T and P are used to indicate Kilo, Mega, Giga, Tera and Peta, for example, *nnnnnK*.

***ppp***

is the percentage of cylinders or pages in use in the extent.

**ACTIVE**

indicates this DRCT extent contains the currently active user directory.

**SHARED**

indicates the volume is owned by another system in the same SSI cluster. This system cannot allocate or release space on the volume, but can read spool data from areas previously allocated and written to by the owning system. No allocation data can be displayed for this volume.

**Notes:**

## QUERY ALLOC

1. The SHARED response line will be displayed only for QUERY ALLOC SPOOL or QUERY ALLOC MAP, unless that volume was specifically requested.
2. A zero (0) will be displayed in the TOTAL, IN USE, HIGH, and % USED fields of this line.

### <DR>

indicates the extent is draining. If DR is indicated, CP is currently not allocating space of that type on that volume. Draining applies only to TDISK, PAGE, and SPOOL space.

### NOT FOUND

indicates no CP-owned extents of the requested allocation type (TDISK or DRCT) were found on the specified *valid*. The *valid* is the *valid* operand specified on the QUERY ALLOC command that was issued. It can, therefore, be a wildcard *valid* specifier, in which case it indicates that no CP-owned extents of the requested type were found on any volume with a *valid* matching the wildcard *valid* specifier. In this case, the *rdev* is displayed as \*.

### Notes:

1. Leading zeros are not displayed for *nnnnnn* and *ppp*.
2. *Valid* and *rdev* are only displayed for the first extent on the volume, unless the command was issued using DIAGNOSE code X'08' and the response was requested in the user's buffer. In this case, *valid* and *rdev* are displayed on every response line.
3. The summary response lines (including the footer line) are displayed only when information for all system volumes is displayed (the default ALL or \* was specified as the only operand) and some space of the requested type was found. The summary information gives system-wide total, in-use, and percent in-use values. The summary information is divided into three sections: SUMMARY, usable, and DRAINING. If DRCT was specified, only the SUMMARY section is displayed. If TDISK was specified, the SUMMARY and usable sections are displayed. The DRAINING section is displayed only if draining TDISK space was found. If DRCT was specified, the SUMMARY section gives system-wide total, in-use, and percent in-use values.

If TDISK was specified, the SUMMARY section gives system-wide total, in-use, and percent in-use values (including both usable and draining TDISK space); the usable section gives system-wide total, in-use, and percent in-use values (excluding any space on volumes that are draining for TDISK); and the DRAINING section gives system-wide total, in-use, and percent in-use values for all draining volumes that are draining for TDISK.

The first line of each section is a summary of all CKD volumes, and the information is displayed in cylinders. The second line of each section is a summary of all FBA volumes and the information is displayed in pages. If no information was displayed for CKD volumes, then no CKD summary line is displayed; only the FBA summary line is displayed. If no information is displayed for FBA volumes, then no FBA summary line is displayed; only the CKD summary line is displayed.

Response 4:

VOLID	RDEV	EXTENT START	EXTENT END	TOTAL	IN USE	HIGH	% USED	ALLOCATION TYPE
<i>valid</i>	<i>rdev</i>	<i>nnnnnnnnnn</i>	<i>nnnnnnnnnn</i>	<i>pppppp</i>	<i>pppppp</i>	<i>pppppp</i>	<i>ppp%</i>	PAGE <DR>
		<i>nnnnnnnnnn</i>	<i>nnnnnnnnnn</i>	<i>nnnnnn</i>	<i>nnnnnn</i>	<i>nnnnnn</i>	<i>ppp%</i>	DRCT ACTIVE
		<i>nnnnnnnnnn</i>	<i>nnnnnnnnnn</i>	<i>pppppp</i>	<i>pppppp</i>	<i>pppppp</i>	<i>ppp%</i>	SPOOL <DR>
		<i>nnnnnnnnnn</i>	<i>nnnnnnnnnn</i>	<i>nnnnnn</i>	<i>nnnnnn</i>	<i>nnnnnn</i>	<i>ppp%</i>	TDISK <DR>
		<i>nnnnnnnnnn</i>	<i>nnnnnnnnnn</i>	<i>pppppp</i>	<i>pppppp</i>	<i>pppppp</i>	<i>ppp%</i>	SPOOL <DR>
<i>valid</i>	<i>rdev</i>	<i>nnnnnnnnnn</i>	<i>nnnnnnnnnn</i>	<i>pppppp</i>	<i>pppppp</i>	<i>pppppp</i>	<i>ppp%</i>	SPOOL DUMP <DR>
		<i>nnnnnnnnnn</i>	<i>nnnnnnnnnn</i>	<i>nnnnnn</i>	<i>nnnnnn</i>	<i>nnnnnn</i>	<i>ppp%</i>	DRCT
		<i>nnnnnnnnnn</i>	<i>nnnnnnnnnn</i>	<i>pppppp</i>	<i>pppppp</i>	<i>pppppp</i>	<i>ppp%</i>	SPOOL DUMP <DR>
<i>valid</i>	<i>rdev</i>	-	-	-	-	-	-	SHARED
<i>valid</i>	<i>rdev</i>	-	-	0	0	0	0%	NOT FOUND

is the response for QUERY ALLOC MAP.

### **valid**

is the volume identification of the CP-owned volume.

**rdev**

is the real device number of the CP-owned volume.

**nnnnnn**

is the starting or ending cylinder or page number of the extent, the total number of cylinders or pages in the extent, the number of cylinders or pages in use in the extent, or the highest cylinder or page number in use in the extent. For CKD volumes, this number is in cylinders. For FBA volumes, this number is in pages. The abbreviations K, M, G, T and P are used to indicate Kilo, Mega, Giga, Tera and Peta, for example, nnnnnK.

**pppppp**

is the total number of pages in the extent, the number of pages in use in the extent, or the highest page number in use in the extent. The abbreviations K, M, G, T and P are used to indicate Kilo, Mega, Giga, Tera and Peta, for example, pppppK.

**ppp**

is the percentage of pages (for all FBA response lines and for CKD PAGE and SPOOL response lines) or cylinders (for CKD DRCT and TDISK response lines) in use in the extent.

**PAGE**

indicates the extent is of CP-use allocation type PAGE.

**SPOOL**

indicates the extent is of CP-use allocation type SPOOL.

**DRCT**

indicates the extent is of CP-use allocation type DRCT.

**TDISK**

indicates the extent is of CP-use allocation type TDISK.

**DUMP**

indicates this SPOOL extent is reserved for DUMP use only.

**ACTIVE**

indicates this DRCT extent contains the currently active user directory.

**SHARED**

indicates the volume is owned by another system in the same SSI cluster. This system cannot allocate or release space on the volume, but it can read spool data from areas previously allocated and written to by the owning system. No allocation data can be displayed for this volume.

**Notes:**

1. The SHARED response line will be displayed only for QUERY ALLOC SPOOL or QUERY ALLOC MAP, unless that volume was specifically requested.
2. A zero (0) will be displayed in the TOTAL, IN USE, HIGH, and % USED fields of this line.

**<DR>**

indicates the extent is draining. If DR is indicated, CP is currently not allocating space of that type on that volume. Draining applies only to TDISK, PAGE, and SPOOL space.

**NOT FOUND**

indicates no CP-owned extents (allocation type PAGE, SPOOL, TDISK, or DRCT) were found on the specified *valid*. The *valid* is the *valid* operand specified on the QUERY ALLOC command that was issued. It can, therefore, be a wildcard *valid* specifier, in which case it indicates that no CP-owned extents of the requested type were found on any volume with a *valid* matching the wildcard *valid* specifier. In this case, the *rdev* is displayed as \*.

**Notes:**

1. Leading zeros are not displayed for *nnnnnn*, *pppppp* and *ppp*.
2. *Valid* and *rdev* are only displayed for the first extent on the volume, unless the command was issued using DIAGNOSE code X'08', and the response was requested in the user's buffer. In this case, *valid* and *rdev* are displayed on every response line.
3. Any volume extents not displayed by QUERY ALLOC MAP are allocated as PERM and PARM space.

**Messages**

- HCP013E Conflicting option - *option*
- HCP1002E Volume identifier *valid* does not exist.

## QUERY BYUSER

### Notes:

<sup>1</sup> If QUERY BYUSER is executed with the AT command, the *userid* operand is required.

<sup>2</sup> A non-class B or E user may specify only the user's own user ID.

## Authorization

Privilege Class: Any, B, E

## Purpose

Use the QUERY BYUSER command to display the BYUSER ID defined for a virtual machine. If you are not a class B or E user, you can display only the BYUSER ID for your own virtual machine. If you are a class B or E user, you can display the BYUSER ID for any virtual machine.

## Operands

\*

displays the BYUSER ID of the user issuing the command.

*userid*

displays the BYUSER ID of the specified virtual machine.

## Usage Notes

1. A BYUSER ID is defined only for a virtual machine that is logged on with the BY option of the LOGON command.
2. When a virtual machine is disconnected, its BYUSER ID remains unchanged.
3. A virtual machine's BYUSER ID is updated on a successful reconnect.

## Responses

Response 1:

```
The BYUSER for userid is byuserid
```

is returned when there is a BYUSER ID for the virtual machine specified in the query.

Response 2:

```
There is currently no BYUSER for userid
```

is returned when there is no BYUSER ID for the virtual machine specified in the query.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP007E Invalid *userid* - *userid*
- HCP045E *userid* not logged on

## QUERY CACHE

### Authorization

Privilege Class: B

### Purpose

Use QUERY CACHE to display caching status for all storage subsystems that support caching.

### Operands

*rdev*

*rdev1-rdev2*

is the real device number of one of the devices in the subsystem, a range of real device numbers, or any combination thereof.

### Usage Notes

1. When the cache is queried for a range of devices or a list of devices attached to an IBM DASD storage controller and the devices in the range or list are attached to the same storage controller, only one subsystem response is issued for each storage controller.

For example, to display the caching status for the cache associated with device 340, enter:

```
query cache 340
```

2. Caching for RAID (Redundant Array of Independent Disks) technology DASD such as an IBM DASD subsystem is always available. It cannot be modified by the user.
3. Error message HCP296E appears if the subsystem is not in the correct mode to accept the QUERY CACHE command.
4. This command may be issued to offline devices.

### Responses

Response 1:

```
rdev CACHE {available    for subsystem}
           {activation for subsystem in progress}
           {unavailable  for subsystem}

[- destage is in progress          ]
[- destage has failed. Data is pinned.]
[- subsystem error                 ]

cccccccK Bytes configured
aaaaaaaK Bytes available
oooooooK Bytes offline
pppppppK Bytes pinned
```

is the response for each IBM DASD subsystem.

If the cache is unavailable:

- `Destage is in progress` is included in the response if the storage control is still in the process of moving changed data from the cache to the backing storage device.
- If an error is encountered during the destaging process, `destage has failed`. Data is pinned. is displayed and the data that encountered the failure is held in the storage control cache.
- `Subsystem error` is included if an internal subsystem error occurred which caused termination of caching.

```
rdev CACHE {activated    for device          }
           {deactivated  for device          }
           {deactivation for device is pending.}
           Destage has failed.}
```

```
[rdev has pinned data]
```

is the response for each device specified in the command; if pinned data exists for the device. The variables `rdev`, `ccccccc`, and `aaaaaaaa` are the same as in Response 1.

**pppppppp**

is the size in kilobytes of subsystem storage that is not available to the storage director for allocation because of DASD exception conditions which prevent successful completion of a subsystem storage to DASD transfer.

**Note:** `ccccccc`, `aaaaaaaa`, `oooooooo`, and `pppppppp` are displayed in decimal.

Response 2:

```
Bytes {available  }
      {unavailable} cannot be determined
      {offline   }
      {bound     }
      {pinned    }
```

is displayed if the storage control is unable to determine the subsystem storage capacity.

**Messages**

- HCP006E Invalid device type - `{rdev/vdev/ldev}`
- HCP009E Invalid range - `range`
- HCP021E A real device number was not supplied or it is invalid.
- HCP026E Operand missing or invalid
- HCP040E Device `{rdev/vdev/ldev}` does not exist
- HCP296E Status is not as required - `rdev; text`
- HCP319E Error processing subsystem command - `cmd` for DASD `rdev`
- HCP332E Invalid control unit type - `rdev`
- HCP1120E The requested `[command|DETACH|GIVE]` for device `[ldev|rdev]` did not complete in the allotted time.
- HCP1150E DASD `{rdev/vdev}` is not a valid base exposure.
- HCP2600I DASD `rdev` subsystem storage status cannot be determined.
- HCP6867E Device `rdev` is an alias HyperParallel Access Volume.

## QUERY CACHEFW

### Authorization

Privilege Class: B

### Purpose

Use the QUERY CACHEFW command to display the cache fast write status for cache storage subsystems.

### Operands

*rdev*

*rdev1-rdev2*

is the real device number, a list of real device numbers, or a range of real device numbers of devices in the subsystems being queried.

### Usage Notes

1. The QUERY CACHEFW command is only valid for cache storage subsystems that support the cache fast write function. An error message is generated if the specified subsystem does not support this function.

### Responses

Response 1:

```
rdev Cache fast write function is {active. }
                                {inactive.}
                                {suspended.}
```

This response is repeated for each **unique subsystem** that is associated with the devices specified when you enter the QUERY CACHEFW command.

*rdev*

is the real device number of one of the specified devices in a subsystem being queried.

**active**

indicates that the cache fast write function is active for the subsystem.

**inactive**

indicates that the cache fast write function is inactive for the subsystem.

**suspended**

indicates that the cache fast write function is suspended for the subsystem. Suspension occurs when an authorized guest issues the Perform Subsystem Function channel command to suspend all fast write operations.

### Messages

- HCP006E Invalid device type - {rdev/vdev/ldev}

- HCP009E Invalid range - *range*
- HCP020E Userid missing or invalid
- HCP021E A real device number was not supplied or it is invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP046E *type rdev* offline
- HCP319E Error processing subsystem command - *cmd* for DASD *rdev*
- HCP332E Invalid control unit type - *rdev*

## QUERY CAPABILITY

► Query — CAPability ◄

### Authorization

Privilege Class: A, B, C, E

### Purpose

Use the QUERY CAPABILITY command to determine the capability values of the processors in the configuration. A processor's capability value indicates its capability relative to that of other CPU models. For more information on CPU capability, see [z/Architecture Principles of Operation](#).

### Responses

Response 1:

```
CAPABILITY: PRIMARY pppppppp SECONDARY ssssssss [NOMINAL nnnnnnnn]
[CAPACITY-ADJUSTMENT INDICATION cai CAPACITY-CHANGE REASON ccr]
[capacity_change_explanation]
```

#### ***pppppppp***

is the capability of a primary CPU in the configuration. See usage note “1” on page 787.

#### ***ssssssss***

is the capability of a secondary CPU in the configuration. See usage note “1” on page 787.

#### ***nnnnnnnn***

is the nominal CPU capability for the configuration. This value is displayed only if it is nonzero. See usage note “1” on page 787.

#### ***cai***

is the capacity-adjustment indication. This decimal value is in the range 1 - 100 and represents the aggregate position of model-dependent controls. When the value is zero, the response line is not displayed. The source of the value is Store System Information (STSI) 1.1.1.

#### ***ccr***

is the capacity-change reason, which explains why the capacity change occurred. This value is the *ccr* value returned by STSI 1.1.1. When the *cai* value is zero, this response line is not displayed.

#### ***capacity\_change\_explanation***

is an explanation of the *cai* and *ccr* values. When the *cai* value is zero, this response line is not displayed. The text of the response will be one of the following:

**RUNNING AT NOMINAL CAPACITY.**

**RUNNING WITH REDUCED CAPACITY DUE TO A MANUAL CONTROL SETTING.**

For example, static power savings mode.

**RUNNING WITH REDUCED CAPACITY DUE TO A MACHINE EXCEPTION CONDITION.**

For example, a cooling problem.

**RUNNING WITH REDUCED CAPACITY DUE TO A MACHINE NON-EXCEPTION CONDITION.**

For example, a firmware update.

**RUNNING WITH REDUCED CAPACITY DUE TO AN EXTERNAL EXCEPTION CONDITION.**

For example, ambient temperature exceeded the specified maximum.

**MACHINE CAPACITY INDICATORS ARE IN AN UNEXPECTED STATE.**

The *ccr* value is not recognized.

**MACHINE CAPACITY IS IN TRANSITION BETWEEN STATES.**

A change to one or more machine capacity-related values is expected to occur soon.

**Usage Notes**

1. The primary, secondary, and nominal capacity values returned in the response can be integers or decimal fractions (such as, 5.125678). In some cases the value might be too large or too small to display, in which case the term "OVERFLOW" or "UNDERFLO" will be displayed.

**Messages**

- HCP263E Too many operands were supplied for this command.

## QUERY CFLINKS

### Authorization

Privilege Class: A, B, G

### Purpose

Use QUERY CFLINKS to display information about links between coupling facilities.

### Operands

#### ALL

specifies that coupling facility to coupling facility link information should be displayed for all coupling facility virtual machines to which the issuer is coupled.

#### NAME *msgprocid*

indicates a specific coupling facility virtual machine that is to be queried.

### Usage Notes

1. If the caller is a class G user, then only coupling facility-to-coupling link information for message processors within the user's current I/O configuration is displayed. A class A or B user may display coupling facility link information for a particular message processors by using the NAME keyword.
2. QUERY CFLINK returns information about the coupling facility-to-coupling facility links that were created by the DEFINE CFLINK command or the SPECIAL MSGP directory statement for a coupling facility virtual machine. The QUERY MSGP command may be used to obtain information for coupling links between OPTION CFUSER and coupling facility virtual machines.

### Responses

The command first produces two lines of output describing the queried coupling facility virtual machine:

```
MESSAGE PROCESSOR=nn   USERID=userid   PEERS=pp
TYPE=SIMDEV  MODEL=001  MFG=IBM  PLANT=EN  SEQ=ND01
```

where:

#### *nn*

is a sequence number assigned to the coupling facility virtual machine by QUERY CFLINKS.

#### *userid*

is the user ID of the coupling facility virtual machine being queried.

#### *pp*

is either the number of sender peers or the number of receiver peers of this coupling facility, whichever is greater.

#### TYPE

is the six-character device type in the worldwide unique ID of the message processor's node descriptor.

**MODEL**

is the three-character model number in the worldwide unique ID of the message processor's node descriptor.

**MFG**

is the three-character code that identifies the manufacturer in the worldwide unique ID of the message processor's node descriptor.

**PLANT**

is the two-character code that identifies the plant of manufacture in the worldwide unique ID of the message processor's node descriptor.

**SEQ**

is the 12-character code that contains the serial number in the worldwide unique ID of the message processor's node descriptor.

Two lines of output are produced for each coupling facility virtual machine to which this coupling facility virtual machine is connected. The first appears as follows:

```
DEVICES=nnnn nnnn ...
```

These are the virtual devices in use as message devices to the target coupling facility virtual machine.

The second of these lines is displayed:

```
CFS=aa bb (PA=dd) CFR=ee ff (PA=hh) S_RLINK=userid
```

where:

**aa**

The sending side's first channel path ID.

**bb**

The sending side's second channel path ID (that might not appear).

**dd**

The sender's path available mask.

**ee**

The receiving side's first channel path ID.

**ff**

The receiving side's second channel path ID (that might not appear).

**hh**

The receiver's path available mask.

**userid**

The user ID of the receiving coupling facility virtual machine.

This pair of lines is repeated for each coupling facility virtual machine to which the queried coupling facility virtual machine is coupled.

**Examples**

CFUSER1 is coupled to coupling facility CFVM1. To find information about the coupling facility-to-coupling facility links for which CFVM1 initiated, CFUSER1 could enter the following:

```
query cflink name cfvm1
```

To find coupling facility-to-coupling facility link information for all coupling facility virtual machines to which CFUSER1 is coupled, CFUSER1 could enter the following:

```
query cflink
```

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP020E Userid missing or invalid
- HCP045E *userid* not logged on
- HCP2800E *msgprocid* is not an authorized CF Service Machine.
- HCP2805E One or more message processors does not exist in your I/O configuration.
- HCP2806E You are not allowed to control message processors.
- HCP2820E You are not coupled to any CF service machines.

## QUERY CHPID

### Authorization

Privilege Class: B

### Purpose

Use QUERY CHPID to display the following:

- All devices in the active configuration with logical channel path *yy* installed
- Logical path status as it pertains to those devices (online, offline, or quiesced).

Use QUERY CHPID *yy* NETID to display the network identifier associated with CHPID *yy*.

Use QUERY CHPID *yy* PCHID to display the physical channel identifier associated with CHPID *yy*.

Use QUERY CHPID *yy* TYPE to display the channel path type of CHPID *yy*.

Use QUERY CHPID *yy* SS *nn* to display the following:

- All devices in the subchannel set *nn* with logical change path *yy* installed.
- Logical path status as it pertains to those devices (online, offline, or quiesced).

### Operands

#### *yy*

is the logical channel path whose device allocation information is requested. The variable *yy* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

#### NETID

requests the display of the network identifiers associated with CHPID *yy*.

#### PCHID

requests the display of the physical channel identifier associated with CHPID *yy*.

**Note:** This parameter is valid only when your machine is capable of logical channel-subsystem support.

#### TYpe

requests the display of the channel path type of CHPID *yy*.

#### SS *nn*

requests the display of devices in subchannel set *nn* with logical channel path *yy* installed. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'03'.

### Usage Notes

1. The QUERY CHPID command shows all devices associated with a specific logical channel path. For information about physical channel paths, use the QUERY CHPIDS command. (See [“QUERY CHPIDS”](#))

on page 796.) For information about logical and physical channel paths associated with a specific device, use the QUERY PATHS command. (See “QUERY PATHS” on page 1064.)

2. If a device has never been initialized, its path information is not available and, therefore, cannot be included in the command response.
3. Internal channel path types such as internal-queued-direct-communications (IQD) channels and internal-coupling-peer (ICP) channels are not associated with physical channel paths (PCHIDs).
4. Internal-queued-direct-communications (IQD) channel paths and OSA\_Direct\_Express (OSD) channel paths are the only channel path types that can have network identifiers associated with them.
5. A VIRTUAL version of this command, QUERY VIRTUAL CHPID, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see “QUERY VIRTUAL CHPID” on page 1275.

### Examples

To display all the devices on path 1A, enter:

```
query chpid 1a
```

A typical response is:

```
PATH 1A ONLINE TO DEVICES 0190, 0191, 0193
PATH 1A OFFLINE TO DEVICES 0192
```

To display the channel path type of path 1A, enter:

```
query chpid 1a type
```

A response might be:

```
Path 1A is an ESCON unswitched channel
```

To display the physical channel identifier associated with path 1A, enter:

```
query chpid 1a pchid
```

A response might be:

```
Path 1A is associated with physical channel 061A
```

To display all the devices on path 1A in subchannel set 1, enter:

```
query chpid 1a ss 1
```

A typical response is:

```
Path 1A ONLINE TO DEVICES 10190, 10191, 10193
PATH 1A OFFLINE TO DEVICES 10192
```

### Responses

Response for Path Status:

```
PATH yy {ONLINE } TO DEVICES xxxx(1)
... xxxx(n)
```

```
PATH yy {OFFLINE} TO DEVICES zzzz(1)
... zzzz(n)
```

indicates that path yy to device xxxx(1) through device xxxx(n) is logically available (online), and path yy to device zzzz(1) through device zzzz(n) is logically unavailable (offline).

**yy** is the logical channel path.

**xxxx**

**zzzz**

are the real device numbers.

Response for Path Status when SS operand is specified:

```
PATH yy {ONLINE} TO DEVICES xxxxx(1)
... xxxxx(n)

PATH yy {OFFLINE} TO DEVICES zzzzz(1)
... zzzzz(n)
```

indicates that path yy to device xxxxx(1) through device xxxxx(n) is logically available (online), and path yy to device zzzzz(1) through device zzzzz(n) is logically unavailable (offline).

**yy** is the logical channel path.

**xxxx**

**zzzz**

are the real device numbers.

Response for No Devices on Path:

```
NO DEVICES ON PATH yy
```

indicates there are no devices on the specified channel path.

**yy** is the logical channel path.

Response for Nonexistent CHPID:

```
INVALID CHPID yy
```

indicates that a nonexistent channel path ID was specified.

**yy** is the nonexistent logical channel path.

Response for Quiesced Path:

```
PATH yy QUIESCED TO DEVICE(S) xxxx(1)... xxxx(n)
```

indicates the path has been quiesced (locked offline) to the specified devices by an IBM Service Representative. Once service on this channel path is completed, a corresponding resume request issued by the Service Representative (SR) will cause this channel path to be varied online to the device or devices, if they were online before being quiesced. If for some reason the resume request did not vary this channel path back online, the FORCE option on the VARY PATH command can be used to override the quiesced path and vary the channel path online to the device or devices. The FORCE option should only be used when the SR indicates that service is complete and a resume was issued but did not vary the channel path online.

**yy** is the logical channel path.

**xxxx**

are the real device numbers.

Responses for Optional NETID Operand:

```
PATH NETIDS
yy 0000000000000000 0000000000000000 0000000000000000 0000000000000000
-OR
Path yy is a type of channel path that does not support network identifiers.
```

-OR  
Network identifiers could not be obtained.

**yy**  
is the logical channel path.

**nnnnnnnnnnnnnnnnnn**

is a network identifier. The order of the network identifiers corresponds to the order of the ports associated with the path. Dashes indicate no network identifier has been assigned to the port.

Responses for Optional PCHID Operand:

Path yy is associated with physical channel xxxx  
Path yy is not associated with a physical channel

**yy**  
is the logical channel path.

**xxxx**  
is the physical channel identifier value found.

Responses for Optional TYPE Operand:

Path yy is a parallel block-multiplexer channel  
Path yy is a parallel byte-multiplexer channel  
Path yy is an ESCON unswitched channel  
Path yy is an ESCON switched channel  
Path yy is an ESCON channel  
(switched or unswitched has not been determined)  
Path yy is an ESCON channel to a parallel block-multiplexer converter  
Path yy is a native-interface channel  
Path yy is an ESCON CTC unswitched channel  
Path yy is an ESCON CTC switched channel  
Path yy is an ESCON CTC channel  
(switched or unswitched has not been determined)  
Path yy is a coupling-facility-sender (CFS) channel  
Path yy is a coupling-facility-receiver (CFR) channel  
Path yy is an ESCON channel to a parallel byte-multiplexer converter  
Path yy is an Open Systems Adapter (OSA) channel  
Path yy is an Open Systems Adapter-Express (OSE) channel  
Path yy is an Open Systems Adapter Direct Express (OSD) channel  
Path yy is an Open Systems Adapter 3270-Console (OSC) channel  
Path yy is an Open Systems Adapter NCP (OSN) channel  
Path yy is an internal-system-device (ISD) channel  
Path yy is a cluster-bus-sender (CBS) channel  
Path yy is a cluster-bus-receiver (CBR) channel  
Path yy is an internal-coupling-sender (ICS) channel  
Path yy is an internal-coupling-receiver (ICR) channel  
Path yy is a FICON unswitched channel  
Path yy is a FICON switched channel  
Path yy is a FICON channel to an ESCON Director FICON Bridge card  
Path yy is a FICON channel  
(switched or unswitched has not been determined)  
Path yy is a High Performance FICON unswitched channel  
Path yy is a High Performance FICON switched channel  
Path yy is a High Performance FICON channel  
Path yy is a direct-system-device (DSD) channel  
Path yy is an emulated-I/O (EIO) channel  
Path yy is a cluster-bus-peer (CBP) channel  
Path yy is a coupling-facility-peer (CFP) channel  
Path yy is an internal-coupling-peer (ICP) channel  
Path yy is an internal-queued-direct-communications (IQDC) channel  
Path yy is an open-fibre-channel-protocol (FCP) channel  
Path yy is a coupling over InfiniBand (CIB) channel  
Path yy is an Open Systems Adapter Direct Express IEDN (OSX) channel  
Path yy is an Open Systems Adapter Direct Express INMN (OSM) channel  
Path yy is a coupling over PCIe (CS5) channel  
Path yy is a coupling over RoCE (CL5) channel  
Path yy is an unknown or unrecognized channel type - xx

**yy**  
is the logical channel path.

**xx**  
is the CHPID descriptor value found.

**Messages**

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid
- HCP846E Invalid channel path identifier.
- HCP1006E Command processing cannot complete because the system does not support the logical-channel-subsystem facility.
- HCP1006E Command processing cannot complete because the system does not support the Utility-String facility.

# QUERY CHPIDS

## Authorization

Privilege Class: B, E

## Purpose

Use QUERY CHPIDS to display all 256 of the machine's channel paths and their physical status.

## Usage Notes

1. The QUERY CHPIDS command shows all 256 channel paths on your system and their physical status. For information about logical channel paths, see the QUERY CHPID command (see [“QUERY CHPID” on page 791](#)). For information about logical and physical channel paths associated with a specific device, see the QUERY PATHS command (see [“QUERY PATHS” on page 1064](#)).
2. If a channel path is in single channel service (SCS) mode, it will appear as "not configured" in the display.
3. To change the status of the channel paths in your I/O configuration, use one of the following commands:
  - DEFINE CHPID or PATH (see [“DEFINE CHPID / PATH” on page 132](#))
  - DELETE CHPID or PATH (see [“DELETE CHPID / PATH” on page 259](#))
  - MODIFY CU or CNTLUNIT (see [“MODIFY CU / CNTLUNIT” on page 688](#))
  - VARY CHPID (see [“VARY CHPID” on page 2046](#))

## Responses

Response 1:

To display the status of your machine's channel paths, enter the following:

```

query chpids
  0  1  2  3  4  5  6  7  8  9  A  B  C  D  E  F
0x  .  .  .  .  +  .  +  +  +  .  .  .  .  +  +  +
1x  .  +  .  .  +  +  .  .  +  +  +  +  .  +  .  -
2x  .  .  .  .  .  .  .  .  .  .  .  .  .  +  +  +
3x  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
4x  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
5x  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
6x  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
7x  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
8x  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
9x  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
Ax  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
Bx  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
Cx  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
Dx  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
Ex  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .
Fx  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .  .

+ Available
- Offline
. Not configured
Ready;
    
```

This response shows that there are 18 physical channel paths that can be used (available), 1 channel path that is not available (offline), and 237 channel paths that are not defined (not configured).

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP6813E Query CHPIDs command failed with return code *nnnn*.
- HCP6814E Command not valid on this processor.

## QUERY CHPIDV

---

► Query — CHPIDV ◄

### Authorization

Privilege Class: G

### Purpose

Use QUERY CHPIDV to display the virtualization directory setting for a user.

### Responses

Response for QUERY CHPIDV:

```
CHPID Virtualization is off
```

or

```
One path CHPID Virtualization is on
```

### Messages

- HCP003E Invalid option - *{option|command contains extra option(s) starting with option}*

## QUERY CMDLIMIT

### Authorization

Privilege Class: A, B

### Purpose

Use QUERY CMDLIMIT to display the number of incorrect passwords the host system accepts.

**Note:** If you exceed this limit, AUTOLOG and XAUTOLOG are disabled for the remainder of your session.

### Operands

#### AUTOLog

#### XAUTOLog

requests a display showing the system limit value for the AUTOLOG and XAUTOLOG commands. This parameter is optional.

### Usage Notes

1. The SET CMDLIMIT command changes the system limit value for the number of incorrect passwords for the AUTOLOG and XAUTOLOG commands.
2. For security reasons, CP limits the number of incorrect passwords allowed in your logon session. Every incorrect password entered for an AUTOLOG or XAUTOLOG command is counted. Once you have exceeded the limit, you must log off and log on again to enter more AUTOLOG or XAUTOLOG commands.
3. AUTOLOG is an accepted synonym for XAUTOLOG. The minimum abbreviation is AUTOL.

### Responses

Response 1:

```
XAUTOLOG/AUTOLOG incorrect password limit is nnn
```

#### **nnn**

indicates the number of incorrect passwords that can be entered before the AUTOLOG and XAUTOLOG commands are disabled for the rest of your logon session.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

## QUERY COLLECT

### Authorization

Privilege Class: G

### Purpose

Use the QUERY COLLECT command to display information about nodes and routes within the ISFC collection.

### Operands

#### ALL

Displays information about the local node and about the immediate neighbors.

#### *nodeid*

Displays the link information for the specified immediate neighbor.

### Responses

Response 1:

```
Node nodeid is local.
```

#### *nodeid*

Specifies the node ID of the local VM node.

Response 2:

```
Node nodeid via link device rdev.
```

#### *nodeid*

Specifies the node ID of the partner node.

#### *rdev*

Specifies the address of the real link device that connects the local node with the partner node.

Response 3:

```
No nodes exist in collection.
```

Response 4:

Up to 16 *rdevs* may be shown for a single node.

```
Node nodeid via link devices rdev1 rdev2 rdev3 rdev4.
```

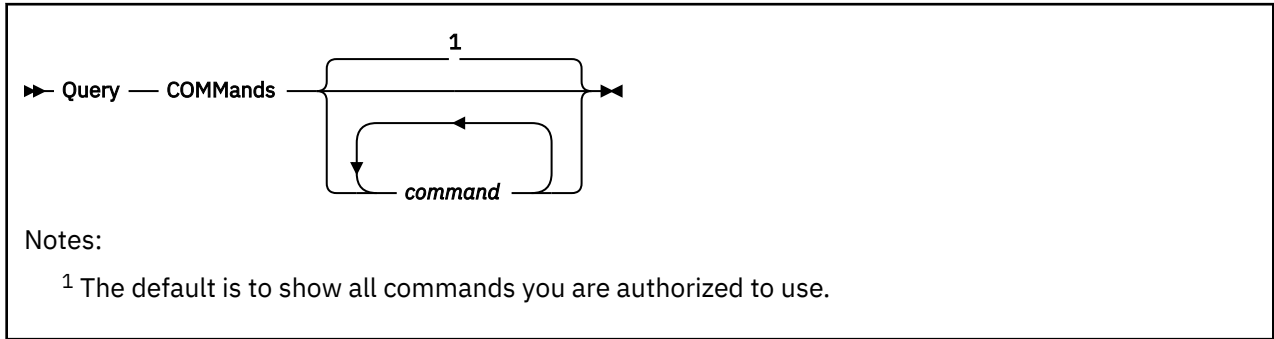

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*

- HCP2726E Node *nodeid* is not directly connected.

## QUERY COMMANDS

### Authorization

Privilege Class: Any

### Purpose

Use QUERY COMMANDS to display the commands and diagnose codes you are authorized to use.

### Operands

***command***

the names of commands to be checked for authorization.

### Usage Notes

1. The same function is available through the COMMANDS command.
2. Some commands have more than one version, but the user may not be authorized to use all versions of the command. If the system rejects a command, it is probably because the user is not authorized to enter the command with the operand or operands entered.
3. To see the command versions you are authorized to use, enter QUERY COMMANDS *cmd*, where *cmd* is the name of the command or commands that interests you. You are shown the default IBM privilege classes of the command that you are authorized to enter.

You may specify any number of commands. If a command name is entered twice, it appears twice in the response. No duplicate-entry checking is done.

4. Diagnose codes cannot be queried separately from commands.
5. IBMCLASS=ANY will output if:
  - the command is allowed before logon and not disabled, or
  - the user privilege class is ANY, meaning the command version is not associated with any particular privilege class and the command is enabled.

### Responses

Response 1:

```
cmd1    cmd2    cmd3    cmd4    cmd5    cmd6
cmd7    ...
:
diag1   diag2   diag3   diag4   diag5   diag6
diag7   ...
```

is the response when the command QUERY COMMANDS is entered alone; all authorized commands and diagnose codes are displayed.

**cmd1,2...**

the names of authorized commands.

**diag1,2...**

the names of authorized diagnose codes.

Response 2:

```
AUTHORIZED {QUERY|SET} OPERANDS:
operand1  IBMCLASS={c1,c2,c3}
           {ANY}
           {NONE}
operand3  IBMCLASS={c1,c2,c3}
           {ANY}
           {NONE}
:
operand2  IBMCLASS={c1,c2,c3}
           {ANY}
           {NONE}
operand4  IBMCLASS={c1,c2,c3}
           {ANY}
           {NONE}
```

is the response when the command COMMANDS is entered with the QUERY or SET operand; all authorized operands of the QUERY or SET command are displayed.

**operand1,2 ...**

the names of authorized QUERY or SET operands.

**c1,c2, ...**

the IBM-defined privilege classes of the operands that you are authorized to enter.

Response 3:

```
cmd1      IBMCLASS=c1,c2,c3
cmd2      IBMCLASS=ANY
cmd3      IBMCLASS=NONE
```

is the response you receive when you specifically enter commands to check authorization for them. The response includes one line of output for each command listed.

**cmdx**

is the name of the command you entered on the command line.

**IBMCLASS=c1,c2,c3**

the IBM-defined privilege classes of the command specified; the privilege class displayed reflects the authorization of the user making the inquiry.

**IBMCLASS=ANY**

indicates that the command is a class ANY command, and all users may enter the command.

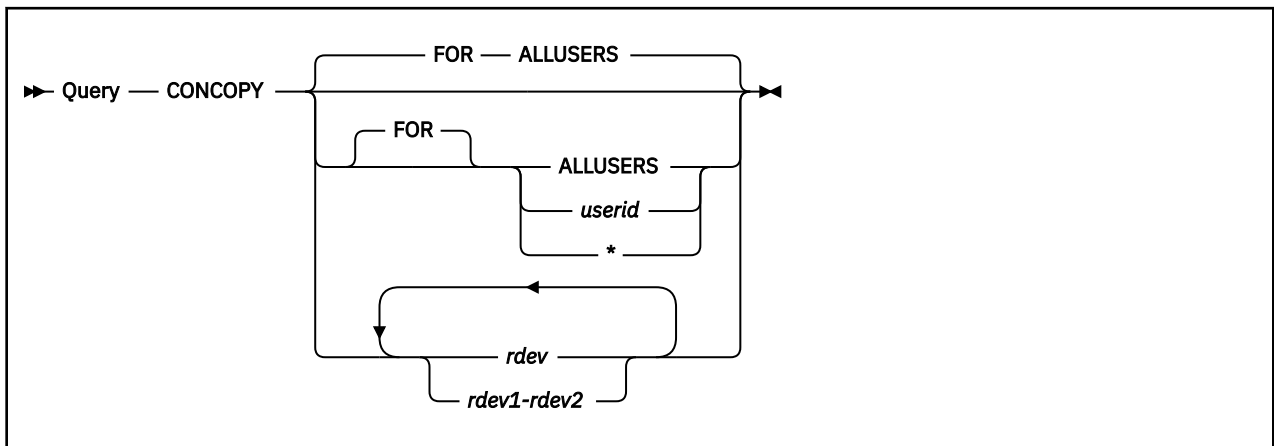

**IBMCLASS=NONE**

indicates that you are not authorized to enter any version of the command.

**Messages**

- HCP003E Invalid option - {option|command contains extra option(s) starting with option}

## QUERY CONCOPY

### Authorization

Privilege Class: B

### Purpose

Use the QUERY CONCOPY command to display Concurrent Copy (CONCOPY) session information.

### Operands

#### ALLUSERS

indicates that the query operation applies to all the virtual machines. This is the default.

#### userid

is the virtual machine for which CONCOPY session information is to be displayed.

\*

indicates that the query operation applies to the virtual machine issuing the command.

#### rdev

#### rdev1-rdev2

identifies the real device number of one of the subsystem devices. You can specify a single device number, a list of device numbers, or a range of device numbers.

### Examples

Example 1:

To find out what users on your system have active CONCOPY sessions, enter:

```
query concopy
```

You receive Response 1 for each user who has an active CONCOPY session. If your system has three such users (ADAMS, BAKER, and DUNCAN), the display might look like this:

```
CONCOPY session(s) for userid ADAMS are on
device(s): 301 321
CONCOPY session(s) for userid BAKER are on
device(s): 333 433 533
CONCOPY session(s) for userid DUNCAN are on
device(s): 321 322
```

Example 2:

To get the CONCOPY status of all devices on your system in the device number range from 320 to 325, enter:

```
query concopy 320-325
```

For each device in the specified range, you receive a CONCOPY status response (Response 2 or Response 5) if the device exists, or an error message if the device does not exist. If your system has three devices in that range (321, 322, and 323), and two (321 and 322) are included in active CONCOPY sessions, the display might look like this:

```
HCPnnn040E Device 320 does not exist
CONCOPY session(s) on device 321 for userid(s):
  ADAMS DUNCAN
CONCOPY session(s) on device 322 for userid(s):
  DUNCAN
No CONCOPY session exists on device 323
HCPnnn040E Device 324 does not exist
HCPnnn040E Device 325 does not exist
```

## Responses

Response 1:

```
CONCOPY session(s) for userid userid are on
device(s): rdev1...
```

indicates that virtual machine *userid* has active CONCOPY sessions and lists the real device numbers of the devices that are part of the CONCOPY sessions.

Response 2:

```
CONCOPY session(s) on device rdev for userid(s):
userid...
```

indicates that real device *rdev* is part of at least one CONCOPY session for the specified user ID or list of user IDs.

Response 3:

```
No CONCOPY session exists for userid userid.
```

indicates that virtual machine *userid* does not have any CONCOPY sessions.

Response 4:

```
No CONCOPY session exists for any user.
```

indicates that there are no CONCOPY sessions for any user on any storage control.

Response 5:

```
No CONCOPY session exists on device rdev.
```

indicates that device *rdev* is not part of any CONCOPY session.

## Messages

- HCP006E Invalid device type - *rdev*
- HCP009E Invalid range - *range*
- HCP026E Operand missing or invalid
- HCP040E Device *rdev* does not exist
- HCP046E *type rdev* offline
- HCP332E Invalid control unit type - *rdev*

## QUERY CONFIGMODE

► Query — CONFIGmode ◄

### Authorization

Privilege Class: B, E

### Purpose

Use QUERY CONFIGMODE to display whether the processor is currently executing commands to dynamically change its I/O configuration.

**Note:** QUERY CONFIGMODE is a dynamic I/O command. Dynamic I/O configuration is only supported on IBM Z servers. If your system is not running on one of these servers, your command will not complete successfully.

### Usage Notes

1. To turn configuration mode on or off, use the SET CONFIGMODE command (see [“SET CONFIGMODE” on page 1436](#)).
2. Whenever you issue one of the following dynamic I/O commands:

DEFINE CHPID	DEFINE PATH
DELETE CHPID	DELETE PATH
MODIFY CHPID	MODIFY PATH
DEFINE CU	DEFINE CNTLUNIT
DELETE CU	DELETE CNTLUNIT
MODIFY CU	MODIFY CNTLUNIT
DEFINE DEVICE	DEFINE IODEVICE
DELETE DEVICE	DELETE IODEVICE
MODIFY DEVICE	MODIFY IODEVICE
DEFINE LPAR	
DELETE LPAR	
SET LSYSTEM	

CP puts the machine in configuration mode, processes the dynamic I/O command, and then takes you out of configuration mode.

3. Whenever you dynamically change your I/O configuration, CP must perform a certain amount of overhead. If you want to issue several dynamic I/O commands in succession and you are concerned about performance, issue the SET CONFIGMODE ON command, issue your dynamic I/O commands, and then issue the SET CONFIGMODE OFF command. This method causes CP to perform the overhead only while processing the SET CONFIGMODE commands, rather than before and after each individual command.

Note that the SET LSYSTEM command is an exception to the above. CP will not process this command while the machine is in configuration mode. If you want to issue the SET LSYSTEM command to set or change the current local system name, you must exit configuration mode and enter the SET LSYSTEM command as an individual command. For more information about the SET LSYSTEM command, see [“SET LSYSTEM” on page 1553](#).

4. While you are in configuration mode, CP will not process any SET DYNAMIC\_I/O OFF commands. If you want to prevent people from making dynamic I/O changes, you must exit configuration mode and enter the SET DYNAMIC\_I/O OFF command as an individual command. For more information about the SET DYNAMIC\_I/O command, see [“SET DYNAMIC\\_I/O” on page 1502](#).

## Responses

Response when Configuration Mode is Off:

To display whether your processor is currently in configuration mode, enter the following:

```
query configmode
System is not in configuration mode.
Ready;
```

This response tells you that your processor is not currently executing commands to dynamically change its I/O configuration.

Response when Configuration Mode is Turned On:

If someone on your system had turned configuration mode on using the SET CONFIGMODE command and was in the process of issuing one or more dynamic I/O commands, you would see the response below. You would also see this response if someone on your system had issued a dynamic I/O command that caused the system to temporarily turn on configuration mode:

```
query configmode
System is in configuration mode for user userid
Ready;
```

Where *userid* is the name of the person who issued the SET CONFIGMODE command.

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP6808E Cannot find the configuration token on the system
- HCP6808E Cannot store LPAR data
- HCP6808E System disabled for dynamic I/O changes
- HCP6808E The configuration mode setting of the hardware and software do not match
- HCP6808E The dynamic I/O support was disabled at the service console
- HCP6808E The VM configuration token does not match the hardware configuration token
- HCP6809E This processor does not support dynamic I/O changes
- HCP6815E Command failed in the channel subsystem
- HCP6816E Dynamic I/O changes are not allowed on this system

## QUERY CONTROLLER

### Authorization

Privilege Class: B

### Purpose

Use QUERY CONTROLLER to display information about the z/VM TCP/IP virtual machines used to manage OSA-Express or HiperSockets Bridge Port devices associated with virtual switches.

### Operands

#### ALL

displays information for all possible virtual switch controllers. This is the default value when an explicit *NAME userid* is omitted.

#### NAME *userid*

restricts the response to the virtual switch controller specified.

### Examples

This example displays all the available detail for CONTROLLER.

```
query controller
Controller DTCVSW1 Available: YES VDEV Range: 8800-88FF Level 630
Capability: IP ETHERNET VLAN_ARP GVRP LINKAGG ISOLATION
BRIDGE_CAPABLE VEPA SHARED_LINKAGG PRIQUEUING
SYSTEM EDUC1 Active Controller: DTCVSW1 RDEV: 8803
SYSTEM TECHNET1 Backup Controller: * RDEV: 8800

Controller DTCVSW2 Available: YES VDEV Range: * Level 630
Capability: IP ETHERNET VLAN_ARP GVRP LINKAGG ISOLATION
BRIDGE_CAPABLE VEPA SHARED_LINKAGG PRIQUEUING

SYSTEM TECHNET1 Active Controller: * RDEV: 1B00

Controller TCPIP1 Available: YES VDEV Range: * Level 630 Failover disabled
Capability: IP ETHERNET VLAN_ARP GVRP LINKAGG ISOLATION
BRIDGE_CAPABLE VEPA SHARED_LINKAGG PRIQUEUING
SYSTEM PAYROLL Active Controller: * VDEV: 2B03
SYSTEM TECHNET1 Backup Controller: * VDEV: 3B00

Controller TCPIP3 Available: YES VDEV Range: * Level 630 Stalled
Capability: IP ETHERNET VLAN_ARP GVRP LINKAGG ISOLATION
BRIDGE_CAPABLE VEPA SHARED_LINKAGG PRIQUEUING
```

### Responses

Each virtual switch that is currently managed is listed, along with the current setting for the Controller option.

#### Available

indicates if the virtual switch controller is available to control an additional set of OSA-Express or HiperSockets Bridge Port devices associated with the virtual switch.

**VDEV Range**

identifies the device range where the OSA-Express or HiperSockets Bridge Port devices associated with a virtual switch can be attached. **VDEV Range: \*** indicates that the virtual device address used to attach the devices is the same as the real device address identified by the virtual switch's RDEV option.

**LEVEL**

indicates the level of the TCP/IP stack running in the controller virtual machine. "Initializing" is displayed if the level is not yet known.

**Failover disabled**

indicates that the TCP/IP stack machine has been configured so that CP does not perform timestamp checking. Timestamp checking is used to confirm that the TCP/IP stack is responding, and it has been disabled in this instance.

**Stalled**

indicates the TCP/IP stack machine is not responding in a timely manner. Use the `FAILOVER_DISABLED` option on the TCP/IP VSWITCH CONTROLLER configuration statement if you need to do tracing or debug for the TCP/IP stack machine that might result in slow response time. See *z/VM: TCP/IP Planning and Customization* for additional information.

**Capability**

indicates what types of virtual switches the controller can manage.

**IP and ETHERNET**

The virtual switch controller can initialize an OSA-Express device in IP or ETHERNET modes.

**VLAN\_ARP**

It can register IP addresses on the OSA-Express with the proper VLAN groups.

**GVRP**

It can register VLAN IDs in use on a virtual switch with GVRP-aware switches (GVRP).

**LINKAGG**

Virtual switches that use link aggregation can be managed.

**ISOLATION**

Virtual switches that use the isolation setting can be managed.

**BRIDGE\_CAPABLE**

The controller can manage a virtual switch configured with a HiperSocket bridge port.

**VEPA**

The controller can manage virtual switches that use the VEPA option on SET VSWITCH.

**SHARED\_LINKAGG**

Virtual switches configured with shared port groups can be managed.

**PRIQUEUING**

Virtual switches configured with priority queuing can be managed.

**Active**

indicates that the device is the current active connection for the virtual switch.

**Backup**

indicates that some initialization has been done so that error recovery can happen more quickly if the active device has a problem.

**[Active | Standby | Undefined | Inactive] Bridge**

indicates that the device is operating as a virtual switch Bridge Port connection.

Typically, the bridge status will be Active or Standby. Undefined and Inactive are expected to be temporary while the port is in transition.

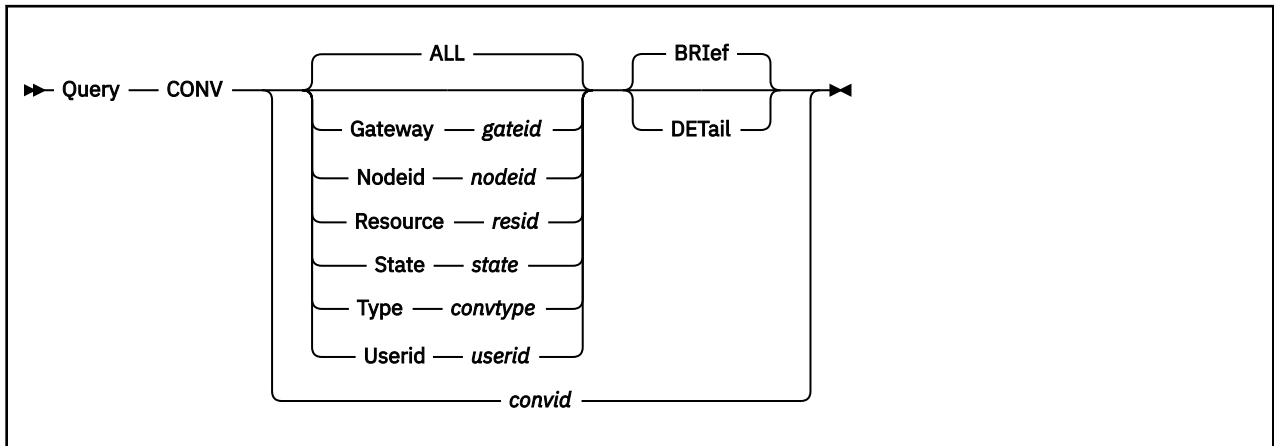

**Controller: \***

indicates that a different z/VM TCP/IP stack takes over in case there is a problem with the current virtual switch controller.

**RDEV: devno**

shows the base real device number attached to the controller for the virtual switch.

## QUERY CONV

### Authorization

Privilege Class: B

### Purpose

Use the QUERY CONV command to display information about the conversations that are managed by the local VM node.

### Operands

#### ALL

displays information for all active conversations that are in the domain of the local VM node. ALL is the default.

#### Gateway *gateid*

displays information for the active conversations that are established through gateways such as, APPC/VM VTAM Support (AVS) or system gateways defined on VM systems in the Communication Services (CS) collection.

#### Nodeid *nodeid*

displays information for the active conversations that are established between the specified remote node and the local VM node.

#### Resource *resid*

displays information for the active conversations that are established for the application *resid*. This application is a global resource.

#### State *state*

displays information for the active conversations that are in the specified state. Valid states are CONFIRM, CONNECT, PENDING, RECEIVE, RESET, SEND, and SEVER.

#### Type *convtype*

displays information about active conversations of the specified type; valid types are APPC, IUCV, CMP, or CPAP.

#### Userid *userid*

displays information for the active conversations established for the user *userid*. This user ID is either:

- The access security user ID specified in the connection request
- The user ID of the owner of a private resource. This private resource is located in a virtual machine on the local z/VM system or on a workstation in the domain of the local VM node.

**BRIef**

displays the number of active conversations. BRIef is the default.

**DETail**

displays detailed information about each conversation.

**convid**

is the hexadecimal conversation identifier of a specific conversation managed by the local VM node.

**Responses**

Response 1:

```
Conversation: convid   Instance: x       Type:           APPC
Node:    nodeid       Bytes Sent:    nnn
State:   state        Bytes Received: nnn
Access Userid: userid Gateway Name:  gateid
```

**convid**

specifies the conversation ID assigned by the local VM node.

**x**

specifies the conversation instance number.

**APPC**

specifies that the conversation is APPC.

**nodeid**

specifies the node ID of the remote node.

**nnn**

specifies the number of bytes sent from the local node or the number of bytes received by the local node.

**state**

specifies if the conversation is in CONFIRM, CONNECT, PENDING, RECEIVE, RESET, SEND, or SEVER state.

**userid**

specifies the access user ID that establishes the conversation.

**gateid**

specifies the system or AVS gateway through which this conversation is allocated.

Response 2:

```
Conversation: convid   Instance: x       Type:           APPC
Node:    nodeid       Bytes Sent:    nnn
State:   state        Bytes Received: nnn
Access Userid: userid Resource Name:  resid
```

**convid**

specifies the conversation ID assigned by the local VM node.

**x**

specifies the conversation instance number.

**APPC**

specifies that the conversation is APPC.

**nodeid**

specifies the node ID of the remote node.

**nnn**

specifies the number of bytes sent from the local node or the number of bytes received by the local node.

**state**

specifies if the conversation is in CONFIRM, CONNECT, PENDING, RECEIVE, RESET, SEND, or SEVER state.

## QUERY CONV

### **userid**

specifies the access user ID that establishes the conversation.

### **resid**

specifies the resource this conversation is connected to.

Response 3:

```
Conversation: convid      Instance: x      Type:          APPC
Node:      nodeid
State     state          Bytes Sent:    nnn
Access Userid: userid    Bytes Received: nnn
Target Userid: targetid
```

### **convid**

specifies the conversation ID assigned by the local VM node.

### **x**

specifies the conversation instance number.

### **APPC**

specifies that the conversation is APPC.

### **nodeid**

specifies the node ID of the remote node.

### **nnn**

specifies the number of bytes sent from the local node or the number of bytes received by the local node.

### **state**

specifies if the conversation is in CONFIRM, CONNECT, PENDING, RECEIVE, RESET, SEND, or SEVER state.

### **userid**

specifies the access user ID that establishes the conversation.

### **targetid**

specifies the target user ID this conversation is connected to.

Response 4:

```
Conversation: convid      Instance: x      Type:          convtype
Node:      nodeid
Bytes Sent:    nnn
Bytes Received: nnn
```

### **convid**

specifies the conversation ID assigned by the local VM node.

### **x**

specifies the conversation instance number.

### **convtype**

specifies if the conversation is APPC, IUCV, CMP, or CPAP.

### **nodeid**

specifies the node ID of the remote node.

### **nnn**

specifies the number of bytes sent from the local node or the number of bytes received by the local node.

Response 5:

```
nnn conversations active.
```

### **nnn**

specifies the number of conversation(s) active.

Response 6:

```
nnn conversation(s) active with user userid
```

**nnn**

specifies the number of conversations active.

**userid**

specifies the access user ID that establishes the conversation.

Response 7:

```
nnn conversation(s) active with node nodeid
```

**nnn**

specifies the number of conversations active.

**nodeid**

specifies the node ID of the remote node.

Response 8:

```
nnn conversation(s) active with resource resid
```

**nnn**

specifies the number of conversations active.

**resid**

specifies the resource to which this conversation is connected.

Response 9:

```
nnn conversation(s) active with gateway gateid
```

**nnn**

specifies the number of conversations active.

**gateid**

specifies the system or AVS gateway through which this conversation is allocated.

Response 10:

```
nnn conversation(s) active of type convtype
```

**nnn**

specifies the number of conversations active.

**convtype**

specifies the type of conversation.

Response 11:

```
nnn conversation(s) currently in state state
```

**nnn**

specifies the number of conversations active.

**state**

specifies the state of the conversation(s).

Response 12:

```
Conversation: convid Instance: x Type: APPC
Node: nodeid Bytes Sent: nnn
PASSTHRU Bytes Received: nnn
Access Userid: userid Gateway Name: gateid
```

**convid**

specifies the conversation ID assigned by the local VM node.

## QUERY CONV

**x**

specifies the conversation instance number.

**APPC**

specifies that the conversation is APPC.

**nodeid**

specifies the node ID of the remote node.

**PASSTHRU**

indicates that this is an intermediate node for the conversation.

**nnn**

Bytes sent specifies the number of bytes transmitted from the target node to the source node by the local node.

Bytes received specifies the number of bytes transmitted from the source node to the target node by the local node.

**userid**

specifies the access user ID that establishes the conversation.

**gateid**

specifies the system or AVS gateway through which this conversation is allocated.

Response 13:

```
Conversation: convid      Instance: x      Type:          APPC
Node:      nodeid      Bytes Sent:    nnn
PASSTHRU   Bytes Received: nnn
Access Userid: userid  Resource Name: resid
```

**convid**

specifies the conversation ID assigned by the local VM node.

**x**

specifies the conversation instance number.

**APPC**

specifies that the conversation is APPC.

**nodeid**

specifies the node ID of the remote node.

**PASSTHRU**

indicates that this is an intermediate node for the conversation.

**nnn**

Bytes sent specifies the number of bytes transmitted from the target node to the source node by the local node.

Bytes received specifies the number of bytes transmitted from the source node to the target node by the local node.

**userid**

specifies the access user ID that establishes the conversation.

**resid**

specifies the resource this conversation is connected to.

Response 14:

```
Conversation: convid      Instance: x      Type:          APPC
Node:      nodeid      Bytes Sent:    nnn
PASSTHRU   Bytes Received: nnn
Access Userid: userid  Target Userid: targetid
```

**convid**

specifies the conversation ID assigned by the local VM node.

**x**

specifies the conversation instance number.

**APPC**

specifies that the conversation is APPC.

**nodeid**

specifies the node ID of the remote node.

**PASSTHRU**

indicates that this is an intermediate node for the conversation.

**nnn**

Bytes sent specifies the number of bytes transmitted from the target node to the source node by the local node.

Bytes received specifies the number of bytes transmitted from the source node to the target node by the local node.

**userid**

specifies the access user ID that establishes the conversation.

**targetid**

specifies the target user ID this conversation is connected to.

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid
- HCP2728E Conversation *convid* does not exist.

## QUERY CPCHECKING

---

► Query — CPCHECKing ◄

### Authorization

Privilege Class: A, C, E

### Purpose

Use QUERY CPCHECKING to display the status of internal CP checking.

### Responses

```
CPCHECKING=ON {ABEND|VMSTOP }  
OFF
```

#### ABEND

indicates that CP internal checking is activated and an abend should occur if CP internal checking finds an error. When it finds an error it produces an ASR001 abend.

#### VMSTOP

indicates that CP internal checking is activated and if any of the conditions specified by CP checking are untrue, CP issues a Diagnose X'08' instruction with a command string length of zero, causing the virtual machine to stop and CP to post a read to the console.

#### OFF

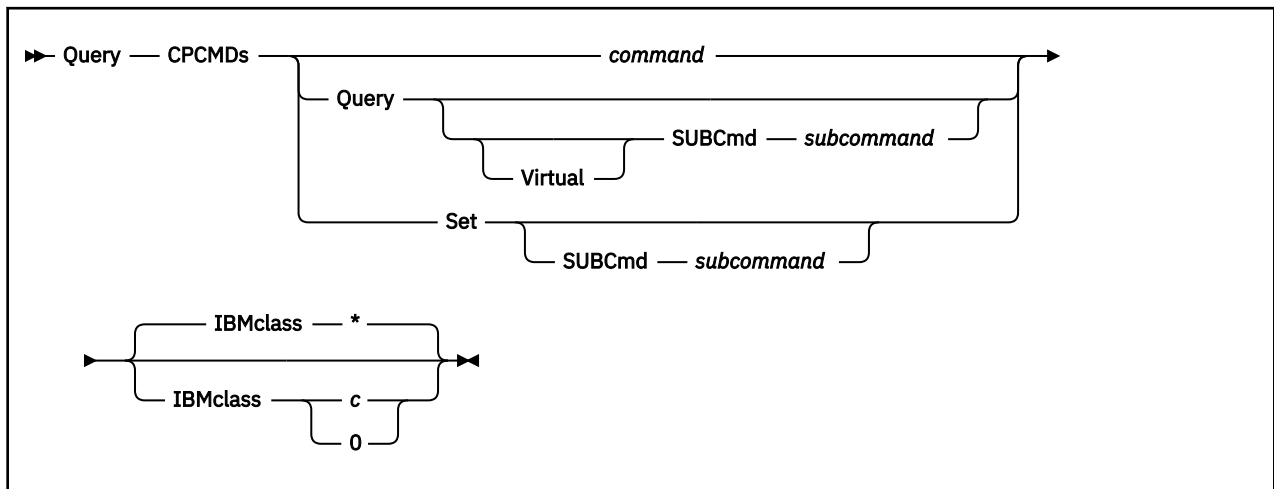

indicates that CP internal checking is deactivated.

### Messages

- HCP1007E The VMSTOP option is only permitted when CP itself is running in a virtual machine.
- HCP6010I The CPCHECKING setting has been changed to OFF to avoid a possible abend loop. It may be set ON again if desired.

## QUERY CPCMDS

### Authorization

Privilege Class: A, C, E

### Purpose

Use QUERY CPCMDS to query the status and display information about a specified CP command. This information includes:

- Enabled/disabled status
- Name of the entry point to handle the command
- IBM Class
- Current User Privilege class of the command
- Address of the CP command table entry block

### Operands

#### **command**

tells CP to query the specified CP command. The variable *command* is any valid CP command, any valid abbreviation of that command, or any character string (including the pattern matching characters, \* and %) representing that command. For more information about minimum abbreviations, see Usage Note [“2”](#) on page 818.

#### **Query**

tells CP to display information about the root CP QUERY command. To query a specific QUERY subcommand, specify the SUBCMD operand.

#### **Virtual**

tells CP that you are querying a QUERY VIRTUAL subcommand.

#### **SUBCmd subcommand**

specifies the name of the QUERY or SET subcommand whose information you want to display. The variable *subcommand* is any valid QUERY or SET subcommand, any valid abbreviation of that subcommand, or any character string (including the pattern matching characters, \* and %) representing that subcommand. For more information about minimum abbreviations, see Usage Note [“2”](#) on page 818.

**Set**

tells CP to display information about the root CP SET command. To query a specific SET subcommand, specify the SUBCMD operand.

**IBMclass \***

specifies that you want to display information for all the IBM classes associated with the specified CP command. If omitted, IBMCLASS \* is the default.

**IBMclass c**

specifies that you only want to display information for the specific IBM class associated with the specified CP command. The variable c is the IBM-defined privilege class A, B, C, D, E, F, or G.

**IBMclass 0**

specifies that you only want to display information for CP commands with no assigned IBM class. Only commands originally defined with privilege class "ANY" have no assigned IBM class.

**Usage Notes**

1. For each command, CP has at least one command table entry block. If the command has more than one IBM class, CP has one command table entry block for each version of the command. For example, the DEFINE command has four IBM classes: A, B, E, and G. To display information for the DEFINE GRAF command, you want the command table entry block for the class G DEFINE command:

```
query cpcmds define ibmclass g
```

The only exceptions to this are the QUERY and SET commands. CP has at least one command table entry block for each QUERY and SET subcommand. To display information for the QUERY TIMEZONES subcommand, you would issue one of the following commands:

```
query cpcmds query subcmd timezones
query cpcmds query subcmd timezones ibmclass g
```

2. You can use the minimum abbreviation of the command or subcommand name. For example, issuing either of the following commands produces the same results:

```
query cpcmds query subcmd privclass
query cpcmds q subcmd priv
```

3. To define a new CP command or a new version (by IBM class) of an existing CP command, use the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD”](#) on page 143).
4. To define a new alias for an existing CP command, use the DEFINE ALIAS command (see [“DEFINE ALIAS”](#) on page 127).
5. To load the command processing code into the system execution space, use the CPXLOAD command (see [“CPXLOAD”](#) on page 111).
6. To activate a CP command:
  - While defining it, use the ENABLE operand of the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD”](#) on page 143).
  - After defining it, use the ENABLE COMMAND or CMD command (see [“ENABLE COMMAND / CMD”](#) on page 460).
7. To change the definition of an existing CP command, use the MODIFY COMMAND command (see [“MODIFY COMMAND / CMD”](#) on page 683).
8. To deactivate a CP command:
  - While defining it, use the DISABLE operand of the DEFINE COMMAND or CMD command (see [“DEFINE COMMAND / CMD”](#) on page 143).
  - After defining it, use the DISABLE COMMAND or CMD command (see [“DISABLE COMMAND / CMD”](#) on page 313).
9. To remove the command processing code from the system execution space, use the CPXUNLOAD command (see [“CPXUNLOAD”](#) on page 117).

10. For more information about user-defined commands, see the [Introduction](#) in *z/VM: CP Exit Customization*.

## Responses

Response 1:

To query the CP MESSAGE command, enter the following:

```
query cpcmds message
Command: MESSAGE
  Status:      Enabled      Not Silent
  IBM Class:   A            PrivClasses: A
  CMDBK Address: 001CCF98   Entry Point: HCPXMGMS
Command: MESSAGE
  Status:      Enabled      Not Silent
  IBM Class:   B            PrivClasses: B
  CMDBK Address: 001CD008   Entry Point: HCPXMGMS
Command: MESSAGE
  Status:      Enabled      Not Silent
  IBM Class:   0            PrivClasses: <ANY>
  CMDBK Address: 001CD078   Entry Point: HCPXMGMS
Ready;
```

In this example,

### Command

shows the name of the command. When querying a QUERY or SET subcommand, the response will include the full subcommand name. See Response 5 for an example.

### Status

tells you whether the command is enabled or disabled and if the SILENTLY option is in effect.

### IBM Class

shows the IBM class of the command. The possible values are:

- A** this is a system-control command to be used by the primary system operator.
- B** this is a command for operational control of real devices.
- C** this is a command to alter system storage.
- D** this is a command for system-wide control of spool files.
- E** this is a command to examine system storage.
- F** this is a command for service control of real devices.
- G** this is a general-use command used to control the functions of a virtual machine.
- 0** (zero) this command has no specific IBM class assigned.

### PrivClasses

shows the privilege class (or classes) of the command. This usually contains 1 or more privilege classes in the range A to Z and 1 to 6. It may also contain "ANY" which indicates that this command can be issued by users with any privilege class.

### CMDBK Address

shows the host logical storage address of the command table entry block for the command.

### Entry Point

shows the name of the entry point which will handle this command.

Response 2:

The CP MSG command is actually an alias for the CP MESSAGE command. CP displays different information for an alias than it does for a command. For example, to display information for the CP MSG command alias, enter the following:

```
query cpcmds msg
Alias: MSG
  Alias Status: Enabled      Not Silent
  Alias CMDBK Address: 001CD388
  Command: MESSAGE
  IBM Class:      A          PrivClasses: A
  CMDBK Address: 001CCF98    Entry Point: HCPXMGMS
Alias: MSG
  Alias Status: Enabled      Not Silent
  Alias CMDBK Address: 001CD3F8
  Command: MESSAGE
  IBM Class:      B          PrivClasses: B
  CMDBK Address: 001CD008    Entry Point: HCPXMGMS
Alias: MSG
  Alias Status: Enabled      Not Silent
  Alias CMDBK Address: 001CD468
  Command: MESSAGE
  IBM Class:      0          PrivClasses: <ANY>
  CMDBK Address: 001CD078    Entry Point: HCPXMGMS
Ready;
```

In this example,

### **Alias**

shows the name of the command and indicates that command is an alias of another. When querying a QUERY or SET subcommand, the response will include the full subcommand name.

### **Alias Status**

tells you whether the alias is enabled or disabled and if the SILENTLY option is in effect.

### **Alias CMDBK Address**

shows the host logical storage address of the command table entry block for the alias.

### **Command**

shows the name of the command that has been aliased. When querying a QUERY or SET subcommand, the response will include the full subcommand name.

### **IBM Class**

shows the IBM class of the command. The possible values are:

#### **A**

this is a system-control command to be used by the primary system operator.

#### **B**

this is a command for operational control of real devices.

#### **C**

this is a command to alter system storage.

#### **D**

this is a command for system-wide control of spool files.

#### **E**

this is a command to examine system storage.

#### **F**

this is a command for service control of real devices.

#### **G**

this is a general-use command used to control the functions of a virtual machine.

#### **O**

(zero) this command has no specific IBM class assigned.

**PrivClasses**

shows the privilege class (or classes) of the command. This usually contains 1 or more privilege classes in the range A to Z and 1 to 6. It may also contain "ANY" which indicates that this command can be issued by users with any privilege class.

**CMDBK Address**

shows the host logical storage address of the command table entry block for the command that has been aliased.

**Entry Point**

shows the name of the entry point which will handle this command.

Response 3:

The CP MESSAGE and MSG commands also share the same minimum abbreviation, M. This means you can display information about both commands by specifying their common minimum abbreviation:

```

query cpcmds m
Command: MESSAGE
  Status:      Enabled      Not Silent
  IBM Class:   A            PrivClasses: A
  CMDBK Address: 001CCF98   Entry Point: HCPXMGMS
Command: MESSAGE
  Status:      Enabled      Not Silent
  IBM Class:   B            PrivClasses: B
  CMDBK Address: 001CD008   Entry Point: HCPXMGMS
Command: MESSAGE
  Status:      Enabled      Not Silent
  IBM Class:   0            PrivClasses: <ANY>
  CMDBK Address: 001CD078   Entry Point: HCPXMGMS
Alias: MSG
  Alias Status: Enabled     Not Silent
  Alias CMDBK Address: 001CD388
  Command: MESSAGE
  IBM Class:   A            PrivClasses: A
  CMDBK Address: 001CCF98   Entry Point: HCPXMGMS
Alias: MSG
  Alias Status: Enabled     Not Silent
  Alias CMDBK Address: 001CD3F8
  Command: MESSAGE
  IBM Class:   B            PrivClasses: B
  CMDBK Address: 001CD008   Entry Point: HCPXMGMS
Alias: MSG
  Alias Status: Enabled     Not Silent
  Alias CMDBK Address: 001CD468
  Command: MESSAGE
  IBM Class:   0            PrivClasses: <ANY>
  CMDBK Address: 001CD078   Entry Point: HCPXMGMS

```

Response 4:

To display information for all CP commands whose name begins with the letter M, enter the following:

```

query cpcmds m*
Command: MESSAGE
  Status:      Enabled      Not Silent
  IBM Class:   A            PrivClasses: A
  CMDBK Address: 001CCF98   Entry Point: HCPXMGMS
Command: MESSAGE
  Status:      Enabled      Not Silent
  IBM Class:   B            PrivClasses: B
  CMDBK Address: 001CD008   Entry Point: HCPXMGMS
Command: MESSAGE
  Status:      Enabled      Not Silent
  IBM Class:   0            PrivClasses: <ANY>
  CMDBK Address: 001CD078   Entry Point: HCPXMGMS
Command: MIGRATE
  Status:      Enabled      Not Silent
  IBM Class:   A            PrivClasses: A
  CMDBK Address: 001CD0E8   Entry Point: HCPNOSCM
Command: MODIFY
  Status:      Enabled      Not Silent
  IBM Class:   A            PrivClasses: A
  CMDBK Address: 001CD158   Entry Point: HCPRSCOV
Command: MODIFY
  Status:      Enabled      Not Silent
  IBM Class:   B            PrivClasses: B

```

## QUERY CPCMD5

```
CMDBK Address: 001CD1C8   Entry Point: HCPRSCOV
Command: MONITOR
Status:      Enabled      Not Silent
IBM Class:   A            PrivClasses: M
CMDBK Address: 001CD238   Entry Point: HCPMNCCM
Command: MONITOR
Status:      Enabled      Not Silent
IBM Class:   E            PrivClasses: S
CMDBK Address: 001CD2A8   Entry Point: HCPMNCCM
Command: MSGNOH
Status:      Enabled      Not Silent
IBM Class:   B            PrivClasses: KRZ
CMDBK Address: 001CD318   Entry Point: HCPXMGNH
Alias: MSG
Alias Status: Enabled      Not Silent
Alias CMDBK Address: 001CD388
Command: MESSAGE
IBM Class:   A            PrivClasses: A
CMDBK Address: 001CCF98   Entry Point: HCPXMGMS
Alias: MSG
Alias Status: Enabled      Not Silent
Alias CMDBK Address: 001CD3F8
Command: MESSAGE
IBM Class:   B            PrivClasses: B
CMDBK Address: 001CD008   Entry Point: HCPXMGMS
Alias: MSG
Alias Status: Enabled      Not Silent
Alias CMDBK Address: 001CD468
Command: MESSAGE
IBM Class:   0            PrivClasses: <ANY>
CMDBK Address: 001CD078   Entry Point: HCPXMGMS
Ready;
```

In this example, note that the classes for the MONITOR and MSGNOH commands were redefined by this installation through user MODIFY commands.

Response 5:

To display information for the SET PRIVCLASS subcommand, enter the following:

```
query cpcmds set subcmd privclass
Command: SET PRIVCLASS
Status:      Enabled      Not Silent
IBM Class:   C            PrivClasses: C
CMDBK Address: 002338A8   Entry Point: HCPPCLSE
Command: SET PRIVCLASS
Status:      Enabled      Not Silent
IBM Class:   0            PrivClasses: <ANY>
CMDBK Address: 00233918   Entry Point: HCPPCLSE
Ready;
```

Response 6:

If someone had used a MODIFY COMMAND command or configuration file statement to override an existing CP DISABLE command, you would see something like this:

```
query cpcmds disable
Command: DISABLE
Status:      Enabled      Not Silent
IBM Class:   A            PrivClasses: A
CMDBK Address: 001CBB08   Entry Point: HCPRSCDI
Command: DISABLE
Status:      Enabled      Not Silent
IBM Class:   B            PrivClasses: Z6
CMDBK Address: 001CBB78   Entry Point: HCPRSCDI
Command: -----
Status:      Enabled      Not Silent
IBM Class:   B            PrivClasses: B
CMDBK Address: 0162F348   Entry Point: HCPRSCDI
Command: DISABLE
Status:      Enabled      Not Silent
IBM Class:   F            PrivClasses: F
CMDBK Address: 001CBBE8   Entry Point: HCPRSCDI
Ready;
```

This response shows you there are command table entry blocks for four DISABLE commands: one for IBM class A, two for IBM class B, and one for IBM class F. The first IBM class B DISABLE command is the one that is active. The second IBM class B DISABLE command was the original IBM class B command.

To return to the original IBM class B DISABLE command, enter the following:

```
modify command disable ibmclass b reset
```

This causes the first IBM class B DISABLE command to disappear from the display and changes the ----- to DISABLE. Thus, the response would look like this:

```
query cpcmds disable
Command: DISABLE
  Status:      Enabled      Not Silent
  IBM Class:   A            PrivClasses: A
  CMDBK Address: 001CBB08   Entry Point: HCPRSCDI
Command: DISABLE
  Status:      Enabled      Not Silent
  IBM Class:   B            PrivClasses: Z6
  CMDBK Address: 001CBB78   Entry Point: HCPRSCDI
Command: DISABLE
  Status:      Enabled      Not Silent
  IBM Class:   F            PrivClasses: F
  CMDBK Address: 001CBBE8   Entry Point: HCPRSCDI
Ready;
```

## QUERY CPDISKS

### Authorization

Privilege Class: A

### Purpose

Use QUERY CPDISKS to display the status of a CP-accessed minidisk or all CP-accessed minidisks.

### Operands

**\***

**fm**

is the file mode letter of the CP-accessed minidisk. If omitted or specified as an asterisk (\*), the default, CP displays the status of all the disks that it has accessed.

### Usage Notes

1. To have CP access a minidisk, you can use the CPACCESS command, or you can specify a CP\_ACCESS statement in the system configuration file.

For more information on the CPACCESS command, see [“CPACCESS” on page 89](#). For more information on the system configuration file, see [CP\\_ACCESS Statement in z/VM: CP Planning and Administration](#).

### Responses

Response 1:

If you enter QUERY CPDISKS with no additional parameters, you see something like this:

Label	Userid	Vdev	Mode	Stat	Vol-ID	Rdev	Type	StartLoc	EndLoc
CF1	MAINT	0CF1	A	R/O	ESARES	0A0F	CKD	2400	2449
CFG1	MAINT	0300	B	R/O	ESARES	0A0F	CKD	95	99
CFBA1	MAINT	0580	F	R/O	ESAFBA	0B40	FBA	45490	45839

Ready;

In this example,

#### Label

is the minidisk label that was assigned to the disk when it was formatted.

#### Userid

is the user ID of the minidisk owner.

#### Vdev

is the virtual device number of the minidisk, as specified in the owner's directory entry in the system directory.

#### Mode

is the file mode that CP used to access the minidisk.

#### Stat

shows whether the minidisk is in read-only (R/O) or read-write (R/W) mode.

**Vol-ID**

is the real volume serial of the DASD volume that contains the minidisk.

**Rdev**

is the real device number of the DASD volume that contains the minidisk.

**Type**

is the device type: CKD or FBA.

**StartLoc**

is the starting cylinder or block of the minidisk.

**EndLoc**

is the ending cylinder or block of the minidisk.

**Messages**

- HCP003E Invalid option - command contains extra option(s) starting with *operand*
- HCP6706E Invalid disk mode - *filemode*
- HCP6727I Disk *filemode* not accessed
- HCP6727I No disks accessed

## QUERY CPLANGLIST

### Authorization

Privilege Class: G

### Purpose

Use QUERY CPLANGLIST to display all the valid:

- Languages in which CP can display control program messages to your virtual machine, or
- Message repository languages available on the system, their component names, and their external symbols, if any.

### Operands

#### ASSOCIATED

tells CP to display all the valid message repository languages available on the system, their component names, and their external symbols, if any.

If omitted, CP displays all the valid languages in which CP can display control program messages to your virtual machine.

### Usage Notes

1. When you specify the ASSOCIATED operand, CP displays message repository information: language identifiers, component identifiers, and external symbol names. This information was associated with the message repositories using the ASSOCIATE MESSAGES or MSGS command (see [“ASSOCIATE MESSAGES / MSGS”](#) on page 24).
2. For more information about user-defined message repositories, see [Understanding the CP Message Repository](#) in *z/VM: CP Exit Customization*.
3. The system default language is the language that is specified in the system configuration file, or the language that was specified by the operator using the SYSTEM operand of the SET CPLANGUAGE command. If neither of these was specified, then the language is the one built into the CP nucleus.
4. If you change the system default language, the response to QUERY CPLANGLIST shows the new system default language. If the user is using the system default language, the user's current language will not change until the user either logs off and logs back on, or issues the CP SET CPLANGUAGE command or CMS SET LANGUAGE command to switch to the new system default language.

### Responses

Response 1:

```

System default language:      xxxxx
User's current language:     xxxxx
Other available languages:   xxxxx
:
```

#### System default language

is the default language for CP.

**User's current language**

is the language that is currently active for CP in your virtual machine.

**Other available languages**

are other available CP languages (or NONE).

**xxxxx**

is the abbreviation, up to five characters, for a language that is valid in your virtual machine.

Response 2:

To display the message repository languages, their component IDs, and their external symbol names, enter the following:

```
query cplanglist associated
Language: AMENG Component: AC$ EPName: AC$CSCT1
Language: UCENG Component: AC$ EPName: AC$CSCT2
Ready;
```

This response tells you that you have 2 local message repositories that someone on your system added with CPXLOAD and ASSOCIATE MESSAGES or MSGS commands. The first one is in American English (AMENG) and the second is in uppercase English (UCENG).

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*

## QUERY CPLANGUAGE

---

► Query — CPLANGUage ◄

### Authorization

Privilege Class: G

### Purpose

Use QUERY CPLANGUAGE to identify the language being used to display control program messages to your virtual machine.

### Responses

#### Response 1:

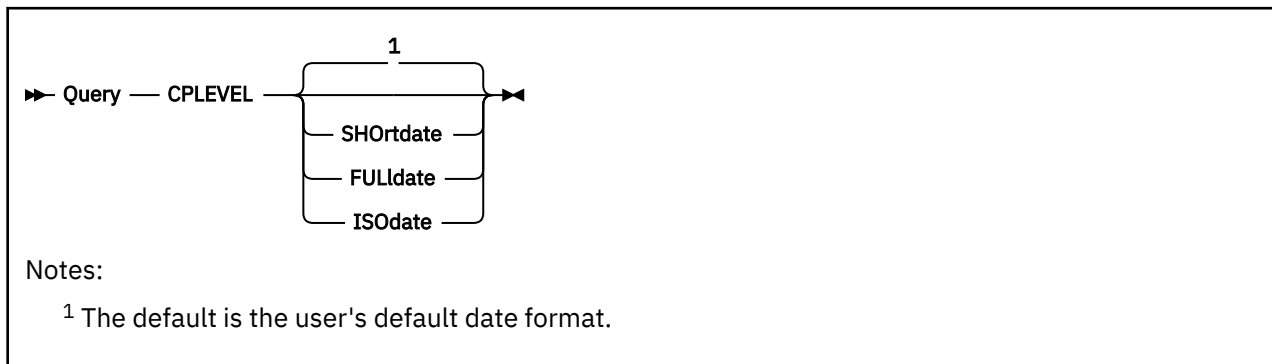

*language*

identifies the CP language currently being used by the virtual machine.

### Messages

- HCP002E Invalid operand - *operand*

## QUERY CPLEVEL

### Authorization

Privilege Class: G

### Purpose

Use QUERY CPLEVEL to determine the following control program attributes:

- The software version level, release level, and release modification level
- The software service level number
- The date and time (translated to the current active time zone) that the CP system software was written to DASD.
- The date and time the CP was last started

### Operands

#### SHOrtdate

specifies that dates in the response to this command will be displayed in *mm/dd/yy* format, where *mm* is the month, *dd* is the day of the month, and *yy* is the 2-digit year.

#### FULldate

specifies that dates in the response to this command will be displayed in *mm/dd/yyyy* format, where *mm* is the month, *dd* is the day of the month, and *yyyy* is the 4-digit year.

#### ISOdate

specifies that dates in the response to this command will be displayed in *yyyy-mm-dd* format, where *yyyy* is the 4-digit year, *mm* is the month, and *dd* is the day of the month.

### Usage Notes

1. The default date format for certain CP and CMS commands can be set on a system-wide basis and also for the individual user. The system-wide default date format is set with the SYSTEM\_DATEFORMAT system configuration statement. The user's default date format is set with the DATEFORMAT directory statement. The system-wide default and the user's default can also be set with the CP SET DATEFORMAT command. The user's default date format defaults to the system-wide default. The system-wide and user settings can be queried with the CP QUERY DATEFORMAT command. The hierarchy of possible date format settings for the QUERY CPLEVEL command, from highest priority to lowest, is:
  - QUERY CPLEVEL command operand
  - User default
  - System-wide default

- The output of the QUERY CPLEVEL command always reflects the level of CP code on which this virtual machine is running. This is true even when the virtual machine's virtual architecture limits its use of CP-provided features to a lower level of CP functionality. This occurs when the virtual machine is assigned to a relocation domain that includes one or more members running at a lower level of CP than the one on which this virtual machine is running. Therefore the output of this command should not be used to determine the level of CP-provided functionality available to the virtual machine. Diagnose X'00' is the proper interface to determine the virtual machine's virtual CP level. For an explanation of relocation domains, see [Using Relocation Domains in z/VM: CP Planning and Administration](#) for more details. See the documentation for [“QUERY VMRELOCATE” on page 1348](#) and [“SET VMRELOCATE” on page 1755](#), and the [VMRELOCATE Directory Statement](#) for details about how a virtual machine is assigned to a relocation domain.

## Responses

Response 1:

If you enter QUERY CPLEVEL SHORTDATE, you get the following response:

```
z/VM VERSION v RELEASE r.m, SERVICE LEVEL yyyn (64-BIT)
GENERATED AT mm/dd/yy hh:mm:ss timezone
IPL AT mm/dd/yy hh:mm:ss timezone
```

Response 2:

If you enter QUERY CPLEVEL FULLDATE, you get the following response:

```
z/VM VERSION v RELEASE r.m, SERVICE LEVEL yyyn (64-BIT)
GENERATED AT mm/dd/yyyy hh:mm:ss timezone
IPL AT mm/dd/yyyy hh:mm:ss timezone
```

Response 3:

If you enter QUERY CPLEVEL ISODATE, you get the following response:

```
z/VM VERSION v RELEASE r.m, SERVICE LEVEL yyyn (64-BIT)
GENERATED AT yyyy-mm-dd hh:mm:ss timezone
IPL AT yyyy-mm-dd hh:mm:ss timezone
```

**v**  
identifies the software version level.

**r.m**  
identifies the software release level and the release modification level.

### **SERVICE LEVEL yyyn**

identifies the software service level number. The number indicates the most recent RSU service tape that has been applied. *yy* is the last 2 digits of the year and *nn* is the sequential number of the RSU tape for that year. It cannot indicate which individual updates have been incorporated into CP. The system programmer can find out what individual updates have been incorporated by using the VMSES/E tool. For more information, see [Using VMSES/E for Service](#) in *z/VM: VMSES/E Introduction and Reference*.

### **GENERATED AT mm/dd/yy hh:mm:ss timezone**

### **GENERATED AT mm/dd/yyyy hh:mm:ss timezone**

### **GENERATED AT yyyy-mm-dd hh:mm:ss timezone**

indicates the date and time (translated to the current active time zone) that the CP system software was written to DASD. One of the above responses is generated depending on the date format specified on the user's default date format.

### **IPL mm/dd/yy hh:mm:ss timezone**

### **IPL mm/dd/yyyy hh:mm:ss timezone**

### **IPL yyyy-mm-dd hh:mm:ss timezone**

indicates the date and time the CP system software was last started. One of the above responses is generated depending on the date format specified on the user's default date format.

**Messages**

- HCP003E Invalid option - command contains extra option(s) starting with *operand*

## QUERY CPLOAD

► Query — CPLOAD ◄

### Authorization

Privilege Class: A, B, E

### Purpose

Use QUERY CPLOAD to display information regarding the last CP IPL. The information displayed includes the location of the CP module that was last used, the location of the parm disk, and how CP was started.

You can load CP only from a module on a CMS-formatted minidisk. When you load CP, you must specify device, system, and logo definition information. You specify this information in files on a parm disk. CP can 'sense' most device definition information, so you do not have to define it. System definition information goes in the system configuration file, and logo definition information goes in the logo configuration file.

### Responses

**Note:** When you use FBA devices, the responses are shown in blocks.

Response 1:

For CKD/ECKD devices:

```
Module CPLOAD2 was loaded from minidisk on volume ESARES at cylinder 2400
Parm disk on volume ESARES, cylinders 2400 through 2420
Last start was system IPL.
```

For FBA devices:

```
Module CPLOAD2 was loaded from minidisk on volume FBARES at block 24000
Parm disk on volume FBARES, blocks 24000 through 43992
Last start was a system IPL.
```

The first line of the response tells you CP was loaded from a module, the name of the module, and the location of the minidisk from which CP loaded the module. The second line of the response tells you CP used a parm disk during the IPL and the location of the parm disk.

CP assumes the parm disk is the same minidisk that contains the module, unless you override that assumption. In the example above, the second line of the response indicates that the person who performed the IPL either:

- Did not override the system's assumption. The Stand Alone Loader used a cylinder or block offset to find the location of the parm disk. The allocation map did not have a parm disk defined at that location.
- Used the PDOFF IPL parameter during the IPL to specify a cylinder or block offset of the location of the parm disk. The value specified for the PDOFF IPL parameter coincides with the location of the minidisk from which CP loaded the module. The allocation map did not have a parm disk defined at that location.

For more information on the PDOFF parameter or any of the other IPL parameters, see [Using the Stand-Alone Program Loader in z/VM: System Operation](#).

To display the current IPL parameters, use the CP QUERY IPLPARMS command. Be aware that the CP SET IPLPARMS command may have changed them since CP was started. For more information on these commands, see [“QUERY IPLPARMS” on page 954](#) and [“SET IPLPARMS” on page 1530](#).

The third line of the response tells you that CP was started by the system operator at the system console. One of the following variations will appear as the third line of the response.

- The response below tells you that CP was started by the system operator at the system console.

```
Last start was a system IPL.
```

The response below tells you that the operator restarted CP using the CP SHUTDOWN command with the REIPL operand.

```
Last start was a system restart from SHUTDOWN REIPL.
```

- The response below tells you that CP restarted itself after abend XXXnnn occurred. Use CP QUERY CPLEVEL to find out when the restart occurred.

```
Last start was a system restart after system failure XXXnnn
```

#### Response 2:

```
Module CPLOAD was loaded from minidisk on volume ESARES at cylinder 20
Parm disk number 2 on volume ESARES, cylinders 90 through 94
Last start was a system IPL
```

In this example, the second line of the response indicates that the person who performed the IPL either:

- Did not override the system's assumption and the allocation map had a parm disk defined for the minidisk containing the CP module.
- Or, used the PDNUM parameter during the IPL to specify a specific parm disk number, as defined in the allocation map
- Or, used the PDOFF parameter during the IPL to specify a cylinder or block offset and the allocation map had a parm disk defined in that location

For more information on the PDNUM or PDOFF parameter or any of the other IPL parameters, see [Using the Stand-Alone Program Loader](#) in *z/VM: System Operation*.

#### Response 3:

```
Module NEWCP loaded from minidisk on volume ESARES at cylinder 2400
Parm disk number 3 on volume OLDRES, cylinders 586 through 590
Last start was a system IPL.
```

In this example, the volume IDs on the first and second lines are different. The person who performed the IPL loaded CP from a module on one volume and used a parm disk on another volume.

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *operand*

## QUERY CPOWNED

### Authorization

Privilege Class: G

### Purpose

Use QUERY CPOWNED to display the list of CP-owned DASD volumes.

### Operands

**DASd rdev**

**DASd rdev1-rdev2**

tells CP to display information on only the CP-owned volumes whose addresses are in the range specified.

**VOLid valid**

tells CP to display information on only the *valid* specified. You can specify the *valid* as a generic volume identifier. A generic volume identifier is a 1- to 6-character pattern that can use asterisks (\*) in place of zero or more characters and percents (%) in place of exactly one character. For example, VOLID \*EM% displays all CP-owned volumes ending with a 3-character sequence that begins with the letters 'EM'.

### Usage Notes

1. If you specify no parameters on the QUERY CPOWNED command, CP displays information on all CP-owned volumes, as well as gaps in the volume list.
2. You can use the DEFINE CPOWNED command (see “DEFINE CPOWNED” on page 150) to bring new CP-owned volumes on line into empty slots in the volume list. CP allocates empty slots for every slot number that was skipped in the system configuration file. You can define additional empty slots at the end of the list of CP-owned DASD by explicitly defining them in the system configuration file with CP\_OWNED statements.

### Responses

Response 1:

If you enter the QUERY CPOWNED command with no operands on system GDLSYSME in SSI cluster GDLSI, you might see a response similar to this:

Slot	Vol-ID	Rdev	Type	Status	SSIOwner	SysOwner
1	ESARES	0A0F	Own	Online and attached	GDLSI	GDLSYSME
2	ESAP01	0A01	Own	Online and attached	GDLSI	GDLSYSME
3	ESAP02	0A02	Share	Online and attached	GDLSI	GDLSYS1
4	ESAP03	0A03	Dump	Online and attached	GDLSI	GDLSYSME
5	-----	----	---	Reserved	-----	-----
6	ESAP05	0A05	Share	Online and attached	GDLSI	GDLSYS1
7	ESAP06	0A06	Share	Online and attached	GDLSI	GDLSYS1
8	ESAP07	0A07	Share	Online and not attached	GDLSI	GDLSYS1

9	ESAP08	0A08	Own	Online and attached	GDLSSI	GDLSYSME
10	ESAP09	----	Own	Offline	-----	-----
11	ESAP0A	0A0A	Own	Online and attached	GDLSSI	GDLSYSME
12	ESAP0B	0A0B	Share	Online and attached	GDLSSI	GDLSYS1
13	ESAP0C	0A0C	Share	Online and attached	GDLSSI	GDLSYS1
14	ESAP0D	0A0D	Share	Online and attached	GDLSSI	GDLSYS1

If you enter the QUERY CPOWNER command with no operands on system GDLSYSME in a non-SSI environment, using the same configuration as in the previous example, you might see a response similar to this:

Slot	Vol-ID	Rdev	Type	Status	SSIOwner	SysOwner
1	ESAP08	0A08	Own	Online and attached	-----	GDLSYSME
2	ESAP01	0A01	Own	Online and attached	-----	-----
3	ESAP02	0A02	Own	Online and attached	-----	-----
4	ESAP03	0A03	Dump	Online and attached	-----	GDLSYSME
5	-----	----	---	Reserved	-----	-----
6	ESAP05	0A05	Own	Online and attached	-----	-----
7	ESAP06	0A06	Own	Online and attached	-----	-----
8	ESAP07	0A07	Own	Online and not attached	-----	-----
9	ESAP08	0A08	Own	Online and attached	-----	GDLSYSME
10	ESAP09	----	Own	Offline	-----	-----
11	ESAP0A	0A0A	Own	Online and attached	-----	-----
12	ESAP0B	0A0B	Own	Online and attached	-----	-----
13	ESAP0C	0A0C	Own	Online and attached	-----	-----
14	ESAP0D	0A0D	Own	Online and attached	-----	-----

The SSI example shows that the volumes are marked with ownership information. The non-SSI example shows that volumes can be marked with ownership information, although this is not required.

In both examples, slot 5 is reserved, and you can use the DEFINE CPOWNER command to add a new volume to the list.

**Own**

indicates that the volume is owned by the local system, which is able to read and write SPOOL files.

**Share**

indicates that the volume is owned by another system in the SSI cluster. The local system can only read SPOOL files that were previously written by the owning system. Note that SHARED can be displayed on a non-SSI system if the volume attached is **not** owned by this system.

**Dump**

indicates that the spool space on the volume is reserved exclusively for dumps.

**Reserved**

indicates that a volume is not associated with the slot, and the slot is available for allocation.

**Offline**

indicates that a volume with this label does not exist, or one does exist but is not attached to the system.

**Online and attached**

indicates that the volume exists, is online, and is attached to the system. This is the normal state of CP-owned volumes.

**Online and not attached**

indicates that the volume exists, is online, but is not yet attached to the system. This is a transient case and not likely to be displayed.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *operand*
- HCP6704E Missing token at end of line
- HCP6706E Invalid {address range|volume label} - {*range|valid*}
- HCP6726E Could not find any CP-owned volumes that met the specified criteria.

## QUERY CPPROTECT

### Authorization

Privilege Class: C

### Purpose

Use QUERY CPPROTECT to display protection settings of the system, of users with protection overrides, or of a specific user, as well as availability of the required machine support for each protection mode.

In addition, if the machine support was not present when z/VM was IPLed and the required service is dynamically applied later, QUERY CPPROTECT can be issued to cause CP to recognize the machine support and put previously requested CPPROTECT settings into effect.

### Operands

#### Users

includes a display of the MODE2 settings for all users for whom a MODE2 override has been requested.

#### AGainst *userid*

displays only the MODE2 settings for a specific user.

#### AGainst \*

displays only the MODE2 settings for the command issuer.

### Usage Notes

1. MODE1 refers to a system-wide mitigation mechanism. MODE2 refers to a mitigation mechanism that the z/VM Control Program (CP) can apply when it interacts with some users but not with others. Details on the protection modes are not provided in this publication. Authorized personnel of IBM clients can consult the IBM Z Security Portal for further information and guidance. To request access to the portal, see the instructions referenced in the SET CPPROTECT command description.
2. To remove a user override, issue: `set cprotect mode2 against userid default.`
3. To remove all user overrides, issue: `set cprotect mode2 against all default.`
4. Users who do not appear in the QUERY CPPROTECT USERS output are operating with the default MODE2 setting.

### Examples

Response 1:

The response to QUERY CPPROTECT consists of the following three lines.

Line 1:

```
MODE1 {AVAILABLE } REQUESTED {ON } CURRENTLY {ON }
      {UNAVAILABLE } {OFF } {OFF }
```

This line indicates whether the machine support required for MODE1 function is present in the machine on which z/VM is running. The REQUESTED clause shows what setting was requested. The CURRENTLY clause shows how the system is currently running. These will differ only if the machine support is absent.

Line 2:

```
MODE2 {AVAILABLE } REQUESTED {ON } CURRENTLY {ON }
      {UNAVAILABLE }          {OFF }          {OFF }
      {INHERENT }             {SELECTIVE } {SELECTIVE }
```

This line indicates whether the machine support required for MODE2 function is present in the machine on which z/VM is running, and if present, whether it is available for optional activation or provided inherently in the machine design. The REQUESTED and CURRENTLY clauses summarize the settings that were requested and those currently in effect. These will differ if ON was requested but the machine support is absent, or if OFF was requested but the machine design inherently delivers the protection. ON and OFF indicate a setting that was requested or is currently active as the system default, with no user overrides in place. SELECTIVE indicates that there are one or more user overrides requested and currently in effect, respectively. Details on the overrides can be displayed using QUERY CPPROTECT USERS.

Line 3:

```
MODE2  DEFAULT          REQUESTED {ON } CURRENTLY {ON }
                          {OFF }          {OFF }
```

This line indicates the system-wide default setting for MODE2 as set by the most recent SET CPPROTECT MODE2 DEFAULT command. If no such command has been issued, the DEFAULT OFF setting established at z/VM IPL is shown. The default setting applies to all users except those for whom an override has been set via SET CPPROTECT MODE2 AGAINST *userid*.

Response 2:

The response to QUERY CPPROTECT USERS consists of Response 1 above, followed by zero or more instances of line 4, as shown below.

Lines 4 to n:

```
MODE2  AGAINST userid  REQUESTED {ON } CURRENTLY {ON }
                          {OFF }          {OFF }
```

Line 4 in this response shows the override setting for a user, as set by SET CPPROTECT MODE2 AGAINST *userid* {ON|OFF}. The override value applies to that user regardless of the system default or any changes to the system default. As above, the REQUESTED and CURRENTLY clauses indicate the saved request and the actual setting, according to the presence of the machine support for MODE2.

Response 3:

The response for QUERY CPPROTECT AGAINST *userid* consists of one line indicating the requested user's MODE2 setting, as shown below.

```
MODE2  AGAINST userid  REQUESTED {ON } CURRENTLY {ON }
                          {OFF }          {OFF }
                          {DEFAULT }
```

This response is displayed for the specified user, regardless of whether an override has been established for the user. The REQUESTED clause indicates whether the user is configured to operate according to an ON or OFF per-user override or according to the system-wide default setting. The CURRENTLY clause indicates how protection is being applied to the user, based on the REQUESTED response, the system-wide default, and the presence of the required machine support.

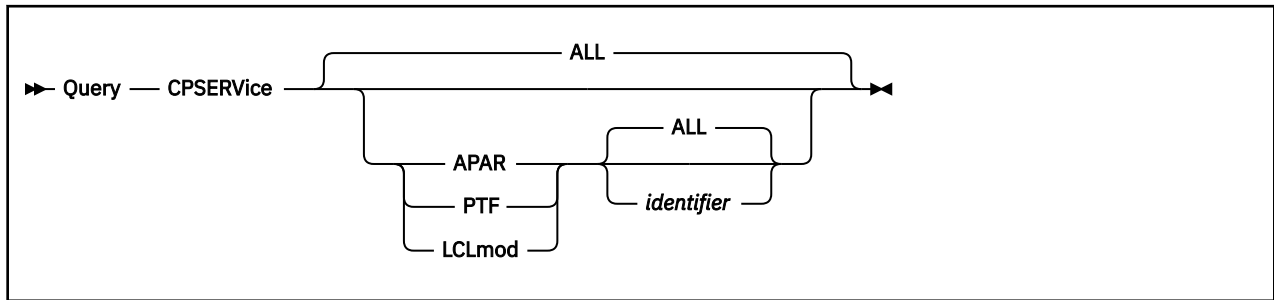

## Messages

- HCP002E Invalid operand - *operand*

## QUERY CPSERVICE

### Authorization

Privilege Class: C, E

### Purpose

Use QUERY CPSERVICE to display information about the APARs, PTFs and local modifications applied to the currently running CP module.

### Operands

#### ALL

displays all APARs, their corresponding PTFs, and all local modifications applied to the system.

#### APAR *identifier*

displays the specified APAR and its corresponding PTF, if it is applied to the system. A message is displayed if the specified APAR is not applied to the system. If no APAR number is specified, or if the ALL keyword is used instead of an APAR number, all APARs applied to the system and their corresponding PTFs are displayed. An asterisk (\*) can be used as a wildcard character to represent one or more characters at the end of an identifier string. The identifier should be 1-8 characters long.

#### LCLmod *identifier*

displays the specified local modification, if it is applied to the system. A message is displayed if the specified local modification is not applied to the system. If no local modification name is specified, or if the ALL keyword is used instead of a local modification name, all local modifications applied to the system are displayed. An asterisk (\*) can be used as a wildcard character to represent one or more characters at the end of an identifier string. The identifier should be 1-8 characters long.

#### PTF *identifier*

displays the specified PTF and its corresponding APAR, if it is applied to the system. A message is displayed if the specified PTF is not applied to the system. If no PTF number is specified, or if the ALL keyword is used instead of an PTF number, all PTFs applied to the system and their corresponding APARs are displayed. An asterisk (\*) can be used as a wildcard character to represent one or more characters at the end of an identifier string. The identifier should be 1-8 characters long.

### Responses

Response 1:

This response is displayed if an APAR or PTF is available on the system, where *aparnum* and *ptfnum* are 1- to 8-character strings that represent APAR and PTF numbers, respectively.

APAR	PTF
<i>aparnum</i>	<i>ptfnum</i>

## QUERY CPSERVICE

For example, QUERY CPSERVICE APAR ALL displays results similar to the following:

```
APAR      PTF
VMRSU02   UMRSU02
VMRSU04   UMRSU04
VM65348   UM34005
VM65352   UM34010
```

QUERY CPSERVICE PTF UM3404\* displays results similar to the following:

```
APAR      PTF
VM65371   UM34046
VM65373   UM34042
VM65375   UM34044
```

Response 2:

This response is displayed if a local modification is available on the system, where *localmod* is a one- to eight-character string that represent a local modification identifier.

```
Local modification
Localmod
```

For example, QUERY CPSERVICE LCLMOD ALL displays results similar to the following:

```
Local modification
PVGDPBYE
PVGD2BXC
SQ475BY0
```

QUERY CPSERVICE LCLMOD MY\* displays results similar to the following:

```
Local modification
MYLCLMOD
MYOTRMOD
```

Note that the service type is sorted in alphanumeric order. If QUERY CPSERVICE ALL is specified, then the APARs will appear first, followed by local modifications, with a single blank line between sections:

```
APAR      PTF
VMRSU02   UMRSU02
VMRSU04   UMRSU04
VM65348   UM34005
VM65352   UM34010

Local modification
PVGDPBYE
PVGD2BXC
SQ475BY
```

Response 3:

This response is displayed when the currently running CP module does not contain any information about CP service that is applied to the system.

```
No APAR/PTF data found.
```

This response is displayed for either of the following reasons:

- No CP APARs are applied to the system
- The SERVICE command was not able to include CP service information in the CP module when it was built. If you believe that this is the case, you should review the service message log (\$VMFSRV \$MSGLOG) for any warnings or errors related to including service information in the CP module.

Response 4:

This response is displayed when the currently running CP module does not contain any information about local modifications that are applied to the system:

```
No local modification data found.
```

This response is displayed for either of the following reasons:

- No local modifications are applied to the system
- The SERVICE command was not able to include local modification information in the CP module when it was built. If you believe that this is the case, you should review the service message log (\$VMFSRV \$MSGLOG) for any warnings or errors related to including service information in the CP module.

Response 5:

This response is displayed when no information about CP service or CP local modifications is available in the currently running CP module:

```
No service content data is available.
```

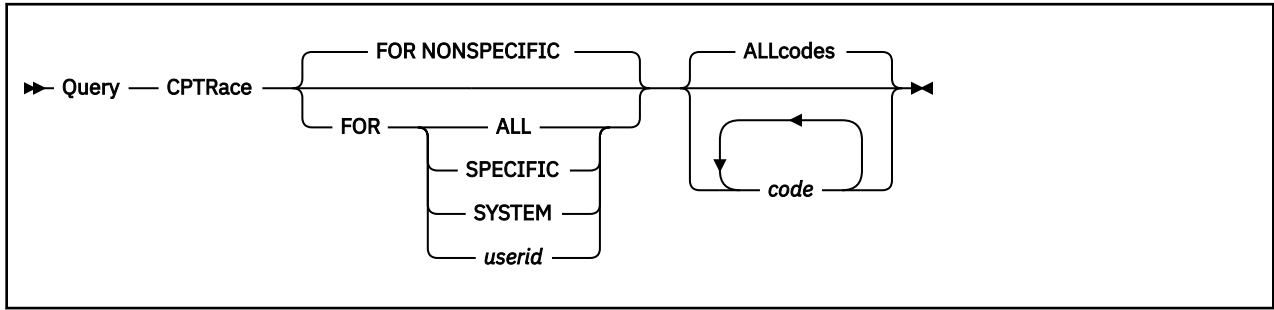

This response is displayed for either of the following reasons:

- No CP service or local modifications are applied to the system
- The SERVICE command was not able to include CP service and/or local modification information in the CP module when it was built. If you believe that this is the case, you should review the service message log (\$VMFSRV \$MSGLOG) for any warnings or errors related to including service information in the CP module.

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *operand*
- HCP2119E The CP service data included in the CP nucleus is incompatible with the QUERY CPSERVICE command.
- HCP6720I No items found to satisfy selection criteria.

## QUERY CPTRACE

### Authorization

Privilege Class: A, C, E

### Purpose

Use QUERY CPTRACE to display status of the trace function for real machine events.

**Note:** This status is specified by SET CPTRACE.

### Operands

#### **NONSPECIFIC**

#### **SPECIFIC**

#### **SYSTEM**

#### **ALL**

#### *userid*

NONSPECIFIC indicates that the specified tracing applies to all virtual machines not specifically set or named by a previous SET CPTRACE command. NONSPECIFIC is the default. All virtual machines begin in the NONSPECIFIC group. All members of the NONSPECIFIC group have the same codes traced.

SPECIFIC indicates that the specified tracing applies only to those virtual machines specifically set or named by a previous SET CPTRACE command. Members of the SPECIFIC group may each have a unique set of codes traced.

SYSTEM indicates that the specified tracing applies to system work. SYSTEM becomes a member of the SPECIFIC group even though the specified tracing may not match the virtual machines already in the group. Therefore, SYSTEM is similar to *userid* in that it names the work for which tracing applies, and SYSTEM can also be a part of either the SPECIFIC or NONSPECIFIC groups.

ALL indicates that the specified tracing applies to both the SPECIFIC and NONSPECIFIC groups of virtual machines and SYSTEM.

The operand *userid* indicates that the specified tracing applies only to this specific virtual machine; *userid* becomes a member of the SPECIFIC group, even though the specified tracing may not match others in the group.

#### **ALLcodes**

displays the setting of all CPTRACE categories.

#### **code**

identifies a single four-digit trace code or the name of a category of codes. Only the setting of this code or category of codes is displayed.

## Usage Notes

1. The SET CPTRACE command determines which events are recorded. QUERY CPTRACE lets you know what tracing events have been set on or off.

To check for *only* NONSPECIFIC categories, enter `query cptrace`.

To check for *only* SPECIFIC categories, enter `query cptrace for specific`.

2. You can use the QUERY CPTRACE response to recreate the CPTRACE setting at some later point. For each response line, in the order displayed, the indicated code or category is set to ON if ENABLED or ENABLED EXCEPT, and is set to OFF if DISABLED or DISABLED EXCEPT. In some cases (see Example 4) the CPTRACE setting can be recreated by entering the following:

```
set cptrace for nonspecific off allcodes
set cptrace for nonspecific on svc
set cptrace for nonspecific off 0200
set cptrace for nonspecific off 3600
set cptrace for nonspecific on realios
set cptrace for nonspecific off ssch
```

## Responses

Response 1:

The QUERY CPTRACE response shows an *indented hierarchy of trace categories* describing, as concisely as possible, the current CPTRACE setting. The output takes the form:

```
FOR qualifier
category ENABLED/DISABLED EXCEPT
  subcategory DISABLED/ENABLED EXCEPT
    subcategory ENABLED/DISABLED
      subcategory DISABLED/ENABLED
```

Response 2:

For categories not specifically traced, the output is:

```
FOR qualifier NO SPECIFIC TRACE SET
```

Response 3:

For a query on the SPECIFIC qualifier, when no specific tracing is in effect, the output is NO SPECIFIC TRACE SET. This response is repeated for each qualifier for which the trace setting is to be displayed. In the following examples, no specific tracing is assumed unless otherwise indicated.

**Note:** For further information on trace categories, see [“SET CPTRACE” on page 1446](#).

## Examples

Example 1:

If all TRACE entries were enabled through the command SET CPTRACE ON (or all TRACE entries were disabled through the command SET CPTRACE OFF), you receive the following response:

```
FOR NONSPECIFIC
ALLCODES ENABLED or (DISABLED)
```

Example 2:

All TRACE entries were enabled through the command SET CPTRACE ON. If you wanted to display the setting of the REALIOS trace category after deactivating trace for CLEAR SUBCHANNEL (X'1000' and

## QUERY CPTRACE

X'1003') through the command SET CPTRACE OFF CSCH, you would enter `query cptrace realios`. You would receive the following response:

```
FOR NONSPECIFIC
REALIOS  ENABLED EXCEPT
CSCH     DISABLED
```

Example 3:

If all TRACE entries were enabled through the command SET CPTRACE ON and you wanted to disable the TRACE entries for CALL-WITH-SAVE AREA (X'2800'), RETURN-WITH-SAVE AREA (X'2C00'), RUN USER (X'0A00'), and IUCV (X'1500'- X'1511') through the command `set cptrace off callret 0A00 iucv`, you receive the following response:

```
FOR NONSPECIFIC
ALLCODES ENABLED EXCEPT
CALLRET  DISABLED
0A00     DISABLED
IUCV     DISABLED
```

Example 4:

All TRACE entries were disabled through the command SET CPTRACE OFF. Perhaps you want to enable all the TRACE entries in category SVC and REALIOS except for SVC INTERRUPTION (X'0200'), EXIT TO THE DISPATCHER (X'3600'), and START SUBCHANNEL (X'1030'-'1033'). To do so, enter `set cptrace on svc realios off 0200 3600 ssch`. You receive the following response:

```
FOR NONSPECIFIC
ALLCODES DISABLED EXCEPT
SVC      ENABLED EXCEPT
0200     DISABLED
3600     DISABLED
REALIOS  ENABLED EXCEPT
SSCH     DISABLED
```

Example 5:

All tracing is enabled for the nonspecific and disabled for BATCH1 by issuing `set cptrace on` and `set cptrace for batch1 off`. You receive the following response for QUERY CPTRACE for all codes:

```
FOR NONSPECIFIC
ALLCODES ENABLED
FOR BATCH1
ALLCODES DISABLED
```

## Messages

- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]

## QUERY CPUAFFINITY

### Authorization

Privilege Class: A

### Purpose

Use QUERY CPUAFFINITY to display the setting for CPU affinity.

### Operands

\*

displays the CPU affinity setting for the user issuing the command.

#### USER *userid*

specifies the user ID of the specific virtual machine for which you want to display the CPU affinity setting.

### Usage Notes

1. A class G user can use QUERY VIRTUAL CPUS to determine the user's own CPU affinity setting.
2. ON means the virtual CPUs are dispatched on only real CPUs of matching type. OFF means the virtual CPUs are dispatched on only real CPUs of primary type.

### Responses

Response 1:

```
CPUAFFINITY = ON
              OFF
```

### Messages

- HCP002E Invalid operand *operand*
- HCP003E Invalid option - *{option | command contains extra option(s) starting with option}*
- HCP045E *userid* not logged on
- HCP6704E Missing token at end of line

## QUERY CPUID

► Query — CPUid ◄

### Authorization

Privilege Class: G

### Purpose

Use QUERY CPUID to display the doubleword processor identifier used by your virtual machine.

### Usage Notes

1. This command returns the CPUID of the issuing user's VIRTUAL processor. The virtual CPUID defaults to the real configuration master processor CPUID unless the user has issued SET CPUID or is using the directory OPTIONS or CPU statements to alter the virtual CPUID, or the user is in a relocation domain that requires its architecture to appear at a lower level than the real configuration master processor.
2. To obtain the CPUID of non-base processors in a virtual configuration, use the CPU command to direct the Q CPUID to each non-base processor.
3. When part of an SSI cluster, the results of QUERY CPUID depend on the relocation domain of the issuing user. This command shows the virtual CPUID of the issuing user. Virtual CPUIDs may differ among users on the same system when they belong to different relocation domains.

### Responses

Response 1:

```
CPUID= aa s s s s s s c c c c d d d d
```

#### **aa**

identifies the version code. These two digits are set to X'FF' to identify that your virtual machine is running under z/VM.

#### **ssssss**

identifies the processor. This field contains six hexadecimal digits and is set at logon from the real configuration master processor. This is the only part of the CPUID that can be modified by means of the SET CPUID command or set by the system directory's OPTION control statement. This portion of the CPUID is not modified if the owning guest is relocated.

#### **cccc**

identifies the model number. This field is set to the model number of the real machine unless the user is in a relocation domain that requires its architecture to appear at a lower level than the real configuration master processor, in which case it is set to the level required by the relocation domain.

#### **dddd**

is bits 48-63 of the CPU identification of the real machine. On all supported servers, this field is set to X'8000'. For details on the value reported by QUERY CPUID, see the STORE CPU ID control instruction in [z/Architecture Principles of Operation](#).

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

## QUERY CPUPOOL

---

### **Purpose**

QUERY CPUPOOL has been superseded by QUERY RESPOOL. See [“QUERY RESPOOL”](#) on page 1140.

## QUERY CPXLOAD

### Authorization

Privilege Class: A, C, E

### Purpose

Use `QUERY CPXLOAD` to display information about the customer-written CP routines that were loaded using the `CPXLOAD` command or configuration file statement and that currently exist in the system execution space.

### Operands

#### ALL

tells CP that you want information about all of the customer-written CP routines that were loaded into the system using `CPXLOAD` commands or configuration file statements and that have not been removed from the system with `CPXUNLOAD` commands. If you do not specify any operands, the default is `ALL`.

#### EPName *name*

tells CP that you only want information about the customer-written CP routines associated with the specified entry point name or names. The variable *name* must be a 1-character to 8-character string. The first character must be alphabetic or one of the following special characters: dollar sign (\$), number sign (#), underscore (\_), or at sign (@). The rest of the string can be alphanumeric characters, the 4 special characters (\$, #, \_, and @), or any combination thereof.

You can use generic entry point names to request information about a specific subset of entry point names. A generic entry point name is a 1-character to 8-character string with asterisks (\*) in place of 1 or more characters and percent signs (%) in place of exactly 1 character. For example,

```
query cpxload epname hcp%rc*
```

displays information about all the entry points that start with HCP and have RC as their fifth and sixth characters.

#### ID *loadid*

#### ID *loadid1-loadid2*

is the number of the load identifier associated with the customer-written CP routines. CP assigned this load ID when you used the `CPXLOAD` command or configuration file statement to load these CP routines into the system execution space. Each *loadid* must be a decimal number between 0 and 2147483647.

**Userid SYSTEM**

tells CP that you want to display only the customer-written CP routines loaded using CPXLOAD statements in the system configuration file.

**Userid userid**

tells CP that you want to display only the customer-written CP routines loaded by a specific user ID. The variable *userid* must be a 1-character to 8-character alphanumeric string that represents a virtual machine on your system that is, or was, capable of issuing CPXLOAD commands.

**Usage Notes**

1. To load customer-written CP routines into the system execution space, use the CPXLOAD command (see “CPXLOAD” on page 111). In response to your CPXLOAD command, CP assigns and displays a load identifier (load ID). This load ID is a number between 0 and 2147483647 that identifies the CP routines that you loaded. If you ever want to unload these routines (using the CPXUNLOAD command), you must specify the load ID in the command for CP to know what to unload.

If you do not know the load ID for some CP routines that have already been loaded, you can use one of the following operands:

- ALL (which is the default) to display information about all of the CP routines that have been loaded.
  - EPNAME *name* to display information about only the routines associated with a specific entry point name.
  - USERID SYSTEM to display information about only the routines loaded by the system configuration file at initialization.
  - USERID *userid* to display information about only the routines loaded by a specific user after initialization.
2. To remove customer-written CP routines from the system execution space, use the CPXUNLOAD command (see “CPXUNLOAD” on page 117). After unloading the CP routines, CP frees the load ID and clears the information that was being stored about those CP routines. CP will not reuse this load ID until such time as your system is reinitialized.
  3. For more information about loading customer-written CP routines into the system execution space, see [Loading Dynamically into the System Execution Space in z/VM: CP Exit Customization](#).
  4. The addresses displayed by QUERY CPXLOAD are host logical storage addresses.

If the loaded routine is greater than 4 KB in length, the frames backing the host logical storage are not necessarily contiguous in host real storage.

If you need to know the host real storage address of the routine, enter the host logical storage address on the DISPLAY (Host Storage) command. The DISPLAY command displays the data at that location and also displays the corresponding host real storage address.

**Responses****Note:**

The following sample responses show information for multiple load IDs listed in ascending order. On your screen, multiple load ID responses may be arranged in ascending, descending, or random order. Options shown in the responses are the options specified on the CPXLOAD command and not the options set as a result of the OPTIONS loader directive.

Response 1 (Display by Load ID):

To display information about the customer-written CP routines loaded as identifier 1, enter the following:

```
query cpxload id 1
```

## QUERY CPXLOAD

**1**

Loaded as identifier 1

**2**

File: ZXXKL STUFF Z

**3**

Loaded by: SYSTEM on 10/12/95 at 11:27:59

**4**

CPXLOAD options: MP NOCONTROL DELAY NOLET PERMANENT

**5**

```
Associated entry points and external symbols:
PLOWERTY is at 078DF3A6
ZXXKLM is at 078DF58E
ZXXKLMFF is at 078DF772
ZXXKLMPQ is at 078DF99C
ZXXKLMQU is at 078DF000 module size is 000EF8
```

Ready;

In this example,

**1**

is the load ID assigned to all the routines that were loaded by the file in line **2**.

**2**

is the file identifier of the file:

- Containing the routines that were loaded,
- Which imbedded or included the routines that were loaded, or
- Some combination thereof.
- The *filemode* indicates the file mode of the CP accessed disk at the time of the CPXLOAD.

**3**

tells you the virtual machine responsible for loading the routines and the date and time they were loaded. If the virtual machine is SYSTEM (as in this example), then the routines were loaded by CPXLOAD statements in your system configuration file.

**4**

are the options from the CPXLOAD command or CPXLOAD configuration file statement. It does not include any information from OPTIONS loader directives imbedded in the loaded files. Note that the specified CPXLOAD options are listed as well as the defaults that were taken because an option was not specified.

**5**

lists all of the entry points and external symbols associated with the routine that was loaded. For each entry point or external symbol, CP displays the starting address in the system execution space where you can find the entry point or external symbol, and for modules, CP also displays the module's size.

### Notes:

1. Private control sections (CSECTs) do not have names. If one was loaded, you will see "P/C" listed as the name of the entry point or external symbol. For example:

```
Associated entry points and external symbols:
PVC0CAEA is at 14217208
PVCE3348 is at 142179CC
PVCF3D2E is at 14217D48
P/C is at 14217000 module size is 000E08
```

2. The displayed addresses are host logical storage addresses. See usage note "4" on page 849 for information on how to determine the host real storage address of an external symbol.

Response 2 (Display by Entry Point Name):

To display information about all the customer-written CP routines that have entry points and external symbols that start with a 4-character string of "MINE", enter the following:

```
query cpxload epname mine*
Loaded as identifier 14
File: LCLCMDS TEXT B
Loaded by: SYSTEM on 12/28/95 at 12:12:02
CPXLOAD options: MP CONTROL DELAY LET PERMANENT
Associated entry points and external symbols:
MINEENTR is at 078E0700
MINEDATA is at 078E0174
MINETABL is at 078E0000 module size is 000C00
```

```
Loaded as identifier 32
File: LCLDIAG TEXT B
Loaded by: SYSTEM on 12/28/95 at 23:48:36
CPXLOAD options: MP CONTROL DELAY LET PERMANENT
Associated entry points and external symbols:
MINE0C4 is at 078DF772
MINE0C6 is at 078DF99C
MINESECT is at 078DF000 module size is 000EF8
Ready;
```

Response 3 (Display by User ID):

To display information about all the customer-written CP routines that were loaded after initialization by user MAINT, enter the following:

```
query cpxload userid maint
Loaded as identifier 4
File: HRH CONTROL B
Loaded by: MAINT on 12/18/95 at 21:57:03
CPXLOAD options: MP CONTROL NODELAY NOLET TEMPORARY
Associated entry points and external symbols:
HRD0CAEA is at 0621F208
HR4E3348 is at 0621F9CC
HR8F3D2E is at 0621FD48
HR6438C8 is at 0621F000 module size is 000E08
```

```
Loaded as identifier 7
File: ABEND TEXT R
Loaded by: MAINT on 12/21/95 at 02:13:59
CPXLOAD options: MP CONTROL NODELAY NOLET PERMANENT
Associated entry points and external symbols:
ADENDEP is at 0B760028
ABEND is at 0B760000 module size is 000048
Ready;
```

Response 4 (Display All):

To display information about all the customer-written CP routines that have been loaded onto (and not yet unloaded from) your system, enter the following:

```
query cpxload all
Loaded as identifier 1
File: ZXXKL STUFF Z
Loaded by: SYSTEM on 10/12/95 at 11:27:59
CPXLOAD options: MP NOCONTROL DELAY NOLET PERMANENT
Associated entry points and external symbols:
PLOQWERTY is at 078DF3A6
ZXXKLM is at 078DF58E
ZXXKLMFF is at 078DF772
ZXXKLMFQ is at 078DF99C
ZXXKLMQU is at 078DF000 module size is 000EF8
```

```
Loaded as identifier 4
File: HRH CONTROL B
Loaded by: MAINT on 12/18/95 at 21:57:03
CPXLOAD options: MP CONTROL NODELAY NOLET TEMPORARY
Associated entry points and external symbols:
HRD0CAEA is at 0621F208
HR4E3348 is at 0621F9CC
HR8F3D2E is at 0621FD48
HR6438C8 is at 0621F000 module size is 000E08
```

## QUERY CPXLOAD

```
Loaded as identifier 7
File: ABEND TEXT R
Loaded by: MAINT on 12/21/95 at 02:13:59
CPXLOAD options: MP CONTROL NODELAY NOLET PERMANENT
Associated entry points and external symbols:
ADENDEP is at 0B760028
ABEND is at 0B760000 module size is 000048
```

```
Loaded as identifier 14
File: LCLCMDS TEXT B
Loaded by: SYSTEM on 12/28/95 at 12:12:02
CPXLOAD options: MP CONTROL DELAY LET PERMANENT
Associated entry points and external symbols:
MINEENTR is at 078E0700
MINEDATA is at 078E0174
MINETABL is at 078E0000 module size is 000C00
```

```
Loaded as identifier 32
File: LCLDIAG TEXT B
Loaded by: SYSTEM on 12/28/95 at 23:48:36
CPXLOAD options: MP CONTROL DELAY LET PERMANENT
Associated entry points and external symbols:
MINE0C4 is at 078DF772
MINE0C6 is at 078DF99C
MINESECT is at 078DF000 module size is 000EF8
Ready;
```

Response 5 (Nothing is Loaded):

If you issue the QUERY CPXLOAD command and no customer-written CP routines are loaded on your system with CPXLOAD commands or configuration file statements, you will see:

```
query cpxload all
There are no routines in CP storage loaded by CPXLOAD operations
Ready;
```

## QUERY CRYPTO

### Authorization

Privilege Class: A, B, C, E

### Purpose

Use QUERY CRYPTO to display the status of the real crypto resources that are available on the system.

### Operands

#### APVIRTual POLLing

requests a display of the polling setting of the shared pool.

#### DOMains

requests a display of installed crypto resources.

#### Users

requests a display of virtual machines that are logged on or disconnected and have access to the system's pool of shared crypto resources.

### Usage Notes

1. The set of crypto resources displayed is limited to the subset available to the logical partition or the virtual machine in which z/VM is running.
2. For information on planning and managing crypto resources on a z/VM system, see [Crypto Planning and Management in z/VM: CP Planning and Administration](#).
3. A VIRTUAL version of this command, QUERY VIRTUAL CRYPTO, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL CRYPTO” on page 1284](#).

### Responses

Response 1:

The following is the response to QUERY CRYPTO if AP crypto instructions are not installed:

```
Crypto Adjunct Processor Instructions are not installed
```

Response 2:

The following is the response to QUERY CRYPTO if AP crypto instructions are installed:

```
Crypto Adjunct Processor Instructions are installed
```

Response 3:

The following is the response to QUERY CRYPTO DOMAINS if crypto adapters are installed:

AP num	AP type	Dom num	Device Status	Config State	Device Assignment
AP 002	CEX7A	Domain 015	operational	online	shared
AP 002	CEX7A	Domain 020	resetting	online	attached to userid
AP 003	UNKN	Domain 015	revoked	online	free
AP 003	UNKN	Domain 020	revoked	online	free
AP 005	CEX8A	Domain 015	operational	offline	free, dedication planned
AP 005	CEX8A	Domain 020	operational	offline	free

**Note:** The column headings are not included in the output and are shown here for clarity.

The output contains the following fields:

**apnum**

The *apnum* field indicates the three-digit crypto adapter number in decimal.

**aptype**

The *aptype* field indicates the crypto adapter type and mode. For dedicated resources, the value indicates the type and mode of the physical resource. For shared resources, the value indicates the maximal common subset of crypto express adapter capabilities that is available in the shared pools of all systems in the user's relocation domain that have the same mode. Shared crypto resources must be configured in accelerator or CCA-coprocessor mode. The value of the *aptype* field can be one of the following:

**CEX3C**

Crypto Express3 configured in CCA coprocessor mode

**CEX3A**

Crypto Express3 configured in accelerator mode

**CEX4C**

Crypto Express4 configured in CCA coprocessor mode

**CEX4A**

Crypto Express4 configured in accelerator mode

**CEX4P**

Crypto Express4 configured in EP11 coprocessor mode

**CEX5C**

Crypto Express5 configured in CCA coprocessor mode

**CEX5A**

Crypto Express5 configured in accelerator mode

**CEX5P**

Crypto Express5 configured in EP11 coprocessor mode

**CEX6C**

Crypto Express6 configured in CCA coprocessor mode

**CEX6A**

Crypto Express6 configured in accelerator mode

**CEX6P**

Crypto Express6 configured in EP11 coprocessor mode

**CEX7C**

Crypto Express7 configured in CCA coprocessor mode

**CEX7A**

Crypto Express7 configured in accelerator mode

**CEX7P**

Crypto Express7 configured in EP11 coprocessor mode

**CEX8C**

Crypto Express8 configured in CCA coprocessor mode

**CEX8A**

Crypto Express8 configured in accelerator mode

**CEX8P**

Crypto Express8 configured in EP11 coprocessor mode

**NONE**

There are no crypto resources attached to the shared pool.

**UNKN**

z/VM is unable to determine the type of crypto adapter.

***domnum***

is the three-digit domain number in decimal. If the resource is shared, then 001 is assigned to the virtual domain number. If the resource is dedicated, then the actual hardware domain number of the resource is assigned.

***device\_status***

can be any of the following:

**operational**

indicates that the crypto resource is installed and operational.

**checkstop**

indicates that the crypto resource is in a checkstop condition and is unavailable.

**deconfigured**

indicates that the adapter is deconfigured and unavailable. This could result from VARY OFF CRYPTO when the environment in which CP is running supports AP reconfiguration, or from an operation performed on the hardware maintenance console (HMC).

**busy**

indicates that the adapter is temporarily busy initializing or doing error recovery.

**resetting**

indicates that the resource is being reset.

**revoked**

indicates the resource was detected by CP, but has since been unassigned from the configuration. If the resource is added back into the configuration, the updated status will be reported. Otherwise, when CP no longer detects this resource in the configuration, it will not be reported in Q CRYPTO output.

**unsupported**

indicates the crypto resource status is unsupported by CP.

***config\_state***

CP's logical view of the resource state, as controlled by VARY CRYPTO. Can be any of the following:

**online**

indicates that the crypto resource is online and available for use.

**offline**

indicates that the crypto resource is offline.

***device\_assignment***

can be any of the following:

**free, dedication planned**

indicates that the crypto resource is not in use, however, it has been specified on a CRYPTO APDED statement in the online user directory.

**attached to *userid***

indicates that the crypto resource is dedicated to a logged on virtual machine.

**free**

indicates that the crypto resource is not in use.

**shared**

indicates that the crypto resource is attached to the system for shared use.

This response is repeated for each crypto resource installed on the system.

Response 4:

## QUERY CRYPTO

The following is the response to QUERY CRYPTO DOMAINS if no crypto adapters are assigned to the zVM system.

```
No AP Crypto Domains are available
```

Response 5:

The following is the response to QUERY CRYPTO DOMAINS USERS.

- The existing output for QUERY CRYPTO DOMAINS is displayed, followed by a blank line.
- If there are no crypto resources available for sharing, the following message is displayed:

```
There are no AP crypto resources available for shared use.
```

- If there are virtual machines that are logged on or disconnected and have access to the shared crypto resources on the system, the following header is displayed, followed by a list of user IDs with up to six user IDs per line:

```
Shared-Crypto Users:
```

- If there are no virtual machines logged on or disconnected that have access to the shared crypto resources on the system, the following message is displayed:

```
There are no shared-crypto users.
```

Response 6:

The following is the response to QUERY CRYPTO POLLING.

If CRYPTO APVIRTUAL POLLING is set ON, the following message is displayed:

```
Shared-crypto polling is ON
```

If CRYPTO APVIRTUAL POLLING is set OFF, the following message is displayed:

```
Shared-crypto polling is OFF
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra options starting with *option*
- HCP1014E A required option is missing.

## QUERY CTCA

### Authorization

Privilege Class: B

### Purpose

Use QUERY CTCA to display the status of real channel-to-channel adapters.

### Operands

#### ACTive

indicates active channel-to-channel adapters. An active device is one that is in use by a user or the system and is specified as neither FREE nor OFFLINE.

#### ALL

indicates all channel-to-channel adapters attached to the system. The status is displayed in the order of ACTIVE, FREE, and OFFLINE. You receive the same response as you would receive if you entered all of the following commands:

```

query ctca active
query ctca free
query ctca offline
  
```

#### ATTach *userid*

indicates the channel-to-channel adapters that are dedicated to a user on the system. If you specify *userid*, only adapters attached to that user's virtual machine are indicated. If you do not specify *userid*, you receive the status of all adapters dedicated to any user on the system. Attached devices are always active.

#### BOXed

indicates the channel-to-channel adapters that are unavailable (usually because of a hardware condition). A boxed adapter can also be active, free, or offline.

#### FREe

indicates all free channel-to-channel adapters. A free adapter is one that is not currently in use by a user or the system and is specified as neither ACTIVE nor OFFLINE.

#### OFFline

indicates all offline channel-to-channel adapters. An offline adapter is one that is specified as neither ACTIVE nor FREE.

## Usage Notes

- A VIRTUAL version of this command, QUERY VIRTUAL CTCA, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL CTCA” on page 1287](#).

## Responses

If the system is using a channel-to-channel adapter that is in an intervention-required state and you enter QUERY CTCA, you see a response like this:

```
CTCA 0300 has intervention required.
```

0300 is the real device number of the channel-to-channel adapter that needs the operator's intervention.

**Note:** This response will be preceded by one of the following.

Response 1:

If you enter QUERY CTCA, QUERY CTCA ACTIVE, or QUERY CTCA ATTACHED and there is a channel-to-channel adapter attached to the system, you see something like this:

```
q ctca active
CTCA 0480 ATTACHED TO PVM      0480
CTCA 0481 ATTACHED TO PVM      0481
CTCA 0482 ATTACHED TO RSCS     0482
CTCA 0483 ATTACHED TO RSCS     0483
CTCA 0484 ATTACHED TO PVM      0485
CTCA 0485 ATTACHED TO PVM      0484
CTCA 0486 ATTACHED TO VTAM     0486
CTCA 0700 ATTACHED TO TCPIP    0500
CTCA 0701 ATTACHED TO TCPIP    0501
Ready;
```

The first number is the real device number of the channel-to-channel adapter. The ATTACHED operand might also read BOX/ATTC, which means that although the device is attached and dedicated to a user, it is unavailable. PVM, RSCS, TCPIP, and VTAM are user IDs to which the CTCAs are dedicated. The last number is the virtual device number which each virtual machine uses to refer to a CTCA.

Response 2:

If you enter a QUERY CTCA FREE command and there is a free channel-to-channel adapter attached to the system, you see something like this:

```
q ctca free
CTCA 0487 FREE      , CTCA 04A1 FREE      , CTCA 04A2 FREE      , CTCA 04A3 FREE
CTCA 04A4 FREE      , CTCA 04A5 FREE      , CTCA 04A9 FREE      , CTCA 04AA FREE
CTCA 04AB FREE      , CTCA 04BC FREE      , CTCA 04BD FREE      , CTCA 04BE FREE
CTCA 04BF FREE
Ready;
```

This response shows the real device number for each free CTCA.

The response for a QUERY CTCA OFFLINE or QUERY CTCA BOXED command is in the same format as the response for a QUERY CTCA FREE command.

Response 3:

When you enter a QUERY CTCA ALL command, CP displays the same responses as it would display if you had entered the QUERY CTCA ACTIVE, QUERY CTCA FREE, and QUERY CTCA OFFLINE commands.

Response 4:

If CP cannot find a channel-to-channel adapter of the type you specify, you see a message like this:

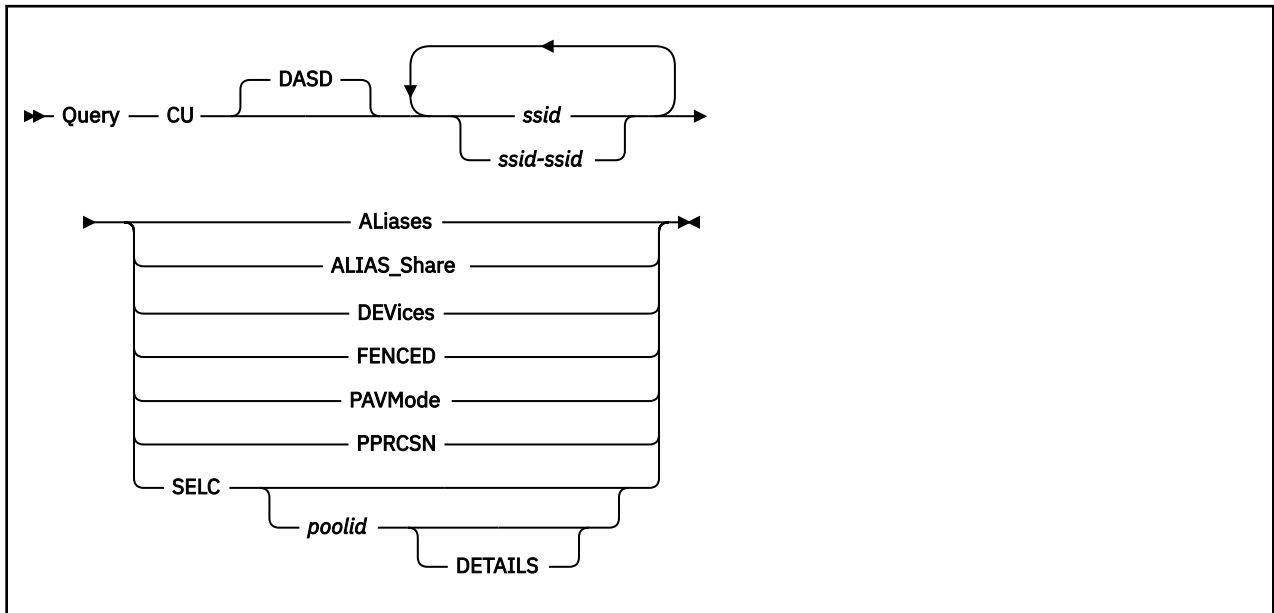

```
q ctca boxed
A BOXED CTCA was not found.
Ready;
```

In this response, BOXED may be replaced with `active`, `attached`, `offline`, or `free`, depending on what you specified on the command.

### Messages

- HCP003E Invalid option - *option*
- HCP006E Invalid device type - *rdev*
- HCP007E Invalid userid - *userid*
- HCP263E Too many operands were supplied for this command.

## QUERY CU

### Authorization

Privilege Class: B

### Purpose

Use QUERY CU to display selected information about a DASD control unit.

#### Notes:

- The QUERY CU command applies only to first-level z/VM systems. When z/VM is running as a guest of another z/VM system, the guest z/VM system does not control the operation of the control unit and cannot query the information about the control unit. If the command is issued to a guest z/VM system, the command is rejected.
- The control unit that is associated with an EDEVICE HyperPAV pool has a subsystem identifier (SSID) that cannot be referenced by the QUERY CU command and cannot be interrogated by the QUERY CU command.

### Operands

#### *ssid*

#### *ssid-ssid*

is the subsystem identifier (SSID) of a control unit as established in a control unit during its installation. The QUERY CU command operates on the control unit that is identified. The variable *ssid* must be a hexadecimal number between X'0000' and X'FFFF'. You can specify a single subsystem identifier, a list, a range, or any combination thereof.

#### **Aliases**

requests the display of PAV or HyperPAV alias devices in a control unit.

#### **ALIAS\_Share**

requests the display of minidisk I/O's and paging I/O's relative shares of and entitlements to system-attached HyperPAV aliases.

#### **DEVICES**

requests the display of all devices in a control unit.

**FENCED**

requests the display of all devices in soft fence state in a control unit.

**PAVMode**

requests the display of information about the Parallel Access Volume (PAV) mode of a control unit. This information includes the current PAV mode of the control unit and the allowed PAV mode of the control unit. (See also the SET CU command.)

**PPRC SN**

requests to display the status of PPRC Summary Notifications for the given control units.

**SELC**

specifies that the space-efficient logical configuration is desired.

**poolid**

specifies the requested space-efficient pool number. If omitted, all pools are displayed.

**DETAILS**

displays additional information regarding persistent FlashCopy relationships that were established on minidisks owned by the current user during the current system IPL session.

**Usage Notes**

1. The z/VM system programmer and the DASD management programmer must work together to make sure each Logical Subsystem (LSS) that is being used on the system has a unique SSID.

**Responses**

Response 1:

To query the devices in control units 4343, 4344, and 4345, enter the following:

```
q cu 4343-4345 dev
DASD CU 4343 DEVICES:
4300 4301 4302 4303 4304 4305 4306 4307
4308 4309 430A 430B 430C 430D 430E 430F
4310 4311 4312 4313 4320 4321 4322 4323
4324
DASD CU 4344 DEVICES:
4410 4411 4412 4413 4420 4421 4422 4423
DASD CU 4345 DEVICES:
4501 4502 4503 4504
Ready;
```

Response 2:

To query the alias devices (PAV or HyperPAV) in control units 4343, 4344, and 4345, enter the following:

```
q cu 4343-4345 a1
DASD CU 4343 ALIASES:
4304 4305 4306 4307 4308 4309 430A 430B
430C 430D 430E 430F 4311 4312 4313 4321
4322 4323 4324
DASD CU 4344 ALIASES:
4411 4412 4413 4421 4422 4423
DASD CU 4345 ALIASES:
4502 4503 4504
Ready;
```

Response 3:

To query the PAV mode of control units 4343, 4344, 4345, and 4346, enter the following:

```
q cu 4343-4346 pavmode
DASD CU 4343 CURRENTLY HYPERPAV, HYPERPAV ALLOWED
DASD CU 4344 CURRENTLY PAV, PAV ALLOWED
DASD CU 4345 CURRENTLY NOPAV, PAV ALLOWED
DASD CU 4346 DOES NOT EXIST, HYPERPAV ALLOWED
Ready;
```

## QUERY CU

This response indicates that CU 4343 is operating at its fully allowed HYPERPAV capability; CU 4344 is operating at its fully allowed PAV capability; CU 4345 is operating without alias devices but is allowed to operate in PAV mode if and when the requisite feature is installed for PAV operation; and CU 4346 is not in the configuration, but a CU statement in the system configuration file or an earlier SET CU command allowed HYPERPAV mode. For CU 4346, the allowance of HYPERPAV mode will take effect if and when the control unit is added to the configuration (for example, with a DEFINE CU command).

Response 4:

If you query a control unit to display its devices but there are none, the following response is displayed:

```
q cu 4347 dev
DASD CU 4347 HAS NO ASSOCIATED DEVICES
Ready;
```

Response 5:

If you query a control unit to display its alias devices but there are none, the following response is displayed:

```
q cu 4347 al
DASD CU 4347 HAS NO ASSOCIATED ALIASES
Ready;
```

Response 6:

If you query a control unit to display its PAV mode but that control unit type does not support alias devices, the following response is displayed:

```
q cu 4348 pavmode
DASD CU 4348 PAV FUNCTIONS DO NOT APPLY
Ready;
```

Response 7:

If you query a control unit and it does not exist in your configuration, the following response is displayed:

```
q cu 4349 dev
DASD CU 4349 DOES NOT EXIST
Ready;
```

**Note:** If you specify a range, and a control unit in that range does not exist, that control unit is not shown in the response unless it is specified in a CU statement in the system configuration file or in an earlier SET CU command.

Response 8:

If you query a control unit for a space-efficient logical configuration, the following response is displayed:

```
q cu dasd 0101 selc
SSID 0101: TYPE=002107 MODEL=921 SN=0000004191
SSID 0101: POOLID RPOSWARN POOLWARN STATUS...
SSID 0101:      0      0%      0% CKD RPOSCONF REPWARN REPFULL
SSID 0101:      1      0%      0% CKD RPOSCONF REPWARN REPFULL
SSID 0101:      3      0%      0% FBA RPOSCONF REPWARN REPFULL
SSID 0101:      4      0%      0% FBA RPOSCONF REPWARN REPFULL
Ready; T=0.01/0.01 11:02:10
```

where the STATUS... data will be:

Status	Meaning
CKD	- This is a CKD volume
FBA	- This is an FBA volume
RPOSCONF	- The extent pool repository is configured
REPWARN	- The repository is at the warning percentage

Status	Meaning
REPFULL	- The repository is full
POOLWARN	- The extent pool is at the warning percentage
POOLFULL	- The extent pool is full

If the command is issued with the *poolid* DETAILS operands, the following additional information is displayed:

```
query cu dasd 0101 selc 1 details
SSID 0101: TYPE=002107 MODEL=921 SN=0000004191
SSID 0101: POOLID RPOSWARN POOLWARN STATUS...
SSID 0101:      1      0%      0% CKD RPOSCONF REPWARN REPFULL
SSID 0101: POOL=1639449/1943298 84%
SSID 0101: RPOS=0/0
SSID 0101: GUAR=0/0
Ready; T=0.01/0.01 11:01:21
```

For POOL=xxx/yyy zzz%, RPOS=xxx/yyy zzz%, and GUAR=xxx/yyy zzz%, the xxx value is the currently allocated extent space, yyy is the max size of the extent, and zzz is just x/y. These are for the extent pool, extent pool repository, and guaranteed space values.

Response 9:

When an SSID has enabled PPRC Summary Notifications, the following response is displayed:

```
DASD CU ssid IS ENABLED FOR PPRCSN
```

Response 10:

When an SSID has disabled PPRC Summary Notifications, the following response is displayed:

```
DASD CU ssid IS DISABLED FOR PPRCSN
```

Response 11:

If you query a control unit to display its devices in soft fence state, the following response is displayed:

```
q cu 4343 fenced
DASD CU 4343 DEVICES IN SOFT FENCED STATE:
4300 4301 4302 4303 4304 4305 4306 4307
4308 4309 430A 430B 430C 430D 430E 430F
4310 4311 4312 4313 4320 4321 4222 4323
4324
Ready;
```

Response 12:

If you query a control unit to display its devices in soft fence state but there are none, the following response is displayed:

```
q cu 4344 fenced
DASD CU 4344 HAS NO DEVICES IN SOFT FENCED STATE.
Ready;
```

Response 13:

To query the alias-shares and entitlements in control unit 4343, when PAGING\_share is 200, MDISK\_share is 100, and the total number of system-attached HyperPAV aliases is 17:

```
q cu 4343 alias_share
DASD CU 4343
MDISK ALIAS: SHARE    100 ENTITLEMENT    6
PAGING ALIAS: SHARE   200 ENTITLEMENT   11
Ready;
```

The minidisk entitlement calculation is:

```
(100 / (100 + 200)) * 17 = 17 / 3 = 5.67 (rounded up to 6)
```

The paging entitlement calculation is:

```
(200 / (100 + 200)) * 17 = 34 / 3 = 11.33 (rounded down to 11)
```

### Messages

## QUERY D8ONECMD

Notes:

<sup>1</sup> The `userid` variable is not permitted for privilege class G.

### Authorization

Privilege Class: A, C, E, G

### Purpose

Use QUERY D8ONECMD to determine the D8ONECMD settings for your own virtual machine or another user's virtual machine.

### Operands

\*

indicates that you wish to display your own virtual machine's D8ONECMD settings. \* is the default.

*userid*

is the user ID of the virtual machine for which you want to display the D8ONECMD settings.

### Usage Notes

1. The initial D8ONECMD settings for your virtual machine are determined by options set in your user directory entry.
2. You can use the class G SET D8ONECMD command to change your D8ONECMD settings. You can use the class A SET D8ONECMD command to change another virtual machine's D8ONECMD settings. For more information, see [“SET D8ONECMD” on page 1482](#).

### Responses

If you enter QUERY D8ONECMD, you receive one of the following responses:

Response 1:

```
userid can enter multiple commands with a DIAGNOSE X'08'.
This setting is locked against changes.
```

*userid*

represents the user ID whose D8ONECMD settings are being displayed.

This response indicates that you can process a DIAGNOSE code X'08' containing multiple CP commands with no restrictions. The second line of the response indicates that only a privileged user who is also not the command issuer can change the settings.

Response 2:

```
CP will log userid's attempts to issue
multiple commands with a DIAGNOSE X'08'.
This setting is locked against changes.
```

### ***userid***

represents the user ID whose D8ONECMD settings are being displayed.

This response indicates that any attempt to process a DIAGNOSE code X'08' containing multiple CP commands will not fail but will cause a message to be sent to operations personnel. The last line of the response indicates that only a privileged user who is also not the command issuer can change the settings.

Response 3:

```
CP will block userid's attempts to issue
multiple commands with a DIAGNOSE X'08'.
This setting is locked against changes.
```

### ***userid***

represents the user ID whose D8ONECMD settings are being displayed.

This response indicates that any attempt to process a DIAGNOSE code X'08' containing multiple CP commands will fail and will cause a message to be sent to operations personnel. The last line of the response indicates that only a privileged user who is also not the command issuer can change the settings.

Any of the above messages may also have the following line as the second line of the response:

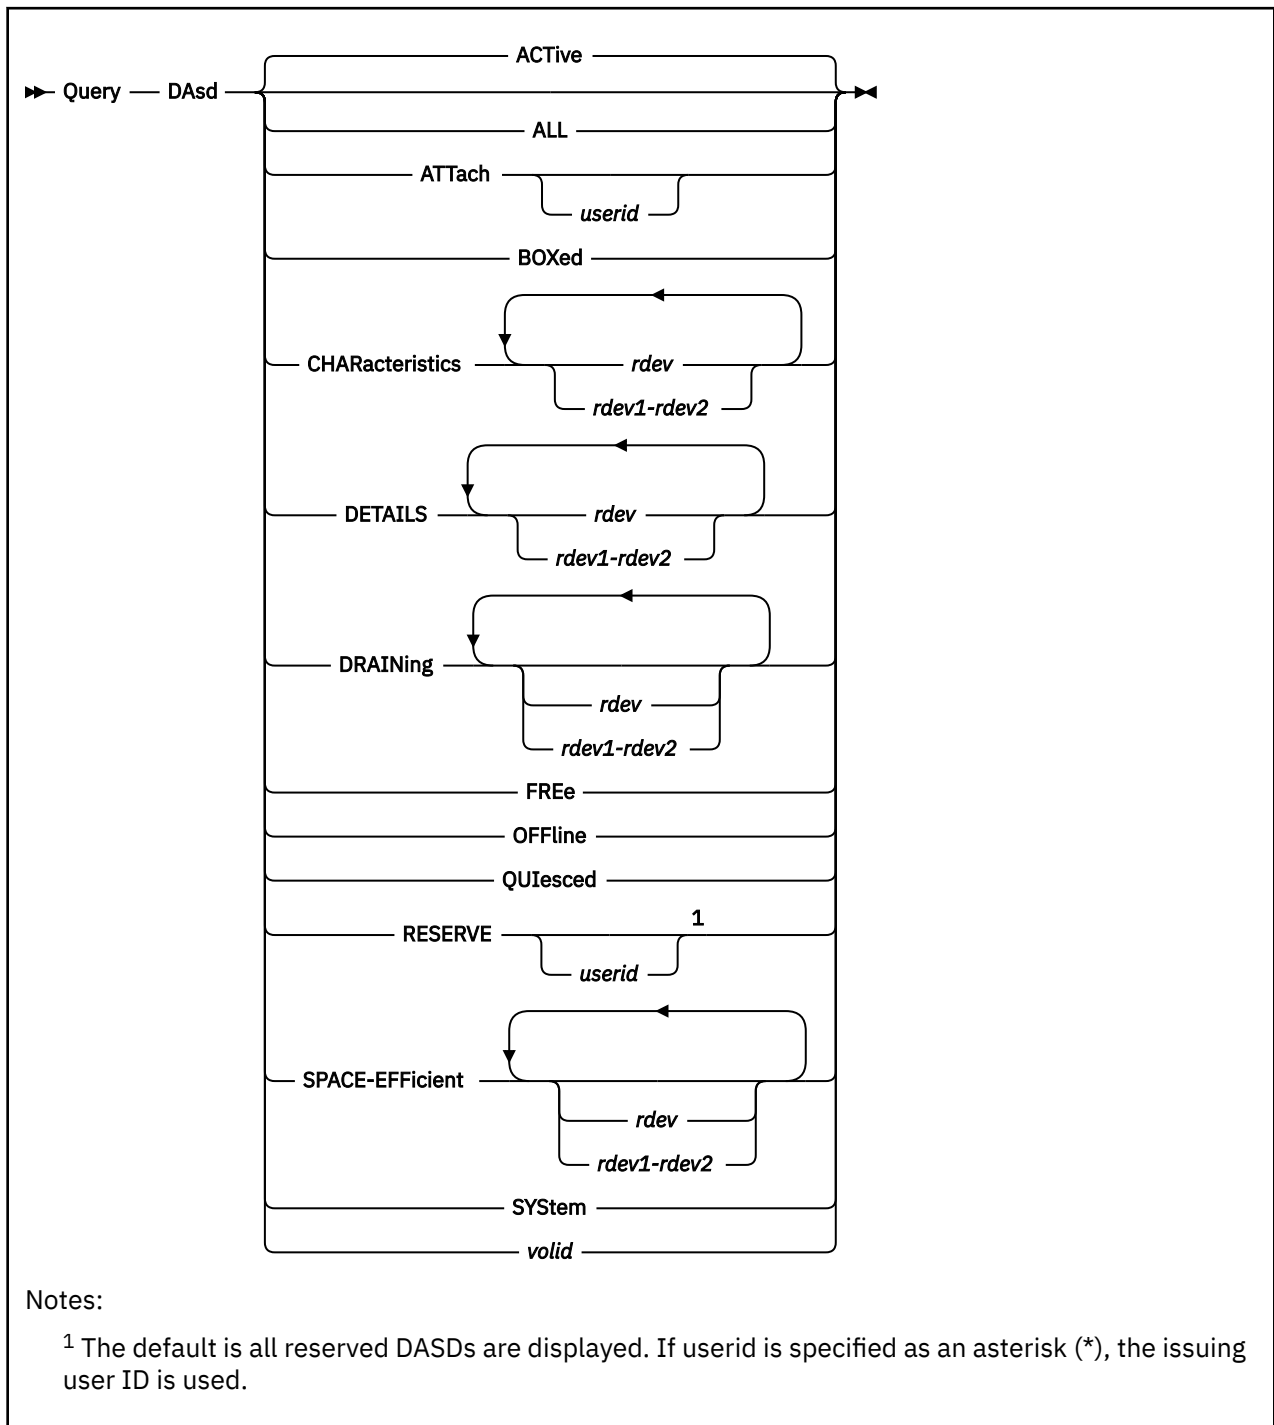

```
This setting is not locked against changes.
```

This response indicates that a privileged user can change the command filtering level for the selected virtual machine (even if the target virtual machine is the command issuer's virtual machine).

## **Messages**

- HCP003E Invalid option - *{option|command contains extra option(s) starting with option}*
- HCP045E *userid* not logged on

# QUERY DASD

## Authorization

Privilege Class: B

## Purpose

Use QUERY DASD to display the status of real direct access storage devices.

## Operands

### ACTive

indicates all active direct access storage devices. An active device is one that is in use by a user or the system and is specified as neither FREE nor OFFLINE. This is the default.

### ALL

indicates all direct access storage devices attached to the system. The status is displayed in the order of ACTIVE, FREE, and OFFLINE. You receive the same response as you would receive if you entered all of the following commands:

```
query dasd active
query dasd free
query dasd offline
```

### ATTach *userid*

indicates the DASDs that are dedicated to a user on the system. If you specify *userid*, only devices attached to that user's virtual machine are indicated. If you do not specify *userid*, you receive the status of all devices dedicated to any user on the system. Attached devices are always active.

### BOXed

indicates the DASDs that are unavailable (usually because of a hardware condition). A boxed device may also be active, free, or offline.

### CHARacteristics

displays a hexadecimal block that contains device configuration and characteristics information. To get formatted output, use the IOEXPLOR utility.

For further details on the information contained in the output, consult your storage hardware vendor.

### DETAILS

displays detailed information about real DASD.

#### *rdev*

#### *rdev1-rdev2*

is the real device number (*rdev*), a list of real device numbers (*rdev rdev rdev*), or a range of real device numbers (*rdev1-rdev2*). A real device can be entered as a 4-digit hexadecimal number between X'0000' and X'FFFF'. For the CHARacteristics and DETAILS operands, a real device in the active configuration can be entered as a 4-digit hexadecimal number between X'0000' and X'FFFF' and all real devices can be specified as a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is configured. A range of devices cannot span subchannel sets.

For DASD attached to a noncaching storage control, the information provided is:

- Control unit type and model
- Device type and model
- Volume serial number (VOLSER).

For DASD attached to a caching storage control (see Usage Notes), the following additional information is provided:

- Caching status for subsystem and device
- Nonvolatile storage status
- DASD fast write device status
- Cache fast write subsystem status
- Pinned data status
- Channel connection address (CCA)
- Director to device connection (DDC) address
- Duplex information
- Concurrent Copy (CONCOPY) session information

- Peer-to-Peer Remote Copy (PPRC) information
- Soft Fence state
- Host Access information.

**DRAINing**

specifies the devices for which status is to be displayed, if they are currently draining. If no real device list is supplied, all DASD is examined.

**FREe**

indicates all free DASDs. A free device is one that is not currently in use by a user or the system and is specified as neither ACTIVE nor OFFLINE.

**OFFline**

indicates all offline DASDs. An offline device is one that is specified as neither ACTIVE nor FREE. The offline response will also show offline devices which are quiesced.

**QUIesced**

indicates all quiesced DASD. A quiesced device is an offline device which cannot be varied online until a resume request is received for the device.

**RESERVE *userid***

indicates all reserved DASD defined as full-pack minidisks. If you specify *userid*, only devices attached to that user's virtual machine are indicated.

**SPACE-EFFicient**

specifies that information regarding space-efficient real volumes is to be listed. The displayed results identify the real device number, volser, space-efficient pool number, pool size and usage statistics.

**SYStem**

indicates the DASDs in use by the system. A system device is always active.

***valid***

specifies the volume identification of a DASD whose status is to be displayed. If a volume has a nonstandard label, the volume ID reported is unpredictable.

**Usage Notes**

1. The DASD DETAILS function is not supported for caching models of the 3880 storage control (Models E21, G21, J21, H21, D23, E23, G23, J23, and H23) and produces error message HCP332E instead of a response. For these devices, you should use the QUERY CACHE *rdev* command.
2. For the DASD RESERVE function, only DASDs defined as full-pack minidisks with the SHARED option and active or pending reserves are displayed.
3. The DASD RESERVE function can be used to determine the reserve status of system DASD.
4. For the DASD RESERVE function, if either the RESERVED BY SYSTEM response or the RESERVE PENDING FOR SYSTEM response appears consistently for the same device over a period of time, the response could be indicating a problem.
5. Users who have been defined in QUICKDSP cannot afford an I/O delay, so DASD DETAILS will not issue Soft Fence and Query Host Access related I/O.
6. The DASD DETAILS function will not issue Soft Fence and Query Host Access related I/O to a device that is already quiesced due to an active HYPERSWAP QUIESCE function. This is because the I/O queued and the issuing user will be hung when the target device is in HYPERSWAP processing.
7. Host Access information can be requested only for dedicated DASD and fullpack minidisks. If the DASD DETAILS function is issued from a second-level system to get Host Access information for the specified device, the information can be obtained only when the underlying first-level disk is a dedicated DASD or a fullpack minidisk. Additionally, Host Access information can be obtained from a base device or a PAV alias device, but not a HyperPAV alias device.
8. A VIRTUAL version of this command, QUERY VIRTUAL DASD, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL DASD” on page 1288](#).

## Responses

### Response 1:

If you enter the QUERY DASD *valid* command when there are no online DASDs, you receive one of the following responses:

```
DASD valid was not found.
```

- or -

```
DASD valid offline, label queried may not be currently on the DASD
```

**Note:** The second response is also issued for the secondary volume of a duplex pair, because secondary volumes can be offline. In this case the label queried is in fact on the DASD, because the secondary volume is a copy of the primary (unless the pair is suspended). Another response describing the primary volume appears with this response.

### Response 2:

If the system is using any DASD that is in an intervention-required state and you enter QUERY DASD, you receive a response that looks like this:

```
DASD 181B has intervention required.
```

181B is the real device number.

**Note:** This response will be preceded by one of the following.

### Response 3:

The following response is displayed if the real device is attached to the system for access as user minidisks or for system paging, spooling, or temporary disk space.

```
q dasd
DASD 0280 CP SYSTEM XAUSR1 49
DASD 0281 CP SYSTEM XAUSR2 24
DASD 0282 CP SYSTEM XAUSR3 49

DASD 0A04 CP OWNED ESAP04 1
DASD 0A05 CP OWNED ESAP05 1
DASD 0C08 CP SYSTEM ESAP7 1
DASD 0C09 CP SYSTEM ESAP6 1
DASD 1800 CP SYSTEM USPK1 4
DASD 1801 CP SYSTEM USPK2 2
Ready;
```

The first number listed is the real device number of the DASD. SYSTEM indicates the device is allocated to the system for use as users' minidisks. OWNED indicates the device is used by the system for paging and spooling activity. XAUSR1, ESAP01, and the rest are volume labels of the devices. The last number indicates the number of links to minidisks contained on the volume.

### Response 4:

The following response is also displayed if the real device is attached to the system for access as user minidisks or for system paging, spooling, or temporary disk space. This response is longer than the previous response because the device may be reserved (shared option is on), it may have a reserve pending, or it is currently reserved.

```
q dasd active
DASD 181A CP SYSTEM ESAP2C SHARED
DASD 181B CP OWNED ESAP2F RESERVE PENDING FOR USER DAVID
DASD 181C CP OWNED ESAP30 RESERVED BY SYSTEM
Ready;
```

Response 5:

If the device is dedicated to a user, you see a message like this:

```
q dasd
DASD 0820 ATTACHED TO OLIVER 01FC R/O XAUSR4
Ready;
```

This means the DASD at the real device number 0820 is attached to OLIVER's virtual machine as the virtual device 01FC. The DASD's volume identifier is XAUSR4. R/O means the user OLIVER has read-only access to the DASD. R/O might also read R/W, which means the user had read-write access. ATTACHED may be replaced with BOX/ATTC, which means that although the device is dedicated to a user, it is unavailable (usually because of a hardware condition).

Response 6:

If you enter QUERY DASD DRAINING, you see something like this:

```
q dasd draining
DASD Vol-ID Rdev Draining: Page LInks SPool TDisk
0C02 DR4209 0C02 Yes Yes Yes Yes
0C04 DR5703 0C04 No No Yes No
Ready;
```

This response shows the device number and volume identifier of the DASD, as well as which operations are prevented on it. The second line indicates that CP will not write pages to the DASD at 0C02, allow LINK commands to minidisks on it, allocate space on it for new spool records, or allocate temporary disk requests on it. The third line indicates that CP will not allocate space for new spool records on the DASD at 0C04.

Response 7:

If you enter QUERY DASD DETAILS and the device is attached to a noncaching storage control, you see the following response:

```
rdev CUTYPE = cccc-mm, DEVTYPE = dddd-mm, VOLSER = vvvvvv,
CYLS = nnnnnnnn
```

If you enter QUERY DASD DETAILS for devices attached to a caching storage control (see Usage Notes), you see something like this:

```
query dasd details 1801
1801 CUTYPE = 3990-EC, DEVTYPE = 3390-06, VOLSER = USPK2, CYLS = 3339
CACHE DETAILS: CACHE NVS CFW DFW PINNED CONCOPY
-SUBSYSTEM Y Y Y - N N
-DEVICE Y - - N N N
DEVICE DETAILS: CCA = 01, DDC = 01, SS = 00, ACTIVE = Y, ESE = Y
DUPLICATE DETAILS: Secondary, OTHER DEVICE = 1800, Active duplex
PAV DETAILS: Base volume with 02 alias volumes
PPRC DETAILS: xxxxxx VOLUME
CU DETAILS: SSID = nnnn, CUNUM = nnnn
SERIAL NUMBER: 01XX-12345
Ready;
```

The first line of the response tells you the DASD at real device number 1801 has a control unit type of 3990-EC, a device type of 3390-06, and a volume serial number of USPK2 and contains 3339 cylinders.

In the control unit type and the device type, the last two digits are a hex code for the model and mode. See the storage control documentation to determine the model and mode for the hex code given.

The second line identifies the columns in the CACHE DETAILS portion of the response:

Details	Meaning
CACHE	tells you about caching
NVS	tells you about nonvolatile storage
CFW	tells you about the cache fast write subsystem

Details	Meaning
DFW	tells you about the DASD fast write device
PINNED	tells you about pinned data
CONCOPY	tells you about Concurrent Copy sessions.

In the third and fourth lines of the response, Y and N indicate the following status:

Column	Y	N
CACHE (See note)	The subsystem cache is available, or the cache is activated for the device.	The subsystem cache is not available, or the cache is not activated for the device.
NVS (See note)	The nonvolatile storage for the subsystem is available.	The nonvolatile storage for the subsystem is not available.
CFW	The cache fast write function is active for the subsystem.	The cache fast write function is not active for the subsystem.
DFW	The DASD fast write function is active for the device.	The DASD fast write function is not active for the device.
PINNED	The subsystem has pinned data for one or more devices, or a data track has become pinned.	There is no pinned data for any of the devices in the subsystem, or there are no pinned data tracks.
CONCOPY	One or more Concurrent Copy (CONCOPY) sessions are associated with the subsystem., or tracks on the device are associated with a CONCOPY session.	No CONCOPY session is associated with the subsystem, or no tracks on the device are associated with a CONCOPY session.

**Note:** For subsystem cache, the status can be one of the following:

- Y subsystem caching active
- N subsystem caching inactive
- T subsystem caching terminated
- M subsystem caching disabled for maintenance
- F subsystem caching pending inactive, destage has failed

For subsystem NVS, the status can be one of the following:

- Y subsystem NVS active
- N subsystem NVS inactive
- T subsystem NVS terminated
- M subsystem NVS disabled for maintenance

The fifth line of the response, DEVICE DETAILS, tells you the channel connection address (CCA = 01), the address of the director-to-device connection (DDC = 01), the device subchannel set number (SS = 00), if the device is in the active subchannel set (ACTIVE = Y), and if the device is an extent space efficient volume (ESE = Y). The channel connection address is the channel connection address at the channel control interface.

The director-to-device connection (DDC) is the director-to-device connection at the control unit interface. The DDC can be used to identify the physical location of a device. Because the 3990 Models 3 and 6 can swap devices around, the CCA no longer has a one-to-one correspondence with the DDC. The DDC can be used to locate a physical device that had previously been swapped because of a suspended primary

device in a duplex pair. When the real device is offline, or is connected via FICON, there is no DDC data, and hyphens (--) are displayed.

The sixth line of the response, DUPLEX DETAILS, tells you about the duplex control operations for the DASD at the specified device number. 1800 is the real device number of the volume that is the other volume of the duplex pair. If the other volume could not be located, hyphens (--) are displayed. The full response above tells you the following:

- The DASD at the real device number 1801 is the secondary device in the duplex pair.
- The other device in the duplex pair is at 1800.
- The duplex operation is active.

If the specified DASD was the primary device in the duplex pair, Secondary would read Primary.

In the above example, the status of the Dual Copy pair is `Active duplex`. Other status conditions that could be indicated here instead, would be `Pending duplex` or `Suspended duplex`.

The seventh line of the response, PAV DETAILS or HYPERPAV DETAILS, tells you whether the queried DASD is a Parallel Access Volume or a HyperParallel Access Volume. If the device is a base Parallel Access Volume, as in the above example, the response indicates the number of alias volumes currently associated with that base. If the device is an alias Parallel Access Volume, the response indicates the real device number of the associated base:

```
PAV DETAILS: Alias volume associated with base rdev
```

If the device is a base HyperParallel Access Volume, the response indicates the associated pool that the device is in:

```
HYPERPAV DETAILS: Base volume in Pool 2
```

If the device is an alias HyperParallel Access Volume, the response indicates the associated pool that the device is in:

```
HYPERPAV DETAILS: Alias volume in Pool 2
```

If the queried DASD is not a Parallel Access Volume or a HyperParallel Access Volume, then the PAV DETAILS and HYPERPAV DETAILS lines are not included in the response.

The eighth line of the response, PPRC DETAILS, tells you the queried active Peer-to-Peer Remote Copy mode. In the above sample, `xxxxxxx` is one of the modes:

#### **PRIMARY**

The volume from which PPRC makes a copy.

#### **SECONDARY**

The volume that maintains a consistent copy of the primary volume.

#### **CASCADING INTERMEDIATE**

The volume that can be both a PPRC primary and secondary volume, allowing a multi-hop operation. In a multi-hop operation, PPRC uses a primary volume to send to a secondary volume and that secondary volume operates as a PPRC Extended Distance primary volume, sending to a tertiary volume many miles away. Such a configuration supports disaster recovery operations.

#### **MT PRIMARY**

The volume is a Multi-Target PPRC primary.

If the queried DASD is not an active PPRC volume, the PPRC DETAILS line is not included in the response.

The ninth line of the response, CU DETAILS, tells you additional information about the control unit associated with the DASD. In the above sample, `SSID = nnnn` is the subsystem identifier associated with the control unit and `CUNUM = nnnn` is the control unit number associated with the control unit.

The tenth line of the response, SERIAL NUMBER, tells you the serial number of the associated DASD. This line is constructed as follows:

- The manufacturer indicator - two bytes ('01' for IBM, 'XX' for non-IBM)

## QUERY DASD

- The plant of manufacture - two bytes
- A hyphen (-)
- The rightmost five digits of the storage facility sequence number.

Response 8:

If you enter QUERY DASD DETAILS for an FBA DASD, such as a 9336 model 20, you see something like this:

```
query dasd details 600
0600 CUTYPE = 6310-80, DEVTYPE = 9336-10, VOLSER = L3RES, CYLS = 16
      BLKS = 34504
Ready;
```

This response tells you the DASD at real device number 600 has a control unit type of 6310-80, a device type of 9336-10, a volume serial number of L3RES, and contains 34,504 512-byte blocks. The number of cylinders displayed (e.g., CYLS = 16) is a calculated value derived from:

```
total number of blocks / number of blocks per access position
```

For the control unit type and the device type, the last two digits of each are hex codes for the associated models. See the device documentation to determine the models for the hex codes given.

Response 9:

If you enter QUERY DASD DETAILS and the device has been expanded and has not yet been varied offline or online to make use of the expanded space, you see the following line in the response:

```
PENDING EXPANSION DETAILS: DEVTYPE = 3390-0A, CYLS = 47229
```

The DEVTYPE contains the model which might or might not have changed. The CYLS contains the new size which will be used by CP once the device is varied offline and online. If the DASD is an emulated device that represents a real SCSI device, the pending expansion information will not be included in the response. Use QUERY EDEVICE DETAILS to see the pending expansion information.

Response 10:

If you issue QUERY DASD RESERVE and the command completes successfully, you would receive the following response:

```
DASD rdev
```

If the command completed successfully but intervention is required, you would receive both of the following responses:

```
DASD rdev
```

and

```
DASD rdev
INT REQUIRED (if the device requires intervention)
DASD rdev <CP SYSTEM> nnnnn volid
      <CP OWNED >
<RESERVED BY      > <USER userid>
<RESERVE PENDING FOR> <SYSTEM      >
```

Response	Meaning
CP SYSTEM	indicates that this is a system DASD.
CP OWNED	indicates that this is a CP-owned volume.
<i>nnnnn</i>	specifies the number of links to this pack.
RESERVED BY	indicates that there is currently a reserve on the DASD.

**Response                    Meaning**

RESERVE PENDING FOR indicates that the user (or the system) is waiting for a reserve on the DASD.

USER *userid* indicates that the real reserve is held by the system for this user.

**Response 11:**

If you issued QUERY DASD RESERVE and no reserved or pending reserved DASD exists, you would receive the following response:

```
A reserved DASD was not found.
```

**Response 12:**

When you QUERY DASD SPACE-EFFICIENT:

You will receive the "not a space-efficient" response if the disk is not in a space-efficient configuration.

You will receive the "not available" message if the hardware indicates that it cannot currently produce the required information.

The pool data is the extent pool ID and the size of the extent pool repository.

The capacity data is the space-efficient volume capacity limit and the capacity limit warning watermark (%).

The guaranteed data is the space-efficient volume guaranteed capacity and the guaranteed capacity warning watermark (%).

The space data is the extent pool space currently allocated to this volume and the space-efficient volume capacity (logical volume size). The ratio of these two is computed as a percentage. If no space is currently defined, the display indicates a value of "- -". If the denominator is zero, - -% will be displayed.

```
q dasd space-efficient
DASD FCE0 RWSCE0 POOL 1 SIZE 1263286 CYLS
VOLUME CAPACITY LIMIT 0 CYLS, 0%
VOLUME GUARANTEED CAPACITY 0 CYLS, 0%
VOLUME SPACE 30 CYLS USED OF 3339 CYLS DEFINED, 1%
DASD FCE1 RWSCE0 POOL 1 SIZE 1263286 CYLS
VOLUME CAPACITY LIMIT 0 CYLS, 0%
VOLUME GUARANTEED CAPACITY 0 CYLS, 0%
VOLUME SPACE 0 CYLS USED OF 3339 CYLS DEFINED, 0%
DASD FEE0 RWSEE0 POOL 1 SIZE 1263286 CYLS
VOLUME CAPACITY LIMIT 0 CYLS, 0%
VOLUME GUARANTEED CAPACITY 0 CYLS, 0%
VOLUME SPACE 20 CYLS USED OF 3339 CYLS DEFINED, 1%
DASD FEE1 RWSEE1 POOL 1 SIZE 1263286 CYLS
VOLUME CAPACITY LIMIT 0 CYLS, 0%
VOLUME GUARANTEED CAPACITY 0 CYLS, 0%
VOLUME SPACE 20 CYLS USED OF 3339 CYLS DEFINED, 1%
Ready; T=0.01/0.01 16:25:14

q dasd space-efficient 1234
A Space-Efficient DASD was not found
Ready; T=0.01/0.01 16:27:40

q dasd space-efficient 1234
DASD 1234 MYDISK: Space-Efficient information is not available
Ready; T=0.01/0.01 16:27:40
```

**Response 13:**

If you issued a QUERY DASD DETAILS command to a volume that resides on a data encryption drive (DED), and/or a solid-state drive (SSD), the "DEVICE DETAILS" line of output will include indicators stating the presence of these facilities. The output will look similar to the following:

```
q dasd details 521d
521D CUTYPE = 2107-E8, DEVTYPE = 3390-0A, VOLSER = ERF001, CYLS = 3339
  CACHE DETAILS:  CACHE NVS CFW DFW PINNED CONCOPY
                   -SUBSYSTEM  Y  Y  Y  -  N  N
```

## QUERY DASD

```
-DEVICE Y - - Y N N
DEVICE DETAILS: CCA = 1D, DDC = --, DED = YES, SSD = NO, SS = 00,
ACTIVE = Y, ESE = N
DUPLEX DETAILS: --
CU DETAILS: SSID = 0102, CUNUM = 5200
SERIAL NUMBER: 01XX-12345
```

If QUERY DASD DETAILS is issued against an emulated device (EDEV) that includes one or both of these facilities, the "DEVICE DETAILS" line of output will be added to the response, but the CCA/DDC text will not be displayed.

```
q dasd details dead
DEAD CUTYPE = 6310-80, DEVTYPE = 9336-10, VOLSER = ERF105, CYLS = 10796
BLKS = 8388608
DEVICE DETAILS: DED = YES, SSD = NO, SS = 00
```

Regardless of device type, at least one facility must be present on a volume for the DED and SSD fields to be displayed.

Response 14:

If you issue a QUERY DASD DETAILS command to a real device that supports Soft Fence and Query Host Access, the soft fence state, CPU serial number, and LPAR ID of the Host System accessing the device will be shown as follows:

```
q dasd details ae50
AE50 CUTYPE = 2107-E8, DEVTYPE = 3390-0A, VOLSER = ERF001, CYLS = 3339
CACHE DETAILS: CACHE NVS CFW DFW PINNED CONCOPY
-SUBSYSTEM Y Y Y - N N
-DEVICE Y - - Y N N
DEVICE DETAILS: CCA = 00, DDC = --, SS = 0, ACTIVE = Y, ESE = N
DUPLEX DETAILS: --
CU DETAILS: SSID = 040A, CUNUM = AE50
SERIAL NUMBER: 01XX-12345
FENCED STATE: NONE
HOST ACCESS: CPU PARTITION GROUPED RESERVED MPATHMODE
312E 15 Y N Y
-LOCAL E276 0D Y N Y
```

The soft fence state will be shown in the response only when the control unit supports the Soft Fence feature. The same applies to Host Access information; that is, whether Host Access information will be shown also depends on the control unit support.

The Host Access section of the response contains the following columns:

### CPU

indicates the CPU serial number.

### PARTITION

indicates the LPAR number.

### GROUPED

indicates the grouped state of the device.

### RESERVED

indicates if the device is reserved to the path group.

### MPATHMODE

indicates if the device is in multi-path mode.

Within the Host Access section, Y and N indicate the following status:

Column	Y	N
GROUPED	The device is grouped to one or more paths in the path group.	The device is not grouped to any path in the path group.
RESERVED	The device is reserved to this path group.	The device is not reserved to this path group.

Column	Y	N
MPATHMODE	The device is grouped in multi-path mode.	The device is in single path mode.

**Note:**

- The CPU serial number and LPAR number come from the CPU identifier of the first-level system used to form the real Path Group ID. They cannot be changed by the SET CPUID command used to change the CPU identifier of a virtual machine. The LPAR number matches the partition ID that can be found in the activation profile for an LPAR.
- Host Access information is obtained only for dedicated DASD and fullpack minidisks, and all of the status information in this response shows what is out on the real hardware. For example, RESERVED shows the real reserved state for the specified device, not the virtual reserve.

Response 15:

If you issue a QUERY DASD DETAILS command to a real device, but errors occur during the processing of Soft Fence and Query Host Access related I/O that prevents the successful completion of the command, the following response is displayed:

```
q dasd details 521d
AE50 CUTYPE = 2107-E8, DEVTYPE = 3390-0A, VOLSER = ERF001, CYLS = 3339
CACHE DETAILS:  CACHE NVS  CFW  DFW  PINNED  CONCOPY
  -SUBSYSTEM   Y    Y    Y    -    N    N
  -DEVICE      Y    -    -    Y    N    N
DEVICE DETAILS: CCA = 00, DDC = --, SS = 0, ACTIVE = Y, ESE = N
DUPLEX DETAILS: --
CU DETAILS: SSID = 040A, CUNUM = AE50
SERIAL NUMBER: 01XX-12345
FENCED STATE: I/O Error
HOST ACCESS: I/O Error
```

Response 16:

If you issue a QUERY DASD DETAILS command and the device is in HyperSwap processing, Soft Fence and Query Host Access related I/O will be suppressed and the following response will be issued:

```
q dasd details 521d
AE50 CUTYPE = 2107-E8, DEVTYPE = 3390-0A, VOLSER = ERF001, CYLS = 3339
CACHE DETAILS:  CACHE NVS  CFW  DFW  PINNED  CONCOPY
  -SUBSYSTEM   Y    Y    Y    -    N    N
  -DEVICE      Y    -    -    Y    N    N
DEVICE DETAILS: CCA = 00, DDC = --, SS = 0, ACTIVE = Y, ESE = N
DUPLEX DETAILS: --
CU DETAILS: SSID = 040A, CUNUM = AE50
SERIAL NUMBER: 01XX-12345
FENCED STATE: SUPPRESSED BY HYPERSWAP
HOST ACCESS: SUPPRESSED BY HYPERSWAP
```

Response 17:

If you issue a QUERY DASD DETAILS command but the user has option QUICKDSP set on, I/O for the Soft Fence and Query Host Access functions will not be issued and the response is displayed as follows:

```
q dasd details 521d
AE50 CUTYPE = 2107-E8, DEVTYPE = 3390-0A, VOLSER = ERF001, CYLS = 3339
CACHE DETAILS:  CACHE NVS  CFW  DFW  PINNED  CONCOPY
  -SUBSYSTEM   Y    Y    Y    -    N    N
  -DEVICE      Y    -    -    Y    N    N
DEVICE DETAILS: CCA = 00, DDC = --, SS = 0, ACTIVE = Y, ESE = N
DUPLEX DETAILS: --
CU DETAILS: SSID = 040A, CUNUM = AE50
FENCED STATE: QUICKDSP option set
HOST ACCESS: QUICKDSP option set
```

Response 18:

If you issue a QUERY DASD DETAILS command but the device is a HyperPAV alias device, the I/O needed for the Query Host Access function will not be issued and the response is displayed as follows:

## QUERY DASD

```
q dasd details 521d
AE50 CUTYPE = 2107-E8, DEVTYPE = 3390-0A, VOLSER = ERF001, CYLS = 3339
CACHE DETAILS:  CACHE NVS CFW DFW PINNED CONCOPY
  -SUBSYSTEM   Y   Y   Y   -   N   N
  -DEVICE      Y   -   -   Y   N   N
DEVICE DETAILS: CCA = 00, DDC = --, SS = 0, ACTIVE = Y, ESE = N
DUPLICATE DETAILS: --
CU DETAILS: SSID = 040A, CUNUM = AE50
SERIAL NUMBER: 01XX-12345
FENCED STATE: NONE
HOST ACCESS: --
```

Response 19:

If you issue a QUERY DASD CHARACTERISTICS command, the following response is displayed:

```
q dasd char 521d
- Begin - RDEV 521D - Read Configuration Data -
DC010100 F0F0F2F1 F0F7F9F0 F0C9C2D4 F7F5F0F0 F0F0F0F0 F0E8F5F8 F1F1071D

## QUERY DASDFW

### Authorization

Privilege Class: B

### Purpose

Use the QUERY DASDFW command to display the DASD fast write status of devices attached to cache storage subsystems.

### Operands

*rdev*

*rdev1-rdev2*

is the real device number, a list of real device numbers, or a range of real device numbers of the devices being queried.

### Usage Notes

1. The QUERY DASDFW command is only valid for cache storage subsystems that support the DASD fast write function. An error message is generated if the specified subsystem does not support this function.
2. Caching for RAID (Redundant Array of Independent Disks) technology DASD such as an IBM DASD subsystem is always active. It cannot be modified by the user.
3. This command may be issued to offline devices.

### Responses

Response 1:

```

rdev DASD fast write function {is active.           }
                             {is inactive.         }
                             {destaging has failed.}
                             {is suspended.       }
  
```

This response is repeated for each specified device when you enter the QUERY DASDFW command.

*rdev*

is the real device number of a device being queried.

**is active**

indicates that the DASD fast write function is active for the device.

**is inactive**

indicates that the DASD fast write function is inactive for the device.

**destaging has failed**

indicates that deactivation of DASD fast write is pending because transfer of modified data to DASD has failed.

### **is suspended**

indicates that the DASD fast write function is suspended for the device. Suspension occurs when an authorized guest issues the Perform Subsystem Function channel command to suspend all fast write operations.

### **Messages**

- HCP006E Invalid device type - {*rdev/vdev/ldev*}
- HCP009E Invalid range - *range*
- HCP020E Userid missing or invalid
- HCP021E A real device number was not supplied or it is invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP319E Error processing subsystem command - *cmd* for DASD *rdev*
- HCP332E Invalid control unit type - *rdev*

## QUERY DATEFORMAT

### Authorization

Privilege Class: G

### Purpose

Use QUERY DATEFORMAT to display the current default date format for the system or an individual user.

### Operands

#### USER

tells CP to display the default date format for this user.

#### SYSTEM

tells CP to display the default date format for the system.

### Usage Notes

1. If your user default date format is set to (or defaults to) the system-wide default date format, and the system-wide default is changed, the response to QUERY DATEFORMAT USER will continue to indicate the old system-wide default as your user default until you either log off and log back on or issue the SET DATEFORMAT SYSDEFAULT command to switch to the new system-wide default.

### Responses

Response 1:

If you issue QUERY DATEFORMAT USER, and your user default date format is set to SHORTDATE, FULLDATE, or ISODATE, you will get one of the following responses:

```
User Dateformat = SHORTDATE
```

```
User Dateformat = FULLDATE
```

```
User Dateformat = ISODATE
```

Response 2:

If you issue QUERY DATEFORMAT USER, and your user default date format is set to (or defaults to) the system-wide default, you will get one of the following responses:

```
User Dateformat = SHORTDATE (SYSDEFAULT)
```

```
User Dateformat = FULLDATE (SYSDEFAULT)
```

```
User Dateformat = ISODATE (SYSDEFAULT)
```

Response 3:

If you issue QUERY DATEFORMAT SYSTEM, you will get one of the following responses:

```
System Dateformat = SHORTDATE
```

## QUERY DATEFORMAT

System Dateformat = FULLDATE

System Dateformat = ISODATE

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - Invalid option - command contains extra option(s) starting with *option*

## QUERY DEVICES

### Authorization

Privilege Class: B

### Purpose

Use the QUERY DEVICES command to display the settings that CP will use if a device is added dynamically to the I/O configuration or is powered on after IPL.

### Operands

#### *rdev*

is the device number of a real device.

#### *rdev1-rdev2*

is a range of real device numbers.

### Usage notes

- Device numbers in the range 0000-FFFF are valid.
- The same settings are used for a device number in all subchannel sets. For example, the settings for device number 1234 are also used for device numbers 11234, 21234, and 31234.
- The initial settings are established by the DEVICES statement in the system configuration file. After IPL, you can change the settings by using the SET DEVICES and SET RDEVICE commands. Those commands affect CP's handling of a new device only when the commands are issued at the following times:
  - Before a device is detected due to a dynamic I/O change that adds the device to the LPAR.
  - Before you power on a device that was unavailable at IPL.

The SET DEVICES command can change the settings that the QUERY DEVICES command displays. When the SET RDEVICE command is issued for a device after the device is initialized, the setting does not affect the settings that the QUERY DEVICES command displays.

- After a device is initialized, you can change some of its settings by using the SET RDEVICE, SET SCMEASURED, and SET THROTTLE commands. The changes are not displayed by QUERY DEVICES and do not affect the settings that CP will use if a device is added dynamically to the I/O configuration or is powered on after IPL.

### Examples

Example 1:

To find out how CP handles device 2345 and devices in range 3401-3420, enter the following command:

```
query devices 2345 3401-3420
```

If the command is successful, you get a response that is like the following example:

## QUERY DEVICES

Device(s)	Accepted	Online at IPL	Sensed	Sensed /Offln	Shared	Dynam I/O	SubCh Meas	Throttled	Assign at IPL
2345	Y	N	Y	N	Y	Y	Y	Y	N
3401-3410	Y	Y	Y	N	N	N	Y	Y	Y
3411-3420	Y	Y	Y	N	N	N	Y	N	Y

### Responses

The response line follows the headings line and is repeated for each device number or range of device numbers that have the same settings. The response line indicates Y (yes) or N (no) for each setting. The response reports the following settings:

#### Accepted

indicates whether CP accepts the device when the device is dynamically added to VM from another partition.

#### Online at IPL

indicates whether CP initializes a device.

#### Sensed

indicates whether CP uses the information that is associated with a sense ID request to establish the device class or type.

#### Sensed /Offln

indicates whether CP does not initialize the device but still issues a sense ID request to determine the device class and type.

#### Shared

indicates whether CP can share the DASD device with other operating systems.

#### Dynam I/O

indicates whether CP allows dynamic I/O changes for the device.

#### SubCh Meas

indicates whether CP collects subchannel measurement data for the device.

#### Throttled

indicates whether CP limits (throttles) the rate of I/O coming from the device.

#### Assign at IPL

indicates whether CP assigns the tape drive device to the system when the device is brought online.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*

- HCP6709E Too many items specified - *item*

## QUERY DIAGNOSE

### Authorization

Privilege Class: A, C, E

### Purpose

Use QUERY DIAGNOSE to display information (status, entry point names, and privilege classes) about one or more DIAGNOSE codes.

### Operands

#### ALL

tells CP to display information about all existing DIAGNOSE codes.

#### *diag*

#### *diag1-dia2*

is the number of the DIAGNOSE code for which you want information. Each *diag* must be a hexadecimal number between X'0000' and X'03FC'. You can specify a single DIAGNOSE code, a range of DIAGNOSE codes, or any combination thereof.

### Usage Notes

1. If you do not specify the ENABLE operand on the DEFINE DIAGNOSE command, a new DIAGNOSE code is initially in a disabled state after being defined. CP treats disabled DIAGNOSE codes as if they were never defined. If you try to use a disabled DIAGNOSE code in a program, CP will give you a program check specification exception.
2. To activate a new DIAGNOSE code:
  - While defining it, use the ENABLE operand of the DEFINE DIAGNOSE command (see [“DEFINE DIAGNOSE”](#) on page 172).
  - After defining it, use the ENABLE DIAGNOSE command (see [“ENABLE DIAGNOSE”](#) on page 463).
3. To change the definition of an existing DIAGNOSE code after initialization, use the MODIFY DIAGNOSE command (see [“MODIFY DIAGNOSE”](#) on page 697).
4. To display the address of the CP DIAGNOSE code table block for a DIAGNOSE code, use the LOCATE DGNBK command (see [“LOCATE DGNBK”](#) on page 608).
5. To deactivate a DIAGNOSE code:
  - While defining it, use the DISABLE operand of the DEFINE DIAGNOSE command (see [“DEFINE DIAGNOSE”](#) on page 172).
  - After defining it, use the DISABLE DIAGNOSE command (see [“DISABLE DIAGNOSE”](#) on page 316).
6. Many external security managers (ESMs) do not support DIAGNOSE codes above X'03FC'. For this reason, CP does not support DIAGNOSE codes above X'03FC'. The DIAGNOSE codes between X'0000' and X'03FC' are divided as follows:

## QUERY DIAGNOSE

### **X'0000' to X'00FC'**

Reserved for IBM use

### **X'0100' to X'01FC'**

Reserved for customer use

### **X'0200' to X'03FC'**

Reserved for IBM use.

7. For more information about user-defined DIAGNOSE codes, see [Defining and Modifying Commands and Diagnose Codes](#) in *z/VM: CP Exit Customization*.

## Responses

Response 1:

To display the current information for DIAGNOSE code X'28' and DIAGNOSE codes X'30' through X'3C', enter the following:

```
query diagnose 28 30-3f
Code Status EPName PrivClasses
0028 Enabled HCPDCHNM <ANY>
0034 Enabled HCPHVC34 CE
003C Enabled HCPUDDS ABC
Ready;
```

This response tells us that DIAGNOSE codes X'28', X'34', and X'3C' are enabled and that DIAGNOSE codes X'30' and X'38' are not defined.

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP021E A Diagnose code was not supplied or it is not valid
- HCP2751E Diagnose code *diag* does not exist.
- HCP2751E Diagnose codes *diag1-dia2* do not exist.
- HCP6706E Invalid Diagnose code - *diag*

# QUERY DUMP

► Query — DUMP ◄

## Authorization

Privilege Class: B

## Purpose

Use QUERY DUMP to display the following:

- The device type and unit or units assigned to receive CP abnormal termination dumps
- The current settings of the DUMP options.

## Usage Notes

1. For DASD only, if you have identified more than one device to receive CP dumps or CP has obtained DASD dump space from more than one device during system initialization and operation, CP responds with the device type DASD, the real device numbers, and the pages allocated from each.
2. If the system was unable to find sufficient SPOOL space, it responds with 'No dump unit'. 'No dump unit' indicates that, at the time CP is ready to create the dump, no dump will be created. CP will still create a symptom record to log the occurrence of the event.

## Responses

Response 1:

When one CP-owned DASD has been assigned with system abend dump space, the response is as follows:

```
{type rdev} dump unit CP {IPL } [pages nnnnnnnn] PGMBKS {DEFAULT } FRMTBL {DEFAULT}
                    {NOIPL}                    {ALL } {YES }
                    {NONE }                    {NO }
                    {FAILUSER}
```

### **type rdev**

indicates the device type and the real device number of the dump device.

### **CP**

is included for compatibility purposes.

### **IPL**

### **NOIPL**

indicates whether the system automatically restarts when the dump is completed. NOIPL indicates that the system enters a wait state upon completion of the dump.

### **pages nnnnnnnn**

indicates the number of pages of spool space, by device, allocated for system dumps. *nnnnnnnn* is a 1-to 8-digit decimal number.

### **FRMTBL DEFAULT|YES|NO**

indicates whether the full CP frame table is included in a hard abend dump. If DEFAULT is displayed, the frame table is included in the cases for which IBM believes the frame table is needed to debug the problem. Otherwise, the dump includes a correlation table describing only the frames whose contents were dumped. YES forces inclusion of the frame table and NO forces the dump to have a correlation table. IBM recommends using the DEFAULT setting unless IBM support personnel instruct you to do otherwise in order to diagnose a specific problem.

**PGMBKs DEFAULT|ALL|NONE|FAILUSER**

indicates whether user PGMBKs are included in a hard abend dump. If DEFAULT is displayed, PGMBKs are included in the cases for which IBM believes they are needed to debug the problem. ALL forces inclusion of all PGMBKs that aren't paged out, and NONE omits user PGMBKs. FAILUSER causes:

- PGMBKs to be included for the guest that was running on the failing processor at the time of the abend.
- PGMBKs owned by the system to be included.

IBM recommends using the DEFAULT setting unless IBM support personnel instruct you to do otherwise in order to diagnose a specific problem.

The frame table and PGMBKs together constitute the vast majority of CP-owned frames, because they contain entries describing each 4K unit of real and virtual memory, respectively. The CP frame table is 1/128th the size of configured memory (8 GB per TB). PGMBKs take up 8K for each 1MB of virtual memory; though they are pageable, a PGMBK must remain resident as long as any page of that megabyte is resident. Omitting these structures from dumps when they are not likely to be needed for diagnosis dramatically reduces dump size and dumping time. With the DEFAULT operand, CP determines whether or not to include the structures based on the abend code and failing module.

Response 2:

When more than one CP-owned DASD has been assigned with system abend dump space, the response is as follows:

Line 1:

```
DASD DUMP SPACE  {CP }  {IPL } PGMBKs {DEFAULT } FRMTBL {DEFAULT}
                  {NOIPL}  {ALL }  {YES }
                  {NONE }  {NO  }
                  {FAILUSER}
```

Lines 2 and 3:

```
RDEV  PAGES
----  -
```

Lines 4 and following:

```
rdev  nnnnnnnnn
:
```

CP, IPL/NOIPL, PGMBKs, and FRMTBL are all explained under Response 1.

Response 3:

When the SET DUMP OFF command has been issued and accepted, the response is:

```
No dump unit - dump function is SET OFF
```

Response 4:

```
No dump unit - insufficient spool space
```

indicates that the system was unable to find sufficient spool space for a system abend dump on CP-owned system DASD at system initialization or after a non-destructive dump (snapdump). This means that at the time CP is ready to create the dump, no dump will be created. In this situation, CP will just create a symptom record when the dump would have occurred.

The system operator should re-issue the SET DUMP command. If a DASD dump is desired, create enough empty spool space to enable the dump to be allocated.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP9259I No dump unit is set. No system abend dump will be generated. To assign a device, enter the SET DUMP command.

## QUERY DUMPDEV

### Authorization

Privilege Class: G

### Purpose

Use the **QUERY DUMPDEV** command to display DUMPDEV parameters for a guest IPL. The parameters are for a list-directed IPL with dump from a SCSI or ECKD device. The parameters can identify the system dumper program and information to pass to the program. The parameters can also identify the virtual device number and specify whether the IPL is a secure IPL. The device that is IPLed is also used to store the dump data.

The DUMPDEV parameters can be set by using the **SET DUMPDEV** command.

For more information, see [SET DUMPDEV](#) in *z/VM: CP Commands and Utilities Reference*.

### Responses

The following lines are displayed if DUMPDEV parameters are set for a SCSI device:

```
SCSI      DEVICE {TBD } {NOSECURE}
           {ddd} {SECURE }
PORTNAME hhhhhhhh hhhhhhhh LUN hhhhhhhh hhhhhhhh BOOTPROG {n }
           {AUTO}
BR_LBA   hhhhhhhh hhhhhhhh
```

The following lines are displayed if DUMPDEV parameters are set for an ECKD device:

```
ECKD      DEVICE {TBD } {NOSECURE}
           {ddd} {SECURE }
BOOTPROG {n } BOOTREC {cylinder head record}
           {AUTO} {LABEL }
```

The following lines are displayed if hex SCPDATA is set:

```
SCPDATA
 00----03 04----07 08----11 12----15 16----19
0000 hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh
0020 hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh
0040 hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh
.
.
```

The following lines are displayed if text SCPDATA is set:

```
SCPDATA
 0-----+----1-----+----2-----+----3-----+----4-----+----
0000 ttttttttttttttttttttttttttttttttttttttttttttttttttttttttttttttt
0050 ttttttttttttttttttttttttttttttttttttttttttttttttttttttttttttttt
0100 ttttttttttttttttttttttttttttttttttttttttttttttttttttttttttttttt
.
.
```

**SCSI**

The SCSI response indicates that DUMPDEV parameters are set for the IPL of a SCSI device. SCSI is the default device type.

**ECKD**

The ECKD response indicates that DUMPDEV parameters are set for the IPL of an ECKD device.

**DEVICE TBD****DEVICE *dddd***

The DEVICE TBD response indicates that the DUMPDEV parameters do not include the device number. The device number is to be specified later.

If the SECURE parameter is not set, then the device number can be specified later as an operand of the **IPL** command. If the SECURE parameter is set, then the device number must be set by using the **SET DUMPDEV** command.

The DEVICE *dddd* response indicates the 4-digit hexadecimal virtual device number (*dddd*) of the device to be IPLed.

There is no default value for the DEVICE parameter.

**PORTNAME *hhhhhhhh hhhhhhhh***

The PORTNAME response indicates the hexadecimal 8-byte fibre channel port name of the SCSI device. The default value is 0.

**LUN *hhhhhhhh hhhhhhhh***

The LUN response indicates the hexadecimal 8-byte logical unit number of the SCSI device. The default value is 0.

**BOOTPROG *n*****BOOTPROG AUTO**

The BOOTPROG response indicates the boot program that is loaded from the IPL device. The *n* value indicates the program number. The program number must be a decimal value in the range 0 - 30. The BOOTPROG AUTO response indicates that the first dump program (not operating system) on the IPL device is loaded. The default value is BOOTPROG 0.

**BR\_LBA *hhhhhhhh hhhhhhhh***

The BR\_LBA response indicates the hexadecimal logical-block address of the boot record of the SCSI device. The default value is 0.

**BOOTREC *cylinder head record*****BOOTREC LABEL**

The BOOTREC response indicates the location of the boot record. The location can be a specification of cylinder, head, and record on the IPL device. The values are delimited by blanks and contain no leading zeros. The values must be in hexadecimal format.

A BOOTREC LABEL response indicates that the location of the boot record is determined from the volume label. BOOTREC LABEL is the default setting.

**SECURE****NOSECURE**

The SECURE response indicates that the SECURE parameter is set. The NOSECURE response indicates that the SECURE parameter is not set. The SECURE parameter must be set before you can initiate a secure IPL. NOSECURE is the default setting.

**SCPDATA**

The SCPDATA response indicates the information that is passed to the IPL program. The information is displayed in the same format (text or hex) as it was entered.

**Usage Notes**

- Parameters for a list-directed IPL without dump (also called LOADDEV parameters) are set by using any of the following methods:
  - **SET LOADDEV** command.

## QUERY DUMPDEV

- LOADDEV user directory statement. The LOADDEV user directory statement can be modified by a directory management tool such as IBM Directory Maintenance (DirMaint). To set load parameters by using DirMaint, use the **DIRM LOADDEV** command. The LOADDEV user directory statement can be modified also by the `Image_IPL_Characteristics_Define_DM` API function.

Parameters for a list-directed IPL **with** dump (also called DUMPDEV parameters) are set by using the CP **SET DUMPDEV** command.

For more information, see [SET LOADDEV](#) and [SET DUMPDEV, LOADDEV Directory Statement](#) in *z/VM: CP Planning and Administration*, [DIRM LOADDEV](#) in *z/VM: Directory Maintenance Facility Commands Reference*, and [Image\\_IPL\\_Characteristics\\_Define\\_DM](#) API function in *z/VM: Systems Management Application Programming*.

2. If a DUMPDEV parameter is not set and has a default value, then the **QUERY DUMPDEV** response displays the default parameter value.
3. The default LOADDEV and DUMPDEV values for the PORTNAME and LUN parameters is 0, which is not a valid device port name and not a valid device LUN. An IPL attempt that uses the default value for the PORTNAME or LUN parameter will fail.

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP2824I No DUMPDEV parameters are currently defined

## QUERY DUPLEX

### Authorization

Privilege Class: B

### Purpose

Use the QUERY DUPLEX command to display the status of duplex pairs of devices attached to the 3990-3 and 3990-6 storage subsystem.

### Operands

**rdev**

**rdev1-rdev2**

is the real device number, a list of real device numbers, or a range of real device numbers of the primary or secondary volumes in the established duplex pairs.

### Usage Notes

1. The device number of either the primary or secondary volume in a duplex pair may be specified on this command.
2. This command may be issued to offline devices.
3. If both the primary and secondary of a duplex pair are included in the device list or device range, two identical responses will be displayed.
4. A VIRTUAL version of this command, QUERY VIRTUAL DUPLEX, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL DUPLEX”](#) on page 1295.

### Responses

Response 1:

```
Duplex pair (prdev,srdev) - active
```

This response is displayed for each duplex pair that is not in suspended duplex state and for which synchronization is not in progress.

When CP is running in a guest virtual machine, hyphens (----) will appear in the *srdev* position if the secondary volume is not in the guest's CP I/O configuration.

**prdev**

is the real device number of the primary volume in the duplex pair.

**srdev**

is the real device number of the secondary volume in the duplex pair.

Response 2:

## QUERY DUPLEX

```
Duplex pair (prdev,srdev) - copy operation  
is in progress.
```

This response is displayed for each duplex pair that is in the process of being synchronized.

When CP is running in a guest virtual machine, hyphens (----) will appear in the *srdev* position if the secondary volume is not in the guest's CP I/O configuration.

### ***prdev***

is the real device number of the primary volume in the duplex pair.

### ***srdev***

is the real device number of the secondary volume in the duplex pair.

Response 3:

```
Duplex pair (prdev,srdev) - suspended
```

This response is displayed for each duplex pair that is in the *suspended duplex* state. Either the primary or the secondary volume has been suspended.

When CP is running in a guest virtual machine, hyphens (----) will appear in the *srdev* position if the secondary volume is not in the guest's CP I/O configuration.

### ***prdev***

is the real device number of the primary volume in the duplex pair.

### ***srdev***

is the real device number of the secondary volume in the duplex pair.

Response 4:

```
rdev The associated {primary|secondary}  
volume in the duplex pair is not online to VM.
```

This response is displayed when the device number of the primary or secondary volume is specified on the command and the device number of the other duplex volume cannot be located.

### ***rdev***

is the real device number of the primary or secondary volume in the duplex pair.

## Messages

- HCP006E Invalid device type - {*rdev/vdev/ldev*}
- HCP009E Invalid range - *range*
- HCP021E A real device number was not supplied or it is invalid.

- HCP1110E Device {*rdev/vdev*} is not in a duplex pair.

## QUERY DYNAMIC\_I/O

### Authorization

Privilege Class: B, E

### Purpose

Use QUERY DYNAMIC\_I/O or QUERY DYNAMIC\_IO to display:

- Whether the processor on which z/VM is running can perform dynamic I/O configuration of the channel subsystem, and if so, whether dynamic I/O changes are currently allowed.
- The approximate number of subchannels, control units, and devices you can dynamically add to your system before running out of hardware system area (HSA) space.

### Operands

#### STATus

tells CP to display whether the dynamic I/O support is installed on your processor, and if so, whether the dynamic I/O support is enabled on your z/VM system. If omitted, STATUS is the default.

#### STORAge

tells CP to display the approximate number of subchannels, control units, and devices you can dynamically add to your system before running out of hardware system area (HSA) space.

### Usage Notes

1. For more information about displaying status or storage information for dynamic I/O changes, see [Using Dynamic I/O Configuration in z/VM: I/O Configuration](#).
2. To enable or disable all dynamic I/O changes on your system:
  - After initialization, use the SET DYNAMIC\_I/O command (see [“SET DYNAMIC\\_I/O” on page 1502](#)).
  - During initialization, use the ENABLE or DISABLE DYNAMIC\_I/O operands of the FEATURES statement in your system configuration file. For more information about the [FEATURES Statement](#), see [z/VM: CP Planning and Administration](#).
3. To prevent anyone from issuing SET DYNAMIC\_I/O commands after initialization, use the ENABLE or DISABLE SET\_DYNAMIC\_I/O operands of the FEATURES statement in your system configuration file. For more information about the FEATURES statement, see the [FEATURES Statement in z/VM: CP Planning and Administration](#).
4. To enable or disable dynamic I/O changes for specific devices on your system:
  - After initialization, use the SET DEVICES command (see [“SET DEVICES” on page 1490](#)).
  - During initialization, use the DYNAMIC\_I/O or NOTDYNAMIC\_I/O operands of the DEVICES statement in your system configuration file. For more information about the [DEVICES Statement](#), see [z/VM: CP Planning and Administration](#).
5. To prevent anyone from issuing SET DEVICES commands after initialization, use the ENABLE or DISABLE SET\_DEVICES operands of the FEATURES statement in your system configuration file. For more information about the FEATURES statement, see the [FEATURES Statement in z/VM: CP Planning and Administration](#).

## Responses

Response 1 (Installed, Enabled):

If someone installed and enabled dynamic I/O support on your processor, you would see:

```
query dynamic_i/o status
Dynamic I/O changes are allowed on this system.
Ready;
```

Response 2 (Installed, Not Enabled):

If someone installed dynamic I/O support on your processor, but did not enable that support, you would see:

```
query dynamic_i/o status
No dynamic I/O changes are allowed on this system.
Ready;
```

Response 3 (Not Installed):

If no one installed dynamic I/O support on your processor, you would see:

```
query dynamic_i/o status
Dynamic I/O configuration is not supported.
Ready;
```

Response 4 (Installed, Enabled, Not Valid):

If someone installed and enabled dynamic I/O support on your processor, but your existing I/O configuration is not valid, you would see:

```
query dynamic_i/o status
Dynamic I/O changes are allowed but the configuration is invalid.
Ready;
```

When your system enters configuration mode (either explicitly, by entering the SET CONFIGMODE ON command, or automatically, by entering a dynamic I/O command), CP turns the "valid bit" off in the channel subsystem. If your dynamic I/O changes complete successfully, CP turns the valid bit back on before exiting configuration mode.

If one of the following events occur while you are in configuration mode:

- The system abends,
- You issue a LOGOFF command,
- You issue a SHUTDOWN REIPL command,
- You issue a CLEAR RESET from the hardware console, or
- You issue a LOAD CLEAR from the hardware console,

Your z/VM system or your hardware takes you out of configuration mode before shutting down the system, but they do not turn the valid bit back on. Thus, if you are interrupted while making dynamic I/O changes, your I/O configuration is not valid. To correct this situation, use the RESET operand of the SET CONFIGMODE command (see [“SET CONFIGMODE”](#) on page 1436).

If the system loses power while you are in configuration mode, your configuration will be valid when you bring it back up, because you choose which I/O configuration data set (IOCDs) file to use before performing the initial machine load (IML) or power-on reset (POR) to bring your system up.

Response 5 (Installed, Not Enabled, Not Valid):

If someone did not enable dynamic I/O support on your processor, and your existing I/O configuration is not valid, you would see:

```
query dynamic_i/o status
No dynamic I/O changes are allowed and the configuration is invalid.
Ready;
```

#### Response 6 (Non-LCSS System):

To display the number of subchannels, control units, and devices you can dynamically add to your system when there is no logical channel-subsystem facility installed, enter the following:

```
query dynamic_i/o storage
Remaining channel subsystem resources for configuration changes:
Number of subchannels for unshared paths: 649
Number of control units: 42
Number of unshared channel paths: 25
Number of subchannels for shared paths: 72
Number of shared channel paths: 3
Ready;
```

This response tells you that you can add a maximum of 649 subchannels on channel paths that are not shared, 72 subchannels on channel paths that are shared, 42 control units, 25 channel paths that are not shared, and 3 channel paths that are shared.

#### Response 7 (LCSS System):

To display the number of subchannels, control units, and devices you can dynamically add to your system when the logical channel-subsystem facility is installed, enter the following:

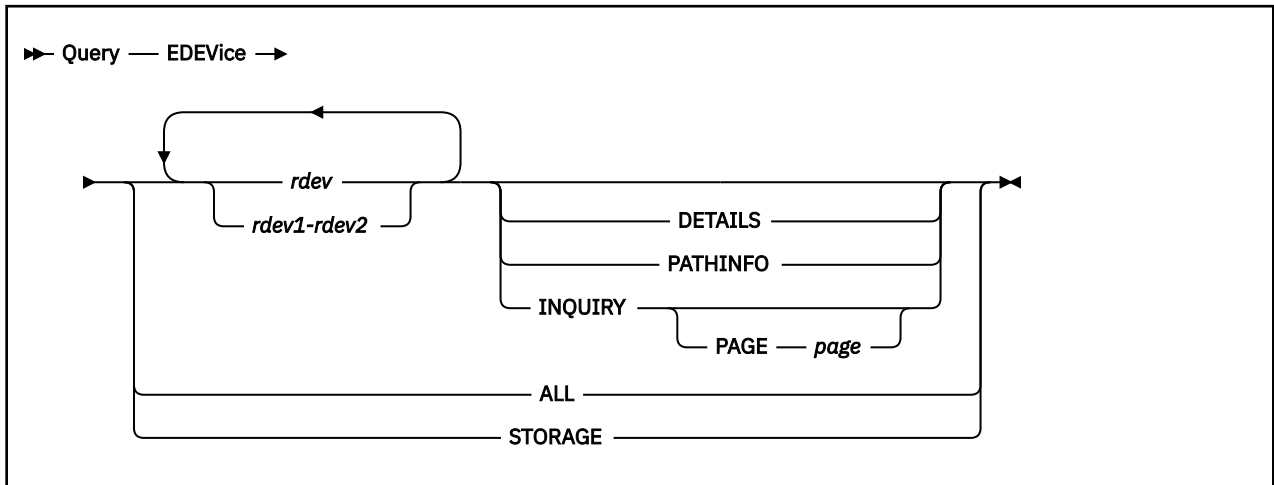

```
query dynamic_i/o storage
Remaining channel subsystem resources for configuration changes:
Number of control units: 63
Number of subchannel elements for CSS 0: 121
Number of channel paths for CSS 0: 13
Number of subchannel elements for CSS 1: 241
Number of channel paths for CSS 1: 21
Number of subchannel elements for CSS 2: 332
Number of channel paths for CSS 2: 32
Ready;
```

This example assumes 3 channel-subsystem images and the response tells you that you can add a maximum of 63 control units, 121 subchannels on CSS 0, 13 channel paths on CSS 0, 241 subchannels on CSS 1, 21 channel paths on CSS 1, 332 subchannels on CSS 2, and 32 channel paths on CSS 2.

## Messages

- HCP002E Invalid operand - *operand*

## QUERY EDEVICE

### Authorization

Privilege Class: B

### Purpose

Use QUERY EDEVICE to display the device type and other detailed information associated with an emulated device.

### Operands

**rdev**

**rdev1-rdev2**

specifies the emulated devices for which you want information to be displayed. An *rdev* in the active configuration can be entered as a 4-digit hexadecimal device number between X'0000' and X'FFFF'. For an *rdev* in the active or standby configuration, the device number can be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set of the device for which you want information to be displayed. A range of devices cannot span subchannel sets.

**DETAILS**

displays detailed information associated with an emulated device.

**ALL**

displays information for all emulated devices in the active configuration, but does not include the information that is displayed with the DETAILS operand.

**PATHINFO**

displays information associated with individual path activity.

**INQUIRY**

displays information from the standard inquiry page of the LUN associated with the emulated device.

The data returned by the INQUIRY option is in hexadecimal format. The IOEXPLOR EXEC can be used as an alternative in order to receive formatted data.

For further details on the information contained in the output, consult your storage hardware vendor.

**PAGE *page***

displays information from the specified vital product data page of the device. The *page* operand must be a hexadecimal page number between X'00' and X'FF'.

**STORAGE**

displays information for the pools of storage used by emulated devices, instead of the configuration of specific emulated devices. This operand will provide (in bytes) the configured size, amount used, and maximum amount used of each pool. It will also include the number of allocation and release requests that were satisfied by the pools.

**Usage Notes**

1. For queries that contain device numbers that represent emulated and non-emulated devices, responses will be generated only for emulated devices.
2. If you query an emulated device that was cleared with the SET EDEVICE command, the response will indicate that the device is still an emulated device, but no other information is associated with it.
3. Detailed information for emulated devices associated with 1750 and 2145 attributes includes an indication for each path specifying whether the path is a preferred (PREF) path or a not-preferred path (NOTPREF).
4. Some of the detailed information will be displayed only after the device is varied online successfully. If you do the QUERY EDEVICE DETAILS before the VARY ON or after a VARY OFFLINE, fewer details will be displayed.
5. The majority of the extra details information is obtained at VARY ON time, not when you issue the QUERY EDEVICE DETAILS command.
6. The maximum length of the inquiry response data display is 255 bytes.
7. An NVMe EDEVICE might indicate that it is not operational by displaying Int Req following the device attributes. The message indicates that intervention is required because there is a problem with the underlying NVMe PCI function. For example, the NVMe PCI function might have been removed from the configuration. To recover, the EDEVICES that are associated with the NVMe function must be deleted and redefined.

**Responses**

Response 1:

To query the emulated devices in the device range 300-305, enter the following:

```
q edev 300-305
EDEV 0300 TYPE FBA ATTRIBUTES 2105
EDEV 0301 TYPE FBA ATTRIBUTES SCSI
EDEV 0302 TYPE FBA ATTRIBUTES 2107
EDEV 0303 TYPE FBA ATTRIBUTES 1750
EDEV 0304 TYPE FBA ATTRIBUTES FLASH
EDEV 0305 TYPE FBA ATTRIBUTES NVM
Ready;
```

**Note:** Devices in the range that are not emulated devices do not appear in the response.

Response 2:

If none of the devices specified on the command are emulated devices, the following response will be displayed:

```
q edev 306-310
None of the devices specified are emulated devices.
Ready;
```

Response 3:

To query detailed information about an emulated device, for example, device 1111, enter the following:

```
q edev 1111 details
EDEV 1111 TYPE FBA ATTRIBUTES 2105
VENDOR: IBM          PRODUCT: 2105F20          REVISION: .293
BLOCKSIZE:          512  NUMBER OF BLOCKS: 390656
PATHS:
FCP_DEV: B908  WWPN: 5005076300CD04DA  LUN: 5144000000000000
```

## QUERY EDEVICE

```
CONNECTION TYPE: POINT_TO_POINT STATUS: ONLINE
EQID: ABCDEFGH
SERIAL NUMBER: 2146561344562
```

This response shows one possible value for STATUS: ONLINE. The other possible values are OFFLINE and RECOVERY. RECOVERY indicates that the system is undergoing error recovery and should return to ONLINE status soon.

Response 4:

To query detailed information about emulated devices in the device range 800-801, 850, and 888, enter the following:

```
q edev 800-801 details
EDEV 0800 TYPE FBA ATTRIBUTES 2105
VENDOR: IBM      PRODUCT: 2105F20      REVISION: .293
BLOCKSIZE:      512  NUMBER OF BLOCKS: 390656
PATHS:
  FCP_DEV: B046 WWPN: 5005076300C904DA LUN: 513A000000000000
  CONNECTION TYPE: SWITCHED STATUS: ONLINE
  FCP_DEV: B906 WWPN: 5005076300C904DA LUN: 513A000000000000
  CONNECTION TYPE: SWITCHED STATUS: ONLINE
EQID: IBM000002105000000000000000144132F6F200000000000000000
SERIAL NUMBER: 00112233445566
EDEV 0801 TYPE FBA ATTRIBUTES 2105
PATHS:
  FCP_DEV: B046 WWPN: 5005076300C904DA LUN: 513B00000000000000
EQID: ABCDEFGH

q edev 850 details
EDEV 0850 TYPE FBA ATTRIBUTES 1750
VENDOR: IBM      PRODUCT: 1750500      REVISION: 1.67
BLOCKSIZE:      512  NUMBER OF BLOCKS: 65536
PATHS:
  FCP_DEV: 2406 WWPN: 500507630E85FC66 LUN: 4010401200000000 NOTPREF
  CONNECTION TYPE: SWITCHED STATUS: ONLINE
  FCP_DEV: 2406 WWPN: 505507630E05FC66 LUN: 4010401200000000 PREF
  CONNECTION TYPE: SWITCHED STATUS: ONLINE
EQID: IBM000002105000000000000000144235F6F20000000000000FFFF
SERIAL NUMBER: 11223344556677

q edev 888 details
EDEV 0888 TYPE FBA ATTRIBUTES 2145
VENDOR: IBM      PRODUCT: 2145      REVISION: 0000
BLOCKSIZE:      512  NUMBER OF BLOCKS: 10485760
PATHS:
  FCP_DEV: 2FCB WWPN: 5005076801402797 LUN: 000E000000000000 NOT PREF
  CONNECTION TYPE: SWITCHED STATUS: ONLINE
  FCP_DEV: 2FCB WWPN: 5005076801402991 LUN: 000E000000000000 PREF
  CONNECTION TYPE: SWITCHED STATUS: ONLINE
EQID: IBM000002105000000000000000141462F6F20000000000000BB00
SERIAL NUMBER: 11223344556677
```

Note that the 801 device does not list much detail because it is not varied online.

Response 5:

To query detailed information about emulated device 500 (which has been cleared using the SET EDEVICE command), enter the following:

```
q edev 500 details
EDEV 0500 TYPE UNK
Ready;
```

Response 6:

If you enter QUERY EDEVICE DETAILS and the emulated device has been expanded and has not yet been varied offline and online to make use of the expanded space, you see the following line in the response:

```
PENDING EXPANSION NUMBER OF BLOCKS: 148493740
```

The blocks are the new size which will be used by CP once the device is varied offline and online.

Response 7:

To query information about the pools of reserved storage that are used for the configuration of emulated devices, enter the following:

```
q edev storage
```

	Size	Used	Maximum	Allocations		Releases	
				Total	Failed	Total	Failed
Primary:	122880	20928	21024	66	0	0	0
Secondary:	6524928	0	0	0	0	0	0

Ready; T=0.01/0.01 15:06:03

Response 8:

To query whether a real device at address 7F00 has an equivalency ID (EQID) assigned to it, enter the following:

```
q edev 7f00 details
```

```
11:58:21 EDEV 7F00 TYPE FBA ATTRIBUTES FLASH
11:58:21 VENDOR: IBM PRODUCT: FlashSystem-9840 REVISION: 1136
11:58:21 BLOCKSIZE: 512 NUMBER OF BLOCKS: 20971520
11:58:21 PATHS:
11:58:21 FCP_DEV: 1741 WWPN: 500507605E819CC1 LUN: 0000000000000000
11:58:21 CONNECTION TYPE: SWITCHED STATUS: ONLINE
11:58:21 EQID: 00020E662C220E6-0000-0201-0005F8C500000000013FFFFFF
11:58:21 SERIAL NUMBER: 20e662c220e6-0000-0166-0001a2
Ready; T=0.01/0.01 11:58:21
```

Response 9:

To query the standard inquiry page of the SCSI LUN backing an emulated device, enter the following:

```
q edev 111 inquiry
- Begin - EDEV 0111 - Standard Inquiry Page -
00000532 9F101002 49424D20 20202020 32313037 39303020 20202020 20202020
2E323034 37353034 31393131 34303020 20202020 20202020 00600DA0 0A000300
03200000 00000000 00000000 00000000 00000000 00000000 00000000 00000000
00323037 35003236 34303400 00000000 00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000
00080000
- End - EDEV 0111 - Standard Inquiry Page -
```

Response 10:

To query the vital product data page 83 of the SCSI LUN backing an emulated device, enter the following:

```
q edev 111 inquiry page 83
- Begin - EDEV 0111 - Vital Product Data Page 83 -
00830024 01030010 60050763 03FFC09C 00000000 00001400 01140004 00000032
01150004 00000000
- End - EDEV 0111 - Vital Product Data Page 83 -
```

Response 11:

To query information associated with path activity on an emulated device, enter the following:

```
query edev 400 pathinfo
EDEV 0400 TYPE FBA ATTRIBUTES 2107 ALUA SUPPORTED: YES
PATHS:
FCP_DEV: 1D1D WWPN: 5005076306081588
LUN: 4064401600000000 ALUA OPTIMIZED: NO
SELECTED: 43
ADAPTER ERRORS: 1
SOFTWARE: 0
HARDWARE: 0
TRANSPORT: 1
OTHER: 0
TIMEOUT ERRORS: 0
SCSI ERRORS: 8
RESERVATION: 0
QUEUE FULL: 0
DEVICE BUSY: 4
```

## QUERY EDEVICE

```
ACA ACTIVE: 1
ABORT TASK: 0
CHECK CONDITIONS: 3
  MEDIUM: 0
  HARDWARE: 0
  NOT READY: 1
  ABORTED: 0
  OTHER: 2
LAST ERROR TIME: Apr 30 2020 08:57:00
LAST ERROR TYPE: SCSI DEVICE BUSY
LAST FAILURE TIME: Apr 30 2020 08:57:00
LAST FAILURE REASON: DIAG
```

The response for QUERY EDEVICE PATHINFO differs from QUERY EDEVICE DETAILS in that path info displays the ALUA state of the specified path. ALUA SUPPORTED can be YES, NO, or UNKNOWN, if the emulated device has yet to perform a discovery on the status.

This response also displays the number and type of errors that have occurred on the paths recently, as well as the time of the most recent error type.

If the error is an adapter error, the following types may be displayed:

### **ADAPTER SOFTWARE**

failure in the adapter microcode

### **ADAPTER HARDWARE**

failure in the adapter hardware

### **TRANSPORT DEAD**

failure in accessing the link

### **OTHER ADAPTER**

another adapter failure; for example, busy link, login failure, etc.

If the error is a SCSI command error, the type of error is listed:

- SCSI RESERVATION
- SCSI QUEUE FULL
- SCSI DEVICE BUSY
- SCSI ACA ACTIVE
- SCSI ABORT TASK
- MEDIUM CHECK COND
- HARDWARE CHECK COND
- NOT READY CHECK COND
- ABORTED CHECK COND
- OTHER CHECK COND

If the device becomes unresponsive, the error displayed is TIMEOUT ERROR.

Below the error type, the time of the most recent failure is also displayed, along with the reason for failure:

### **NONE**

No failures have occurred on this path since the last reset.

### **INIT**

The last failure occurred on this path during initialization.

### **DIAG**

The last failure occurred on this path during self-diagnostics.

### **ADAP**

The last failure occurred on this path as a result of an adapter error.

### **SCSI**

The last failure occurred on this path as a result of a SCSI command error.

**INQ**

The last failure occurred on this path as a result of a SCSI Inquiry peripheral error.

**RETRY**

The last failure occurred on this path due to too many retries of the IO operation.

Response 12:

The DETAILS response for an NVMe EDEVICE might include the following lines:

```
SEGMENT: segment number/number of segments  
HYPERPAV POOL: pool number  
PCIFUNCTION: rpfid
```

The *segment number* value is the number of the first disk block that is accessible via the emulated device. The *pool number* value is the HyperParallel Access Volume pool number that is associated with the device. The *rpfid* value is the identifier of the real PCIe function that is used to access the NVMe device.

**Messages**

- HCP002E Invalid operand - *operand*

- HCP8711E EDEV *rdev* does not support VPD page *page*

## QUERY ENCRYPT

### Authorization

Privilege Class: A, C, E

### Purpose

Use the QUERY ENCRYPT command to determine the settings for host level encryption used by the z/VM hypervisor.

### Operands

#### ALL

lists settings for all the host services for which encryption is available.

#### PAGING

lists z/VM host level encryption settings for CP paging of guest memory and virtual-disk-in-storage (VDISK).

### Usage Notes

1. The QUERY ENCRYPT command lists host-level encryption configuration for both the initial system state and the current state. This information is provided for auditing purposes.
2. For a record of any user IDs that changed their initial encryption setting, refer to monitor records or to auditing records from your External Security Manager.

### Responses

Response 1:

```

Encrypt Paging settings:
  Currently: Required AES256
  At IPL: Off
Ready;
  
```

This response is issued when PAGING or ALL is specified on the QUERY ENCRYPT command. It displays the setting at the time of IPL, the present setting, and the current algorithm. The setting at the time of IPL is determined by the ENCRYPT configuration statement and can either be OFF (the default), ON, or REQUIRED. If the setting is ON or REQUIRED, the current encryption algorithm is also noted. The encryption setting can be changed with the SET ENCRYPT command; this setting can be OFF, ON, or REQUIRED. See [“SET ENCRYPT” on page 1513](#) for more information about these settings.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - {*option|command* contains extra option(s) starting with *option*}

## QUERY EQID

### Authorization

Privilege Class: B

### Purpose

Use QUERY EQID to display the device equivalency IDs (EQIDs) for specified RDEVs, and to display the RDEVs associated with a specified equivalency ID (EQID).

### Operands

#### *eqid*

displays all RDEVs that have an EQID equal to the specified value. The *eqid* can be a string of 1–8 alphanumeric characters for a user-defined EQID or a string of 50 alphanumeric characters plus a dash ("-") for a system-generated EQID.

#### **FOR ALL\_user\_defined**

displays all RDEVs that have been assigned a user-defined EQID and the EQIDs for those RDEVs.

#### *rdev*

#### *rdev1-rdev2*

displays the EQIDs for the RDEVs within the specified range. They can be specified as a single RDEV, a range of RDEVs, or a series of both. Only RDEVs that have an EQID (either system-generated or user-defined) are displayed. RDEVs that do not exist or have no EQID are ignored. For a device in the active configuration, the device number entered can be a 4-digit hexadecimal number between X'0000' and X'FFFF'. For a device in the active or standby configuration, the device can be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is configured. A range of devices cannot span subchannel sets.

### Usage Notes

1. The device number in the response will always be a 5-digit device number.

### Responses

Response 1:

This is a sample response to the command QUERY EQID ABCDEFGH:

```

DEVICES FOR ABCDEFGH:
00191 00192 00193 00194 00195 00196 00197 00198

- HCP048E No EQID exists for *rdev*.
- HCP1003E *rdev* was not found.

## QUERY EXITS

### Authorization

Privilege Class: A, C, E

### Purpose

Use QUERY EXITS to display status and usage statistics information for one or more exit points.

### Operands

#### ALL

tells CP to display information about all existing exit points.

#### exit

#### exit1-exit2

is the number of the exit point for which you want information. Each *exit* must be a hexadecimal number between X'0000' and X'FFFF'. You can specify a single exit number, a range of exit numbers, or any combination thereof.

### Usage Notes

- For a static exit, CP does not create CP exit control blocks until you associate one or more entry points or external symbols with that exit point. If you try to issue a QUERY EXITS command against such an exit point, CP issues message HCP2752E as the response to your QUERY EXITS command. For a dynamic exit, QUERY EXITS responds with the definition of the exit, even if there are no entry points associated with it.
- To create a new dynamic exit point, use the DEFINE EXIT command (see [“DEFINE EXIT”](#) on page 176).
- To activate an exit point:
  - While defining it, use the ENABLE operand of the ASSOCIATE EXIT command (see [“ASSOCIATE EXIT”](#) on page 20).
  - After defining it, use the ENABLE EXITS command (see [“ENABLE EXITS”](#) on page 465).
- To display the address of the CP exit block for a specific exit point, use the LOCATE XITBK command (see [“LOCATE XITBK”](#) on page 649).
- To display the address of the CP indirect call locator block for a specific exit point, use the LOCATE ICLBK command (see [“LOCATE ICLBK”](#) on page 614).
- To deactivate an exit point:
  - While defining it, use the DISABLE operand of the ASSOCIATE EXIT command (see [“ASSOCIATE EXIT”](#) on page 20).
  - After defining it, use the DISABLE EXITS command (see [“DISABLE EXITS”](#) on page 319).
- To change the definition of an existing dynamic exit point, or to remove the exit point from the system, use the MODIFY EXIT command (see [“MODIFY EXIT”](#) on page 700).

8. For more information about user-defined exit points, see [Dynamic Exit Points](#) in *z/VM: CP Exit Customization*.

## Responses

Response 1:

To display the current information for exit point X'77', enter the following:

```
query exits 77
Exit Status      Calls   Returns Seconds
0077 Enabled       3       3 0.000633
      EPNAME      Attempts Calls   Seconds
      HCPSRC00    3       3 0.000598
Ready;
```

In this example,

*Lines 1 and 2 – Information about the Exit Point*

### Exit

shows the number of the exit point.

### Status

tells you whether CP is accepting requests to process this exit point. If "Enabled", CP is accepting requests; if "Disabled", CP is not accepting requests.

### Calls

tells you how many times CP has entered this exit point.

### Returns

tells you how many times this exit point has returned control to CP.

**Note:** If the number of times entered equals the number of times exited (as in this example), then you know the exit point is not currently active. If the number of times entered is greater than the number of times exited, then you know the exit point is currently processing a request.

### Seconds

shows the total elapsed time CP used to process this exit point. This number includes the time it took for CP to set up the exit point plus the total elapsed times that CP used to process all calls to all entry points.

*Lines 3 and 4 – Information about Each Entry Point Associated With the Exit Point*

### EPNAME

shows you each entry point associated with this exit point, in the order that CP calls them. (The exit point in this example only has 1 entry point, HCPSRC00.)

### Attempts

shows you how many times CP has tried to call this entry point.

### Calls

shows you how many times CP succeeded in calling this entry point.

**Note:** If the number of attempts equals the number of calls, you know that CP had no trouble finding the entry point and passing control over to it. If the number of attempts is greater than the number of calls, then CP could not locate the entry point during 1 or more attempts to call it.

### Seconds

shows the total elapsed time CP used to process this specific entry point. (In this example, it is the total time CP used to process all 3 calls to entry point HCPSRC00.)

Response 2:

To display the current information for CP exit point X'D5', enter the following:

```
query exits d5
Exit Status      Calls   Returns Seconds
```

```
00D5 Enabled      8      8 10.008833
      EPNAME      Attempts  Calls  Seconds
      HCPSRC00     8      8 0.002598
      HCPSRCZZ     8      0 0.000000
      HCPSRC08     8      4 0.002833
      HCPSRC99     6      6 10.002668
Ready;
```

In this example, the first 2 lines show that CP:

- Is accepting requests to process this exit point.
- Entered and exited this exit point 8 times, which means the exit point is not currently active.
- Used a little more than 10 seconds to set up this exit point and process all calls to all its entry points.

The remaining lines show that:

- Exit point X'D5' currently has 4 entry points (HCPSRC00, HCPSRCZZ, HCPSRC08, and HCPSRC99).
- CP tried to call HCPSRC00 8 times and succeeded in each case.
- CP tried to call HCPSRCZZ 8 times, but none of the attempts were successful. (This probably means that someone did not load HCPSRCZZ yet.)
- CP tried to call HCPSRC08 8 times. Only 4 of those attempts were successful. (This can happen when someone loads an entry point after associating it with an exit point.)
- CP tried to call HCPSRC99 6 times and succeeded in each case. However, there are 2 odd things about HCPSRC99:
  1. CP called the other entry points 8 times, but only called HCPSRC99 6 times. (This probably means that someone associated the entry point with the exit point sometime after the other 3 entry points.)
  2. The elapsed time to process HCPSRC99 is substantially longer than that of the other 3 entry points. (Unless this entry point is substantially larger than the others, this probably means someone should investigate this entry point.)

Response 3:

To display the current information for CP exit point X'1234', enter the following:

```
query exits 1234
Exit Status      Calls  Returns Seconds
1234 Enabled      3      3 0.000803
      Location      Instruction Resolution
      HCPXMGMS+0004 41700000  RESOLVE
      Defined by: OPERATOR at 13:27:54 on 09/03/98
      PARM R9
      RC
      EPNAME      Attempts  Calls  Seconds
      EXITSTDP    3      3 0.000785
Ready;
```

In this example, the first 2 lines show that CP:

- Is accepting requests to process this exit point.
- Entered and exited this exit point 3 times, which means the exit point is not currently active.
- Used a little less than 1 millisecond to set up this exit point and process all calls to its associated entry point.

The next five lines show that:

- The exit point was defined dynamically.
- The exit point is located at 4 bytes past entry point HCPXMGMS, where instruction X'41700000' occurs.
- The resolution of the entry point associated with the exit was performed when the association was made between them.
- The exit point was defined by user OPERATOR on September 3, 1998, at 13:27:54 local time.
- The exit receives two parameters, namely the contents of general registers 9 and 12 at the point of exit, in addition to the three parameters that are passed to every dynamic exit.

## QUERY EXITS

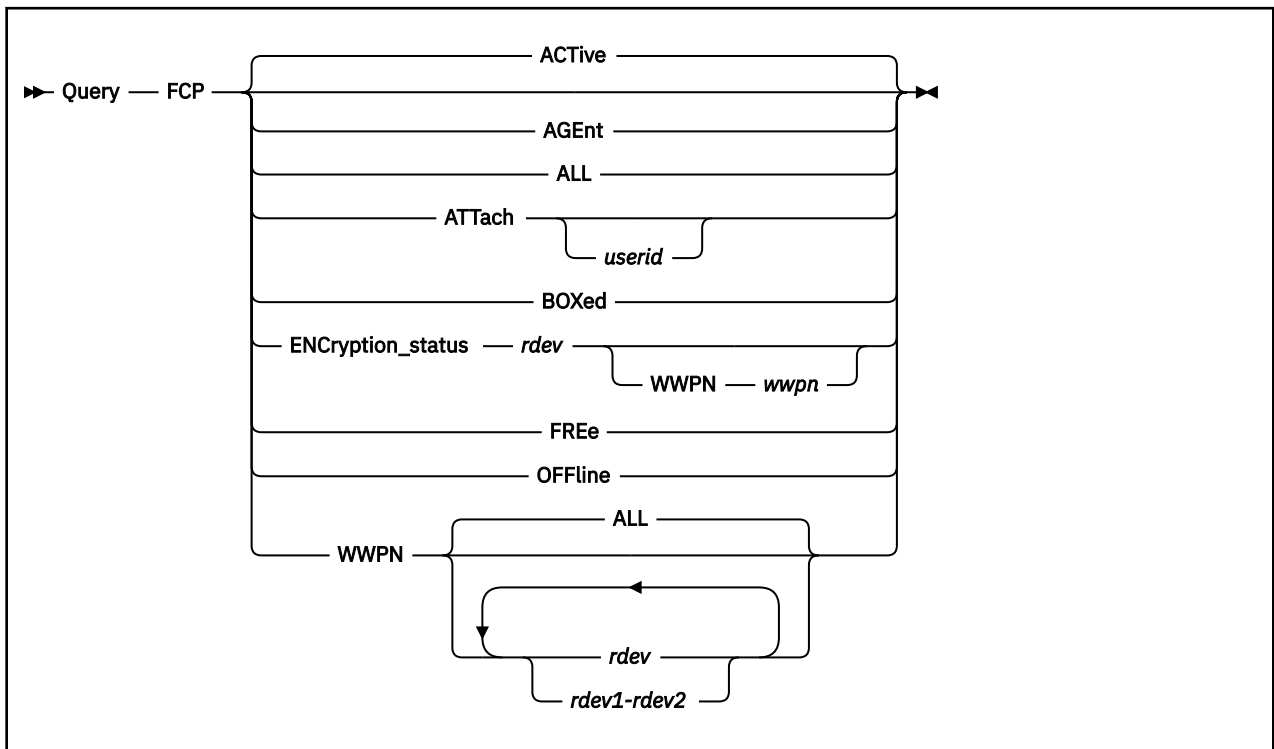

The last two lines show that:

- Exit point X'1234' currently has 1 entry point (EXITSTDP).
- CP tried to call EXITSTDP 3 times and succeeded in each case.

## QUERY FCP

### Authorization

Privilege Class: B

### Purpose

Use QUERY FCP to display the status of real FCP Adapter devices.

### Operands

#### ACTIVE

indicates active FCP Adapter devices. An active device is one that is in use by a user or the system and is specified as neither FREE nor OFFLINE.

#### AGEnt

indicates the Fibre Channel Protocol Agent device. The FCP Agent device is used to control FCP configuration.

#### ALL

indicates all FCP Adapter devices attached to the system. The status is displayed in the order of ACTIVE, FREE, OFFLINE, and AGENT. You receive the same response as you would receive if you entered all of the following commands:

- query fcp active
- query fcp free
- query fcp offline
- query fcp agent

**ATTach *userid***

indicates the FCP devices that are dedicated to a user on the system. If you specify *userid*, only FCP devices attached to that user's virtual machine are indicated. If you do not specify *userid*, you receive the status of all FCP devices dedicated to any user on the system. Attached devices are always active.

**BOXed**

indicates the FCP devices that are unavailable (usually because of a hardware condition). A boxed adapter can also be active, free, or offline.

**ENCryption\_status**

indicates the encryption status of a target WWPN (if a WWPN is specified) or the encryption status of all of the target WWPNs that are associated with the specified FCP device.

**WWPN *wwpn***

indicates a target WWPN on the storage controller (associated with the HBA).

**FREE**

indicates all free FCP devices. A free FCP device is one that is not currently in use by a user or the system and is specified as neither ACTIVE nor OFFLINE.

**OFFline**

indicates all offline FCP devices. An offline FCP device is one that is specified as neither ACTIVE nor FREE.

**WWPN**

indicates for each FCP device the NPIV worldwide port name (WWPN) associated with the device and the physical WWPN associated with the device's channel path. The status of the device will also be displayed (ATTACHED, FCP AGENT, FREE, OFFLINE, BOXED).

**Usage Notes**

1. There is a Linux Access Control Table that is used to control FCP LUN access. VM userids are entered in this table with corresponding LUNs. For details, refer to Linux documentation.
2. A VIRTUAL version of this command, QUERY VIRTUAL FCP, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL FCP” on page 1297](#).

**Responses**

If the system is using an FCP device that is in an intervention-required state and you enter QUERY FCP, you see a response like this:

```
FCP 0300 has intervention required.
```

0300 is the real device number of the FCP device that needs the operator's intervention.

**Note:** This response will be preceded by one of the following.

Response 1:

If you enter QUERY FCP, QUERY FCP ACTIVE, or QUERY FCP ATTACH and there is an FCP device attached to the system, you see something like this:

```
q fcp active
FCP 0480 ATTACHED TO LINUX1 0480 CHPID 80
FCP 0481 ATTACHED TO LINUX2 0481 CHPID 80 USERACCESSID = userid
FCP 0482 ATTACHED TO LINUX2 0482 CHPID 80
FCP 0700 ATTACHED TO TEST1 0500 CHPID F1
FCP 0701 ATTACHED TO TEST2 0500 CHPID F1
Ready;
```

The first number is the real device number of the FCP device. The operand might also read BOX/ATTC, which means that although the device is attached and dedicated to a user, it is unavailable. LINUX1, LINUX2, TEST1, and TEST2 are user IDs to which the FCP devices are dedicated. The number following

the user IDs is the virtual device number which each virtual machine uses to refer to an FCP device. The number following the CHPID is the real CHPID (channel path ID) associated with the device.

If the FCP subchannel being displayed was attached using the Attach USERACCESSID option, the USERACCESSID will be displayed as part of the response.

Response 2:

If you enter QUERY FCP, QUERY FCP ACTIVE, or QUERY FCP ATTACH as above, and NPIV is enabled on the FCP subchannels being queried, you see something like this:

```
q fcp active
FCP 2FC1 ATTACHED TO NP0RT      2FC1 CHPID 23
   WWPN C05076FFFD8018EC
FCP 2FC2 ATTACHED TO NP0RT      2FC2 CHPID 23
   WWPN C05076FFFD8018F0
FCP 2FC3 ATTACHED TO NP0RT      2FC3 CHPID 23
   WWPN C05076FFFD8018F4
Ready;
```

The number following WWPN is the unique world wide port name associated with the FCP device.

Response 3:

If you enter a QUERY FCP FREE command and there is a free FCP device attached to the system, you see something like this:

```
q fcp free
FCP 0487 FREE      , FCP 04A1 FREE      , FCP 04A2 FREE      , FCP 04A3 FREE
FCP 04A4 FREE      , FCP 04A5 FREE      , FCP 04A9 FREE      , FCP 04AA FREE
FCP 04AB FREE      , FCP 04BC FREE      , FCP 04BD FREE      , FCP 04BE FREE
FCP 04BF FREE
Ready;
```

This response shows the real device number for each free FCP device.

The response for a QUERY FCP OFFLINE or QUERY FCP BOXED command is in the same format as the response for a QUERY FCP FREE command.

Response 4:

When you enter a QUERY FCP ALL command, CP displays the same responses as it would display if you had entered the QUERY FCP ACTIVE, QUERY FCP FREE, and QUERY FCP OFFLINE commands.

Response 5:

If CP cannot find an FCP device of the type you specify, you see a message like this:

```
q fcp boxed
A BOXED FCP was not found.
Ready;
```

In this response, BOXED may be replaced with active, attached, offline, or free, depending on what you specified on the command.

Response 6:

When you enter a QUERY FCP AGENT command and there is an FCP AGENT attached to the system, you see something like this:

```
q fcp agent
FCP 0280 is an FCP Agent.
Ready;
```

or, in the case where there is no agent, you will see:

```
q fcp agent
An FCP Agent was not found.
Ready;
```

Response 7:

## QUERY FCP

When you enter a QUERY FCP WWPN command, you see something like this:

```
q fcp wwpn 2f00-2fff
FCP 2F00      NPIV WWPN NONE
      CHPID 24 PERM WWPN C05076FFFD8018FD
      OFFLINE

FCP 2F08      NPIV WWPN NONE
      CHPID 25 PERM WWPN C05076FFFD8018FE
      FREE

FCP 2FF0      NPIV WWPN C05076FFFD8018EC
      CHPID 26 PERM WWPN C05076FFFD8018FF
      ATTACHED TO NPORT
Ready;
```

Response 8:

When you enter a QUERY FCP WWPN command and there are no FCP devices that exist related to the query, you see something like this:

```
q fcp wwpn 1f00-1fff
A valid FCP device was not found.
Ready;
```

Response 9:

When you enter a QUERY FCP ENCRYPTION\_STATUS command for an FCP device, you see something like this:

```
q fcp enc 8181
FCP 8181 WWPN C05076FFFD8018F0 AVAILABLE
FCP 8181 WWPN C05076FFFD8018F2 AUTHENTICATED
FCP 8181 WWPN C05076FFFD8018F4 ENCRYPTED
Ready;
```

Response 10:

When you enter a QUERY FCP ENCRYPTION\_STATUS command for an FCP device and a target WWPN, you see something like this:

```
q fcp enc 8181 C05076FFFD8018F4
FCP 8181 WWPN C05076FFFD8018F4 ENCRYPTED
Ready;
```

## Messages

## QUERY FENCES

### Authorization

Privilege Class: B

### Purpose

Use QUERY FENCES to display the following:

- A list of internal fences created by an IBM DASD subsystem, as a result of internal errors, to inhibit use of various subsystem resources.
- Devices which have been put into the soft fence state to protect the devices from read or write operations.

### Operands

*rdev*

*rdev1-rdev2*

is the real device number, a list of real device numbers, or a range of real device numbers of the devices being queried.

### Usage Notes

1. The QUERY FENCES command is only valid for IBM DASD subsystems. An error message is generated if the specified device is not attached to an IBM DASD subsystem.

### Responses

Response 1:

```
rdev No fences exist for this device.
```

This response is issued when no fences exist for the specified subsystem, and is repeated for each specified device.

*rdev*

is the real device number of a device being queried.

Response 2:

```
rdev type fenced:
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
or
rdev type fenced:
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
```

This response is issued when fences do exist for the specified subsystem, and is repeated for each specified device.

## QUERY FENCES

### ***rdev***

is the real device number of a device being queried.

### ***type***

Storage path | Channel attachment | Device attachment

### **XXXXXXXX**

Four hexadecimal bytes of storage path status data

For 3990 Model 3, 16 bytes of storage path status data is returned. For all other models of IBM DASD subsystems, 24 bytes of storage path status is returned.

Response 3:

```
rdev is in a Soft Fenced State.
```

This response is issued when the soft fence state exists for the device and is repeated for each specified device in that state.

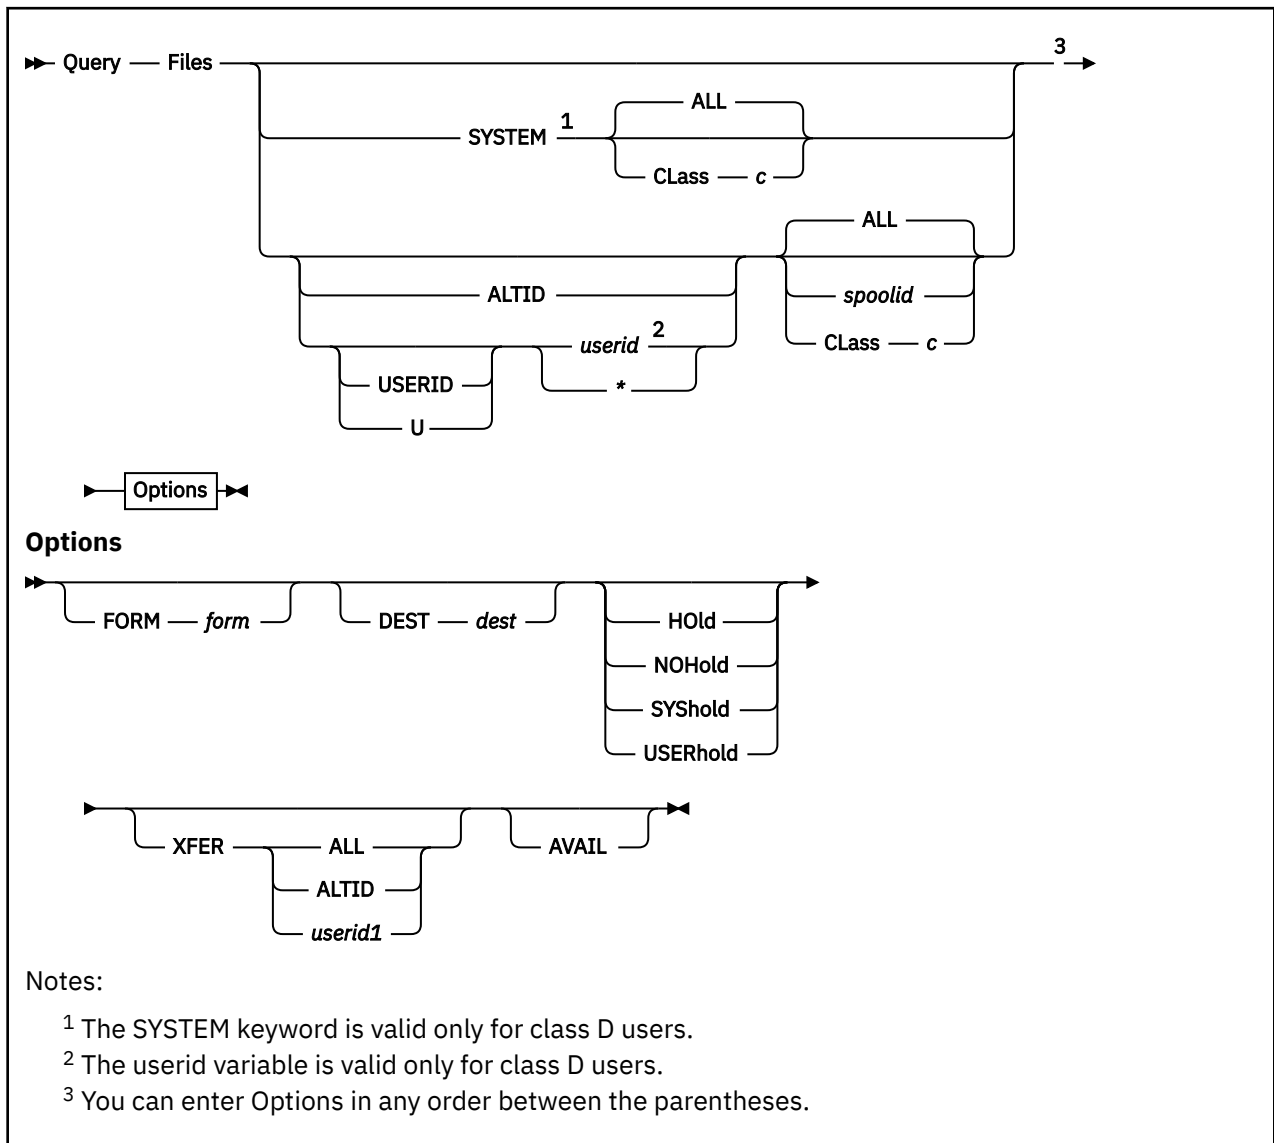

### ***rdev***

is the real device number of a device being queried.

## Messages

- HCP332E Invalid control unit type - *rdev*
- HCP1109E The *command* command cannot be processed for device *rdev* because the device is the secondary in a duplex pair.

# QUERY FILES

## Authorization

Privilege Class: D, G

## Purpose

Use QUERY FILES to display a count of spool files. The count includes the following:

- Files open on virtual devices
- Files being processed on real devices.

## Operands

### SYSTEM

obtains a count of all spool files in the system. The SYSTEM option is the default for class D users, and can only be used by class D users. It is not valid with the *spoolid* option.

## QUERY FILES

### USERID

#### U

indicates that the next parameter is a userid. Class G users can specify only an asterisk (\*) following USERID or U. U is the only abbreviation allowed for USERID.

### ALTID

#### *userid*

#### \*

identifies the user whose spool files are to be queried. You can specify *userid* as an asterisk (\*) for information on your own files. You can specify ALTID for information on files belonging to your alternate user ID. For a class G user, the asterisk (\*) is the default.

### ALL

queries all of your files and is the default.

### Class c

designates an existing spool file class; the operand *c* is a 1-character alphanumeric field from A through Z or 0 through 9.

### *spoolid*

identifies the file to be queried; this number is assigned by the system. This option is not valid with the SYSTEM keyword, nor can it be used if a class D user is defaulting to SYSTEM. This option can only be used by a class D user if a user ID or an asterisk (\*) is specified in the command.

### FORM *form*

indicates that you want to count the number of spool files with the specified form. The operand *form* is one to eight characters long. For the class G user, *form* is the user form name. For the class D operator, *form* is the user form name when asterisk (\*) is specified. Otherwise, *form* is the operator form number.

### DEST *dest*

indicates that you want to count the number of spool files with the specified destination value. The operand *dest* is a one to eight character name.

### HOLD

#### NOHOLD

#### SYSHOLD

#### USERHOLD

indicates that you want to query files that are in a particular hold status. Specify HOLD to query files that are in user or system hold. Specify USERHOLD to query files that have only user hold in effect. Specify SYSHOLD to query files that have only system hold in effect. Specify NOHOLD to query files that are not in user or system hold.

A file that is in hold status cannot be processed by a spooling device; you can use CHANGE to alter the file's hold status.

### XFER ALL

### XFER ALTID

### XFER *userid1*

indicates that you want to query files generated by the specified user ID or ALTID and owned by another user ID. Class D users may use the SYSTEM option to obtain a count of all files in the system owned by a user ID other than the originating user ID. XFER *userid1* displays a count of the spool files generated by the specified user ID or ALTID and which are owned by the user specified as *userid1*. Files generated and owned by the same user are not counted. XFER ALTID displays a count of files generated by the specified user ID and owned by ALTID. XFER ALL displays a count of all spool files generated by the specified user ID or ALTID and which are not owned by the originating user ID.

### AVAIL

displays only a count of available files, not those files that are open or in use.

## Usage Notes

1. Privilege class G users can enter QUERY FILES to display the number of spool files they own or have generated. Privilege class D users can enter QUERY FILES to display all spool files in the system, or all files that belong to a particular user of that system.
2. If the user ID option is used with the XFER option by a class D user, the specified user ID is treated as the originator of the files. The result is a count of the files generated by the first user, and includes those files owned by the user specified after the XFER option.

For example, if a class D user enters `query files user1`, a count is returned of the files that USER1 owns.

If a class D user enters `query files xfer user2`, a count is returned of the files that USER2 owns, but did not generate.

If a class D user enters `query files user1 xfer user2`, a count is returned of the files generated by USER1 and owned by USER2.

3. In an SSI cluster, if the AVAIL operand is not specified, this command displays information about all files in the system on which the command is processed. If the AVAIL operand is specified, this command does not display information about files that are locked by another system.

## Responses

Response 1:

For the class D user:

```
FILES: {nnnnnnn} RDR, {nnnnnnn} PRT, {nnnnnnn} PUN
       {      NO}   {      NO}   {      NO}
```

where *nnnnnnn* is the number of spool files of each type.

For the class G user:

```
FILES: {nnnn} RDR, {nnnn} PRT, {nnnn} PUN
       { NO}     { NO}     { NO}
```

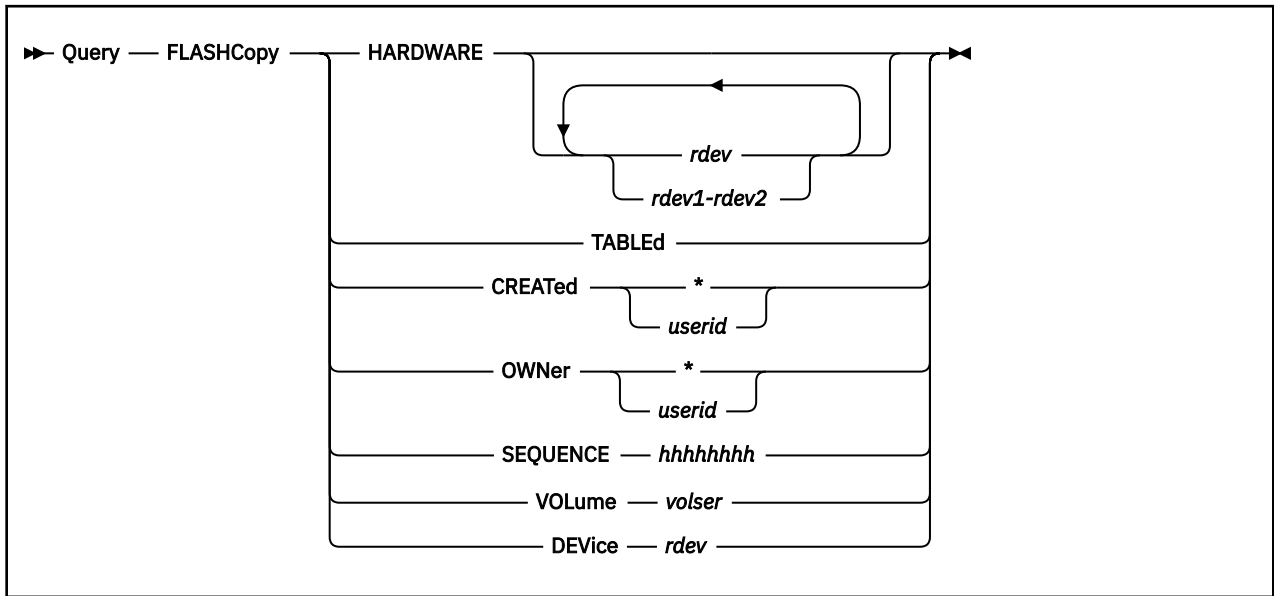

where *nnnn* is the number of spool files of each type.

**Note:** If a class G user issues QUERY FILES (or if a privileged user issues QUERY FILES \*), and if that user has more than 9999 rdr, prt, or pun files, the response will still only show 9999 files.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP053E *userid* not in CP directory
- HCP364E No alternate *userid* is currently set.
- HCP413E Command processing cannot complete due to a spool paging error.
- HCP422E The same option was specified twice.
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP848E SYSTEM parameter is invalid with the spoolid option
- HCP849E A user ID must be specified with the spoolid
- HCP1558E Command processing cannot complete.

## QUERY FLASHCOPY

### Authorization

Privilege Class: B

### Purpose

This command allows interrogation of persistent FlashCopy relationships in the hardware and the Persistent FlashCopy Relationship Table. Each FlashCopy relationship is identified with a unique sequence number that is derived from the TOD clock when the relationship is established.

The Persistent FlashCopy Relationship Table is maintained by z/VM to preserve additional information regarding FlashCopy relationships. Note that this table is NOT maintained over system IPLs and is intended to be used as supplemental information regarding FlashCopy relationships.

### Operands

#### **HARDWARE**

specifies the real hardware devices that are to be interrogated. The resulting display will indicate all the persistent relationships that exist on the devices.

#### **TABLEd**

displays all additional information regarding persistent FlashCopy relationships that were established during the current system IPL session.

#### **CREATed \***

##### **CREATed *userid***

displays additional information regarding persistent FlashCopy relationships that were established by the specified user during the current system IPL session.

#### **OWNer \***

##### **OWNer *userid***

displays additional information regarding persistent FlashCopy relationships that were established on minidisks owned by the specified user during the current system IPL session.

#### **SEQUENCE *hhhhhhh***

displays additional information regarding persistent FlashCopy relationships that were established and assigned the specified sequence number during the current system IPL session.

**VOLume volser**

displays additional information regarding persistent FlashCopy relationships that were established on the specified real volume during the current system IPL session.

**DEVICE rdev**

displays additional information regarding persistent FlashCopy relationships that were established on the specified real device during the current system IPL session.

**Usage Notes**

1. The contents of the Persistent FlashCopy Relationship Table are lost when the system is IPLed.
2. Entries might exist in the list for relationships that have been partially withdrawn by this or another LPAR.
3. Entries will not exist for relationships that have been completely withdrawn.
4. When the number of tracks remaining to be background copied is nonzero and you want to issue the FLASHCOPY WITHDRAW command, you must use the FORCE option.
5. If flag X'0002' is set to one, the number of remaining tracks to be copied is reported as '?'.  
 6. A VIRTUAL version of this command, QUERY VIRTUAL FLASHCOPY, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see ["QUERY VIRTUAL FLASHCOPY"](#) on page 1300.

**Responses**

```

## QUERY FLASHCOPY

**Note:** If an RDEV in a FlashCopy relationship is not attached to this z/VM image, you will receive a display such as:

```
q flashcopy hardware
-----SOURCE-----
SEQUENCE FLGS RDEV VOLSER CC...CC/HH RDEV VOLSER CC...CC/HH REMAINING/TOTAL
62320413 E818 ssid *lsua*          0/00 FCE2 GESE01          0/00 50084/50085
```

When *\*lsua\** is displayed for the VOLSER, the RDEV value that is displayed is the partner's subsystem ID and the *\*lsua\** value is the partner's logical subsystem number and unit address, respectively.

Example:

```
q flashcopy hardware
-----SOURCE-----
SEQUENCE FLGS RDEV VOLSER CC...CC/HH RDEV VOLSER CC...CC/HH REMAINING/TOTAL
62320413 E818 0202 *0200*          0/00 FCE2 GESE01          0/00 50084/50085
```

The FLGS field of the QUERY FLASHCOPY HARDWARE response is in hexadecimal and has the following meaning:

Flag Bit	Definition
8000	0 = Source, 1 = Target
4000	1 = Full Volume Relationship
2000	1 = Background copy pending (NOCOPY)
1000	1 = Background copy in progress (BACKGNDCOPY)
0800	1 = Persistent Relationship (ESTABLISH)
0400	1 = Target extents are write protected (NOTGTWRITE)
0200	1 = Validation required
0100	1 = Change recording is active (CHGRECORD)
0080	1 = Reversible relationship (not set by z/VM)
0040	1 = Source write inhibited (not set by z/VM)
0020	1 = Virtual flash initialize relationship
0010	1 = Space efficient target volume or extent
0008	1 = Fail if no space (FAILNOSPACE)
0004	1 = Relationship is failed
0002	1 = Number of remaining tracks to copy is unknown
0001	1 = Source volume write inhibited due to full repository

For the --SOURCE-- and --TARGET-- areas, the CC...CC/HH fields are the decimal cylinder and head numbers for the beginning of the respective extent. (Note that the CC...CC cylinder field could contain as many as nine characters.) The REMAINING field contains the number of unmodified source tracks that have yet to be copied to the target, and the TOTAL field contains the total number of tracks in the extent.

Response 2: QUERY FLASHCOPY TABLED

```
q flashcopy tabled
SEQUENCE ---DATE--- --TIME-- RDEV VOLSER CREATOR OWNER VDEV

```

```
4B14700A 2008-04-30 15:20:00 >5101 PACK02 RWS RWS 0310
Ready; T=0.01/0.01 15:20:40
```

The RDEV> indicates a source relationship and the >RDEV indicates a target relationship.

The CREATOR is the VM user ID that issued the FLASHCOPY ESTABLISH command.

The OWNER and VDEV are the minidisk owner's information. For example, if you did this:

```
LINK MAINT 190 999 RR
FLASHCOPY ESTABLISH SOURCE 999 TARGET 200
QUERY FLASHCOPY CREATED RWS
```

you would get back

```
q flashcopy vol rws541
SEQUENCE ---DATE--- --TIME-- RDEV VOLSER CREATOR OWNER VDEV
C1D5410F 2008-01-21 18:23:40 5C81> PACK03 RWS MAINT 0190
```

rather than

```
q flashcopy vol rws541
SEQUENCE ---DATE--- --TIME-- RDEV VOLSER CREATOR OWNER VDEV
C1D5410F 2008-01-21 18:23:40 5C81> PACK03 RWS RWS 0999
```

### Response 3: QUERY FLASHCOPY CREATED

```
q flashcopy created rws
SEQUENCE ---DATE--- --TIME-- RDEV VOLSER CREATOR OWNER VDEV
4B145C34 2008-04-30 15:19:55 5100> PACK01 RWS RWS 0200
4B145C34 2008-04-30 15:19:55 >5101 PACK02 RWS RWS 0300
4B14700A 2008-04-30 15:20:00 5100> PACK01 RWS RWS 0210
4B14700A 2008-04-30 15:20:00 >5101 PACK02 RWS RWS 0310
Ready; T=0.01/0.01 15:20:53
```

### Response 4: QUERY FLASHCOPY OWNER

```
q flashcopy owner rws
SEQUENCE ---DATE--- --TIME-- RDEV VOLSER CREATOR OWNER VDEV
4B145C34 2008-04-30 15:19:55 5100> PACK01 RWS RWS 0200
4B145C34 2008-04-30 15:19:55 >5101 PACK02 RWS RWS 0300
4B14700A 2008-04-30 15:20:00 5100> PACK01 RWS RWS 0210
4B14700A 2008-04-30 15:20:00 >5101 PACK02 RWS RWS 0310
Ready; T=0.01/0.01 15:21:33
```

### Response 5: QUERY FLASHCOPY VOLUME

```
q flashcopy volume pack02
SEQUENCE ---DATE--- --TIME-- RDEV VOLSER CREATOR OWNER VDEV
4B145C34 2008-04-30 15:19:55 >5101 PACK02 RWS RWS 0300
4B14700A 2008-04-30 15:20:00 >5101 PACK02 RWS RWS 0310
Ready; T=0.01/0.01 15:21:45
```

### Response 6: QUERY FLASHCOPY SEQUENCE

```
q flashcopy sequence 4B14700A
SEQUENCE ---DATE--- --TIME-- RDEV VOLSER CREATOR OWNER VDEV
4B14700A 2008-04-30 15:20:00 5100> PACK01 RWS RWS 0210
4B14700A 2008-04-30 15:20:00 >5101 PACK02 RWS RWS 0310
Ready; T=0.01/0.01 15:22:13
```

### Response 7: QUERY FLASHCOPY DEVICE

```
q flashcopy device 5101
SEQUENCE ---DATE--- --TIME-- RDEV VOLSER CREATOR OWNER VDEV
4B145C34 2008-04-30 15:19:55 >5101 PACK02 RWS RWS 0300
4B14700A 2008-04-30 15:20:00 >5101 PACK02 RWS RWS 0310
Ready; T=0.01/0.01 15:22:41
```

### Response 8: If Information Is Not Available

## QUERY FLASHCOPY

In some cases, information might no longer be available, and you could see \*UNKNOWN.

```
q flashcopy created rws
SEQUENCE ---DATE--- --TIME--  RDEV  VOLSER  CREATOR  OWNER  VDEV
4B145C34 2008-04-30 15:19:55 5100> PACK01 RWS      *UNKNOWN 0200
4B145C34 2008-04-30 15:19:55 >5101 PACK02 RWS      RWS      0300
4B14700A 2008-04-30 15:20:00 5100> PACK01 *UNKNOWN RWS      0210
4B14700A 2008-04-30 15:20:00 >5101 PACK02 RWS      RWS      0310
Ready; T=0.01/0.01 15:20:53
```

## QUERY FRAMES

► Query — FFrames ◄

### Authorization

Privilege Class: A, B, E

### Purpose

Use QUERY FRAMES to display the status of host real storage.

### Responses

```
All frames:
Configured=n Real=n Usable=n Offline=n
Pageable=n NotInitialized=n GlobalClearedAvail=n
LocalClearedAvail=n LocalUnclearedAvail=n
LockedPageable=n% LockedWarning=--% LockedFail=--%
IOATSize=n IOATUsed=n% IOATMaxUsed=n% IOATWarning=--%
Permanent=n Reconfigurable=n Vacating=n
```

```
Frames < 2G:
GlobalUnclearedAvail=n Pageable=n LogicalFreeStorage=n
RealFreeStorage=n LockedRS=n LockedCmd=n
MinidiskCache=n Nucleus/Prefix=n Trace=n Other=n
```

```
Frames > 2G:
GlobalUnclearedAvail=n Pageable=n LogicalFreeStorage=n
RealFreeStorage=n LockedRS=n LockedCmd=n
MinidiskCache=n Other=n
```

### All Frames

#### Configured

indicates the amount of real storage, in frames, that is assigned to the logical partition in which z/VM is running. The amount of storage represented by this operand is equal to the CONFIGURED= value in the response to the QUERY STORAGE command.

#### Real

indicates the amount of real storage, in frames, that is assigned to the logical partition in which z/VM is running. The Real= and Configured= values are always equal.

#### Usable

indicates the number of frames that are online to z/VM.

Usable = Permanent + Reconfigurable - Offline.

Usable = Configured - Offline.

**Note:** If the IPL parameter STORE=n was used when IPLing a second-level z/VM system in a configuration without standby or reserved storage, then Usable <= Configured - Offline.

The amount of storage represented by Usable + Offline equals the STORAGE=n value in the response to the QUERY STORAGE command.

#### Offline

indicates the number of frames taken offline because of error.

#### Pageable

indicates the number of frames available for paging.

**NotInitialized**

indicates the number of frames that have not been initialized. Because all storage below 2 GB is initialized, this refers only to storage above 2 GB.

**GlobalClearedAvail**

indicates the number of frames on the Global Cleared Avail list, which identifies frames that have been cleared to 0 and are available for use by CP. These frames may be above or below 2 GB. There is only one Global Cleared Avail list, regardless of the number of processors.

**LocalClearedAvail**

indicates the sum of the number of frames on all the Local Cleared Avail lists. There is one Local Cleared Avail list for each processor. It identifies frames that have been cleared to 0 and are available for use by CP. The frames may be above or below 2 GB.

**LocalUnclearedAvail**

indicates the sum of the number of frames on all the Local Uncleared Avail lists. There is one Local Uncleared Avail list for each processor. It identifies frames that have not been cleared to 0 and are available for use by CP. The frames may be above or below 2 GB.

**LockedPageable**

is the percentage of pageable storage currently pinned.

**LockedWarning**

is specified by the system programmer in the system configuration file. Message HCP401I is sent when the percentage of locked pageable storage exceeds this percent.

The percent value for LockedWarning is displayed as -- if STORAGE LOCKING is not specified in the system configuration file.

**LockedFail**

is specified by the system programmer in the system configuration file. PCIe function translation fails when this limit is reached. Message HCP401I is sent when this happens.

The percent value for LockedFail is displayed as -- if STORAGE LOCKING is not specified in the system configuration file.

**IOATSize**

is the number of frames reserved by the system program in the system configuration file for the IOAT subpool.

**IOATUsed**

is the percentage of the IOAT subpool currently used.

**IOATMaxUsed**

is the highest percentage of the IOAT used since IPL.

**IOATWarning**

is specified by the system programmer in the system configuration file. Message HCP401I is sent when the percentage of IOAT subpool storage in use exceeds this percent.

The percent value for IOATWarning is displayed as -- if STORAGE IOAT is not specified in the system configuration file.

**Permanent**

indicates the number of permanent frames in use by z/VM.

**Reconfigurable**

indicates the number of reconfigurable frames in use by z/VM. Reconfigurable storage can be removed from the z/VM configuration using the SET STORAGE command. If your z/VM system is running on a machine that does not support reconfigurable storage, the reconfigurable value is displayed as Reconfigurable = --.

**Vacating**

indicates the number of frames to be taken offline by the SET STORAGE remove operation in progress. Vacating frames are included in the Reconfigurable count, but not in any Available count. Frames within storage increments already removed from the configuration are not included in this count. When no SET STORAGE remove operation is in progress, the value of this field is 0.

**Frames < 2G****GlobalUnclearedAvail**

indicates the number of frames on the below 2 GB Global Uncleared Avail list, which identifies frames below 2 GB that have not been cleared to 0 and are available for use by CP. There is only one below 2 GB Global Uncleared Avail list, regardless of the number of processors.

**Pageable**

indicates the number of frames below 2 GB that are available for paging.

**LogicalFreeStorage**

indicates the number of frames below 2 GB that are allocated for host logical free storage.

**RealFreeStorage**

indicates the number of frames below 2 GB that are allocated for host real free storage.

**LockedRS**

indicates the number of frames below 2 GB that are locked in host real storage by CP.

**LockedCmd**

indicates the number of frames below 2 GB that are locked in host real storage as a result of the CP LOCK and UNLOCK commands.

**MinidiskCache**

indicates the number of frames below 2 GB that are used for minidisk track cache.

**Nucleus/Prefix**

indicates the number of all identity-mapped frames (host real storage address of the frame = host logical storage address of the system execution space page), including the CP nucleus and prefix pages.

**Trace**

indicates the number of frames in use for trace tables across all processors.

**Other**

indicates the number of all nonpageable CP frames below 2 GB that are not included elsewhere in the response. Other = total number of nonpageable CP frames < 2 GB - (LogicalFreeStorage < 2 GB + RealFreeStorage < 2 GB + Nucleus/Prefix + LockedRS < 2 GB + Trace).

**Frames > 2G****GlobalUnclearedAvail**

indicates the number of frames on the above 2 GB Global Uncleared Avail list, which identifies frames above 2 GB that have not been cleared to 0 and are available for use by CP. There is only one above 2 GB Global Uncleared Avail list, regardless of the number of processors.

**Pageable**

indicates the number of frames above 2 GB that are available for paging.

**LogicalFreeStorage**

indicates the number of frames above 2 GB that are allocated for host logical free storage.

**RealFreeStorage**

indicates the number of frames above 2 GB that are allocated for host real free storage.

**LockedRS**

indicates the number of frames above 2 GB that are locked in host real storage by CP.

**LockedCmd**

indicates the number of frames above 2 GB that are locked in host real storage as a result of the CP LOCK and UNLOCK commands.

**MinidiskCache**

indicates the number of frames above 2 GB that are used for minidisk track cache.

**Other**

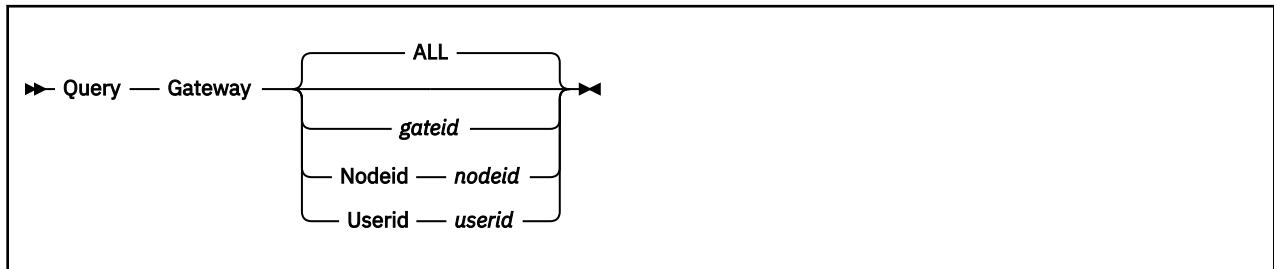

indicates the number of all nonpageable CP frames above 2 GB that are not included elsewhere in the response. Other = total number of nonpageable CP frames > 2 GB - (LogicalFreeStorage > 2 GB + RealFreeStorage > 2 GB + LockedRS > 2 GB). Note that if the total number of nonpageable CP frames > 2 GB = 0, then Other = 0.

### Messages

- HCP263E Too many operands were supplied for this command.

## QUERY GATEWAY

### Authorization

Privilege Class: G

### Purpose

Use the QUERY GATEWAY command to display information about the system and APPC/VM VTAM Support (AVS) gateways defined in the Communication Services (CS) collection. Each node in the CS collection identifies a system gateway that can be used by programs, in the domain of the local VM node, to connect to and from programs in remote nodes.

### Operands

#### ALL

Displays information for all of the defined system gateways and AVS gateways.

#### *gateid*

Displays information for the specified system gateway or AVS gateway.

#### **Nodeid** *nodeid*

Displays information about gateways owned by *nodeid*.

#### **Userid** *userid*

Displays information about gateways owned by *userid* on the local VM node.

### Responses

Response 1:

```
Gateway: gateid Owning Nodeid: nodeid [via tnode]
```

#### *gateid*

Specifies the name of the gateway known in the CS collection.

#### *nodeid*

Specifies the node ID of the system in the CS collection that owns the gateway.

#### *tnode*

Specifies the node through which the *gateid* is known.

Response 2:

```
Gateway: gateid Owning Userid: userid.
```

#### *gateid*

Specifies the name of the gateway defined on the local system.

#### *userid*

Specifies the user ID on the local system that owns the gateway.

**Note:** The owning user ID is displayed only if the gateway resides on the local z/VM system. If a system gateway is defined on the local system, the owning user ID is SYSTEM because the gateway is owned by the local system.

Response 3:

```
Status: status.
```

### ***status***

Specifies either an identify pending or a revoke pending. This response is suppressed if the gateway is identified.

Response 4:

```
No gateways identified.
```

Response 5:

```
No gateways identified by node nodeid.
```

### ***nodeid***

Specifies the node ID that has no gateways identified.

Response 6:

```
No gateways identified by user userid.
```

### ***userid***

Specifies the user ID that has no gateways identified.

## **Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid
- HCP2724E Gateway *gateid* is undefined.

## QUERY GRAF

### Authorization

Privilege Class: B

### Purpose

Use QUERY GRAF to display the status of graphic display devices and 328x display printers.

### Operands

#### ACTIVE

indicates active graphic display devices. An active device is one that is in use by a user or the system and specified as neither FREE nor OFFLINE.

#### ALL

indicates all graphic display devices attached to the system. The status is displayed in the order of ACTIVE, FREE, and OFFLINE. You receive the same response as you would receive if you entered all of the following commands:

```
query graf active
query graf free
query graf offline
```

#### EXTENDED

specifies that logical unit network qualifiers, or logical device host names and IP addresses, are displayed, if they exist.

An IPv4 address is displayed in dotted-decimal format.

**Example:** 9 . 130 . 44 . 144

An IPv6 address is displayed in compressed format (":" designates multiple 16-bit groups of zeros).

**Example:** The following is an IPv6 address:

```
F802:0000:0000:0000:0000:0000:0A00:0001
```

This address is displayed in compressed format as:

```
F802::A00:1
```

#### ATTACH *userid*

indicates the graphic display devices that are dedicated to a user on the system. If you specify *userid*, only displays attached to that user's virtual machine are indicated. If you do not specify *userid*, you

receive the status of all displays dedicated to any user on the system. Attached devices are always active.

**BOXed**

indicates the display devices that are unavailable (usually because of a hardware condition). A boxed display may also be active, free, or offline.

**FREe**

indicates all free display devices. A free display is one that is not currently in use by a user or the system and is not specified as ACTIVE or OFFLINE.

**OFFline**

indicates all offline display devices. An offline display is one specified as neither ACTIVE nor FREE.

**Usage Notes**

1. Within a single VSM that supports network qualified names, multiple responses can occur with the same *luname* when Extended is not specified and one or more VSMS support network qualified names.
2. A VIRTUAL version of this command, QUERY VIRTUAL GRAF, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL GRAF” on page 1303](#).

**Responses**

If the system is using a graphic display device that is in an intervention-required state and you enter QUERY GRAF, you receive a response like this:

```
GRAF 0BDA has intervention required.
```

0BDA is the real device number.

**Note:** This response will be preceded by one of the following.

Response 1:

If you enter a QUERY GRAF, QUERY GRAF ACTIVE, or QUERY GRAF ATTACHED command and a real graphic display is dedicated to a virtual machine, you see something like this:

```
q graf attach
GRAF 0BCD ATTACHED TO OLIVER 0010
Ready;
```

This message means the graphic display device at the real device number 0BCD is attached to OLIVER's virtual machine as the virtual device 0010. ATTACHED may be replaced with BOX/ATTC, which means that although the device is dedicated to a user, it is unavailable (usually because of a hardware condition).

Response 2:

If you enter QUERY GRAF or QUERY GRAF ACTIVE and a graphic display device has a user logged on or dialed through it, you see something like this:

```
q graf
GRAF 08E0 LOGON AS SVCDIR 0009
VTAM CONTROLS THE FOLLOWING LU'S
GRAF WGU9E316 LOGON AS DONNA 0009
GRAF TN6PV192 LOGON AS CORAK 0009
Ready;
```

This response tells you the user SVCDIR is logged on through the graphic display device at 08E0. The number 0009 is SVCDIR's virtual console device number. The second line of the response tells you the terminals that follow are SNA/CCS terminals, and the VTAM user controls them. VTAM is a VTAM service machine (VSM) recognized by z/VM CP. Any logical units controlled by this VTAM service machine that are logged onto, or dialed into, the system are described in the response following this line. The numbers WGU9E316 and TN6PV192 identify SNA/CCS terminals controlled by a VTAM service machine. They are

the names from the VTAM definition of the terminals as SNA logical units. DONNA and CORAK are the users logged on through VTAM. Each has 0009 as the virtual console device number.

Response 3:

If you enter a QUERY GRAF BOXED, QUERY GRAF FREE, or QUERY GRAF OFFLINE command, you see something like this:

```
q graf free
GRAF 08E1 ENABLED, GRAF 08E2 ENABLED, GRAF 08E3 ENABLED, GRAF 08E4 ENABLED
GRAF 08E5 ENABLED, GRAF 08E6 ENABLED, PRT 08E7 ENABLED, GRAF 0BC0 ENABLED
GRAF 0BC1 ENABLED, GRAF 0BC2 ENABLED, GRAF 0BC3 ENABLED, GRAF 0BC4 ENABLED
GRAF 0BC5 ENABLED, GRAF 0BC6 ENABLED, GRAF 0BC7 ENABLED, GRAF 0BC8 ENABLED
Ready;
```

The word ENABLED might be replaced by OFFLINE, FREE, or BOXED, depending on what you entered.

Response 4:

If you enter a QUERY GRAF ALL command, CP displays all the responses as if you had entered QUERY GRAF ACTIVE, QUERY GRAF FREE, and QUERY GRAF OFFLINE commands.

Response 5:

If CP cannot find a graphic display device of the type you specified, you see a message like this:

```
q graf boxed
A BOXED display was not found.
Ready;
```

In this response, BOXED may be replaced with active, attached, free, or offline, depending on what you specified on the command.

Response 6:

If you enter a QUERY GRAF, QUERY GRAF ACTIVE, or QUERY ALL command with the EXTended option, the response shows the fully qualified logical unit name and might look something like this:

```
Q GR EXT
GRAF 03E0 DIALED TO VTAM 03E0
GRAF 03E1 DIALED TO VTAM 03E1
VTAM CONTROLS THE FOLLOWING LU'S
GRAF VTAM1.LU3E0 LOGON AS CMS0001 03E0
GRAF VTAM1.LU3E1 LOGON AS CLASSG 03E0
```

If instead you enter a QUERY GRAF, QUERY GRAF ACTIVE, or QUERY ALL command without the EXTended option you might see something like this:

```
Q GR
GRAF 03E0 DIALED TO VTAM 03E0
GRAF 03E1 DIALED TO VTAM 03E1
VTAM CONTROLS THE FOLLOWING LU'S
GRAF LU3E0 LOGON AS CMS0001 03E0
GRAF LU3E1 LOGON AS CLASSG 03E0
```

## Messages

## QUERY HCD

---

►► Query — HCD ◄◄

### Authorization

Privilege Class: B

### Purpose

Use the Query HCD command to display whether HCD is active. If HCD is active, the current production IODF, dynamic hardware change status, software configuration control information, and recovery status will also be displayed.

### Responses

Response 1:

When the Query HCD command is issued and the VM/HCD service virtual machine is not in control of the hardware or software I/O configuration, then the following response is issued:

```
query hcd
HCD is not active
Ready;
```

Response 2:

When the Query HCD command is issued and the VM/HCD service virtual machine is in control of the hardware I/O configuration, but currently is disabled for dynamic hardware changes and is not in control of the software I/O configuration and HCD recovery is not required, then the following response is issued:

```
query hcd
HCD is currently active: IODF = IODF02 PRODIODF
HCD is disabled for dynamic hardware changes
HCD is not controlling the software configuration
HCD recovery is not currently required
Ready;
```

Response 3:

When the Query HCD command is issued and the VM/HCD service virtual machine is in control of the hardware I/O configuration and currently is enabled for dynamic hardware changes, but is not in control of the software I/O configuration and HCD recovery is not required, then the following response is issued:

```
query hcd
HCD is currently active: IODF = IODF02 PRODIODF
HCD is enabled for dynamic hardware changes
HCD is not controlling the software configuration
HCD recovery is not currently required
Ready;
```

Response 4:

When the Query HCD command is issued and the VM/HCD service virtual machine is in control of the hardware I/O configuration and currently enabled for dynamic hardware changes and is also in control of the software I/O configuration and HCD recovery is not required, then the following response is issued:

```
query hcd
HCD is currently active: IODF = IODF02 PRODIODF
HCD is enabled for dynamic hardware changes
HCD is controlling the software configuration: OSCONFIG ID = VMCONFIG
```

```
HCD recovery is not currently required  
Ready;
```

#### Response 5:

When the Query HCD command is issued and the VM/HCD service virtual machine is in control of the hardware I/O configuration but currently disabled for dynamic hardware changes and is also in control of the software I/O configuration, and HCD recovery is required, then the following response is issued:

```
query hcd  
HCD is currently active: IODF = IODF02 PRODIODF  
HCD is disabled for dynamic hardware changes  
HCD is controlling the software configuration: OSCONFIG ID = VMCONFIG  
HCD recovery is currently required  
Ready;
```

### Messages

- HCP003E Invalid option - *option*
- HCP263E Too many operands were supplied for this command.

## QUERY HOLD

### Authorization

Privilege Class: B, D

### Purpose

Use QUERY HOLD to display the following:

- Users in logon hold status
- Users with output in system hold status.

### Operands

#### LOG

displays logon hold information. If you are a class B user, you must specify LOG; this option is restricted to users with class B privileges. The logon hold information is displayed.

### Usage Notes

1. If you are a class B user, you can display logon hold information. If you are a class D user, you can display output hold data. If you hold both privilege classes, you can display either.
2. Users in logon hold status can also have output files in hold status.

### Responses

Response 1:

```
HOLD: {nnnnnnn} PRT, {nnnnnnn} PUN
      {      NO}   {      NO}
```

#### nnnnnnn

#### NO

is the number of files of the type indicated (PRT or PUN), or NO (if none) in hold status. For the class B user, this is the number of files belonging to users in logon hold status. For the class D user, this is the number of files in system hold status. For a user with both classes, it is the combined total.

This response is always the first of two responses issued.

Response 2:

```
NO USERS HELD
```

For the command QUERY HOLD (class D), this means there are no users currently in output hold status. For the command QUERY HOLD LOG (class B), this response means there are no users currently in logon hold status.

Response 3:

```
userid - {ALL},... (up to four users per line)
         {PRT}
         {PUN}
```

is displayed in response to the QUERY HOLD (class D) command for each user in output hold status.

**userid**

identifies the user in output hold status.

**ALL**

**PRT**

**PUN**

indicates which type of output is being held for the user. PRT for printer files only, PUN for punch files only, and ALL for both printer and punch files.

Response 4:

*userid* - LOG, ... (up to four users per line)

is displayed in response to the QUERY HOLD LOG (class B) command for each user in logon hold status.

**userid**

identifies the user in logon hold status.

Response 5:

```
userid - LOG {ALL},...
           {PRT}
           {PUN}
```

is displayed in response to the QUERY HOLD LOG command (Classes B and D) for any user in both logon and output hold status.

**ALL**

**PRT**

**PUN**

indicates in which type of output hold the user may be.

## Messages

- HCP026E Operand missing or invalid
- HCP422E The same option was specified twice.

## QUERY HOTIO

► Query — HOTIO ◄

### Authorization

Privilege Class: B

### Purpose

Use QUERY HOTIO to display the current hot I/O rate settings for devices in the active I/O configuration. (The hot I/O rate is the maximum number of consecutive, unsolicited interrupts per second that CP should allow from an I/O device before refusing to accept input from it.) For information on how to change the hot I/O rate settings for your system, see [“SET HOTIO” on page 1516](#).

### Usage Notes

1. When you enter the QUERY HOTIO command, CP displays the current list of hot I/O rate settings in a form similar to the SET HOTIO command you issued. In some cases, you may see multiple response lines for specific devices because their range and class overlap. When this happens, CP displays the responses in order of precedence: last in, first out.
2. If you want to set the hot I/O rate before the system IPLs, use the HOT\_IO\_RATE statement in the system configuration file. For more information, see [HOT\\_IO\\_RATE Statement in z/VM: CP Planning and Administration](#).

### Responses

If you enter QUERY HOTIO, you receive one of the following responses for each device range and class:

```
HOTIO ON device RATE rate
HOTIO OFF device
```

#### ***device***

indicates the device or devices to which this hot I/O rate setting applies. The variable *device* can be any of the following:

ALL	<i>rdev-rdev</i>	TAPE
DASD	SPECIAL	TERMINAL
GRAF	SWITCH	UR
<i>rdev</i>		

The variables *rdev* and *rdev-rdev* represent a real device number

#### ***rate***

is either:

- A decimal number from 1 to 62500 that indicates the hot I/O rate setting for the specified device or devices
- The word DEFAULT, which indicates a hot I/O rate of 16 for the specified device or devices.

Response 1:

You will see the following response when you do not specify any HOT\_IO\_RATE statements in the system configuration file and you have not issued any SET HOTIO commands:

```
HOTIO ON ALL RATE DEFAULT
```

Note that DEFAULT=16, so all devices in the active I/O configuration have a hot I/O rate of 16.

Response 2:

```
HOTIO ON DASD RATE 00050
```

This response indicates that you either:

- Issued a SET HOTIO DASD 50 command, or
- Specified HOT\_IO\_RATE DASD 50 statement in your system configuration file.

Although they are not listed, all other devices in the active I/O configuration have a hot I/O rate of 16 (DEFAULT). In most of the QUERY HOTIO responses you see, CP will not explicitly tell you that I/O devices are using the default hot I/O rate of 16. There are only two reasons you will see DEFAULT in a QUERY HOTIO response:

1. When no HOT\_IO\_RATE statements or SET HOTIO commands have been processed (as you saw in Response 1).
2. When you use a HOT\_IO\_RATE statement or SET HOTIO command to change the hot I/O rate for one or more devices and you use a second statement or command to change that same device (or devices) back to the default. (You will see an example of this for DASD devices in Response 3.)

Response 3:

This example shows you the responses you would see before and after issuing various SET HOTIO commands.

The following response indicates that all devices in the active I/O configuration are using the default hot I/O rate of 16:

```
q hotio
HOTIO ON ALL RATE DEFAULT
Ready;
```

Here is what you would see if you issued a SET HOTIO DASD command followed by a QUERY HOTIO command:

```
set hotio dasd 25
Ready;

q hotio
HOTIO ON DASD RATE 00025
Ready;
```

Note that you no longer see the response line that indicated all devices were using the default.

Here is what you would see if you issued a SET HOTIO command for a specific range of devices followed by another QUERY HOTIO command:

```
set hotio 280-28f 32
Ready;

q hotio
HOTIO ON 0280-028F RATE 00032
HOTIO ON DASD RATE 00025
Ready;
```

Note that you see the results of both of the SET HOTIO commands you have issued thus far with the last command that you issued as the first response in the list. This response tells you that all DASD devices have a hot I/O rate of 25 and all devices in the range X'0280' to X'028F' have a hot I/O rate of 32. Because the last command you issued is the most recent hot I/O rate change, CP displays that command first. In

## QUERY HOTIO

this example, if any of the devices in the range X'0280' to X'028F' are DASD devices, they will have a hot I/O rate of 32, because your second command overrides the global rate defined in your first command.

Here is what you would see if you issued a SET HOTIO command for a specific device number followed by another QUERY HOTIO command:

```
set hotio 28e 124
Ready;

q hotio
HOTIO ON  028E      RATE 00124
HOTIO ON  0280-028F RATE 00032
HOTIO ON  DASD     RATE 00025
Ready;
```

Note that you see the results of all three SET HOTIO commands you have issued thus far and note that they appear in last in, first out order. This response tells you that all DASD devices have a hot I/O rate of 25 and all devices in the range X'0280' to X'028F' have a hot I/O rate of 32, except for the device at X'028E', which has a hot I/O rate of 124. Again, if any of the devices in the range X'0280' to X'028F' are DASD devices, then they will have a hot I/O rate of 32 (or 124) instead of 25.

Here is what you would see if you issued a SET HOTIO DASD DEFAULT command followed by another QUERY HOTIO command:

```
set hotio dasd default
Ready;

q hotio
HOTIO ON  DASD     RATE DEFAULT
HOTIO ON  028E     RATE 00124
HOTIO ON  0280-028F RATE 00032
Ready;
```

This response tells you that all devices in the range X'0280' to X'028F' have a hot I/O rate of 32 (except for the device at X'028E', which has a hot I/O rate of 124) and all DASD devices have the default hot I/O rate of 16. Note that you issued four SET HOTIO commands and you only see three responses. Two of the commands (the first and the fourth) affecting the same devices (DASD). Because your fourth command completely overrode your first command, CP no longer needs to display the results of your first SET HOTIO DASD command.

Here is what you would see if you issued a SET HOTIO command to turn hot I/O detection off for a specific device followed by a final QUERY HOTIO command:

```
set hotio 28f off
Ready;

q hotio
HOTIO OFF 028F
HOTIO ON  DASD     RATE DEFAULT
HOTIO ON  028E     RATE 00124
HOTIO ON  0280-028F RATE 00032
Ready;
```

This response tells you that all devices in the range X'0280' to X'028F' have a hot I/O rate of 32 (except for the device at X'028E', which has a hot I/O rate of 124, and device X'028F', which has turned off hot I/O detection) and all DASD devices have the default hot I/O rate of 16. Again, if device X'028F' is a DASD device, then your last SET HOTIO command (which turned off hot I/O detection for device X'028F') will override your previous command (SET HOTIO DASD DEFAULT), causing all DASD devices have the default hot I/O rate of 16, except for the DASD at X'028F' which is no longer detecting interrupts.

## Messages

- HCP002E Invalid operand - *operand*
- HCP6816E Hot I/O rates are being controlled by HCD.

## QUERY HYPERSWAP

### Authorization

Privilege Class: B

### Purpose

Use the QUERY HYPERSWAP command to display the status of a device or to display z/VM capabilities with respect to the HyperSwap function.

### Operands

#### *rdev*

#### *rdev.numDevs*

specifies a single real device (*rdev*) or a real device combined with a decimal range count (*rdev.numDevs*). A single *rdev*, a series (*rdev rdev*), a range (*rdev.numDevs*) or a combination of these forms may be entered. For a device in the active configuration, the device number entered must be a 4-digit hexadecimal number between X'0000' and X'FFFF'. For a device in the standby configuration, the device must be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is configured. A range of devices cannot span subchannel sets.

#### **CAPabilities**

displays the system's capabilities related to the HyperSwap function.

### Usage Notes

1. Responses are issued for individual devices and appear only for devices that are either quiesced or enabled for automatic quiesce processing. Refer to the HYPERSWAP command (see [“HYPERSWAP” on page 525](#)) for more information.
2. If a device is enabled for automatic quiesce processing and is also currently quiesced, the response indicates that the device is quiesced.
3. Responses to the CAPABILITIES operand are blank delimited tokens which might be in any order. Programs parsing these results must be able to handle tokens in any arbitrary order as well as tolerate undefined tokens.

### Responses

Response 1:

To query the HyperSwap status of devices 190-19F and 200 when the device has been enabled for automatic quiesce, enter the following:

```
Q HYP 190.16 200
Device 0190 is enabled for automatic quiesce processing
  MIH Trigger: Disabled
Device 0191 is quiesced
Device 0192 is enabled for automatic quiesce processing
```

## QUERY HYPERSWAP

```
MIH Trigger: Enabled after 3 missing interrupt(s)
Device 019A is quiesced
Device 019D is enabled for automatic quiesce processing
MIH Trigger: Disabled
Device 019E is enabled for automatic quiesce processing
MIH Trigger: Enabled after 5 missing interrupt(s)
Device 019F is quiesced
Ready;
```

The MIH Trigger line will not be displayed for devices that are already quiesced because the trigger is not relevant at this point.

Response 2:

To query the HyperSwap status of devices 200-207, enter the following:

```
Q HYP 200.8
There are no Hyperswap functions now in effect for the specified devices
Ready;
```

Response 3:

To query the z/VM capabilities related to the HyperSwap function, enter the following:

```
Q HYP CAP
Capabilities: SSI MSS PPRCSN MT OFFSEC
Ready;
```

Response token definitions are:

### SSI

z/VM CP contains support required for a Geographically Dispersed Parallel Sysplex (GDPS) to tolerate a z/VM Single System Image (SSI) in a GDPS HyperSwap environment. Specifically, this pertains to support required by GDPS to automate recovery of GDPS initiated system resets directed to SSI member LPARs.

### MSS

z/VM CP contains support to place secondary Peer-to-Peer Remote Copy (PPRC) DASD in an alternate Subchannel Set for the purpose of being exploited in a GDPS HyperSwap environment.

### MSS4

z/VM CP contains support for 4 subchannel sets limited to only DASD devices in subchannel sets 0, 1, 2 and 3.

### PPRCSN

z/VM CP enables and processes PPRC Suspend Summary Notifications for the purpose of reducing CP host overhead during PPRC state changes, specifically in a GDPS HyperSwap environment.

### MT

z/VM CP contains support for Multi-Target Peer-to-Peer Remote Copy (MT PPRC) DASD.

### OFFSEC

z/VM CP supports the OFFSEC operand on the HYPERSWAP command to vary offline specified additional secondary devices in a Multi-Target PPRC scenario.

### VARYON

z/VM CP contains support for parallel VARY ON of real devices.

## Messages

- HCP002E Invalid operand - *operand*
- HCP6704E Missing token at end of line
- HCP6706E Invalid device address - *address*

## QUERY ICLNAME

```
► Query — ICLNAME — epname ►
```

### Authorization

Privilege Class: A, C, E

### Purpose

Use QUERY ICLNAME to display usage statistics information about indirect calls to external entry points.

### Operands

#### *epname*

is the name of the external entry point for which you want to display information. The variable *epname* must be a 1-character to 8-character string. The first character must be alphabetic or one of the following special characters: dollar sign (\$), number sign (#), underscore (\_), or at sign (@). The rest of the string can be alphanumeric characters, the 4 special characters (\$, #, \_, and @), or any combination thereof.

You can use generic entry point names to request information about a specific subset of entry point names. A generic entry point name is a 1-character to 8-character string with asterisks (\*) in place of 1 or more characters and percent signs (%) in place of exactly 1 character. For example,

```
query iclname hcp%rc*
```

displays all the entry points that start with HCP and have RC as their fifth and sixth characters.

### Usage Notes

1. To display the address of the CP indirect call locator block for a specific exit point, use the LOCATE ICLBK command (see [“LOCATE ICLBK”](#) on page 614).
2. For more information about indirect calls to external entry points, see [Available Diagnostic Facilities in z/VM: CP Exit Customization](#).

### Responses

Response 1:

To display the current usage statistics for all external entry points whose names begin with the letters "RDF", enter the following:

```
query iclname rdf*
ICLNAME      Count Seconds
RDFSAMPL     90 0.000123
RDFEXECU      1 0.000041
Ready;
```

In this example,

#### **ICLNAME**

is the name of the external entry point in the indirect call locator block (ICLBK).

#### **Count**

shows you the total number of successful indirect calls to this external entry point.

### Seconds

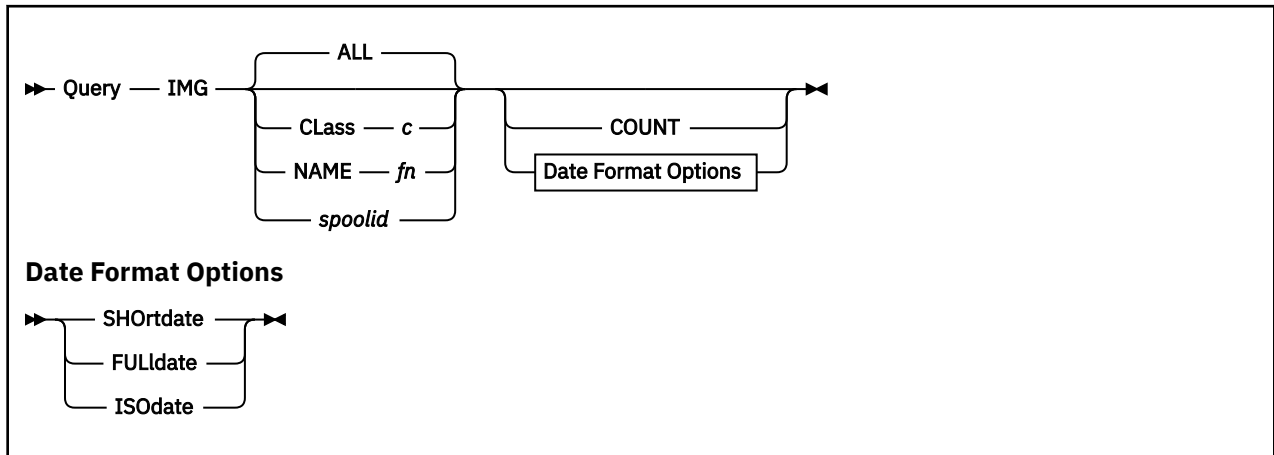

shows the total elapsed time CP used to process all of the successful indirect calls to this external entry point. For each successful indirect call, CP records how long it took (the elapsed time, not CPU time) to process the external entry point from the time it was called to the time it finished processing.

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid
- HCP6706E Invalid entry point name - *epname*
- HCP6720I No items found to satisfy selection criteria.

## QUERY IMG

### Authorization

Privilege Class: A, B, C, D, E

### Purpose

Use QUERY IMG to display information about image library (IMG) files.

### Operands

#### ALL

lets you display information on all files of the specified type. This is the default.

#### Class *c*

specifies the class of files to be queried. The operand *c* is either A or P, where A indicates that the file is in the available state and P indicates that the file is in the pending purge state.

#### NAME *fn*

specifies the file name of the file for which information is displayed.

#### *spoolid*

identifies the file to be queried; this number is assigned by the system.

#### COUNT

displays only the number of image library files that match the criteria specified on the command. No other information is provided.

### Options

#### SHOrtdate

Specifies that dates in the response to this command will be displayed in mm/dd format, where mm is the month and dd is the day of the month.

#### FULldate

Specifies that dates in the response to this command will be displayed in mm/dd/yyyy format, where mm is the month, dd is the day of the month, and yyyy is the 4-digit year.

#### ISOdate

Specifies that dates in the response to this command will be displayed in yyyy-mm-dd format, where yyyy is the 4-digit year, mm is the month, and dd is the day of the month.

## Usage Notes

1. Class G users can use QUERY RDR/PRT/PUN to display comparable information for spool files.
2. If no date format option is specified, then the user's default date format setting is used.

## Responses

Response 1:

The following response is issued when you specify QUERY IMG with the SHORTDATE option.

```
OWNERID  FILE TYPE CL RECS DATE  TIME      FILENAME FILETYPE ORIGINID
*IMG     spid typ  c  nnnn mm/dd hh:mm:ss filename filetype originid
```

Response 2:

The following response is issued when you specify QUERY IMG with the FULLDATE option.

```
OWNERID  FILE TYPE CL RECS DATE      TIME      FILENAME FILETYPE ORIGINID
*IMG     spid typ  c  nnnn mm/dd/yyyy hh:mm:ss filename filetype originid
```

Response 3:

The following response is issued when you specify QUERY IMG with the ISODATE option.

```
OWNERID  FILE TYPE CL RECS DATE      TIME      FILENAME FILETYPE ORIGINID
*IMG     spid typ  c  nnnn yyyy-mm-dd hh:mm:ss filename filetype originid
```

### OWNERID

indicates that the file is an IMG file owned by the system. The designation \*IMG is not a user ID; it indicates the queue on which the file resides.

### FILE

identifies the spool file.

### TYPE

identifies the type of system data file. This is IMG for image library files.

### CL

identifies the file class, either A or P. Class A indicates that the file is available. Class P indicates that the file is in the pending purge state; it is purged during the next system IPL or RESTART.

### RECS

identifies the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines in thousands rounded to the nearest 1000. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines in millions rounded to the nearest million.

### DATE

identifies the date the file was closed. The format of the date is determined by the SHORTDATE, FULLDATE, or ISODATE options.

### TIME

identifies the time the file was closed, in hours, minutes, and seconds. If the file has not yet been closed, this is the time the file was opened.

### FILENAME

identifies the file name assigned to the file.

### FILETYPE

identifies the file type assigned to the file.

### ORIGINID

identifies the originator of the file.

Response 2:

```
FILES: NO IMG
```

is returned if none of the specified files exists.

Response 3:

If the COUNT option is specified on the QUERY IMG command, only the number of image library files that match the criteria specified is displayed:

```
FILES: {nnnn} IMG
        { NO }
```

### **nnnn**

identifies the number of image library files. If no files are found that match the selection criteria, NO replaces *nnnn*.

### **Messages**

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP413E Command processing cannot complete due to a spool paging error.
- HCP422E The same option was specified twice.
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP848E SYSTEM parameter is invalid with the spoolid option
- HCP849E A user ID must be specified with the spoolid
- HCP1558E Command processing cannot complete.

## QUERY IO\_OPT

### Authorization

Privilege Class: B, G

### Purpose

Use QUERY IO\_OPT to determine the current status of all I/O options for a virtual machine. The setting for I/O options are controlled by the SET IO\_OPT command.

### Operands

#### USER *userid*

\*

specifies an individual user for which the I/O options status is to be reported.

An asterisk (\*), which is the default, specifies the virtual machine (user ID) from which the command is issued.

If QUERY IO\_OPT is executed with the AT command, *userid* operand is required.

### Usage Notes

1. When the setting for all users is OFF, that virtual machine I/O option is disabled for all virtual machines, including any new users that may logon, regardless of the individual setting.  
When the setting for all users is ON, then the individual user setting determines whether I/O options are enabled or disabled for the requested user ID.
2. The default setting for the UID I/O option is to be set ON for all users and each virtual machine. When this option is ON for a virtual machine, two real PCI functions with the same UID value cannot be attached to the same virtual machine.
3. The default setting for the ENFORCE\_BY\_VOLID I/O option is determined by the ENFORCE\_BY\_VOLID configuration statement. When this option is ON, CP enforces attachment of DASD devices by their VOLIDs.

### Responses

Response 1:

If you enter QUERY IO\_OPT with an *userid* or \*, you will see something like:

```
ALL USERS SET IO_OPT UID - {OFF}
                        {ON}
ENFORCE_BY_VOLID - {OFF}
```

```

                                {ON})
OPTION SETTINGS FOR {userid}:
OPTION SETTING
UID      {ON}
        {OFF}

```

The first section of the response displays the setting for all I/O options for all users. The second section of the response displays the settings for all I/O options for the virtual machine specified.

**OPTION**

displays the I/O options which are set to be enabled/disabled.

**SETTING**

displays the individual user setting.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP007E Invalid userid - *userid*
- HCP020E Userid missing or invalid
- HCP045E *userid* not logged on
- HCP263E Too many operands were supplied for this command

## QUERY IOASSIST

### Authorization

Privilege Class: B, G

### Purpose

Use QUERY IOASSIST to determine the current status of all I/O assists for a virtual machine. The setting for I/O assists are controlled by the SET IOASSIST command, as well as the SET QIOASSIST command.

### Operands

#### USER *userid*

\*

specifies an individual user for which the I/O assist status is to be reported.

An asterisk (\*), which is the default, specifies the virtual machine (user ID) from which the command is issued.

If QUERY IOASSIST is executed with the AT command, *userid* operand is required.

### Usage Notes

1. When the setting for all users is OFF, eligibility for virtual machine assists is disabled for all virtual machines, including any new users that may logon, regardless of the individual setting.

When the setting for all users is ON, then the individual user setting determines whether I/O assists are allowed or disallowed for the requested user ID.

### Responses

Response 1:

If you enter QUERY IOASSIST with an *userid* or \*, you will see something like:

```
ALL USERS SET IOASSIST - {OFF}
                        {ON}

ASSIST SETTINGS FOR {userid}:

ASSIST SETTING STATUS
ALL      {ON}      {ACTIVE}
         {OFF}    {PENDING ACTIVE}
         {INACTIVE}
         {NOT AVAILABLE}
```

```
{USER DISABLED}
{CP DISABLED}
```

The first line of response displays the setting for all I/O assists for all users. The second line of response displays the userid of the specific virtual machine for which this assist is setting.

**ASSIST**

displays the I/O millicode assists which are set to be enabled/disabled.

**SETTING**

displays the individual user setting.

**STATUS**

displays status for all assists which will each be one of the following:

**ACTIVE**

the specified userid is currently enabled to use the assist.

**PENDING ACTIVE**

the specified userid is in the process of being enabled to use the assist.

**PENDING INACTIVE**

the specified userid is in the process of being disabled from using the assist.

**INACTIVE**

the specified userid is currently not using the assist.

**NOT AVAILABLE**

the assist is not available to the virtual machine.

**USER DISABLED**

the virtual machine was made ineligible to use the assist by the SET IOASSIST OFF or SET QIOASSIST OFF command for the userid.

**CP DISABLED**

the virtual machine cannot use the assist because of special conditions in the virtual machine environment. For example, if the user enabled the tracing of I/O interruptions via the TRACE I/O or TRACE AIF CP commands, the queue-I/O assist is disabled in order to trace the events.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP007E Invalid userid - *userid*
- HCP020E Userid missing or invalid
- HCP045E *userid* not logged on
- HCP263E Too many operands were supplied for this command

## QUERY IOPRIORITY

### Authorization

Privilege Class: A, E

### Purpose

Use QUERY IOPRIORITY to display a user's I/O priority settings or the I/O priority range available to CP.

### Operands

*userid*

\*

specifies the user identification of the virtual machine whose I/O priority range is to be displayed. You can specify an asterisk (\*) to display information about your own virtual machine.

**SYSTEM**

notifies CP to display information about the I/O priority range available to CP.

### Usage Notes

1. The initial I/O priority settings for a user can be specified by the IOPRIORITY statement in the user's directory entry. If an IOPRIORITY statement is not found and LPAR I/O Priority Facility is enabled, LOGON processing requests RELATIVE I/O priority range with a low value of 0 and a high value of 0. The user's effective range is computed based on the I/O priority range available to CP.
2. The I/O priority settings of a user can be changed by the SET IOPRIORITY command. For more information about this command, see [“SET IOPRIORITY” on page 1527](#).

### Responses

Response 1:

The following is the response to QUERY IOPRIORITY SYSTEM:

**LPAR I/O Priority Facility is not installed. Simulated range is 0 to 255**

indicates that the LPAR I/O Priority Facility is not installed, but CP is simulating a range from 0 to 255.

**LPAR I/O Priority Facility is not enabled**

indicates that the LPAR I/O Priority Facility is installed but not enabled for your local partition (LPAR). CP is simulating a range from 0 to 255.

**LPAR I/O Priority Facility is enabled. Range is *nnn* to *mmm***

indicates that the LPAR I/O Priority Facility is installed and enabled for your local partition (LPAR). *nnn* is the lowest I/O priority available to your logical partition and *mmm* is the highest.

Response 2:

One of the following is the response to QUERY IOPRIORITY *userid*:

```

userid  REQUESTED RANGE nnn mmm ABSOLUTE
        EFFECTIVE RANGE xxx yyy-
  
```

or

```
userid  REQUESTED RANGE nnn mmm RELATIVE
        EFFECTIVE RANGE xxx yyy
```

**userid**

is the user ID whose I/O priority settings are being displayed.

**REQUESTED RANGE nnn mmm**

indicates the low and high values of the I/O priority range requested for this user.

**ABSOLUTE****RELATIVE**

indicates the type of range that was requested for this user.

**EFFECTIVE RANGE xxx to yyy**

indicates the low and high values of the I/O priority range that CP will allow this user to use.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*}
- HCP020E Userid missing or invalid
- HCP045E *userid* not logged on

## QUERY IPLPARMS

► Query — IPLparms ◄

### Authorization

Privilege Class: A

### Purpose

Use QUERY IPLPARMS to display the initial program load (IPL) parameters currently in CP storage that CP will use for a shutdown re-IPL or a software restart.

### Usage Notes

1. This command displays exactly what was stored in the 240-byte field in CP storage. HCPSAL (the stand-alone loader) passes the IPL parameters to CP and then CP places them into the 240-byte field. You can change the IPL parameters stored in this 240-byte field:
  - a. When creating the Stand-Alone Program Loader (SAPL) using the IPLPARMS operand of the SALIPL utility.
  - b. During initialization, using the panel interface of SAPL.
  - c. After initialization using the SET IPLPARMS command (see [“SET IPLPARMS” on page 1530](#)). The new IPL parameters you specify will then be used during the next shutdown re-IPL or a software restart. They have no effect on the current system.
2. For a description of each of the IPL parameters and more information about SALIPL and SAPL, see [Running Utility Programs in z/VM: System Operation](#).

### Responses

Response 1:

To display the parameters currently stored in the IPL record, enter the following:

```
query iplparms
Current IPL parameters:
FN=SYSTEM      FT=CONFIG      CONS=08E6      PROMPT
Ready;
```

This response tells you that the last time you IPLed, or used the SET IPLPARMS command, you used four IPL parameters to:

- Define the file name of the system configuration file
- Define the file type of the system configuration file
- Specify the address of the operator console
- Indicate that you want CP to prompt you for startup parameters during the next IPL.

CP will use the default values for all the IPL parameters that you did not specify.

Response 2:

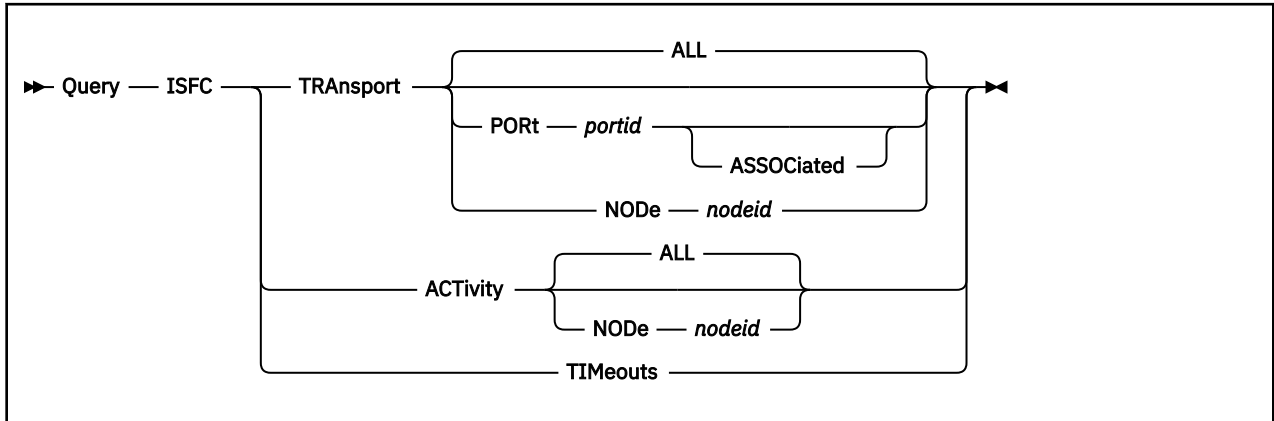

If you did not enter any IPL parameters, you would see the following response:

```
query iplparms  
No IPL parameters are currently defined  
Ready;
```

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*

## QUERY ISFC

### Authorization

Privilege Class: B

### Purpose

Use the QUERY ISFC command to display information about the ISFC Transport end points that have been created or to display logical link information about the logical links to directly connected nodes in the ISFC collection.

### Operands

#### TRANsport

Displays information about the ISFC Transport end points that have been created.

#### ACTivity

Displays logical link information about the logical links to directly connected nodes in the ISFC collection. The information displayed includes message and byte counts.

A logical link is made up of one or more link devices. Use the QUERY ISLINK command to display information about specific link devices.

#### ALL

Displays transport information for all ISFC end points or activity for all nodes. ALL is the default.

#### PORt *portid*

Requests a display of information about the end point matching the specified *portid*.

#### ASSOCiated

Requests a display of information about all end points associated with *portid*.

#### NODe *nodeid*

Requests a display of information about all end points associated with remote node *nodeid*, or all activity associated with remote node *nodeid*.

#### TIMEouts

Displays the status of cross-system timeouts: enabled or disabled. For more information, refer to the CROSS\_SYSTEM\_TIMEOUTS operand on the FEATURES statement in the system configuration file. See [FEATURES statement in z/VM: CP Planning and Administration](#).

### Responses

Response 1:

## QUERY ISLINK

### ***devno1***

Specifies the device number used at *nodeid* to connect to link device *devno*.

Response 2:

```
No links are defined.
```

### **Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid
- HCP2720E Link device *rdev* not found.
- HCP2720E Node *nodeid* not found.

# QUERY IUCV

Notes:

- <sup>1</sup> Options are valid only for class B users.
- <sup>2</sup> If QUERY IUCV is executed with the AT command, the *userid* or *\*syserv* operand is required.

## Authorization

Privilege Class: B, G

## Purpose

QUERY IUCV displays information about IUCV connections. A class G user can display the user's own IUCV connections. A class B user can display IUCV connection information for any user or IUCV system service.

## Operands

### USER *userid*

identifies a specific user whose IUCV connections are to be displayed.

### \**syserv*

identifies an IUCV system service whose IUCV connections are to be displayed.

## Responses

The command produces a table describing the IUCV paths:

Source	Path	Target	Path	Messages
<i>sourceid</i>	<i>ssss</i>	<i>targetid</i>	<i>tttt</i>	<i>mmmmmmm</i>

where:

### *sourceid*

is the user identifier of the source path owner.

### *ssss*

is the source path ID in hexadecimal.

### *targetid*

is the user identifier of the target path owner.

### *tttt*

is the target path ID in hexadecimal.

### *mmmmmmm*

is the number of outstanding messages on the path.

If \*SCLP connections are displayed, the following response is produced:

Source	Path	Target	Path	Messages	Owner	Class Mask
<i>sourceid</i>	<i>ssss</i>	<i>targetid</i>	<i>tttt</i>	<i>mmmmmmm</i>	<i>ownerid</i>	<i>ccccccc</i>

where:

## QUERY IUCV

**sourceid**

is the user identifier of the source path owner.

**ssss**

is the source path ID in hexadecimal.

**targetid**

is the user identifier of the target path owner.

**tttt**

is the target path ID in hexadecimal.

**mmmmmmmm**

is the number of outstanding messages on the path.

**ownerid**

is the user identifier of the owner of the event class.

**cccccccc**

is the event class mask in hexadecimal.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP007E Invalid userid - *userid*
- HCP045E *userid* not logged on
- HCP6704E Missing token at end of line
- HCP6706E Invalid string - *string*

# QUERY JOURNAL

---

► Query — JOURNAL ◄

## Authorization

Privilege Class: A, E

## Purpose

Use QUERY JOURNAL to determine status of the security journaling function.

## Usage Notes

1. The QUERY JOURNAL command can be used only if the SET\_AND\_QUERY ON operand is specified on the JOURNALING statement in the system configuration file.

Response 1:

```
Journal: LOGON- {on }, LINK- {on }
               {off}, {off}
```

### LOGON ON

### LOGON OFF

Indicates whether accounting records are generated and messages are sent to operations personnel when excessive LOGON attempts with not valid passwords are detected. It also indicates the status of the logon inductor.

### LINK ON

### LINK OFF

Indicates whether type 06 accounting records are generated and messages are sent to operations personnel when excessive LINK attempts with invalid passwords are detected.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

## QUERY KEYALIAS

### Authorization

Privilege Class: G

### Purpose

Use the QUERY KEYALIAS command to display current key label alias definitions. Key label aliases are used on the ATTACH and SET RDEV commands to identify the key label(s) to be used for encrypting data written to a tape.

### Operands

#### ALL

displays the alias name, encoding mechanism, and key label for all defined key aliases. This is the default.

#### *aliasname*

displays the encoding mechanism and key label for the specified alias.

### Responses

Response 1:

Display all defined key label aliases:

```
q keya all
KEYALIAS: (L) DEPTU18
          = TAPE_PVT_U18
KEYALIAS: (L) MYALIAS
          = TAPE_ERF_JLM_LHR_PVT_1024_LBL_01
KEYALIAS: (L) ABC Company
          = E3RW33RSSESYQYPSFTQQPX05399
Ready;
```

Response 2:

Display the definition for the alias "MYALIAS":

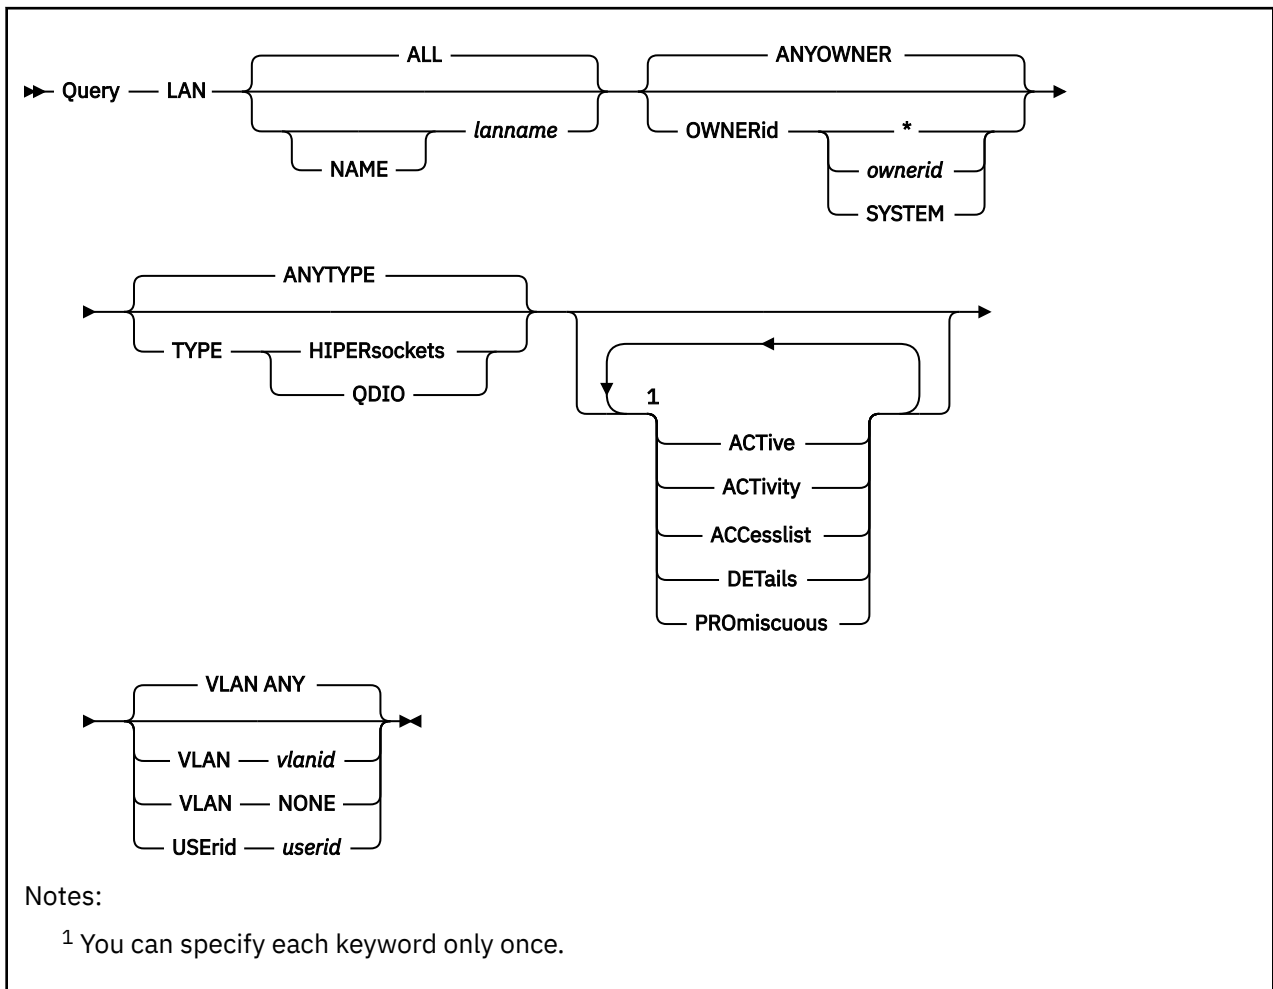

```
q keya myalias
KEYALIAS: (L) MYALIAS
          = TAPE_ERF_JLM_LHR_PVT_1024_LBL_01
Ready;
```

### Messages

- HCP002E Invalid operand - *operand*.
- HCP003E Invalid option - command contains extra option(s) starting with *option*.
- HCP263E Too many operands were supplied for this command.
- HCP6704E Missing token at end of line.
- HCP6706E Invalid string - *string*.

- HCP9968E The key alias does not exist.
- HCP9968I No key aliases found.

## QUERY LAN

### Authorization

Privilege Class: B, G

### Purpose

Use **QUERY LAN** to display information about the designated guest LAN (or any LAN in the System LAN Table). The command keywords and responses documented relate to guest LANs. For information and responses for virtual switches, see [“QUERY VSWITCH” on page 1351](#). When *lanname* represents a virtual switch, use **QUERY VSWITCH** to receive more detailed information.

A Class G user can view any information about any UNRESTRICTED LAN. A Class G user can view information about a RESTRICTED LAN, if the user is the owner of the LAN, in the CP access list for the LAN, or if the user currently has an adapter connected to the LAN.

A Class B user can view information about any LAN in the system.

### Operands

#### ALL

displays information for all possible guest LANs. This is the default when an explicit *lanname* is omitted.

***lanname*****NAME *lanname***

restricts the responses to guest LANs with the specified *lanname*. Both *lanname* and *ownerid* must be known to fully qualify a LAN.

**ANYOWNER**

indicates a request for all qualified guest LANs, regardless of *ownerid* value. This is the default if **OWNERid** is omitted.

**OWNERid \*****OWNERid *ownerid*****OWNERid SYSTEM**

restricts the responses to guest LANs owned by the specified *ownerid*. When **OWNERid \*** is specified, it indicates any LAN owned by the invoker.

**ANYTYPE**

indicates a request for any LAN regardless of LAN TYPE. This is the default when the TYPE operand is omitted.

**TYPE HIPERsockets****TYPE QDIO**

restricts the responses to guest LANs of the specified type.

**ACTive****ACTivity**

displays information about each active connections. Each active connection represents a simulated network interface card (NIC) that has been coupled to the guest LAN. The information displayed includes:

- Identity of the guest LAN.
- The list of users connected to each guest LAN, including the VLAN IDs each is authorized to use.
- IP Addresses registered to the adapter.

**ACcesslist**

displays the current access list for each LAN. For a RESTRICTED LAN, this is the list of all users who are authorized to connect to this LAN with a simulated network adapter. For an UNRESTRICTED LAN, the list will be empty.

This is the list authorized through the use of the SET LAN command using the GRANT and REVOKE operands. If the guest LAN is protected by an External Security Manager (ESM), ESM interfaces must be used to determine the true authorization list.

**DEtails**

displays all available information for each LAN. This is similar to specifying **ACTIVE**, except the display includes users that are coupled, but not active.

**PRomiscuous**

displays a list of users who are authorized for PROMISCUOUS mode on the guest LAN. For an UNRESTRICTED LAN or a HIPERSOCKETS LAN, the list will be empty. No authorization is required for PROMISCUOUS mode with an UNRESTRICTED LAN. PROMISCUOUS mode is not supported on a HIPERSOCKETS LAN.

This is the list authorized through the use of the SET LAN command using the GRANT and REVOKE operands. If the guest LAN is protected by an External Security Manager (ESM), ESM interfaces must be used to determine the true authorization list.

**USERid *userid***

displays the information as requested by other specified options, along with the subset of QUERY LAN DETAILS that applies to the named guest. An error is displayed if *userid* is not coupled.

**VLAN *vlanid***

displays information restricted to connections that have the specified *vlanid* active. **VLAN ANY** displays all connections regardless of any VLAN settings. **VLAN NONE** displays connections that have not enabled VLAN support.

**Examples**

1. QUERY LAN

List information about a specific guest LAN.

```
cp query lan subnta
LAN SYSTEM SUBNTA      Type: QDIO    Connected: 15    Maxconn: INFINITE
PERSISTENT UNRESTRICTED IP      Accounting: ON
IPTimeout: 5           MAC Protection: Unspecified
Isolation Status: OFF    VEPA Status: OFF
Unicast IP address count: 0
```

2. QUERY LAN ACCESSlist:

This example shows the CP access information for LAN SUBNTA.

```
cp query lan subnta accesslist
LAN SYSTEM SUBNTA      Type: QDIO    Connected: 3     Maxconn: INFINITE
PERSISTENT UNRESTRICTED IP      Accounting: ON
IPTimeout: 5           MAC Protection: Unspecified
Isolation Status: OFF    VEPA Status: OFF
Unicast IP address count: 0
```

Note that access is unrestricted, so no list of authorized user IDs is shown.

3. QUERY LAN DETails:

This example displays all the available detail for LAN SUBNTA.

```
cp query lan subnta details
LAN SYSTEM SUBNTA      Type: QDIO    Connected: 3     Maxconn: INFINITE
PERSISTENT UNRESTRICTED IP      Accounting: ON
IPTimeout: 5           MAC Protection: Unspecified
Isolation Status: OFF    VEPA Status: OFF
Unicast IP address count: 4
Adapter Connections:
  Adapter Owner: LINUX5 NIC: 5000.P00 Name: PORT5000 Type: QDIO
  PQUplinkTX: Normal
  RX Packets: 9         Discarded: 0     Errors: 0
  TX Packets: 7         Discarded: 12    Errors: 0
  RX Bytes: 816        TX Bytes: 396
  Device: 5002 Unit: 002 Role: DATA Port: 0079
  Options: Broadcast Multicast IPv6 IPv4 VLAN

```

The fields of this response are described as follows (Additional fields may be displayed for virtual switches, see [“QUERY VSWITCH” on page 1351](#)):

**item**

identifies the item being displayed as either a guest LAN or virtual switch (VSWITCH). *ownerid name* uniquely identifies the LAN or VSWITCH.

**Type**

is the LAN type of the adapter (QDIO or HIPERS) or the type of VSWITCH (QDIO or IVL).

**Connected**

*count* indicates the number of coupled adapters.

**Domain: x**

where *x* is the IVL VSWITCH domain and *x* can be A to H.

**Maxconn**

*max* indicates the maximum number of connections (may be INFINITE).

**persistence**

indicates whether the LAN is PERSISTENT or TRANSIENT

**restriction**

indicates whether the LAN is RESTRICTED or UNRESTRICTED.

**transport**

indicates whether the LAN is ETHERNET or IP.

**MFS**

*mfssize* indicates the Maximum Frame Size. It is displayed only for HiperSocket LANs.

**Accounting: ON**

**Accounting: OFF**

indicates whether accounting records will be generated for this LAN.

**user(n)**

represents one user ID in a list of users authorized to COUPLE to this LAN. This is shown for restricted LANs.

**IPTimeout**

indicates the length of time in minutes that a transient IP address table entry remains in the IP address table for the virtual network. A transient entry is an entry added to the virtual network by one guest on behalf of another. This value has no meaning for ETHERNET networks.

**MAC Protection**

*setting* indicates the level of MAC address protection to be used for network devices coupled to the LAN whose MAC address protection settings are not specified (set to UNSPECIFIED) by the SET NIC CP command.

**Isolation Status**

*nnn* indicates the isolation status of the virtual switch and its QDIO data connection.

**Unicast IP address count**

*nnn* indicates the number of Unicast IP addresses associated with this guest LAN.

**Adapter Owner**

*userid* indicates the userid of the virtual machine owning the simulated NIC.

**NIC**

*dev.Pnn* indicates the base virtual device address and port number of the simulated NIC.

**Name**

*portname* indicates the portname assigned to the virtual adapter. The value "UNASSIGNED" is displayed if your software does not assign a value.

**PQUplinkTX**

*priority* indicates the priority with which outbound traffic will be sent to the external network. This is not applicable to guest LANs, so priority for all simulated NICs connected to a guest LAN is Normal.

**RX packets**

*rxpackets* is the number of packets received.

**TX packets**

*txpackets* is the number of packets transmitted.

**Discarded**

*nnn* indicates the number of packets discarded. A packet can be discarded because it is not formatted correctly, for example, or contains an unauthorized VLAN ID. Packets can also be discarded if the LAN is a virtual switch and its internal buffer limit has been reached. The internal buffer limit is reached when the virtual switch is unable to deliver packets to a guest VM port. An example of this is when a guest VM port input buffer is not being serviced quickly enough by the guest operating system. This can happen when a highly utilized guest operating system needs additional resources (memory or processor) to handle the workload.

**Errors**

*nnn* indicates the number of error packets discarded.

**RX bytes**

*rxbytes* is the number of bytes received.

**TX bytes**

*txbytes* is the number of bytes transmitted.

**Device**

*vdev* indicates one of the devices assigned to this connection.

**Unit**

*nnn* indicates the relative device number of this adapter. The base device is unit 000.

**Role**

*role* indicates the role assigned to this device (CTL-READ, CTL-WRITE, or DATA).

**Port**

*portnum* is the port number associated with the guest connection or the virtual switch network connection.

**VLAN**

*ipversion* can be IPv4 or IPv6 when a single VLAN is set per IP Protocol.

*nnnn(n)* indicates the effective VLAN ID or IDs for the device. Multiple VLAN ID lines may be shown.

*status* is "Assigned by system" or "Assigned by user". If the specified VLAN ID conflicts with the authorizations for this user, "Conflicting VLAN ID" is displayed.

**Router**

*type ipversion* indicates the adapter has configured itself as a router with type Primary, Secondary or Multicast in IP version IPv4 or IPv6. *vlan* is either VLAN followed by the VLAN ID, if it is a VLAN-specific router, or Global, if it is a global router. If it is a global router, lines will follow to describe which VLAN IDs the adapter is routing for.

The router line is displayed only when a router is configured.

**Options**

*options* indicates the currently enabled features for this interface, such as Broadcast, Multicast, IPv4 or IPv6.

***ipaddr***

represents one Unicast IP address that has been registered to this device and optional information relating to the IP address.

An IPv4 address is displayed in dotted-decimal format, for example 9 . 130 . 44 . 144.

An IPv6 address is displayed in compressed format ("::" designates multiple 16-bit groups of zeros). For example, the IPv6 address

```
F802:0000:0000:0000:0000:0A00:0001
```

is displayed in compressed format as F802::A00:1.

***mpaddr***

represents one Multicast IP Address.

For IPv4, the address is displayed in dotted-decimal format with the associated MAC address.

For IPv6, the address is displayed in compressed format ("::" designates multiple 16-bit groups of zeros).

**MAC**

*macaddr* represents a MAC address.

***flags***

additional information that may be displayed with the IP address. These include:

- Remote indicates that this address was registered automatically to represent a source address found in a datagram. This entry is automatically removed after the IP Timeout (IPTimeout) has expired.
- Manual indicates that this address was registered manually by an ARP cache control command from the driver. This entry will be automatically removed after the IP Timeout (IPTimeout) has expired, or it may be removed earlier by the driver.
- NotOwner means that the IP address was registered by the guest using an ARP Add Unconditional setting, but another guest on the virtual switch had already registered the IP address. If the owner of the IP address removes its registration, this guest can become the owner and receive incoming traffic for the IP address.

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP2783E LAN *ownerid lanname* does not exist
- HCP2783E LAN *ownerid lanname* of type *type* does not exist
- HCP2836E VLAN was not found

## QUERY LDEVS

### Authorization

Privilege Class: B, G

### Purpose

Use QUERY LDEVS to display the status of logical devices.

### Operands

#### LDEVs

displays information about logical devices. If you specify LDEVs, the responses show the user ID of the virtual machine that created the logical device.

#### *ldev*

#### *ldev1-ldev2*

displays information about the specified logical devices. Specify each *ldev* as an L followed by 1 to 4 hexadecimal digits. You can specify 1 logical device, a range of logical devices, or any combination thereof.

### Responses

In the following responses, PRT is a printer and GRAF is a display station. Most of the following examples show responses where someone specified LDEVs on the QUERY command. If you omit LDEVs, CP does not display the host information at the end of each response. The rest of the response remains unchanged.

The responses to this query command may be suffixed with one of the following status indicators:

#### 'HOST *hostid*'

usual response - may be followed by 'FROM *ipaddress*' for TCP/IP.

An IPv4 address is displayed in dotted-decimal format.

**Example:** 9 . 130 . 44 . 144

An IPv6 address is displayed in compressed format ("::" designates multiple 16-bit groups of zeros).

**Example:** The following is an IPv6 address:

```
F802:0000:0000:0000:0000:0A00:0001
```

This address is displayed in compressed format as:

```
F802::A00:1
```

#### 'NO HOST'

defined without a *hostid*

#### 'LDBBK DEAD'

LDBBK was flagged as terminated.

## QUERY LDEVS

Response 1:

If a virtual machine user is logged on at the device, you see a response like this:

```
query ldev L101
GRAF L0101 LOGON AS JIM    0009 HOST PVM
Ready;
```

This means that user ID JIM is logged on to the graphic display device at logical device number L0101 and is using virtual console address 0009. PVM is the user ID that created the specified logical device.

Response 2:

If the logical device is dedicated to a user, you see a response like this:

```
query L102
PRT L0102 ATTACHED TO SUSIE  002A
Ready;
```

L0102 is the logical device number of the printer. The printer is attached as the virtual device 002A to user SUSIE's virtual machine.

Response 3:

If the system is using a logical device that needs operator intervention, you see a response like this:

```
query ldev L103
GRAF L0103 has intervention required.
GRAF L0103 LOGON AS LAYLA  03E0 HOST PVM
Ready;
```

L0103 is the logical device number of the graphic display that needs intervention. PVM is the user ID that created the specified logical device.

If the logical device that needs system intervention is a printer, you see a response like this:

```
q L102
Printer L0102 has intervention required.
PRT L0102 ATTACHED TO SUSIE  0102
Ready;
```

Response 4:

If the device is free, you see a response like this:

```
query ldev L102-L105
GRAF L0102 ENABLED  HOST TCPIP    FROM 9.130.58.78
GRAF L0103 ENABLED  HOST PVM
PRT L0104 DISABLED  HOST PVM
GRAF L0105 ENABLED  HOST TCPIP    FROM 9.130.58.29
Ready;
```

PVM and TCPIP are the user IDs that created the specified logical devices.

If you do not specify LDEVS, CP omits the host information at the end of each response and displays instead information on up to 3 logical devices on each line:

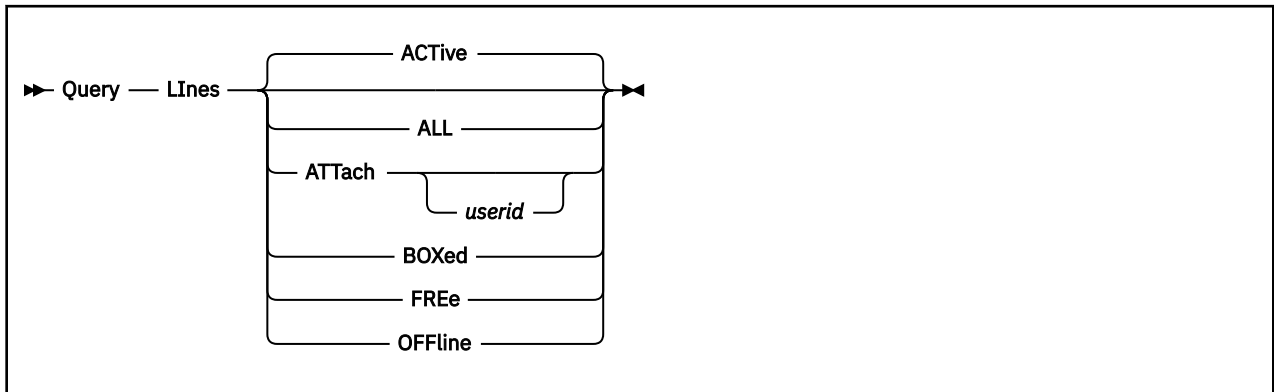

```
query ldevs L0102-L0105
GRAF L0102 ENABLED  , GRAF L0103 ENABLED  , PRT L0104 DISABLED
GRAF L0105 ENABLED
Ready;
```

## Messages

- HCP003E Invalid option - *option*
- HCP009E Invalid range - *range*
- HCP040E Device *ldev* does not exist
- HCP1003E *ldev* was not found.

- HCP1100E A logical device number was not supplied or it is invalid.

## QUERY LINES

### Authorization

Privilege Class: B

### Purpose

Use QUERY LINES to display the status of real communication lines.

### Operands

#### ACTive

indicates active communication lines. An active device is one in use by a user or the system and specified as neither FREE nor OFFLINE.

#### ALL

indicates all communication lines attached to the system. The status is displayed in ACTIVE, FREE, and OFFLINE order and is equivalent to the response you would receive if you entered all of the following commands:

```
query lines active
query lines free
query lines offline
```

#### ATTach *userid*

indicates the communication lines that are dedicated to a user on the system. If you specify *userid*, only lines attached to that user's virtual machine are indicated. If you do not specify *userid*, you receive the status of all lines dedicated to any user on the system. Attached devices are always active.

#### BOXed

indicates the communication lines that are unavailable (usually because of a hardware condition). A boxed line may also be active, free, or offline.

#### FREe

indicates all free communication lines. A free line is one that is not currently in use by a user or the system and is specified as neither ACTIVE nor OFFLINE.

#### OFFline

indicates all offline communication lines. An offline communication line is one specified as neither ACTIVE nor FREE.

### Usage Notes

1. The QUERY LINES, QUERY LINKS, and QUERY VIRTUAL LINES commands share the two possible abbreviations "LI" and "LIN". If you are authorized to issue these commands, it is recommended that

you specify at least 4 character abbreviations of the LINES/LINKS operand to ensure that you invoke the intended command. For example, instead of "Q LI" specify "Q LINE".

2. A VIRTUAL version of this command, QUERY VIRTUAL LINES, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see ["QUERY VIRTUAL LINES"](#) on page 1305.

## Responses

If the system is using a communication line that is in an intervention-required state and you enter QUERY LINES, you receive a response like this:

```
LINE 0FE0 has intervention required.
```

0FE0 is the real device number of the communication line that needs the operator's intervention.

**Note:** This response will be preceded by one of the following.

Response 1:

If you enter QUERY LINES, QUERY LINES ACTIVE, or QUERY LINES ATTACHED and a real communication line is dedicated to a user, you see something like this:

```
q lines attach
LINE 00F0 ATTACHED TO OLIVER 0010
Ready;
```

This response means the communication line with the real device number 00F0 is attached to OLIVER's virtual machine as the virtual device 0010. ATTACHED may be replaced with BOX/ATTC, which means that although the device is dedicated to a user, it is unavailable (usually because of a hardware condition).

Response 2:

If you enter QUERY LINES or QUERY LINES ACTIVE for a communication line that has a user logged on at it or dialed through it, you see something like this:

```
q lines
LINE 00FA LOGON AS DAVID 0009
LINE 00FB DIALED TO PVM 00F9
Ready;
```

This response tells you that the user DAVID is logged on through the communication line at 00FA. The number 0009 is the virtual device number of the virtual console where DAVID is logged on. The second line tells you that the terminal connected to communications line 00FB is dialed to PVM's virtual device number 00F9.

Response 3:

If you enter a QUERY LINES BOXED, QUERY LINES FREE, or QUERY LINES OFFLINE command, you see something like this:

```
q lines free
LINE 00C1 FREE , LINE 00C2 FREE , LINE 00C3 FREE , LINE 00C4 FREE
LINE 00C5 FREE , LINE 00C6 FREE , LINE 00C7 FREE , LINE 00C8 FREE
LINE 00E1 FREE , LINE 00E2 FREE , LINE 00E3 FREE , LINE 00E4 FREE
LINE 00E5 FREE , LINE 00E6 FREE , LINE 00C0 FREE
Ready;
```

The word FREE is replaced by OFFLINE or BOXED, depending on what you entered.

Response 4:

If you enter a QUERY LINES ALL command, CP displays the same response as it would if you had entered QUERY LINES ACTIVE, QUERY LINES FREE, and QUERY LINES OFFLINE commands.

Response 5:

If CP cannot find a communication line of the type you specified, you see a message like this:

## QUERY LINES

```
q lines boxed
A BOXED line was not found.
Ready;
```

BOXED may be replaced with *active*, *attached*, *free*, or *offline*, depending on what you specified on the command.

### Messages

- HCP003E Invalid option - *option*
- HCP020E Userid missing or invalid
- HCP263E Too many operands were supplied for this command.

## QUERY LINKS

### Authorization

Privilege Class: G

### Purpose

Use QUERY LINKS to display link information about a virtual device.

### Operands

#### Links *vdev*

requests the display of information about links to virtual device located at the virtual device number *vdev*.

#### STABLE

requests that QUERY LINKS only display those links that were done with either SR or SW access modes.

### Usage Notes

1. In order to determine if any of the accesses to the specified minidisk are stable accesses, you must issue the command again with the STABLE option.
2. The QUERY LINES, QUERY LINKS, and QUERY VIRTUAL LINES commands share the two possible abbreviations "LI" and "LIN". If you are authorized to issue these commands, it is recommended that you specify at least 4 character abbreviations of the LINES/LINKS operand to ensure that you invoke the intended command. For example, instead of "Q LI" specify "Q LINK".
3. In an SSI cluster where there is sharing of real DASD among multiple z/VM images, QUERY LINKS will display the user IDs of users on the system from which the query is made as well as user IDs of users linked on other systems in the SSI cluster.

### Responses

Response 1:

```

userid vdev {R/W} ,... (up to four responses per line)
            {R/O}
            {R/W ADJUNCT}
            {R/O ADJUNCT}
  
```

#### *userid*

is the user ID of the user who has a link to the specified virtual device.

#### *vdev*

is the virtual device number by which user *userid* refers to the device.

#### R/O

#### R/W

is the type of access user *userid* has to the virtual device. R/O is read-only and R/W is read-write access.

#### ADJUNCT

signifies the virtual device is linked to the named user's adjunct configuration.

## QUERY LINKS

Response 2:

In an SSI cluster, each line of output is prefixed with the system ID and might look similar to this:

```
SYSTEM1 : userid1 0191 R/W, userid2 0191 R/0, userid3 0191 R/0  
SYSTEM2 : userid1 0191 R/0, userid4 0191 R/0
```

### Messages

- HCP6638I LINK information has been truncated.
- HCP6638I No LINK information from other systems in the SSI cluster is included in the response.

# QUERY LKFAC

## Authorization

Privilege Class: G

## Purpose

Use QUERY LKFAC to display information about a Multi-Path Lock Facility RPQ (MPLF) simulation configuration.

## Operands

### ALL

displays the names of all currently defined MPLF configurations.

### config\_name

is the name of the MPLF configuration you want to display.

## Usage Notes

1. If you enter QUERY LKFAC without parameters, CP displays information for the configuration to which the user is currently connected.
2. If you enter QUERY LKFAC with a configuration name, CP displays the information for the specified configuration if the named configuration exists.
3. If you enter QUERY LKFAC ALL, CP displays the names of all defined configurations.

## Responses

Response 1:

```
DEFINED LKFAC CONFIGURATION NAMES:
config_name1 config_name2 config_name3 config_name4
config_name5 .....
```

### config\_name

is the name of the currently defined MPLF configurations.

Response 2:

```
LKFAC config_name  USERS:
                  userid1  useris2  userid3  userid4
                  userid5  userid6  userid7  userid8

I/O Configuration:  SSID      DEVICE RANGE
                   ssss      vdev-vdev
                   ssss      vdev-vdev
                   ssss      vdev-vdev
                   .
                   .
                   .
                   ssss      vdev-vdev
```

## QUERY LKFAC

### **config\_name**

is the name of the MPLF configuration being displayed.

### **userid**

is the user ID of the connected user or users.

### **ssss**

is the virtual subsystem ID (SSID) assigned.

### **vdev**

is the virtual device number ranges associated with the SSID.

## **Messages**

- HCP9961E LKFAC configuration *config\_name* cannot be found
- HCP9962E *userid* not attached to a LKFAC configuration
- HCP9963I No LKFAC configurations defined

## QUERY LKFACR

### Authorization

Privilege Class: G

### Purpose

Use QUERY LKFACR to determine which full-pack minidisks are using the real Multi-Path Lock Facility (MPLF).

### Operands

#### ALL

indicates that the query will list all full-pack minidisks and all dedicated DASD in the virtual configuration that are enabled for real MPLF.

#### *vdev*

#### *rdev1-rdev2*

is the virtual device number or range of virtual device numbers of the devices to be queried for real MPLF.

### Responses

Response 1:

```
Real MPLF is {enabled} for DASD vdev
             {disabled}
```

is issued when the command completes successfully.

Response 2:

```
Real MPLF is enabled for the following full-pack
minidisks: vdev1 vdev2 ... vdevn
```

```
Real MPLF is always enabled for the following dedicated
devices: vdev1 vdev2 ... vdevn
```

is issued when the command completes successfully, and at least one device in each response is enabled for real MPLF. All eligible devices that are part of the queried range are listed in their respective responses. Either response is suppressed if there are no eligible devices for its list.

Response 3:

```
Real MPLF is not available for any virtual devices
in your configuration
```

is issued when the command completes successfully, and no devices from the queried range are enabled for real MPLF.

Response 4:

```
Real MPLF is always enabled for dedicated DASD vdev
```

is issued when the target device is dedicated.

Response 5:

```
Real MPLF is always disabled for non-full-pack  
minidisk vdev
```

is issued when the target device is a non-full-pack minidisk.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

- HCP9967E *type vdev* LKFACR cannot be used - no real MPLF is available

# QUERY LOADDEV

► Query — LOADDEV ◄

## Authorization

Privilege Class: G

## Purpose

Use the **QUERY LOADDEV** command to display LOADDEV parameters for a guest IPL. The parameters are for a list-directed IPL without dump from a SCSI or ECKD device. The parameters can identify the operating system program and information to pass to the program. The parameters can also identify the virtual device number and specify whether the IPL is a secure IPL.

## Responses

The following lines are displayed if LOADDEV parameters are set for a SCSI device:

```
SCSI    DEVICE {TBD } {NOSECURE}
             {ddd} {SECURE  }
PORTNAME hhhhhhhh hhhhhhhh          LUN hhhhhhhh hhhhhhhh          BOOTPROG {n }
                                       {AUTO}
BR_LBA  hhhhhhhh hhhhhhhh
```

The following lines are displayed if LOADDEV parameters are set for an ECKD device:

```
ECKD    DEVICE {TBD } {NOSECURE}
             {ddd} {SECURE  }
BOOTPROG {n } BOOTREC {cylinder head record}
          {AUTO}       {LABEL }
```

The following lines are displayed if hex SCPDATA is set:

```
SCPDATA
00----03 04----07 08----11 12----15 16----19
0000 hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh
0020 hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh
0040 hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh hhhhhhhh
.
.
```

The following lines are displayed if text SCPDATA is set:

```
SCPDATA
0-----1-----2-----3-----4-----
0000 ttttttttttttttttttttttttttttttttttttttttttttttttttttttttttttttt
0050 ttttttttttttttttttttttttttttttttttttttttttttttttttttttttttttttt
0100 ttttttttttttttttttttttttttttttttttttttttttttttttttttttttttttttt
.
.
```

## SCSI

The SCSI response indicates that LOADDEV parameters are set for the IPL of a SCSI device. SCSI is the default device type.

## ECKD

The ECKD response indicates that LOADDEV parameters are set for the IPL of an ECKD device.

**DEVICE TBD**

**DEVICE *dddd***

The DEVICE TBD response indicates that the LOADDEV parameters do not include the device number. The device number is to be determined later.

If the SECURE parameter is not set, then the device number can be specified later as an operand of the **IPL** command. If the SECURE parameter is set, then the device number must be set by using the **SET LOADDEV** command.

The DEVICE *dddd* response indicates the 4-digit hexadecimal virtual device number (*dddd*) of the device to be IPLed.

There is no default value for the DEVICE parameter.

**PORTNAME *hhhhhhhh hhhhhhhh***

The PORTNAME response indicates the hexadecimal 8-byte fibre channel port name of the SCSI device. The default value is 0.

**LUN *hhhhhhhh hhhhhhhh***

The LUN response indicates the hexadecimal 8-byte logical unit number of the SCSI device. The default value is 0.

**BOOTPROG *n***

**BOOTPROG AUTO**

The BOOTPROG response indicates the boot program that is loaded from the IPL device. The *n* value indicates the program number. The program number must be a decimal value in the range 0 - 30. The BOOTPROG AUTO response indicates that the first operating system (not dump program) on the IPL device is loaded. The default value is BOOTPROG 0.

**BR\_LBA *hhhhhhhh hhhhhhhh***

The BR\_LBA response indicates the hexadecimal logical-block address of the boot record of the SCSI device. The default value is 0.

**BOOTREC *cylinder head record***

**BOOTREC LABEL**

The BOOTREC response indicates the location of the boot record. The location can be a specification of cylinder, head, and record on the IPL device. The values are delimited by blanks and contain no leading zeros. The values must be in hexadecimal format.

A BOOTREC LABEL response indicates that the location of the boot record is determined from the volume label. BOOTREC LABEL is the default setting.

**SECURE**

**NOSECURE**

The SECURE response indicates that the SECURE parameter is set. The NOSECURE response indicates that the SECURE parameter is not set. The SECURE parameter must be set before you can initiate a secure IPL. NOSECURE is the default setting.

**SCPDATA**

The SCPDATA response indicates the information that is passed to the IPL program. The information is displayed in the same format (text or hex) as it was entered.

**Usage Notes**

- Parameters for a list-directed IPL without dump (also called LOADDEV parameters) are set by using any of the following methods:
  - **SET LOADDEV** command.
  - LOADDEV user directory statement. The LOADDEV user directory statement can be modified by a directory management tool such as IBM Directory Maintenance (DirMaint). To set load parameters by using DirMaint, use the **DIRM LOADDEV** command. The LOADDEV user directory statement can be modified also by the Image\_IPL\_Characteristics\_Define\_DM API function.

Parameters for a list-directed IPL **with** dump (also called DUMPDEV parameters) are set by using the CP **SET DUMPDEV** command.

For more information, see [SET LOADDEV](#) and [SET DUMPDEV](#), [LOADDEV Directory Statement](#) in *z/VM: CP Planning and Administration*, [DIRM LOADDEV](#) in *z/VM: Directory Maintenance Facility Commands Reference*, and [Image\\_IPL\\_Characteristics\\_Define\\_DM](#) API function in *z/VM: Systems Management Application Programming*.

2. If a LOADDEV parameter is not set and has a default value, then the **QUERY LOADDEV** response displays the default parameter value.
3. The default LOADDEV and DUMPDEV values for the PORTNAME and LUN parameters is 0, which is not a valid device port name and not a valid device LUN. An IPL attempt that uses the default value for the PORTNAME or LUN parameter will fail.

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP2824I No LOADDEV parameters are currently defined

## QUERY LOGMSG

### Authorization

Privilege Class: A, B, C, D, E, F, G

### Purpose

Use QUERY LOGMSG to display the system log messages. The log messages can reside in either a CMS file or the checkpoint area.

If the FEATURES ENABLE LOGMSG\_FROM\_FILE statement is specified in the system configuration file, CP reads the CMS files on the CP-accessed minidisks to determine which log message files to display, and the QUERY LOGMSG command options are valid for a class B user. For more information on the FEATURES statement, see *z/VM: CP Planning and Administration*.

If the FEATURES ENABLE LOGMSG\_FROM\_FILE statement is not specified in the system configuration file, CP displays the log message saved by the SET LOGMSG command.

### Operands

#### ACCount *accountid*

tells CP to display either the contents or origin information of the file that only users whose account ID (set in the user's directory entry) matches *accountid* would see. If you are using a non-DBCS terminal and have not specified the DBCS option, CP searches for a file called *accountid* LOGMSACC on the lowest accessed CP disk. If you are using a DBCS terminal or have specified the DBCS option, CP searches for a file called *accountid* LOGDBACC on the lowest accessed CP disk. If no such file exists, CP searches for a file called *accountid* LOGMSACC.

#### ACIgroup *groupname*

tells CP to display either the contents or origin information of the file that only users who are in the ACI group identified by *groupname* would see. If you are using a non-DBCS terminal and have not specified the DBCS option, CP searches for a file called *groupname* LOGMSACI on the lowest accessed CP disk. If you are using a DBCS terminal or have specified the DBCS option, CP searches for a file called *groupname* LOGDBACI on the lowest accessed CP disk. If no such file exists, CP searches for a file called *groupname* LOGMSACI.

#### System

tells CP to display either the contents or origin information of the file that all users of the system would see. If you are using a non-DBCS terminal and have not specified the DBCS option, CP searches

for a file called SYSTEM LOGMSG on the lowest accessed CP disk. If you are using a DBCS terminal or have specified the DBCS option, CP searches for a file called SYSTEM LOGDBCS on the lowest accessed CP disk. If no such file exists, CP searches for a file called SYSTEM LOGMSG.

### **Userid *userid***

tells CP to display either the contents or origin information of the file that only the specified *userid* would see. If you are using a non-DBCS terminal or have not specified the DBCS option, CP searches for a file called *userid* LOGMSUSR on the lowest accessed CP disk. If you are using a DBCS terminal or have specified the DBCS option, CP searches for a file called *userid* LOGDBUSR on the lowest accessed CP disk. If no such file exists, CP searches for a file called *userid* LOGMSUSR.

### **Userid \***

tells CP to display either the contents or origin information of the file that only your user ID would see. If you are using a non-DBCS terminal or have not specified the DBCS option, CP searches for a file called *userid* LOGMSUSR on the lowest accessed CP disk. If you are using a DBCS terminal or have specified the DBCS option, CP searches for a file called *userid* LOGDBUSR on the lowest accessed CP disk. If no such file exists, CP searches for a file called *userid* LOGMSUSR. In either case, *userid* is the user ID of the command issuer.

### **Contents**

tells CP you wish to see the contents of a file. This is the default.

### **ORIGIN**

tells CP you wish to see on which CP-accessed minidisk the file resides instead of seeing the contents of the selected file.

### **DBCS**

tells CP you wish to see origin information or content for the file that would be displayed to users on DBCS-capable terminals. If neither DBCS nor SBCS are specified, CP assumes you wish to see origin information or content for the file that would be displayed to users on terminals similar to your own.

### **SBCS**

tells CP you wish to see origin information or content for the file that would be displayed to users on SBCS-capable terminals. If neither DBCS nor SBCS are specified, CP assumes you wish to see origin information or content for the file that would be displayed to users on terminals similar to your own.

## **Usage Notes**

1. If the file-based LOGMSG support is not enabled through the FEATURES statement in the system configuration file, QUERY LOGMSG cannot be entered with additional operands.
2. If you enable the file-based LOGMSG support but you do not also enable the LOGMSG support for account IDs, ACI groups, and user IDs, CP searches only for a file called SYSTEM LOGMSG (or SYSTEM LOGDBCS if you are on a DBCS terminal).
3. If you enter the QUERY LOGMSG command with no additional operands, you have enabled the file-based LOGMSG support, and you have also enabled LOGMSG support based on account IDs, ACI groups, or user IDs, CP displays the contents of the appropriate files in the following order:
  - System log message
  - Account log message
  - ACI group log message
  - User log message.

You will be unable to determine where the contents of one file ends and the contents of the next file begins by looking at the response to the QUERY LOGMSG command.

4. If you are a class G user and you enter the QUERY LOGMSG command, you see a log message containing information seen by everyone, information seen only by other users that have your account ID, information seen only by other users that are in the same ACI group as you, and information seen only by you.

5. When you log on, CP processes a special QUERY LOGMSG on your behalf. Only records beginning with an asterisk (\*) are displayed in response to this command. If you enter a QUERY LOGMSG, all records in the log message are displayed.
6. To change the contents of the log message, you must first determine whether you have enabled the file-based LOGMSG support. If you have enabled the file-based LOGMSG support, you must edit the files containing the log messages and enter the CPACCESS command to have CP access the changed files. If you have not enabled the file-based LOGMSG support, you must use the SET LOGMSG command to change the contents of individual lines in the log message.

### Responses

If there is no log message data available, you get this response:

```
There is no logmsg data
```

Otherwise, the contents of the log message, preceded by the LOGMSG header, are displayed on your terminal.

If old-style log message support is in effect, class B users see each line of log message data preceded by a line number. These numbers allow class B users to edit the log message using the class B SET LOGMSG command.

When you specify ORIGIN on the command, you get this type of response:

```
LOGMSG file SYSTEM LOGMSG located on CP accessed disk A (MAINT's 300).
```

If the requested file does not exist, you see this:

```
LOGMSG file MAINT LOGMSUSR not located on any CP-accessed disk.
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *operand*
- HCP007E Invalid userid - *userid*
- HCP026E Operand missing or invalid
- HCP041E LOGMSG *nn* does not exist.
- HCP1506E The last line (50) in the log message is already in use.
- HCP6704E Missing token at end of line
- HCP6706E Invalid {group name|account ID} - {*groupname*|*accountid*}
- HCP6734E Support for file-based LOGMSG is not enabled.
- HCP6771E LOGMSG support based on {Account ID|ACI group|Userid} is not enabled.

## QUERY LPARS

### Authorization

Privilege Class: B

### Purpose

Use QUERY LPARS to list all the logical partitions (LPARs) defined on your machine and to display which LPAR is currently active, to list all of the LPARs that have access to a particular channel-subsystem image, to list all of the reserved LPARs in the system or in a particular channel-subsystem image, to display the network name associated with your processor, or to display the CPC name associated with your processor.

### Operands

#### CSS *nn*

is the channel-subsystem ID for which you want partition access information. The variable *nn* must be a 1- to 2-digit hexadecimal number between X'00' and X'0F'. Your machine is likely to support less than 16 channel-subsystem images.

**Note:** This operand requires that the logical channel-subsystem facility be installed.

#### REServed

indicates that only reserved partition slots be displayed.

**Note:** This operand requires that the logical-partition-configuration facility be installed.

#### CPCname

indicates that the CPC name associated with your processor should be displayed.

#### NETworkname

indicates that the network name associated with your processor should be displayed.

### Usage Notes

1. If your system is not enabled for dynamic I/O capabilities, then this command will not complete successfully. However, it will issue a response that indicates the name of the logical partition where your system is running.
2. For more information about logical partitions (LPARs), see *z/VM: CP Planning and Administration*.
3. The network name and CPC name that can be displayed by this command are user-defined names that are created and modified by the Hardware Management Console (HMC) and the Service Element (SE).

### Responses

Response 1 (non-LCSS system):

The response appears as follows when there is no logical channel-subsystem facility installed.

```
query lpars
Partitions on your machine:
Active partition: ZVMLPAR1 Partition number: 1
Partition name:   ZVMLPAR2 Partition number: 2
Partition name:   ZOSLPAR1 Partition number: 3
Partition name:   ZOSLPAR2 Partition number: 4
Ready;
```

This response tells you that you have 4 partitions and that the partition processing this command is ZVMLPAR1.

Response 2 (LCSS system):

The response appears as follows when the logical-channel-subsystem facility is installed and there are no reserved partition slots.

```
query lpars
Partitions on your machine:
Active partition: ZVMLPAR1 CSS: 0 MIF-ID: 1
Partition name:   ZOSLPAR1 CSS: 0 MIF-ID: 2
Partition name:   ZVMLPAR2 CSS: 1 MIF-ID: 1
Partition name:   ZOSLPAR2 CSS: 1 MIF-ID: 2
Ready;
```

This response tells you that you have 4 partitions, two that have access to channel-subsystem image 0 and two that have access to channel-subsystem image 1. The partition processing this command is ZVMLPAR1.

Response 3 (LCSS system with reserved partitions):

The response appears as follows when both the logical-channel-subsystem facility and the logical-partition-configuration facility are installed, and there are reserved partition slots defined.

```
query lpars
Partitions on your machine:
Active partition: ZVMLPAR1 CSS: 0 MIF-ID: 1
Partition name:   ZOSLPAR1 CSS: 0 MIF-ID: 2
Reserved:         *      CSS: 0 MIF-ID: 4
Partition name:   ZVMLPAR2 CSS: 1 MIF-ID: 1
Partition name:   ZOSLPAR2 CSS: 1 MIF-ID: 2
Reserved:         *      CSS: 1 MIF-ID: 3
Ready;
```

This response tells you that you have 4 partitions, two that have access to channel-subsystem image 0 and two that have access to channel-subsystem image 1. The response also tells you that you have two reserved partition slots, one available in channel-subsystem image 0 and one available in channel-subsystem image 1. The partition processing this command is ZVMLPAR1.

Response 4 (Query for a defined CSS):

To display information about the logical partitions that have access to channel-subsystem image 0 when the logical channel-subsystem facility is installed, enter the following:

```
query lpars css 0
Partitions with access to CSS 0:
Active partition: ZVMLPAR1 CSS: 0 MIF-ID: 1
Partition name:   ZOSLPAR1 CSS: 0 MIF-ID: 2
Ready;
```

This response tells you that you have 2 partitions that have access to channel-subsystem image 0. The partition processing this command is ZVMLPAR1.

Response 5 (Query for a defined CSS with reserved partitions):

To display information about the logical partitions that have access to or are reserved in channel-subsystem image 0 when the logical-channel-subsystem facility and the logical-partition-configuration facility are installed, enter the following:

```

query lpars css 0
Partitions with access to CSS 0:
Active partition: ZVMLPAR1  CSS: 0  MIF-ID: 1
Partition name:  ZOSLPAR1  CSS: 0  MIF-ID: 2
Reserved:        *         CSS: 0  MIF-ID: 4
Ready;

```

This response tells you that you have 2 partitions that have access to channel-subsystem image 0 and that you have 1 reserved partition slot available in channel-subsystem image 0. The partition processing this command is ZVMLPAR1.

Response 6: (Reserved partitions in LCSS system):

To display information about the reserved logical partitions on your machine, enter the following:

```

query lpars reserved
Reserved partitions on your machine:
Reserved:        *         CSS: 0  MIF-ID: 4
Reserved:        *         CSS: 1  MIF-ID: 3
Ready;

```

This response tells you that you have 2 reserved partition slots available on your machine, one in channel-subsystem image 0 and one in channel-subsystem image 1.

Response 7: (Reserved partitions in a CSS):

To display information about the reserved logical partitions in a channel-subsystem image, enter the following:

```

query lpars css 1 reserved
Reserved partitions in CSS1:
Reserved:        *         CSS: 1  MIF-ID: 3
Ready;

```

This response tells you that you have 1 reserved partitions slot available in channel-subsystem image 1.

Response 8 (Query for an undefined CSS):

If no logical partitions have access to the specified channel-subsystem image, the response appears as follows.

```

query lpars css 5
There are no partitions that have access to CSS 5.
Ready;

```

Response 9 (Query when no reserved partitions in system):

If no reserved logical partition slots are available on your machine, the response appears as follows.

```

query lpars reserved
There are no reserved partitions available on your machine.
Ready;

```

Response 10 (Query when no reserved partitions in CSS):

If no reserved logical partition slots are available in the specified channel-subsystem image, the response appears as follows.

```

query lpars css 5 reserved
There are no reserved partitions in CSS 5.
Ready;

```

Response 12 (No LPAR Data - Dynamic I/O not enabled):

If your logical partition is not enabled for dynamic I/O changes, the response appears as follows.

```

query lpars
No LPAR data is available.
Active partition: ZVMLPAR1
Ready;

```

## QUERY LPARS

Response 13 (CPC name):

To display the CPC name associated with your processor, enter the following:

```
query lpars cpcname
The CPC name for this processor is FSISKIS9.
Ready;
```

Response 14 (No CPC name):

If there is no CPC name associated with your processor, you would see:

```
query lpars cpcname
There is no CPC name assigned to this processor.
Ready;
```

Response 15 (Network name):

To display the network name associated with your processor, enter the following:

```
query lpars network
The network name assigned for this processor is IBM390PS.
Ready;
```

Response 16 (No Network name):

If there is no network name associated with your processor, you would see:

```
query lpars network
There is no network name assigned to this processor.
Ready;
```

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*

# QUERY LSYSTEM

---

► Query — LSYStem ◄

## Authorization

Privilege Class: B

## Purpose

Use QUERY LSYSTEM to display the machine name of the local system. This name is used when identifying two machines connected by CIB (coupling over InfiniBand) channel paths.

## Operands

### LSYStem

requests the display of the machine name of the local system.

## Responses

Response 1:

If you enter QUERY LSYSTEM and the name of your system is CPCSYS43, the response is:

```
q lsys
The name of this system is CPCSYS43.
Ready;
```

Response 2:

If you enter QUERY LSYSTEM and no name has been assigned to your system, the response is:

```
q lsys
This system has no name assigned.
Ready;
```

- HCP6815E Command failed in channel subsystem.

## QUERY MAXLDEV

---

► Query — MAXLdev ◄

### Authorization

Privilege Class: E

### Purpose

Use QUERY MAXLDEV to display the maximum number of logical devices that can exist at the same time.

### Usage Notes

1. The number of logical devices may be greater than the maximum specified on the command response. This can happen when the limit is lowered to a value less than the current number of logical devices. If this occurs, the existing logical devices will be unaffected, but no new logical devices can be created until the number of logical devices is less than the maximum allowed.
2. All logical devices will be created with a device address less than the limit in effect.

### Responses

Response 1:

```
MAXLDEV = nnnnn
```
