#### ***nnnnn***

identifies the maximum number of logical devices that can be created.

### Messages

- HCP026E Operand missing or invalid

## QUERY MAXSPOOL

### Notes:

- <sup>1</sup> If QUERY MAXSPOOL is executed with the AT command, the SYSTEM or *userid* operand is required.
- <sup>2</sup> SYSTEM is valid only for class D users.
- <sup>3</sup> A class G user may specify only the user's own user ID.

### Authorization

Privilege Class: D, G

### Purpose

Use QUERY MAXSPOOL to display the spool file limit for the system or for any individual user of that system.

### Operands

**\***

displays the maximum number of spool files allowed for the user who issues the command.

### SYSTEM

displays the total number of spool files allowed for the system.

### *userid*

displays the maximum number of spool files allowed for the specified user.

### Usage Notes

1. The user maximum spool file number is set through the SPOOLFILE directory statement.

### Responses

Response 1:

```
MAXIMUM SPOOL FILE COUNT FOR {SYSTEM} IS number
                               {userid}
```

indicates the maximum spool file count allowed.

### SYSTEM

### *userid*

identifies the system or *userid* specified on the QUERY MAXSPOOL command.

### *number*

identifies the maximum spool file count allowed. If you specify SYSTEM, the number is the total number of files allowed in the system. If you specify *userid*, this is the total number of files that this user is allowed to maintain.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP007E Invalid userid - *userid*

- HCP475I Fatal I/O error trying to read directory from *volid* [for user *userid*]

# QUERY MAXUSERS

---

► Query — MAXUsers ◄

## Authorization

Privilege Class: A

## Purpose

Use QUERY MAXUSERS to display the maximum number of logged-on users allowed.

## Usage Notes

1. The number of users actually logged on may be greater than the maximum value displayed. This can happen when the user logon limit is lowered to a point below the current number of users logged on, when the operator logs on and the maximum number of users is already logged on, or if a virtual machine is logged on that has the IGNMAXU operand of the OPTION control statement included in its user directory.

## Responses

Response 1:

```
MAXUSERS = nnnnn
```

is the response when a user logon limit is in effect.

### **nnnnn**

identifies the maximum number of users allowed to be logged onto the system at any one time.

Response 2:

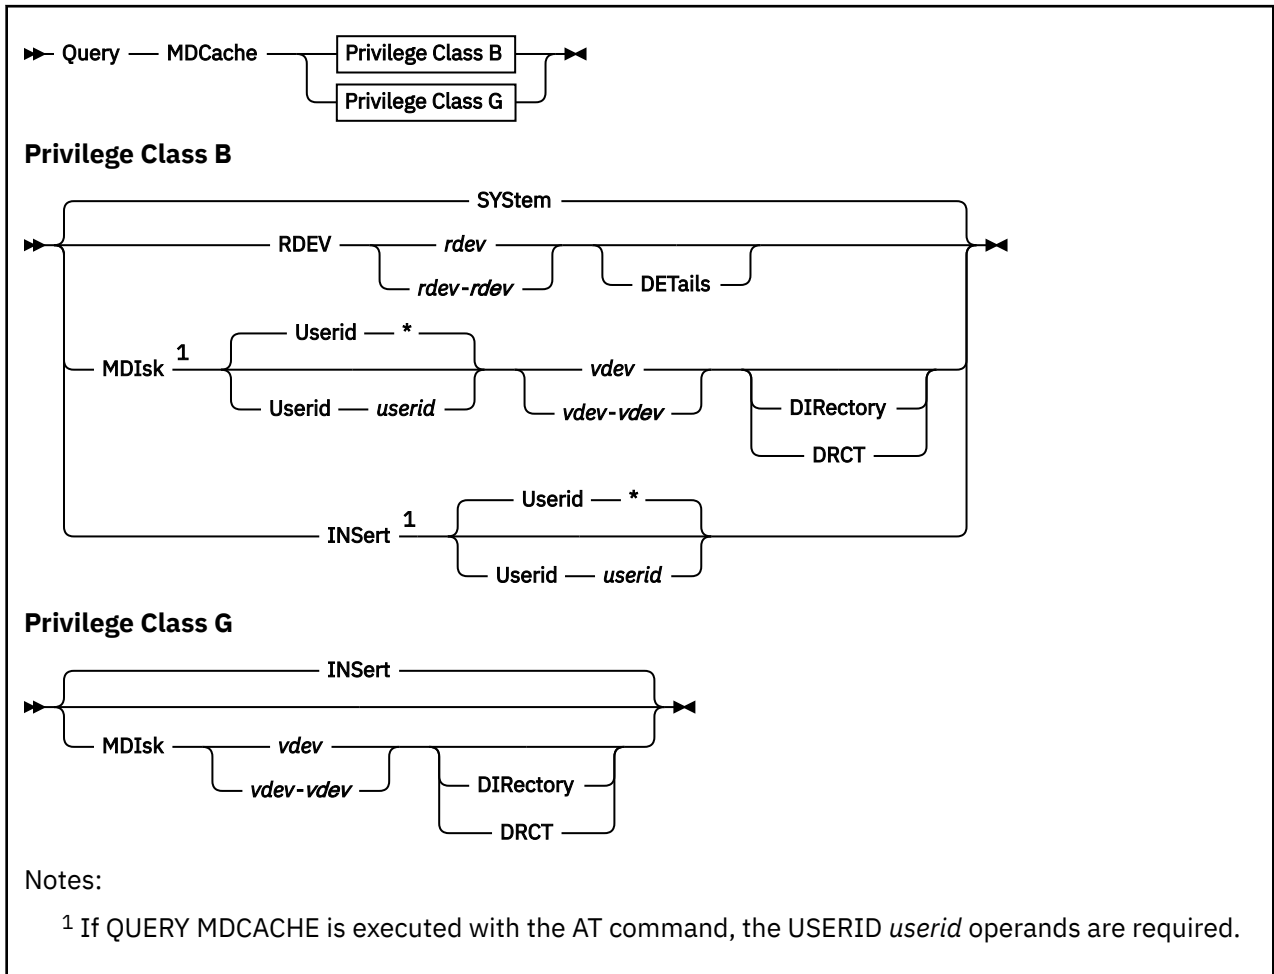

```
NO MAXUSERS LIMIT IS SET
```

is the response if no user logon limit has been set. In that case, the default system maximum of 99,999 users is in effect.

## Messages

- HCP002E Invalid operand - *operand*

## QUERY MDCACHE

### Authorization

Privilege Class: B, G

### Purpose

Use QUERY MDCACHE to display minidisk cache settings or a user's ability to insert data into the cache.

A class B user can query:

- Minidisk cache settings for the entire system, a real device, an active minidisk, or a minidisk defined in the directory.
- Another user's ability to insert data into the cache.

A class G user can query:

- The user's ability to insert data into the cache.
- An active minidisk or a minidisk defined in the user's directory entry.

### Operands

#### SYSTEM

indicates that the cache setting for the system is being queried.

**RDEV**

indicates that the cache settings for one or more real devices are being queried.

**rdev****rdev-rdev**

identifies the real device numbers whose cache eligibility is being queried.

**DEtails**

indicates that cache settings for any active minidisks on the real device(s) being queried will be displayed in the response.

**MDisk**

indicates that the cache settings for active minidisks are being queried.

**Userid \*****Userid *userid***

is the user ID of the virtual machine for which you want to query minidisk cache settings. If omitted or specified as an asterisk (\*), CP uses the user ID of the virtual machine issuing the command. For the class B command, if DRCT or DIRectory is not specified, the userid specified must be logged on.

**vdev****vdev-vdev**

identifies the virtual device number or the range of virtual device numbers for which cache settings are to be queried. For the class B command, the virtual device numbers specified correspond to the userid's current configuration if the DIRECTORY or DRCT option is not specified and to the userid's directory entry if the DIRECTORY or DRCT option is specified. For the class G command, the virtual device numbers specified correspond to the userid's directory entry.

**DIRectory****DRCT**

indicates that the virtual device numbers correspond to the userid's directory entry. For the class B command, if DRCT or DIRectory is not specified, the userid specified must be logged on.

**INSert**

queries a user's ability to insert information into the cache.

**Usage Notes**

1. In z/Architecture mode, minidisk cache uses host real storage above the 2 GB line.

**Responses**

Response 1:

The following response is issued when you specify Query MDCache from a userid with privilege class B and caching is enabled for the system.

```
Minidisk cache ON for system
Storage MDC min=nnnM max=nnnM, usage=ppp%, bias=b.bb
```

**min=nnnM**

indicates the current minimum value for the size of minidisk cache in megabytes.

**max=nnnM**

indicates the current maximum value for the size of minidisk cache in megabytes.

**usage=ppp%**

indicates the percentage of real storage in use by minidisk cache.

**bias=bb.b**

indicates the bias factor used by the arbiter to determine the target size for the storage type.

Response 2:

The following response is issued when you specify Query MDCache from a userid with only privilege class G.

```
Minidisk cache inserts {ON } for userid
                       {OFF }
```

***userid***

identifies the *userid* where the command was issued.

Response 3:

The following response is issued when you specify Query MDCache SYStem and caching is disabled for the system.

```
Minidisk cache OFF for system
```

Response 4:

The following response is issued when you specify Query MDCache RDEV *rdev*.

```
Minidisk cache {DFLTON } for rdev
                {DFLTOFF }
                {OFF   }
```

***rdev***

identifies the real device number of the device being queried.

Response 5:

The following response is issued when you specify Query MDCache RDEV *rdev-rdev*.

```
Minidisk cache {DFLTON } for rdev-rdev
                {DFLTOFF }
                {OFF   }
```

***rdev-rdev***

identifies the first and last real device numbers in the range.

Response 6:

The following response is issued for each active real device when you issue Query MDCache RDEV *rdev* DETails or Query MDCache RDEV *rdev-rdev* DETails. The additional lines for each real device contain cache eligibility information for any active minidisks on that device. The first ON/OFF for each minidisk indicates whether caching is currently enabled for the minidisk. The information in parenthesis which indicates that cache setting for the minidisk plus the cache setting for the real device add up the current cache eligibility of the minidisk.

```
Minidisk cache {DFLTON } for rdev {ON } ({ON      } for userid vdev)
                {DFLTOFF }          {OFF }  {OFF     }
                {OFF   }            {OFF }  {DEFAULT }
```

***rdev***

identifies the real device number of the device being queried.

***userid***

identifies the owner of an active minidisk on the device being queried.

***vdev***

identifies the owning device number of an active minidisk on the device being queried.

Response 7:

The following response is issued for each device when you specify Query MDCache MDIsk *vdev* or Query MDCache MDIsk *vdev-vdev*. The first ON/OFF for each minidisk indicates whether caching is currently enabled for the minidisk. The information in parenthesis indicates the cache setting for the minidisk, provides minidisk owner information, and indicates the cache setting for the real device. The minidisk and real device settings combine to indicate the current cache eligibility of the minidisk. In an SSI cluster,

you will receive additional information in parenthesis when MDC is suppressed due to a write link from another system in the SSI cluster.

```
DASD vdev MDCACHE {ON } ({ON } for userid ovdev; {DFLTON }
                {OFF} {OFF} {DEFAULT} {DFLTOFF}
Continued:
for DASD rdev) [recordmdc enabled] (MDC suppressed due to WRITE link
on {system})
```

***ivdev***

is the *vdev* from the command line whose minidisk cache status is provided. When the DIRECTORY option is specified, *ivdev* is with respect to the directory. When DIRECTORY is not specified, *ivdev* is with respect to the user configuration specified or implied on the command line.

***userid***

identifies either the user whose directory entry has the MDISK statement for this minidisk or the user who issued the DEFINE command that defined the minidisk. This is the *userid* that 'owns' the minidisk.

***ovdev***

identifies the device number from either the MDISK statement or as specified on the DEFINE command. This is the *vdev* from the perspective of the owning *userid*.

***rdev***

identifies the real device on which the virtual device resides.

**recordmdc enabled**

indicates that record level caching rather than normal full track caching is active for this minidisk.

Response 8:

The following response is issued when you specify Query MDCache INSert Userid *userid* or the class G command Query MDCache INSert.

```
Minidisk cache inserts {ON } for userid
                    {OFF}
```

***userid***

identifies the *userid* whose ability to insert into the cache is being queried.

Response 9:

The following response is issued when you specify Query MDCache MDIsk *vdev1-vdev2* and caching was last disabled by Transport Mode I/O.

```
DASD vdev1 MDCACHE ON (DEFAULT for userid vdev1; DFLTON for DASD rdev1)
DASD vdev2 MDCACHE OFF (OFF for userid vdev2; DFLTON for DASD rdev2)
Disabled by Transport Mode I/O
```

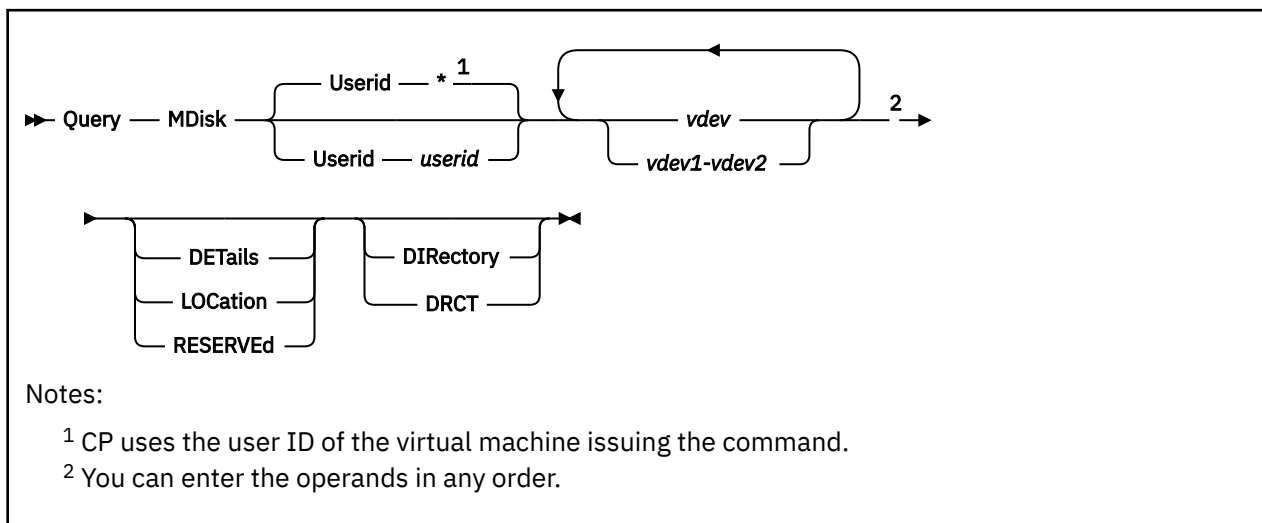

***userid***

identifies the *userid* whose ability to insert into the cache is being queried.

**Messages**

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP0013E Conflicting option - *option*

## QUERY MDISK

### Authorization

Privilege Class: G

### Purpose

Use QUERY MDISK to display the device characteristics of minidisks: dedicated DASD, full-pack minidisks, user (permanent) minidisks, temporary disks (T-disks), and virtual disks in storage.

### Operands

#### Userid \*

#### Userid *userid*

is the user ID of the virtual machine for which you want to display minidisk information. If omitted or specified as an asterisk (\*), CP uses the user ID of the virtual machine issuing the command.

#### *vdev*

#### *vdev1-vdev2*

specifies the virtual device number (or numbers) of the minidisks for which you want to see information.

#### DEtails

tells CP you want information about the type of minidisk and the duplex control operations performed for it. If you specify DETAILS, you cannot specify LOCATION.

#### LOCation

tells CP you want information about the location and size of the specified minidisk. If you specify LOCATION, you cannot specify DETAILS.

#### RESERVEd

tells CP you want information about who holds a reserve on a minidisk.

#### DIRectory

#### DRCT

tells CP you want information about the minidisk defined in the CP user directory, rather than information about the currently defined minidisks for the target user ID. The minidisk must be on a dasd that is online and attached to the system.

## Usage Notes

1. For more information about the DEVNO information that CP displays when you specify DETAILS, see the [MDISK Statement in z/VM: CP Planning and Administration](#).
2. For more information on the duplex control operations that CP provides when you specify DETAILS, see “DUPLEX” on page 448.
3. The OwnerID and Odev listed in the output can be different, depending on how the disk was defined. If the disk definition in the system directory has been changed, the new OwnerID and Odev may not be immediately reflected in the QUERY MDISK output. The old designation will be shown until there are no users accessing the disk. Use the form of the command consistent with the output needed for your application.

## Responses

Response 1:

If you do not specify DETAILS or LOCATION, you see this type of response:

```
query mdisk 190
TargetID Tdev OwnerID Odev
RICH      0190 MAINT    0190
Ready;
```

This example tells you that RICH's 190 disk is really MAINT's 190 disk (MAINT is the owner of the disk).

Response 2:

If you specify DETAILS, CP adds more information to the response:

```
query mdisk 190 details
TargetID Tdev OwnerID Odev Minidisk DEVNO Duplex
RICH      0190 MAINT    0190 Regular   No    No
Ready;
```

This example tells you MAINT's 190 disk is a regular minidisk, it does not have the DEVNO operand of the MDISK statement defined in the user's directory entry, and no duplex control operations are in effect for this disk.

The possible values for the Minidisk column are:

### Dedicated

The real device associated with the specified virtual device is dedicated.

### Full pack

The specified virtual device is a full-pack minidisk.

### Regular

The specified virtual device is a non-full-pack minidisk. **Note:** This category includes T-disks and virtual disks in storage.

The possible values for the DEVNO column are:

### No

The minidisk is not defined using the DEVNO operand of the MDISK statement in the user's directory entry.

### Yes

The minidisk is defined using the DEVNO operand of the MDISK statement in the user's directory entry.

The possible values for the Duplex column are:

### No

The minidisk has no duplex control operations in effect.

## Primary

The minidisk is the primary device of a duplex pair.

## Secondary

The minidisk is the secondary device of a duplex pair.

Response 3:

If you specify LOCATION, CP displays information about the volume on which the minidisk resides. For example:

```
query mdisk 190 location
TargetID Tdev OwnerID Odev Dtype Vol-ID Rdev StartLoc Size
RICH      0190 MAINT    0190 3380 XAUSR5 0284      2276    40
Ready;
```

gives you information about the:

- Device type of the real disk on which the minidisk resides; for a virtual disk in storage, this is the device type of the device simulated in storage.
- Volume label of the real disk; for a virtual disk in storage, this is always (VDSK).
- Real device address of the disk; for a virtual disk in storage, this is always VDSK.
- Starting offset of the minidisk (in cylinders or blocks) into the real disk; for a virtual disk in storage, this is always 0.
- Size (in cylinders or blocks) of the minidisk.

Response 4:

In an SSI cluster, if you specify DETAILS, CP adds more information to the response:

```
query mdisk 190 details
TargetID Tdev OwnerID Odev Minidisk DEVNO Duplex Scope
REESELIS 0191 REESELIS 0191 Regular No No Local
REESELIS 0495 REESELIS 0495 Regular No No Global
REESELIS 0690 REESELIS 0690 Regular No No Local - DEFINE MDISK
Ready;
```

The possible values for the Scope column are:

### Local

The minidisk is restricted to a particular system in the SSI cluster.

### Global

The minidisk is not restricted to a particular system in the SSI cluster.

### Local - DEFINE MDISK

The DEFINE MDISK command has been used to create the minidisk.

Response 5:

The RESERVED operand will display one of the following based on the reserved state of each specified minidisk:

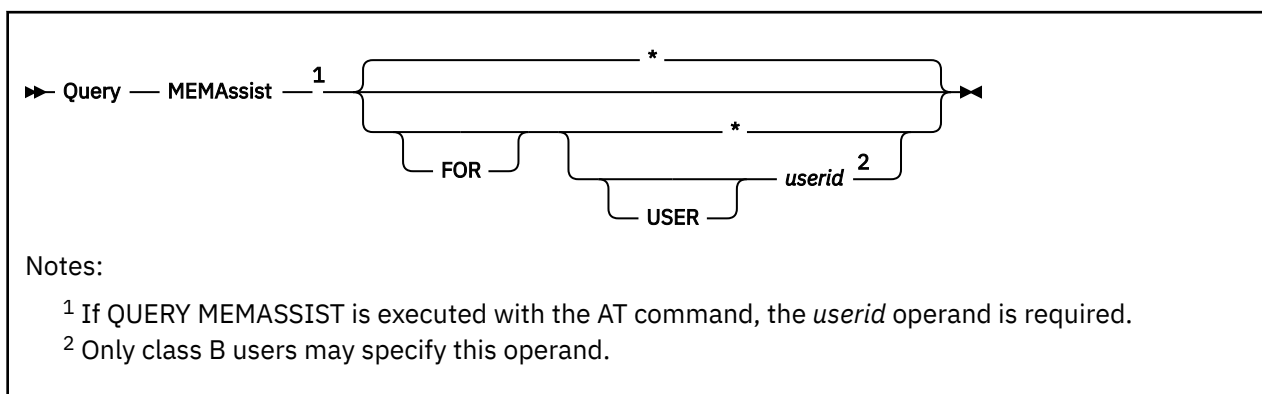

```
NO RESERVE HELD FOR vdev
vdev RESERVED BY userid
```

## Messages

- HCP003E Invalid option - *option*
- HCP007E Invalid userid - *userid*

## QUERY MEMASSIST

### Authorization

Privilege Class: B, G

### Purpose

Use QUERY MEMASSIST to determine the collaborative memory management assist settings for your own virtual machine or another user's virtual machine.

### Operands

\*

indicates that you wish to display your own virtual machine's MEMASSIST settings.

#### **USER** *userid*

is the user ID of the virtual machine for which you want to display the MEMASSIST settings.

### Usage Notes

1. The initial MEMASSIST settings for your virtual machine are determined as follows:
  - a. If the collaborative memory management assist is installed on the system, the initial setting is ON unless the OPTION NOMEMASSIST is specified in the user directory entry.
  - b. If the collaborative memory management assist is not installed, the initial setting is OFF.
2. At z/VM IPL, the initial MEMASSIST FOR ALL setting is ON, even if the assist is not installed on the machine. This allows a virtual machine to SET MEMASSIST ON, causing the assist to be simulated by z/VM for guest testing purposes.
3. You can use the class G SET MEMASSIST command to change your MEMASSIST setting. You can use the class B SET MEMASSIST command to change another virtual machine's MEMASSIST setting. For more information, see [“SET MEMASSIST” on page 1568](#).
4. If the collaborative memory management assist is not installed on the machine, guests can still use it by means of the simulation that is built into CP. However, because of the overhead incurred by simulation, this mode of operation is recommended for testing purposes only.

### Responses

The response displays the overall setting for all users, followed by the setting and status for the individual user. The response pattern is:

```
ALL USERS SET - {ON | OFF}
```

USER	SETTING	STATUS
<i>userid</i>	<i>setting</i>	<i>status</i>

The possible *setting* and *status* combinations are:

SETTING	STATUS
OFF	INACTIVE
ON	INACTIVE
ON	INACTIVE,PENDING OFF
(ON)	INACTIVE,PENDING OFF
ON	ACTIVE
ON	ACTIVE,PENDING OFF
(ON)	ACTIVE,PENDING OFF

Any of these may be suffixed by *, SIMULATED*.

**ALL USERS SET - {ON | OFF}**

The setting for ALL USERS is either ON or OFF. The setting is controlled by the class B command SET MEMASSIST ON|OFF FOR ALL, which controls access to the collaborative memory management assist on a system-wide basis.

ON means users can enable the assist for their virtual machines through the SET MEMASSIST ON command and use the assist by executing the EXTRACT AND SET STORAGE ATTRIBUTES (ESSA) instruction.

OFF means users cannot enable the assist for their virtual machines (SET MEMASSIST ON is rejected), and users who are not currently using the assist are not able to begin using it (the ESSA instruction causes an operation exception). However, users who are currently using the assist continue to have access to it until the next virtual machine reset.

**USER**

The *userid* field contains the user ID of the virtual machine being queried.

**SETTING**

This field is ON, (ON), or OFF. This setting is independent of the system-wide setting. That is, the system-wide setting is like one gate to pass through, which can be open or closed. The user setting is like a second gate, which can be open or closed independently of the first gate.

ON means the user has access to the assist and may begin using it if not already doing so.

(ON) means that the user's current setting is ON, but system-wide access to the assist is denied because that setting is OFF. The user may continue using the assist if already doing so.

OFF means the user does not have access to the assist and that execution of the ESSA instruction results in an operation exception.

The default value for this field is determined during logon processing and is set ON if the assist is installed on the machine and OPTION NOMEMASSIST does not appear in the user's directory entry; it is set OFF otherwise.

**STATUS**

The status field indicates the current disposition of the virtual machine with respect to the assist. The field can be INACTIVE; INACTIVE,PENDING OFF; ACTIVE; or ACTIVE,PENDING OFF. In addition, SIMULATED is appended to the status, if applicable.

INACTIVE means the user is not currently using the assist.

ACTIVE means the user is currently using the assist (that is, the guest has executed at least one ESSA instruction since the last virtual machine reset).

PENDING OFF means the user might be currently using the assist, but that the SET MEMASSIST OFF command has been issued by or for the user. The user might begin or continue using the assist until the next virtual machine reset, at which time the SET MEMASSIST OFF command takes effect.

SIMULATED means the assist is not installed on the machine, and that it is simulated by CP.

Sample responses are:

## QUERY MEMASSIST

**Response 1:** In the following response, the assist is SET ON FOR ALL, SET ON FOR LINUX01, and the software in the LINUX01 virtual machine has begun using the assist.

```
ALL USERS SET - ON
USER      SETTING  STATUS
LINUX01  ON           ACTIVE
```

**Response 2:** In the following response, the assist is SET ON FOR ALL and SET ON FOR MANSELL, but the software in the MANSELL virtual machine is not using the assist.

```
ALL USERS SET - ON
USER      SETTING  STATUS
MANSELL  ON           INACTIVE
```

**Response 3:** In the following response, the assist is SET OFF FOR ALL, superseding the current setting of ON FOR MANSELL. The virtual machine is not now using the assist, and is not permitted to start using it (the assist appears not available to the virtual machine).

```
ALL USERS SET - OFF
USER      SETTING  STATUS
MANSELL  (ON)       INACTIVE, PENDING OFF
```

**Response 4:** In the following response, the assist is SET OFF FOR ALL, which would normally supersede the individual user setting, ON FOR MANSELL. Because the virtual machine had already begun using the assist before it was SET OFF FOR ALL, it is permitted to continue using it until the next virtual machine reset. At that point, the assist will become INACTIVE, and will appear not available to the virtual machine.

```
ALL USERS SET - OFF
USER      SETTING  STATUS
B         (ON)       ACTIVE, PENDING OFF
```

# QUERY MITIME

► Query — MITime ◄

## Authorization

Privilege Class: A, B

## Purpose

Use QUERY MITIME to determine the current time interval settings for the missing interrupt detector.

## Operands

### MITime

requests the display of the current time interval settings for the missing interrupt detector.

## Usage Notes

1. When you enter QUERY MITIME, each current MITIME setting is displayed in a form similar to the one you used when you issued the SET MITIME command to invoke the specifications.
2. When multiple responses are displayed for specific devices because of the overlap in their range and class, the first response takes precedence, because the command displays previous SET MITIME settings in a last-in, first-out sequence.
3. For storage subsystems that provide a primary time-out value for missing interrupt handler, a response is displayed for each device or range of devices defined in the same storage subsystem. It is recommended that all devices belonging to the same storage subsystem be defined in a single ascending range.

## Responses

Response 1:

*Example of Multiple Responses:* Assume the valid range of DASD addresses is 190 through 400 and several SET MITIME commands were entered previously. If you wish to determine the current missing interrupt time interval for DASD 251 and 291, enter `query mitime`. If the response is as follows:

```
MITIME ON 250-252 00:10
MITIME ON 190-255 01:40
MITIME ON DASD 00:30,
```

the current time interval for device 251 is 10 seconds, and the current time interval for device 291 is 30 seconds.

```
MITIME {ON } {devclass } [mm:ss]
      {OFF} {rdev }
          {rdev-rdev}
          {ALL }
```

### ON

### OFF

indicates whether time intervals for the specified devices have been set on. ON specifies that the intervals have been set; OFF specifies that time intervals have been set off and that no monitoring for missing interrupts is being done for the specified devices.

## QUERY MITIME

### ***devclass***

indicates the device class for which you want to display the missing interrupt detector settings. The operand *devclass* may be DASD, TAPE, GRAF, DISPLAY, UR, SWITCH, or MISC. GRAF and DISPLAY do not include the 328x, and UR does not include the 3800. MISC includes 328x, 3800, and any DASD defined as a mass storage subsystem device.

### ***rdev***

#### ***rdev-rdev***

is a real device number or range or real device numbers for which you want to display the missing interrupt detector settings.

### **ALL**

indicates that the missing interrupt detector setting is in effect for all of your devices.

### ***mm:ss***

indicates the time interval in minutes and seconds. The maximum value for *mm* is 99, while the maximum value for *ss* is 59. This operand is displayed only if MITIME is set ON.

## **Messages**

- HCP002E Invalid operand - *operand*

## QUERY MONDATA

---

► Query — MONData ◄

### Authorization

Privilege Class: C

### Purpose

Use QUERY MONDATA to determine if user display data would be present in monitor event records for terminals.

### Usage Notes

1. To change the MONDATA option, enter the SET MONDATA command.

### Responses

Response 1:

```
MONDATA {ON }  
         {OFF}
```

#### **ON**

indicates that input from, and output to, user display stations is included with the terminal event records. It is the responsibility of the installation to protect the security of this data.

#### **OFF**

indicates that input from, and output to, user display stations is not included with the terminal event records.

### Messages

- HCP002E Invalid operand - *operand*

## QUERY MONITOR

### Authorization

Privilege Class: A, E

### Purpose

Use QUERY MONITOR to display the current profile information for monitor.

### Operands

#### ALL

requests a display of all settings and information about CP monitoring. This includes both event and sample monitoring. This is the default.

#### BLock

requests a display of the current number of 4 KB pages of the saved segment that are accumulated before an IUCV message is sent to the virtual machine indicating that there is event data to be read.

The value displayed is as set or defaulted by the BLOCK option of the MONITOR command.

#### EVent

requests a display of all current settings established for event monitoring. Included in this display are the settings, listings, and status of applicable domains and their elements, users connected to \*MONITOR for event data collections, and partitioning of the saved segment, among other things.

#### INTerval

requests a display of the interval value currently in effect for sample monitoring. This value is as set or defaulted by the INTERVAL option of the MONITOR SAMPLE command.

#### PARTition

requests a display of the size of a saved segment that is currently partitioned for event records. The value is as set or defaulted by the PARTITION option of the MONITOR EVENT or MONITOR START command.

#### RATE

requests a display of the rate value currently in effect for high frequency sample monitoring. This value is as set or defaulted by the RATE option of the MONITOR SAMPLE command.

#### SAMPlE

requests a display of all current settings established for sample monitoring. Included in this display are the settings, listings, and status of applicable domains and their elements, users connected to \*MONITOR for sample data collections, and partitioning of the saved segment, among other things.

**Examples**

**Note:** In these examples, leading zeros are converted to blanks, and blank spaces and indents have been added to improve readability.

Example for QUERY MONITOR SAMPLE:

```

MONITOR SAMPLE ACTIVE      NEXT 12/15/2022 11:00:00
                        INTERVAL 30 SECONDS  PENDING INTERVAL 20 SECONDS
                        RATE 11.21 SECONDS
MONITOR DCSS NAME - MONDCSS
CONFIGURATION SIZE 50    LIMIT 2 MINUTES
CONFIGURATION AREA BE FREED WITHIN - 1 MINUTES 30 SECONDS

I/O      DOMAIN ENABLED
    PCIF CLASS ENABLED
    THE FOLLOWING DEVICES ARE ENABLED:
        01A0-01AF 08C0-08FF 0900 0934-093F
        0999-1010 1030-104F
        2222      3000-32FF 3400-3404
NETWORK  DOMAIN DISABLED
ISFC     DOMAIN DISABLED
APPLDATA DOMAIN ENABLED
    THE FOLLOWING USERIDS ARE ENABLED:
        APPLID  USER06  USER07
SSI       DOMAIN DISABLED
    
```

**SAMPLE**

describes the monitor sample domain.

**ACTIVE**

indicates that sample recording is active.

**NEXT 12/15/2022 11:00:00**

indicates that the next sample collection will begin on date 12/15/2022 at time 11:00:00.

**INTERVAL 30 SECONDS**

indicates that the current monitor sampling interval is set to 30 seconds.

**PENDING INTERVAL 20 SECONDS**

indicates that a new sampling interval of 20 seconds takes effect after the current sampling interval is completed.

**RATE 11.21 SECONDS**

indicates that high-frequency sampling is active, with a current rate of 11.21 seconds. The *first* leading zero in the RATE value is converted to a blank, if applicable (for example, 8.21 not 08.21).

**MONITOR DCSS NAME - MONDCSS**

indicates that the name of the DCSS used to collect monitor data is MONDCSS.

**CONFIGURATION SIZE 50 LIMIT 2 MINUTES**

indicates 50 pages are allocated for sample configuration records and that users have two minutes to reply to the sample configuration IUCV message.

**CONFIGURATION AREA WILL BE FREED WITHIN - 1 MINUTE 30 SECONDS**

indicates that the configuration area is freed for any pending users within 1 minute and 30 seconds. Users processing configuration records must reply within this time, or the IUCV configuration message is purged, and the associated pages are released for reuse.

**USERS CONNECTED TO \*MONITOR - USER45 ... USER46 QUIESCED**

indicates that users USER45, USER46, USER47, and USER48 are connected to \*MONITOR to receive sample data notifications.

## QUERY MONITOR

- USER45's IUCV path to \*MONITOR is not quiesced. This user is eligible to receive sample data notifications.
- USER46's IUCV path to \*MONITOR is quiesced. This user is eligible to receive sample data notifications.
- USER47's IUCV path to \*MONITOR is not quiesced. This user has not replied to the IUCV send for the configuration records. USER47 is eligible to receive data.
- USER48's IUCV path to \*MONITOR is not quiesced. This user is waiting for the sample configuration area to free up. (The area is freed when USER47 replies or the configuration time limit is reached.) USER48 is not eligible to receive data notification, but becomes eligible after having been notified of configuration records.

Since there is more than one user connected, you know \*MONITOR is executing in shared mode. The user IDs are displayed in alphabetic order.

### **MONITOR DOMAIN ENABLED**

indicates that the monitor domain is enabled.

### **SYSTEM DOMAIN ENABLED**

indicates that the system domain is enabled.

### **PROCESSOR DOMAIN DISABLED**

indicates that the processor domain is disabled.

### **STORAGE DOMAIN DISABLED**

indicates that the storage domain is disabled.

### **USER DOMAIN ENABLED**

indicates that the user domain is enabled.

### **ABLEFOX MAINT USER01 USER02 USER03 USER04 USER05 WILLIAMS WILSON**

indicates that there are nine users currently being monitored: ABLEFOX, MAINT, USER01, USER02, USER03, USER04, USER05, WILLIAMS, and WILSON. The user IDs are displayed in alphabetic order.

### **I/O DOMAIN ENABLED**

indicates that the I/O domain is enabled.

### **PCIF CLASS ENABLED**

indicates that the PCIF class is enabled.

### **01A0-01AF 08C0-08FF 0900 0934-093F 0999-1010 1030-104F 2222 3000-32FF 3400-3404**

indicates that device 0900 and device 2222 are being monitored. Also, all devices in the following ranges are being monitored: 01A0-01AF, 08C0-08FF, 0934-093F, 0999-1010, 1030-104F, 3000-32FF, 3400-3404.

Devices are shown in ascending order. All leading zeros, if applicable, are shown. For example, device number 3 is displayed as 0003.

### **NETWORK DOMAIN DISABLED**

indicates that the NETWORK domain is disabled.

### **ISFC DOMAIN DISABLED**

indicates that the ISFC domain is disabled.

### **APPLDATA DOMAIN ENABLED**

indicates that the APPLDATA domain is enabled.

### **APPLID USER06 USER07**

indicates that there are three users whose application data is being collected, if a DIAGNOSE X'DC' START has been issued: APPLID, USER06, and USER07.

### **SSI DOMAIN DISABLED**

indicates that the SSI domain is disabled.

## Responses

**Note:** To make it easier to find the various responses, every response is listed by option (ALL, BLOCK, EVENT, INTERVAL, PARTITION, RATE, and SAMPLE).

Response 1 (ALL):

When QUERY MONITOR ALL is issued, the following responses are displayed:

- Response 3 (EVENT)
- Response 7 (SAMPLE)

Response 2 (BLOCK):

If QUERY MONITOR BLOCK is specified, the response is:

```
MONITOR BLOCK n
```

### BLOCK n

shows the maximum number of 4 KB pages accumulated before an IUCV message is sent to the virtual machine indicating that there is event data to be read.

Response 3 (EVENT):

If QUERY MONITOR EVENT is specified, the response is:

```
MONITOR EVENT {ACTIVE    } BLOCK n PARTITION n
               {INACTIVE  }
               {SUSPENDED}
               {PENDING   }

MONITOR DCSS NAME - {dcssname          }
                   {NO DCSS NAME DEFINED}

CONFIGURATION  SIZE n          LIMIT {n MINUTES}
                                       {n SECONDS}
CONFIGURATION AREA {WILL BE FREED WITHIN - {n MINUTES n SECONDS}}
                  {IS FREE}

USERS CONNECTED TO *MONITOR {NO USERS CONNECTED}
                            {userid[QUIESCED] [PROCESSING-CONFIG] [EXCLUSIVE]}
                            [PENDING-CONFIG ]
```

### EVENT

describes the status of event monitoring.

#### ACTIVE

indicates that EVENT recording is active.

#### INACTIVE

indicates that EVENT monitoring is not active.

#### SUSPENDED

indicates that EVENT monitoring is suspended either because monitor is in exclusive mode and the user connected has quiesced the path to \*MONITOR and/or the event partition of the DCSS is full; or because there are no CP frames available to write event data.

#### PENDING

indicates that EVENT recording is not being performed because either there is no eligible monitor user to receive data notification for event data or sample data is still in the event area of the DCSS.

#### BLOCK n

indicates the maximum number of 4 KB pages accumulated before an IUCV message is sent to the virtual machine, indicating there is event data to be read.

#### PARTITION n

indicates the number of 4 KB pages allocated for the entire event area (configuration and data record pages). If no users are connected, and event monitoring has been started with no partition specified, n is displayed as 50% to show that the default size of 50% of the DCSS size is used.

**MONITOR DCSS NAME**

indicates the name of DCSS to collect monitor data.

***dcssname***

is the name of the DCSS being used.

**NO DCSS NAME DEFINED**

indicates that no DCSS name is defined.

**CONFIGURATION SIZE *nn***

indicates the number of 4 KB pages (within the event partition) allocated for event configuration records. Leading zeros, if any, are removed.

**LIMIT *n* MINUTES**

**LIMIT *n* SECONDS**

displays the time limit in which a reply is required to the configuration IUCV message. If the value does not fall on a whole minute, the value is displayed in seconds, and the suffix SECONDS is displayed. Leading zeros, if any, are removed.

**CONFIGURATION AREA WILL BE FREED WITHIN - *n* MINUTES *n* SECONDS**

displays the amount of time that the users holding the configuration area have left to reply to the configuration IUCV message.

**CONFIGURATION AREA IS FREE**

is displayed if no users are holding the configuration area.

**USERS CONNECTED TO \*MONITOR**

lists, in alphabetic order, the user IDs of the users connected to \*MONITOR to collect event data.

**NO USERS CONNECTED**

indicates that no user is connected to \*MONITOR to collect event data.

***userid***

identifies the users connected to \*MONITOR for event data.

**QUIESCED**

indicates that the user is not allowing \*MONITOR to send IUCV messages over this path to the user's virtual machine.

**Note:** If a user's path is at its IUCV message limit, the user remains quiesced) until the user responds to previous messages from \*MONITOR.

**EXCLUSIVE**

indicates that monitor is running in exclusive mode, not shared mode. The mode is specified by the format of the connect interface used by the first user that connects to \*MONITOR.

The following response lines are given based on the specifications in the event profile:

```
MONITOR   DOMAIN  ENABLED
PROCESSOR DOMAIN  {DISABLED}
           {ENABLED }
STORAGE   DOMAIN  {DISABLED}
           {ENABLED }
SCHEDULER DOMAIN  {DISABLED}
           {ENABLED }
```

**Note:** The following additional responses are issued only if the SCHEDULER domain is enabled, based on the specifications for the SCHEDULER domain in the event profile:

```
ALL USERS  ENABLED
```

- or -

```
ALL USERS EXCEPT:
  userid [userid...]
```

- or -

THE FOLLOWING USERIDS ARE ENABLED:  
*userid [userid...]*

User IDs are displayed in alphabetic order.

SEEKS      DOMAIN {DISABLED}  
                                   {ENABLED }

**Note:** The following additional responses are issued only if the SEEKS domain is enabled, based on the specifications for the SEEKS domain in the event profile:

ALL DEVICES ENABLED

- or -

ALL DEVICES EXCEPT:  
*rdev[-rdev] or [rdev... rdev]*

- or -

THE FOLLOWING DEVICES ARE ENABLED:  
*rdev[-rdev]*

USER      DOMAIN {DISABLED}  
                                   {ENABLED }

**Note:** The following additional responses are issued only if the USER domain is enabled, based on the specifications for the USER domain in the event profile:

ALL USERS ENABLED

- or -

ALL USERS EXCEPT:  
*userid [userid...]*

- or -

THE FOLLOWING USERIDS ARE ENABLED:  
*userid [userid...]*

I/O      DOMAIN {DISABLED}  
                                   {ENABLED }

**Note:** The following additional responses are issued only if the I/O domain is enabled, based on the specifications for the I/O domain in the event profile:

PCIF CLASS ENABLED

- or -

PCIF CLASS DISABLED

- and -

ALL DEVICES ENABLED

- or -

ALL DEVICES EXCEPT:  
*rdev[-rdev] or [rdev... rdev]*

- or -

THE FOLLOWING DEVICES ARE ENABLED:  
*rdev[-rdev]*

**Note:**

1. For the APPLDATA domain, a user is enabled only if the OPTION APPLMON statement is specified in its directory entry.
2. The following additional responses are issued only if the APPLDATA domain is enabled, based on the specifications for the APPLDATA domain in the event profile:

```
ALL USERS ENABLED
```

- or -

```
ALL USERS EXCEPT:
  userid [userid...]
```

- or -

```
THE FOLLOWING USERIDS ARE ENABLED:
  userid [userid...]
```

```
APPLDATA  DOMAIN  {DISABLED}
             {ENABLED }
```

```
NETWORK    DOMAIN  {DISABLED}
             {ENABLED }
```

```
ISFC       DOMAIN  (DISABLES}
             {ENABLED }
```

```
SSI        DOMAIN  {DISABLED}
             {ENABLED }
```

```
COMMAND    DOMAIN  {DISABLED}
             {ENABLED }
```

Response 4 (INTERVAL):

If QUERY MONITOR INTERVAL is specified, the response is:

```
MONITOR INTERVAL {n MINUTES} PENDING INTERVAL [n MINUTES]
                 {n SECONDS}  [n SECONDS]
```

**INTERVAL *n* MINUTES**

**INTERVAL *n* SECONDS**

describes the current monitor sampling rate, where *n* is the current interval value (1 through 60 for minutes, 6 through 3600 for seconds). If an INTERVAL value does not fall on a whole minute, the value is displayed in seconds, and the suffix SECONDS is displayed.

**PENDING INTERVAL *n* MINUTES**

**PENDING INTERVAL *n* SECONDS**

indicates that a new sampling interval is to take effect after the current sampling interval has occurred. If the new INTERVAL value does not fall on a whole minute, the value is displayed in seconds, and the suffix SECONDS is displayed.

Response 5 (PARTITION):

If QUERY MONITOR PARTITION is specified, the response is:

```
MONITOR PARTITION n
```

**PARTITION *n***

indicates the number of 4 KB pages allocated to hold for event configuration and data records.

Response 6 (RATE):

If QUERY MONITOR RATE is specified, the response is:

```
MONITOR RATE {m SECONDS} [PENDING RATE {n SECONDS}]
             {STOP      }             { STOP  }]
```

**RATE *n* SECONDS**

**RATE STOP**

describes the current monitor high-frequency sampling rate, where *n* is a value between 0.01 and 30 seconds. STOP indicates that high-frequency sampling is inactive.

**PENDING RATE *n* SECONDS**

**PENDING RATE STOP**

indicates that a new high-frequency sampling rate is to take effect after the current high-frequency sampling rate has occurred, where *n* is a value between 0.01 and 30 seconds. STOP indicates that high-frequency sampling becomes inactive when the current RATE expires.

Response 7 (SAMPLE):

If QUERY MONITOR SAMPLE is specified, the response is:

```

MONITOR SAMPLE {ACTIVE      } {NEXT date time}
                {INACTIVE   }
                {SUSPENDED  }
                {PENDING    }
                INTERVAL {n MINUTES} [PENDING INTERVAL {n MINUTES}]
                {n SECONDS} [ {n SECONDS}]
                RATE     {n SECONDS} [PENDING RATE     {n SECONDS}]
                {STOP     } [ {STOP     } ]

MONITOR DCSS NAME - {dcssname      }
                   {NO DCSS NAME DEFINED}

CONFIGURATION  SIZE n          LIMIT {n MINUTES}
                                           {n SECONDS}

CONFIGURATION AREA {WILL BE FREED WITHIN - {n MINUTES n SECONDS}}
                  {IS FREE}

USERS CONNECTED TO *MONITOR {NO USERS CONNECTED
                             {userid[QUIESCED][PROCESSING-CONFIG][EXCLUSIVE]}
                             [PENDING-CONFIG ]

```

**SAMPLE**

describes the status of sample monitoring.

**ACTIVE**

indicates that SAMPLE monitoring is being performed because a MONITOR START or MONITOR SAMPLE START command was issued and there are eligible monitor users to receive sample data notification messages.

**INACTIVE**

indicates that SAMPLE monitoring is not being performed because no monitor start command for a sample has been issued.

**SUSPENDED**

indicates that SAMPLE monitoring is suspended because monitor is running in exclusive mode and the user connected is quiesced. (If the user is quiesced before the start command is issued, the monitor is in a PENDING state.)

**PENDING**

indicates that SAMPLE monitoring is not being performed because there is no eligible monitor user to receive data notification for sample data.

**NEXT *date time***

for ACTIVE, SUSPENDED, or PENDING, reports the date and time that the next sample collection will begin, if SAMPLE is ACTIVE at that time.

**INTERVAL *n* MINUTES**

**INTERVAL *n* SECONDS**

describes the current monitor sampling interval, where *n* is the current interval value (1 through 60 for minutes, 6 through 3600 for seconds). If an INTERVAL value does not fall on a whole minute, the value is displayed in seconds, and the suffix SECONDS is displayed.

### **PENDING INTERVAL *n* MINUTES**

### **PENDING INTERVAL *n* SECONDS**

indicates that a new sampling interval is to take effect after the current sampling interval has occurred. If the new INTERVAL value does not fall on a whole minute, the value is displayed in seconds, and the suffix SECONDS is displayed.

### **RATE *n* SECONDS**

### **RATE STOP**

describes the current monitor high-frequency sampling rate, where *n* is a value between 0.01 and 30 seconds. STOP indicates that high-frequency sampling is inactive.

### **PENDING RATE *n* SECONDS**

### **PENDING RATE STOP**

indicates that a new high-frequency sampling rate is to take effect after the current high-frequency sampling rate has occurred; *n* is a value between 0.01 and 30 seconds. STOP indicates that high-frequency sampling is inactive when the current RATE expires.

### **MONITOR DCSS NAME**

provides the name of the DCSS that is to collect monitor data.

#### **dcssname**

is the name of the DCSS being used.

### **NO DCSS NAME DEFINED**

indicates that no DCSS name is defined.

### **CONFIGURATION SIZE *n***

indicates the number of 4 KB pages (within the sample portion of the DCSS) allocated for sample configuration records. Leading zeros, if any, are removed.

### **LIMIT *n* MINUTES**

### **LIMIT *n* SECONDS**

displays the time limit in which a reply is required to the configuration IUCV message. If the value does not fall on a whole minute, the value is displayed in seconds, and the suffix SECONDS is displayed. Leading zeros, if any, are removed.

### **CONFIGURATION AREA WILL BE FREED WITHIN *-n* MINUTES *n* SECONDS**

displays the amount of time that the users holding the configuration area have left to reply to the configuration IUCV message.

### **CONFIGURATION AREA IS FREE**

is displayed if no users are holding the configuration area.

### **USERS CONNECTED TO \*MONITOR**

lists, in alphabetic order, the user IDs of the users connected to \*MONITOR to collect SAMPLE data.

### **NO USERS CONNECTED**

indicates that no user is connected to \*MONITOR to collect sample data.

#### **userid**

identifies the users connected to \*MONITOR for SAMPLE data.

### **QUIESCED**

indicates that the user is not allowing \*MONITOR to send IUCV messages over this path to the user's virtual machine.

### **PROCESSING-CONFIG**

indicates that the user received the notification for the configuration send, but the user has not yet replied to the send.

### **PENDING-CONFIG**

indicates that the user is waiting for a configuration notification message. The user is not eligible for data notification until after a configuration message has been successfully sent.

**Note:** If a user's path is at the IUCV message limit, the user remains quiesced) until the user responds to previous messages from \*MONITOR.

**EXCLUSIVE**

indicates that monitor is running in exclusive mode, not shared mode. The mode is specified by the format of the connect interface used by the first user that connects to \*MONITOR.

The following additional response lines are given based on the specifications in the sample profile:

```
MONITOR  DOMAIN  ENABLED
SYSTEM   DOMAIN  ENABLED

PROCESSOR DOMAIN  {DISABLED      }
          {ENABLED CPUMFC }
          {ENABLED NOCPUMFC}

STORAGE  DOMAIN  {DISABLED}
          {ENABLED }

USER     DOMAIN  {DISABLED}
          {ENABLED }
```

**Note:** The following additional responses are issued only if the USER domain is enabled, based on the specifications for the USER domain in the sample profile:

```
ALL USERS ENABLED
```

- or -

```
ALL USERS EXCEPT:
  userid [userid...]
```

- or -

```
THE FOLLOWING USERIDS ARE ENABLED:
  userid [userid...]
```

```
I/O      DOMAIN  {DISABLED}
          {ENABLED }
```

**Note:** The following additional responses are issued only if the I/O domain is enabled, based on the specifications for the I/O domain in the sample profile:

```
PCIF CLASS ENABLED
```

- or -

```
PCIF CLASS DISABLED
```

- and -

```
ALL DEVICES ENABLED
```

- or -

```
ALL DEVICES EXCEPT:
  rdev[-] or rdev
```

- or -

```
THE FOLLOWING DEVICES ARE ENABLED:
  rdev[-rdev] or [rdev... rdev]
```

```
APPLDATA DOMAIN  {DISABLED}
          {ENABLED }
```

**Note:**

1. For the APPLDATA domain, a user is enabled only if the OPTION APPLMON statement is specified in its directory entry.

2. The following additional responses are issued only if the APPLDATA domain is enabled, based on the specifications for the APPLDATA domain in the sample profile:

```
ALL USERS ENABLED
```

- OR -

```
ALL USERS EXCEPT:  
  userid [userid...]
```

- OR -

```
THE FOLLOWING USERIDS ARE ENABLED:  
  userid [userid...]
```

```
NETWORK    DOMAIN {DISABLED}  
            {ENABLED }
```

```
ISFC       DOMAIN {DISABLES}  
            {ENABLED }
```

```
SSI        DOMAIN {DISABLED}  
            {ENABLED }
```

## QUERY MSS

► Query — MSS ◄

### Authorization

Privilege Class: B

### Purpose

Use QUERY MSS to display the status of multiple subchannel set support and its configuration.

### Usage Notes

1. The *active* configuration is the set of accessible devices currently being used by or available for use by the z/VM system and virtual machines. The *standby* configuration is the set of accessible devices not currently available for use. For example, if the system was IPLed from a device in subchannel set 0, all devices in that subchannel set would be part of the active configuration while devices in other configured subchannel sets would be part of the standby configuration. If a HYPERSWAP command was used to swap some devices in subchannel set 0 with counterparts in another subchannel set, the swapped subchannel set 0 devices would become part of the standby configuration and the corresponding devices in the swapped subchannel set would become part of the active configuration.
2. Last HYPERSWAP contains the date and time of the last successful HYPERSWAP, the userid which issued the HYPERSWAP command and the source, and target subchannel set of the HYPERSWAP.

### Responses

Response 1:

If multiple subchannel set support is not enabled, you will receive the following response:

```
MSS Disabled
```

Response 2:

If multiple subchannel set support is enabled with subchannel sets 0-3 configured, the system was IPL'd from a device in SS0 and a HYPERSWAP has occurred from subchannel set 0 to subchannel set 1, you will receive a response that looks like this:

```
MSS Enabled
Subchannel Sets Configured: 0, 1, 2, 3
Subchannel Set of IPL Device: 0
Last HYPERSWAP: 2017-08-23 13:19:04, Userid = USERG, Source = SS0, Target = SSI
```

Response 3:

If multiple subchannel set support is enabled with subchannel sets 0-1 configured, the system was IPL'd from a device in SS0 and a HYPERSWAP has not occurred, you will receive a response that looks like this:

```
MSS Enabled
Subchannel Sets Configured: 0, 1
Subchannel Set of IPL Device: 0
Last HYPERSWAP: None
```

### Messages

## QUERY MULTITHREAD

### Authorization

Privilege Class: A, B, C, E, G

### Purpose

Use QUERY MULTITHREAD to display the system's multithreading (MT) status and thread information.

### Operands

#### INITIAL

This optional operand requests that the initial configuration values specified on the MULTITHREADING statement in the system configuration file be displayed with the resulting effective configuration values.

If INITIAL is omitted the current configuration settings are displayed.

### Usage Notes

1. For information about configuring multithreading, see the MULTITHREADING system configuration statement in *z/VM: CP Planning and Administration*. To display processor core utilization information, use the INDICATE MULTITHREAD command.  
Set the “[SET MULTITHREAD](#)” on page 1578 command for information about how to modify the multithreading configuration.
2. The multithreading configuration information displayed by the QUERY MULTITHREAD command is the current configuration resulting from the MULTITHREADING statement, or as modified by a successful SET MULTITHREAD command.
3. If Q MULTITHREAD is issued while SET MULTITHREAD processing is active the command will respond that the multithreading configuration is in transition. This will be indicated by message HCP6513I and corresponding return code.
4. In order to delay processing in an automation script until the asynchronous processing for a previously issued SET MULTITHREAD command is complete, the script can loop (with a delay) on QUERY MULTITHREAD until the return code no longer indicates SET MULTITHREAD is in progress. The INITIAL operand should not be specified for this use because it completes with a zero return code even if a configuration change is in progress.
5. The system can be restored to the initial values by use of the SET MULTITHREAD INITIAL command.

### Responses

Response 1:

```
The Multithreading Facility is not installed.
```

is displayed if the multithreading facility is not installed on the hardware or the logical partition, or if the z/VM system is running as a guest.

Response 2:

```
Multithreading is disabled.
```

is displayed if the processor or configuration supports multithreading but multithreading is disabled. There are a number of reasons why multithreading might be disabled. For example, a MULTITHREADING statement might not be included in the system configuration file. Review the system initialization messages in the operator's console log.

Response 3:

```
Multithreading is enabled.
      Requested   Activated
      Threads     Threads
MAX_THREADS      nn         nn
CP core          nn         nn
IFL core         nn         nn
ICF core         nn         nn
zIIP core        nn         nn
```

This response is displayed if the processor or configuration supports multithreading and multithreading is enabled in the system configuration file.

**Requested Threads**

This column indicates the specified or default value from the associated operand on the MULTITHREADING configuration statement, or as modified by a successful SET MULTITHREAD command. If the operand was not specified or the MAX keyword was specified, this column will show the string "MAX".

**Activated Threads**

For MAX\_THREADS, the activated threads number is the least of the following:

- The value specified for the MAX\_THREADS operand on the MULTITHREADING statement
- The highest number of threads per core supported for any CPU type that is available on the hardware or the configuration where z/VM is running
- The highest number of threads per core supported by z/VM for any CPU type

The activated threads value for MAX\_THREADS, rounded up to a power of 2, is the number of CPU addresses assigned to each core.

For each CPU type, the activated threads number is the least of the following:

- The activated threads value for MAX\_THREADS
- The requested threads value for that CPU type on the MULTITHREADING statement, or as modified by a successful SET MULTITHREAD command.
- The number of threads per core supported for that CPU type on the hardware or the configuration where z/VM is running
- The number of threads for that CPU type supported by z/VM

The activated threads value for each CPU type is the number of threads available for use by CP in an online core of the specified CPU type. Activated threads appear as processors to z/VM. If this number is less than the activated MAX\_THREADS value, or if the activated MAX\_THREADS value is not a power of 2, then there will be gaps in the range of online CPU addresses.

Response 4:

```
Multithreading is enabled and these are the initial values
      Requested   Activated
      Threads     Threads
MAX_THREADS      nn         nn
CP core          nn         nn
IFL core         nn         nn
ICF core         nn         nn
zIIP core        nn         nn
```

This response is displayed when the INITIAL operand is specified, if the processor or configuration supports multithreading and multithreading is enabled in the system configuration file. These are the initial values which were in effect at system initialization which may have since been modified by a SET MULTITHREAD command.

## QUERY MULTITHREAD

See response 3 for an explanation of the output with the following differences in mind. This response describes the multithreading configuration resulting from the requested configuration on the MULTITHREADING configuration statement. The current multithreading configuration may have been changed by a SET MULTITHREAD command.

### Examples

If the ENABLE operand was specified on the MULTITHREADING statement in the system configuration file, and you issue the QUERY MULTITHREAD and INDICATE MULTITHREAD commands on a system that is capable of multithreading, you might see responses similar to the following example. Note that gaps might occur in the sequence of processor addresses for cores that have less than the maximum number of activated threads.

**Note:** This example is for z/VM 6.3, which supports up to 2 threads on an IFL core and 1 thread on a core of any other type.

```
query mt
Multithreading is enabled.
           Requested  Activated
           Threads   Threads
MAX_THREADS  MAX      2
CP core      MAX      1
IFL core     MAX      2
ICF core     MAX      1
zIIP core    MAX      1
```

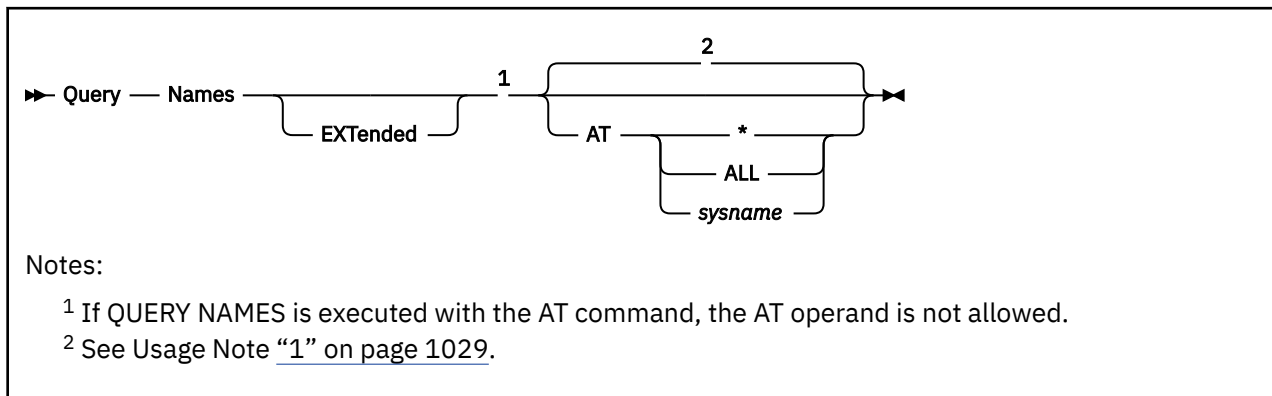

```
query proc
PROCESSOR 00 MASTER CP CORE 0000
PROCESSOR 02 ALTERNATE CP CORE 0001
PROCESSOR 04 ALTERNATE CP CORE 0002
PROCESSOR 06 ALTERNATE IFL CORE 0003
PROCESSOR 07 ALTERNATE IFL CORE 0003
PROCESSOR 08 ALTERNATE IFL CORE 0004
PROCESSOR 09 ALTERNATE IFL CORE 0004
PROCESSOR 0A ALTERNATE IFL CORE 0005
PROCESSOR 0B ALTERNATE IFL CORE 0005
PROCESSOR 0C ALTERNATE ZIIP CORE 0006
PROCESSOR 0E ALTERNATE ZIIP CORE 0007
PROCESSOR 10 ALTERNATE CP CORE 0008
```

```
indicate mt
Multithreading is enabled.
Statistics from the interval 13:00:30 - 13:01:00
Core Type CP   Busy 8%   TD 1.00 of 1   Prod 100%   Util 8%
CF 100%   MaxCF 100%
Core Type IFL  Busy 67%   TD 1.24 of 2   Prod 82%   Util 55%
CF 107%   MaxCF 131%
Core Type ZIIP Busy 5%   TD 1.00 of 1   Prod 100%   Util 5%
CF 100%   MaxCF 100%
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP6513I A multithreading configuration change is in progress.

## QUERY NAMES

### Authorization

Privilege Class: A, B, C, D, E, F, G

### Purpose

Use QUERY NAMES to display:

- A list of all logged-on users
- The real or logical device number of the display to which each user is connected

### Operands

#### EXTENDED

specifies that logical unit network qualifiers or logical device host names and IP addresses are displayed if they exist. See [Response 2](#) for details on how the EXTENDED operand changes the responses.

#### AT \*

displays logged-on users for the system you are logged on to and the real or logical device number of the displays where those users are connected. This is the default if the system is not a member of an SSI cluster.

#### AT ALL

displays logged-on users for all systems in the SSI cluster and the real or logical device number of the displays where those users are connected. A response is issued for each active member of the cluster. Responses are displayed in the order they are received, and are prefixed with the source member name.

#### AT sysname

displays logged-on users for a specific system in the SSI cluster and the real or logical device number of the displays where those users are connected.

### Usage Notes

1. If the AT operand is not specified:

- If QUERY NAMES is not executed with the AT command:
  - If the issuer's system is not a member of an SSI cluster, the default is AT \*.
  - If the issuer's system is a member of an SSI cluster, the command displays all users defined by single-configuration virtual machine definitions logged on to any member of the cluster, and local logon instances of users defined by multiconfiguration virtual machine definitions.

## QUERY NAMES

If you want to display all logon instances of users defined by multiconfiguration virtual machine definitions, issue QUERY NAMES AT ALL. If you want to display only the users on the local system, issue QUERY NAMES AT \*.

- If QUERY NAMES is executed with the AT command, the AT operand function is bypassed (there is no default), and information is displayed for the system specified on the AT command.
2. Multiple, concurrent VTAM service machines are supported; therefore, multiple listings of logical unit names (*lunames*) owned by VTAM service machines might be displayed in the response. This portion of the QUERY NAMES response follows the *rdev/ldev* listings of users connected to the system; it is displayed only if there is an active VTAM service machine connected to the system.
3. Within a single VSM that supports network qualified names, multiple listings of logical unit names (*lunames*) owned by VTAM service machines might be displayed in the response, if EXTENDED is not specified.
4. If a large virtual machine is logged off multiple times and two or more logged-off instances are still going through memory reset, the user ID (transformed from uppercase to lowercase) will appear multiple times in the responses to this command. Eventually, each instance will finish memory reset and will disappear from the responses.

The following sequence of events is an example of this type of situation:

- a. A user logs on virtual machine "LARGEONE" and runs a workload that instantiates a large amount of memory.
- b. The user logs off the virtual machine. This instance of virtual machine "LARGEONE" becomes known as instance "largeone."
- c. Responses to QUERY NAMES include "largeone - LOF."
- d. The user logs back on to virtual machine "LARGEONE" and runs a workload that instantiates a large amount of memory.
- e. The user logs off. This instance of virtual machine "LARGEONE" also becomes known as instance "largeone."
- f. Responses to QUERY NAMES now include two occurrences of "largeone - LOF."
- g. Eventually instance "largeone" from Step "4.b" on page 1030 completes reset and disappears.
- h. Responses to QUERY NAMES now include only one occurrence of "largeone - LOF."
- i. Eventually instance "largeone" from Step "4.e" on page 1030 completes reset and disappears.

### Examples

Example 1:

When you issue QUERY NAMES to display logged-on users to the SSI cluster, you might get a response similar to this:

```
0001      - SSI , 0002      - SSI
OPERATOR  - 2000
```

Example 2:

The source member name is prefixed in an SSI cluster when you specify Q N AT ALL.

```
PERRY2    : 0002      - DSC ,0001      - DSC , OPERATOR - 2000
PERRY3    : OPERATOR - 2000
```

### Responses

Response 1:

```
{userid } - {SSI }
{userid } - {rdev}
{userid } - {LOF }
```

... up to four responses per line

```
{LOGLxxxx}   {ldev}
{LOGNxxxx}   {DSC }
{LOGVxxxx} - luname}
{LOGNMxxx} - DSC}
{LOGNSYSC}   {SYSC}
{LOGNSYSG}   {SYSG}
{lognauto}   {DSC }
[VSM - userid
 [userid - luname, userid -luname,... ]
 [userid - luname, userid -luname,... ]
```

**userid**

**LOGNxxxx**

**LOGLxxxx**

**LOGVxxxx**

**LOGNMxxx**

**LOGNSYSC**

**LOGNSYSG**

**lognauto**

identifies the virtual machine. If a user has not completed logon processing to a real device, *userid* is displayed in the form LOGNxxxx, where xxxx is the real device number of the display being used. If a user has not completed logon processing to a logical device, *userid* is displayed in the form LOGLxxxx, where xxxx is the logical device number of the display being used. If a user has not completed logon processing to an SNA/CCS terminal, *userid* is displayed in the form LOGVxxxx, where xxxx is a unique identifier. If a user is in the process of being relocated on to this system from another member of the SSI cluster, LOGNMxxx is displayed, where xxx is a unique value. If a user has not completed logon processing to the system console, user ID LOGNSYSC is displayed. If a user has not completed logon processing to the integrated 3270 console, user ID LOGNSYSG is displayed. If a user has not completed AUTOLOG or XAUTOLOG processing, the *userid* is displayed as lognauto. There might be multiple instances of lognauto for different users.

**xxx and xxxx**

can be any character, number, or symbol. Userids starting with LOGN, LOGL, and LOGV are restricted.

**rdev**

**ldev**

**DSC**

**SYSC**

**SYSG**

**SSI**

identifies the device number where the user is logged on. The device may be real (*rdev*) or logical (*ldev*). DSC is displayed if the user is disconnected and does not have a real display. SYSC is displayed if the user is logged on to the system console. SYSG is displayed if the user is logged on to the integrated 3270 console. SSI is displayed if the user is logged on to a remote member of the SSI cluster.

**LOF**

indicates that the user has logged off but its memory is still in the process of being released.

**VSM - userid**

identifies the user ID of the VTAM service machine managing the following users.

**userid - luname**

identifies the user IDs and the SNA logical unit names (*lunames*) of their terminals for all users accessing the system from an SNA/CCS terminal managed by that VTAM service machine.

**Response 2:**

```
userid - ldev HOST hostname [FROM IP-address]
userid - netname.luname
```

## QUERY NAMES

### **HOST *hostname***

identifies the virtual machine that created and manages the logical device where the user is logged in.

### **FROM IP-*address***

identifies the IP address associated with the logical device.

An IPv4 address is displayed in dotted-decimal format.

**Example:** 9 . 130 . 44 . 144

An IPv6 address is displayed in compressed format ("::" designates multiple 16-bit groups of zeros).

**Example:** The following is an IPv6 address:

```
F802:0000:0000:0000:0000:0A00:0001
```

This address is displayed in compressed format as:

```
F802::A00:1
```

### ***userid - netname.luname***

identifies the user IDs and the fully qualified SNA logical unit names (*netname.luname*) of their terminals for all users accessing the system from an SNA/CCS terminal managed by that VTAM service machine.

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP361E [XAUTOLOG failed for *userid*:] LOGOFF/FORCE pending for user *userid*
- HCP1142E The AT option is not allowed when this command is executed remotely with the AT command.
- HCP2970E The SSI cluster member name is missing or invalid.
- HCP2971I Specified SSI cluster member is not joined.

## QUERY NEW\_DEVICES

► Query — NEW\_DEVICES ◄

### Authorization

Privilege Class: C

### Purpose

Use QUERY NEW\_DEVICES to display whether CP initializes new real devices as they are added to a running system.

### Usage Notes

1. To add a new device to a running system, use the DEFINE DEVICE command (see [“DEFINE DEVICE / IODEVICE”](#) on page 167).
2. If CP does not initialize a new device when you add it to the system, you must vary the device online using the VARY (real device) command (see [“VARY \(Real Device\)”](#) on page 2063) before anyone can use that device.
3. To change the way CP initializes new real devices as they are added to a running system:
  - During initialization, use the ENABLE or DISABLE NEW\_DEVICES\_INITIALIZED\_WHEN\_ADDED operands of the FEATURES Statement in your system configuration file. For more information, see *z/VM: CP Planning and Administration*.
  - After initialization, use the SET NEW\_DEVICES command (see [“SET NEW\\_DEVICES”](#) on page 1581).
4. For more information about adding new devices to a running system, see the [FEATURES Statement](#) in *z/VM: CP Planning and Administration*.

### Responses

Response 1 (Devices Are Initialized):

To display how CP handles new real devices as they are added to your running system, enter the following:

```
query new_devices
New devices are initialized when added.
Ready;
```

This response tells you that any new device you add will be immediately available for use.

Response 2 (Devices Are Not Initialized):

If CP is not initializing new devices as they are added, you would see:

```
query new_devices
New devices are not initialized when added.
Ready;
```

This response tells you that new devices must be varied online before they become available for use.

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*

## QUERY NIC

### Authorization

Privilege Class: B

### Purpose

Use QUERY NIC to display the system-level information and the MAC addresses assigned or being used by the selected network devices.

### Operands

#### SYSTEM

display the current system level information.

#### rdev

is the real network device number on this system for which information will be returned. RDEV information is only displayed when a MACID has been set.

#### USERid \*|USERid userid vdev

is the user ID of the virtual machine and virtual network device number for which you want to query information. If *userid* is specified as an asterisk (\*), CP uses the user ID of the virtual machine issuing the command.

#### vdev

is the virtual network device number for which information will be returned. If a *vdev* is not specified, all virtual network devices for the specified user ID will be returned.

#### ALL

will display information for the system and all network devices.

#### MACID

to display MAC addresses assigned or being used by the selected network devices.

When running z/VM as a single system image cluster, the command will also display MAC addresses originally assigned by this system that were moved by Live Guest Relocation to another member of the single system image cluster. The query will not display all the MAC addresses assigned within a single system image cluster. It will only display MAC addresses originally assigned by this system.

#### DETAils

to display detailed information about the selected network devices.

### Usage Notes

The SET NIC command is used to modify NIC settings.

### Examples

1. QUERY NIC:

Display the system level information:

```
q nic
Default System MAC Protection: OFF
Network Device Allocation: Permitted
```

2. QUERY NIC ALL MACID DETAILS:

Display the system level information and all MAC addresses being used by the network devices:

```
q nic all macid details
Default System MAC Protection: ON
Network Device Allocation: Permitted
  MAC: 02-22-90-00-00-00 SYSTEM 0000
  MAC: 02-22-90-00-00-01 SYSTEM ETH1
A MAC: 02-22-90-00-00-02 TCPIP 0600
  Protection: Unspecified
A MAC: 02-22-90-00-00-03 TCPIP 4100
  Protection: OFF
  MAC: 02-22-90-00-00-04 SYSTEM ETH2
  Protection: Unspecified
R MAC: 02-22-FF-00-03-21 TCPIP 0600 ON 2NDLVLF
R MAC: 02-22-FF-00-9C-08 OPERATOR 9C08 ON 2NDLVLF
R MAC: 02-22-FF-01-42-00 LINUX3 7000 ON 2NDLVLF
W MAC: 02-55-90-00-03-21 TCPIP 0600
  Protection: Unspecified
  MAC: 02-55-90-00-9C-08 OPERATOR 9C08 ON 9C08
PA MAC: 02-55-90-01-42-00 LINUX3 7000
  Protection: ON
```

3. A VIRTUAL version of this command, QUERY VIRTUAL NIC, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL NIC” on page 1310](#).

**Responses**

Response 1:

The QUERY NIC response includes optional lines. The general format is:

```
Default System MAC Protection: level
Network Device Allocation: state
ps MAC: mm-mm-mm-mm-mm userid vdev/switchname ON rdev/system
  Protection: setting
```

**level**

Default system MAC address protection

**ON**

specifies the MAC address is protected and cannot be overridden by the guest when establishing a network connection.

**OFF**

specifies the MAC address is not protected. A guest can override an assigned MAC address when establishing a network connection.

The system MAC address protection setting is used when MAC address protection is set to UNSPECified for a specific device, a coupled virtual switch or guest LAN

**state**

Network Device Allocation: *state*

**Permitted**

The SSI cluster is in a STABLE mode. While the SSI cluster is STABLE, HiperSocket or OSA type network devices may either be created or attached to a guest's virtual I/O configuration.

**Prohibited**

The SSI cluster is currently NOT in a STABLE mode. Creating or attaching a network device to a guest's virtual I/O configuration will not be allowed in order to maintain network integrity. The CP DEFINE NIC and ATTACH commands issued for a HiperSocket or OSA device will fail until the SSI cluster returns to a STABLE mode. The CP QUERY SSI command may be used to determine the reason the SSI cluster is not in a STABLE mode.

**ps**

MAC Address Attributes

**P**

In the *p* column indicates the MAC address is protected and cannot be overridden by the guest when establishing a network connection. If *p* is not indicated, then the MAC address is not protected.

**R**

in the *p* column indicates the MAC address is remote and specifies that the MAC address is currently assigned to a network device, adapter or virtual switch in another member of an SSI cluster.

**Note:** When displaying a remote MAC address, no other MAC address attributes will be displayed.

**W**

in the *s* column indicates the MAC address is waiting to be assigned the next time a network connection is reestablished.

**A**

in the *s* column indicates the MAC address is assigned to a virtual NIC adapter. This is the default MAC address that will be used when establishing a network connection on a device that doesn't have a MAC address assigned by a SET NIC MACID CP command.

**MAC: mm-mm-mm-mm-mm-mm**

MAC address assigned by this system.

**userid**

is the user ID that owns the MAC address.

**vdev/switchname**

is either the four digit virtual device number or the eight character virtual switch name assigned to the MAC address. When an entry is displayed for a MAC address assigned to a virtual switch that is being used by another system in the SSI, *vdev* will be a pseudo device number. In this case, the device number can be ignored.

**ON rdev/system**

is either the four digit real device number for a MAC address assigned by the local system or the eight character system name of another system in the single system image cluster that is using a MAC address assigned by this system. This information will only be displayed if there is a real device associated with the network device or the MAC address assigned by this system is being used by another system in the single system image cluster.

A system name of "Unknown" could indicate a problem with the single system image cluster.

**setting**

MAC address protection

**ON**

specifies the MAC address is protected and can't be overridden by the guest when establishing a network connection.

**OFF**

specifies the MAC address is not protected. A guest can override an assigned MAC address when establishing a network connection.

**Unspecified**

specifies the MAC address is not protected. A guest can override an assigned MAC address when establishing a network connection.

This is the device MAC protection setting as specified with the SET NIC command.

**Messages**

- HCP003E Invalid option - command contains extra option(s) starting with xxx
- HCP2768E Missing user ID
- HCP2836E [RDEV | VDEV | USERID] was not found.
- HCP6706E Invalid user ID - xxxxxxxx

## QUERY NLS

### Authorization

Privilege Class: E

### Purpose

Use QUERY NLS to display:

- Message repository file information
- The count of message repository files

**Note:** Message repository files are created by the system programmer.

### Operands

#### ALL

queries all message repository files. This is the default.

#### Class *c*

specifies the class of files to be queried. The operand *c* can be either A or P, where A indicates that the repository file is in the available state and P indicates that the file is in the pending purge state.

#### NAME *fn*

specifies the file name of the file or files to be queried. This is the file name specified when the file was created. More than one file can exist with the same file name, although only one may be class A.

#### *spoolid*

specifies the system-assigned number of the file to be queried.

#### SHOrtdate

specifies that dates in the response to this command will be displayed in *mm/dd* format, where *mm* is the month and *dd* is the day of the month.

#### FULldate

specifies that dates in the response to this command will be displayed in *mm/dd/yyyy* format, where *mm* is the month, *dd* is the day of the month, and *yyyy* is the 4-digit year.

#### ISOdate

specifies that dates in the response to this command will be displayed in *yyyy-mm-dd* format, where *yyyy* is the 4-digit year, *mm* is the month, and *dd* is the day of the month.

#### COUNT

displays only the number of message repository files that match the criteria specified on the command.

## Usage Notes

1. The default date format for certain CP and CMS commands can be set on a system-wide basis and also for the individual user. The system-wide default date format is set with the SYSTEM\_DATEFORMAT system configuration statement. The user's default date format is set with the DATEFORMAT directory statement. The system-wide default and the user's default can also be set with the CP SET DATEFORMAT command. The user's default date format defaults to the system-wide default. The system-wide and user settings can be queried with the CP QUERY DATEFORMAT command. The hierarchy of possible date format settings for the QUERY NLS command, from highest priority to lowest, is:
  - QUERY NLS command operand
  - User default
  - System-wide default

## Responses

Response 1:

The following response is issued when you specify QUERY NLS SHORTDATE:

OWNERID	FILE	TYPE	CL	RECS	DATE	TIME	FILENAME	FILETYPE	ORIGINID
*NLS	nnnn	type	c	nnnn	mm/dd	hh:mm:ss	fn	ft	originid

Response 2:

The following response is issued when you specify QUERY NLS FULLDATE:

OWNERID	FILE	TYPE	CL	RECS	DATE	TIME	FILENAME	FILETYPE	ORIGINID
*NLS	nnnn	type	c	nnnn	mm/dd/yyyy	hh:mm:ss	fn	ft	originid

Response 3:

The following response is issued when you specify QUERY NLS ISODATE:

OWNERID	FILE	TYPE	CL	RECS	DATE	TIME	FILENAME	FILETYPE	ORIGINID
*NLS	nnnn	type	c	nnnn	yyyy-mm-dd	hh:mm:ss	fn	ft	originid

### OWNERID

indicates that the file is an NLS file owned by the system. The designation \*NLS is not a user ID. It indicates the queue on which the file resides.

### FILE

identifies the spool file.

### TYPE

identifies the type of system data file. In this case, it is NLS and indicates a message repository file.

### CL

identifies the file class, either A or P. Class A indicates that the file is available. Class P indicates that the file is in the pending purge state; it is purged during the next system IPL or RESTART.

### RECS

identifies the number of 4 KB pages in the file.

### DATE

identifies the date the file was closed. The format of the date is determined by the SHORTDATE, FULLDATE, or ISODATE operand. If no date format operand is specified, the user's default date format setting is used.

### TIME

identifies the time the file was closed in hours, minutes, and seconds.

### FILENAME

identifies the file name associated with the file.

## QUERY NLS

### FILETYPE

identifies the file type associated with the file.

### ORIGINID

identifies the originator of the file.

Response 4:

```
FILES:  NO NLS
```

appears if none of the specified files exist.

Response 5:

```
FILES:  {nnnn} NLS  
        { NO }
```

appears if the COUNT option is specified on the QUERY NLS command. Only the number of repository files that match the specified criteria is displayed.

### nnnn

identifies the number of repository files. If no files are found that match the selection criteria, NO replaces nnnn.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP413E Command processing cannot complete due to a spool paging error.
- HCP422E The same option was specified twice.
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP848E SYSTEM parameter is invalid with the spoolid option
- HCP849E A user ID must be specified with the spoolid
- HCP1558E Command processing cannot complete.

## QUERY NSS

### Authorization

Privilege Class: E

### Purpose

Use QUERY NSS to display information about system data files that contain named saved systems (NSSs) and saved segments.

### Operands

#### ALL

requests information on all NSS and saved segment files. This is the default.

#### Class *c*

specifies the class of files to be queried. The operand *c* can be one of the following:

#### A

Available nonrestricted.

#### P

Pending purge.

#### R

Available restricted.

#### S

Skeleton.

For further definitions of these classes, see "Response 7 (MAP)" under ["Responses" on page 1042](#).

#### NAME *fn*

specifies the file name of the file for which information is requested.

#### *spoolid*

specifies the spool file number of the file to be queried.

#### ATTRIBUTES

displays additional information specific to NSS and saved segment files.

**COUNT**

displays only the number of files that match the criteria specified on the command. No other information is provided.

**ENVIRONMENT**

for NSS files only, displays the information about the IPL environment, such as the minimum virtual machine size and the allowed virtual machine modes.

**MAP**

indicates that information specific to NSS and saved segment files should be displayed, such as beginning and ending page numbers of the saved NSS and saved segments.

**SHORTDATE**

specifies that dates in the response to this command will be displayed in *mm/dd* format, where *mm* is the month and *dd* is the day of the month.

**FULLDATE**

specifies that dates in the response to this command will be displayed in *mm/dd/yyyy* format, where *mm* is the month, *dd* is the day of the month, and *yyyy* is the 4-digit year.

**ISODATE**

specifies that dates in the response to this command will be displayed in *yyyy-mm-dd* format, where *yyyy* is the 4-digit year, *mm* is the month, and *dd* is the day of the month.

**USERS *fn***

requests a list of the user IDs that are actively using the NSS or saved segment.

**Usage Notes**

1. QUERY NSS is equivalent to the QUERY RDR/PRT/PUN command for spool files.
2. The QUERY NSS ALL MAP command does not reflect all associations of a member that is within multiple segment spaces. QUERY NSS NAME *spacename* MAP should be used to determine the members of a particular segment space.
3. For security purposes, if the issuing user is not authorized to use a system data file, then the MAP, ENV and ATTR options of the QUERY NSS command will not provide information on those system data files.
4. The default date format for certain CP and CMS commands can be set on a system-wide basis and also for the individual user. The system-wide default date format is set with the SYSTEM\_DATEFORMAT system configuration statement. The user's default date format is set with the DATEFORMAT directory statement. The system-wide default and the user's default can also be set with the CP SET DATEFORMAT command. The user's default date format defaults to the system-wide default. The system-wide and user settings can be queried with the CP QUERY DATEFORMAT command. The hierarchy of possible date format settings for the QUERY NSS command, from highest priority to lowest, is:
  - QUERY NSS command operand
  - User default
  - System-wide default
5. Processing of a QUERY NSS command might be delayed if DIAGNOSE code X'64' is concurrently performing the initial load of a large DCSS.

**Responses**

Response 1 (ALL, CLASS, NAME, spoolid):

This response format is displayed for an ALL, CLASS, NAME, or *spoolid* request if SHORTDATE is specified or is the user's default date format. The response contains one record for each file that matches the criteria specified on the command. The fields in the response contain the following information:

OWNERID	FILE TYPE	CL	RECS	DATE	TIME	FILENAME	FILETYPE	ORIGINID
*NSS	<i>spid</i> NSS	<i>c</i>	<i>recs</i>	<i>mm/dd</i>	<i>hh:mm:ss</i>	<i>fn</i>	<i>ft</i>	<i>originid</i>

Response 2 (ALL, CLASS, NAME, spoolid):

This response format is displayed for an ALL, CLASS, NAME, or *spoolidrequest* if FULLDATE is specified or is the user's default date format. The response contains one record for each file that matches the criteria specified on the command. The fields in the response contain the following information:

OWNERID	FILE	TYPE	CL	RECS	DATE	TIME	FILENAME	FILETYPE	ORIGINID
*NSS	<i>spid</i>	NSS	<i>c</i>	<i>recs</i>	<i>mm/dd/yyyy</i>	<i>hh:mm:ss</i>	<i>fn</i>	<i>ft</i>	<i>originid</i>

Response 3 (ALL, CLASS, NAME, spoolid):

This response format is displayed for an ALL, CLASS, NAME, or *spoolidrequest* if ISODATE is specified or is the user's default date format. The response contains one record for each file that matches the criteria specified on the command. The fields in the response contain the following information:

OWNERID	FILE	TYPE	CL	RECS	DATE	TIME	FILENAME	FILETYPE	ORIGINID
*NSS	<i>spid</i>	NSS	<i>c</i>	<i>recs</i>	<i>yyyy-mm-dd</i>	<i>hh:mm:ss</i>	<i>fn</i>	<i>ft</i>	<i>originid</i>

**OWNERID**

identifies the owner of the file. The designation \*NSS indicates that the file is owned by the system. \*NSS is not a user ID; it is the name of the queue on which the file resides.

**FILE**

identifies the spool file number.

**TYPE**

identifies the type of system data file. All files containing NSSs or saved segments are type NSS.

**Note:** Do not confuse this with the file type of the system data file.

**CL**

identifies the file class. For the list of these classes, see "Response 7 (MAP)" under ["Responses"](#) on page 1042.

**RECS**

specifies the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where *nnn* is the number of lines in thousands rounded to the nearest thousand. If the number is greater than 999499, the number is shown as *nnnM*, where *nnn* is the number of lines in millions rounded to the nearest million.

**DATE**

identifies the date the NSS or saved segment was defined. The format of the date is determined by the SHORTDATE, FULLDATE, or ISODATE operand. If no date format operand is specified, the user's default date format setting is used.

**TIME**

identifies the time the NSS or saved segment was defined, in hours, minutes, and seconds.

**FILENAME**

identifies the file name of the system data file that contains the NSS or saved segment.

**FILETYPE**

identifies the file type of the system data file. This is NSS for a named saved system, DCSSG for a discontinuous saved segment (DCSS) above 2047 MB, and DCSS for any other type of saved segment.

**ORIGINID**

identifies the user ID of the user who saved the NSS or saved segment (for class A, R, or P files). If the file is a skeleton (class S), this is the user who defined the NSS or saved segment.

Response 4 (ATTRIBUTES):

FILE	FILENAME	FILETYPE	CL	ATTRIBUTES
<i>spid</i>	<i>fn</i>	<i>ft</i>	<i>c</i>	<i>attr</i>

This response format is displayed for an ATTRIBUTES request. The response contains one record for each file that matches the criteria specified on the command. The fields in the response contain the following information:

## QUERY NSS

### FILE

identifies the spool file number.

### FILENAME

identifies the file name of the system data file that contains the NSS or saved segment.

### FILETYPE

identifies the file type of the system data file:

<u>Type</u>	<u>Meaning</u>
NSS	Named saved system
DCSS	DCSS below 2047 MB
DCSSG	DCSS above 2047 MB
DCSS-S	Segment space
DCSS-M	Member segment
CPNSS	CP system service NSS
CPDCSS	CP system service DCSS

### CL

identifies the file class. For the list of these classes, see "Response 7 (MAP)" under "[Responses](#)" on [page 1042](#).

### ATTRIBUTES

identifies the set of additional attributes that pertain to this file. Items in this list are delimited by a blank. Possible values are:

<u>Value</u>	<u>Meaning</u>
LOADNSHR	This attribute pertains only to DCSSs and segment spaces. It means that this saved segment may be loaded nonshared (using DIAGNOSE code X'64') by any user. Users do not need NAMESAVE directory privilege to obtain an exclusive write copy of this saved segment.
NONE	There are no additional attributes for this NSS or saved segment. Enter the QUERY NSS command with the MAP option to get more information about this file.

Response 5 (COUNT):

```
FILES: {nnnn} NSS
       { NO }
```

This response format is displayed for a COUNT request, or for any other version of the command (except QUERY NSS USERS *fn*) if no files match the selection criteria.

### Value

#### Meaning

### **nnnn**

is the number of NSS and saved segment files that match the selection criteria.

### **NO**

No files match the selection criteria.

Response 6 (ENVIRONMENT):

```
FILE FILENAME FILETYPE CL MINSIZE MACHMODE
spid fn          ft      c  minsize mm1(,mm2,...)
```

This response format is displayed for an ENVIRONMENT request and supplies information about NSS files only. The response contains one record for each file that matches the criteria specified on the command. The fields in the response contain the following information:

**FILE**

identifies the spool file number.

**FILENAME**

identifies the file name of the system data file that contains the NSS.

**FILETYPE**

identifies the file type of the system data file. This is either NSS or CPNSS.

**CL**

identifies the file class. For the list of these classes, see "Response 7 (MAP)" under ["Responses"](#) on page 1042.

**MINSIZE**

specifies the minimum storage size of the virtual machine into which the NSS can be loaded. Storage is represented in multiples as follows:

<u>Representation</u>	<u>Multiples</u>
<i>nnnnnnnK</i>	Decimal kilobytes
<i>000nnnnM</i>	Decimal megabytes

**MACHMODE**

identifies the set of virtual machine modes in which this NSS can be IPLed:

<u>Value</u>	<u>Meaning</u>
<i>mm1,mm2,...</i>	This is a list of one or more virtual machine modes, separated by commas with no intervening blanks. Each entry in this list is either ESA, XC, or Z, corresponding to ESA/390, ESA/XC, or z/Architecture respectively. An NSS with more than one mode listed is called a multimode NSS.
<i>—</i>	This NSS is a skeleton and the MACHMODE operand was not specified on the DEFSYS command. The virtual machine mode in which this NSS can be IPLed is that of the virtual machine that issues the SAVESYS command.

Response 7 (MAP):

This response is displayed for a MAP request. The response contains one record for each file that matches the criteria specified on the command; more than one page range may be displayed.

Also, for a QUERY NSS NAME *fn* MAP request:

- If *fn* is a member of a segment space, the response contains one record for the member, followed by one record for the space.
- If *fn* is a segment space, the response contains one record for the space, followed by one record for each member of the space.

For an NSS, a segment space, a member saved segment, or a DCSS below 2047 MB, the response format is:

```
FILE FILENAME FILETYPE MINSIZE BEGPAG ENDPAG TYPE CL #USERS PARMREGS VMGROUP
spid fn ft minsize nnnnn nnnnn type c nnnnn parmregs vmgroup
```

For a DCSS above 2047 MB, the response format is:

```
FILE FILENAME FILETYPE BEGPAG ENDPAG TYPE CL #USERS
spid fn DCSSG nnnnnnnnnnnnnn nnnnnnnnnnnnnn type c nnnnn
```

**Note:** The format for NSSs and saved segments below 2047 MB will be displayed first in the response, followed by the format for DCSSs above 2047 MB.

## QUERY NSS

The fields in the response contain the following information:

### FILE

identifies the spool file number.

### FILENAME

identifies the file name of the system data file.

### FILETYPE

identifies the file type of the system data file:

<u>Type</u>	<u>Meaning</u>
NSS	Named saved system
DCSS	DCSS below 2047 MB
DCSSG	DCSS above 2047 MB
DCSS-S	Segment space
DCSS-M	Member segment
CPNSS	CP system service NSS
CPDCSS	CP system service DCSS

### MINSIZE

for NSS files only, specifies the minimum storage size of the virtual machine into which the NSS can be loaded. This field does not apply to a saved segment, for which N/A is displayed.

Storage is represented in multiples as follows:

<u>Representation</u>	<u>Multiples</u>
<i>nnnnnnnK</i>	Decimal kilobytes
<i>000nnnnM</i>	Decimal megabytes

### BEGPAG

specifies the beginning page number of a page range of the NSS or saved segment. For a segment space, this is the beginning page number of the entire segment space.

### ENDPAG

specifies the ending page number of a page range of the NSS or saved segment. For a segment space, this is the ending page number of the entire segment space.

### TYPE

identifies the page descriptor code of a page range of the NSS or saved segment. It indicates the type of virtual machine access permitted to pages in the range. See the DEFSEG or DEFSYS command for a more detailed discussion of page descriptor codes. Valid codes are:

#### Code

#### Meaning

#### EW

Exclusive read/write access.

#### EN

Exclusive read/write access, no data saved.

#### ER

Exclusive read-only access.

#### SW

Shared read/write access.

#### SN

Shared read/write access, no data saved.

**SR**  
Shared read-only access.

**SC**  
CP writable pages, shared read-only access by virtual machine, no data saved.

For a segment space, the access type might not apply to the entire range, so a dash (-) is displayed.

**CL**  
indicates the current class (state) of the system data file. The possible file classes are:

**Class**  
**Meaning**

**A**  
Available state. This means the system data file has been defined and saved. To determine whether the NSS or saved segment is in use, examine the #USERS field in the response.

**P**  
Pending purge state. This means the PURGE NSS command (or DIAGNOSE code X'64') has been issued for the name of this NSS or saved segment but virtual machines are still accessing it. No new users can access this NSS or saved segment. The file will be purged when the last virtual machine releases the NSS or saved segment, or during the next system IPL or RESTART.

**R**  
Restricted access available state. This means the system data file has been defined (with the RSTD option) and saved. Access to a restricted NSS or saved segment requires a NAMESAVE directory statement. To determine whether the NSS or saved segment is in use, examine the #USERS field in the response.

**S**  
Skeleton state. This means the file has been defined by a DEFSEG or DEFSYS command, and the SAVESEG or SAVESYS command can now be run to complete this system data file.

**#USERS**  
specifies the number of users attached to the NSS or saved segment.

**Note:** The number of users pertains to that file name only.

**PARMREGS**  
for NSS files only, identifies the registers in which parameters are passed to the virtual machine at IPL. Possible values are:

<u>Value</u>	<u>Meaning</u>
<i>m-n</i>	A range of registers, where <i>m</i> and <i>n</i> are decimal integers between 00 and 15 (inclusive) and <i>m</i> is less than or equal to <i>n</i> .
NONE	PARMREGS=NONE was specified on the DEFSYS command.
OMITTED	The PARMREGS option was not specified on the DEFSYS command.

This field does not apply to a saved segment, for which N/A is displayed.

**VMGROUP**  
for NSS files only, specifies whether the NSS is part of a virtual machine group. Possible values are:

**Value**  
**Meaning**

**YES**  
A user who IPLs the NSS becomes part of the virtual machine group, identified by the name of the NSS.

**NO**  
The VMGROUP option was not specified on the DEFSYS command.

This field does not apply to a saved segment, for which N/A is displayed.

## QUERY NSS

Response 8 (USERS):

```
FILE FILENAME FILETYPE CLASS
  spid fn      ft      cl
  userid1 userid2 userid3 ...
```

This response format is displayed for a USERS request. More than one response may be displayed:

- If *fn* is an NSS or DCSS, one response is displayed.
- If *fn* is a member of a segment space, one response is displayed for the member saved segment, followed by one response for the segment space.
- If *fn* is a segment space, one response is displayed for the segment space, followed by one response for each member saved segment.

The fields in the response contain the following information:

### FILE

identifies the spool file number.

### FILENAME

identifies the file name of the system data file.

### FILETYPE

identifies the file type of the system data file:

<u>Type</u>	<u>Meaning</u>
NSS	Named saved system
DCSS	DCSS below 2047 MB
DCSSG	DCSS above 2047 MB
DCSS-S	Segment space
DCSS-M	Member segment
CPNSS	CP system service NSS
CPDCSS	CP system service DCSS

### CLASS

indicates the file class. For the list of these file classes, see "Response 7 (MAP)" under ["Responses"](#) on page 1042.

### *userid1 userid2 userid3 ...*

is a list of the user IDs of the users who are using the NSS or saved segment. In the display for a segment space and its members, the space itself and some members may not currently be loaded by any user. In that case, the list of users is replaced by the word NONE.

**Note:** A user ID of SYSTEM in the response means that part of the CP system is using the DCSS or NSS. There can be multiple parts of the CP system using a DCSS or NSS at the same time. Therefore, the response to QUERY NSS USERS could have SYSTEM listed more than once.

Response 9 (USERS):

```
fn NOT IN USE OR AN INVALID NSS/DCSS NAME
```

This response is displayed for a USERS request if the specified name is nonexistent or not in use.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP413E Command processing cannot complete due to a spool paging error.

- HCP422E The same option was specified twice.
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP848E SYSTEM parameter is invalid with the spoolid option
- HCP849E A user ID must be specified with the spoolid
- HCP1558E Command processing cannot complete.

## QUERY NVS

### Authorization

Privilege Class: B

### Purpose

Use QUERY NVS to display the status of the nonvolatile storage (NVS) associated with a DASD storage subsystem.

### Operands

**rdev**

**rdev1-rdev2**

is the real device number, a list of real device numbers, or a range of real device numbers of devices in the subsystem being queried.

### Usage Notes

1. QUERY NVS is only valid for cache storage subsystems that have nonvolatile storage. An error message is generated if the specified subsystem does not have nonvolatile storage.
2. Caching for RAID (Redundant Array of Independent Disks) technology DASD such as an IBM DASD subsystem is always available. It cannot be modified by the user.

### Responses

Response 1:

If the amount of configured and pinned bytes are able to be determined, the following response is issued.

```

rdev Nonvolatile storage {is available.
                        {is unavailable.
                        {has failed.
                        {is disabled for maintenance.
                        {is being destaged.
                        {destaging has failed.

ccccccccK Bytes are configured.
ppppppppK Bytes are pinned.
  
```

This response is repeated for each *unique subsystem* identified by the devices specified on the command line.

**rdev**

is the real device number of a device in the subsystem.

**cccccccc**

is the configured size of the nonvolatile storage in kilobytes (1024-byte blocks).

**pppppppp**

is the size in kilobytes (1024-byte blocks) of nonvolatile storage that is not available because of exception conditions that prevent successful destaging of data to the backing storage device.

Response 2:

If the amount of configured and pinned bytes cannot be determined, the following response is issued.

```

rdev Nonvolatile storage {is available.
                        {is unavailable.
                        {has failed.
                        {is disabled for maintenance.
                        {is being destaged.
                        {destaging has failed.

```

```

Bytes configured cannot be determined.
Bytes pinned cannot be determined.

```

This response is repeated for each *unique subsystem* identified by the devices specified on the command line.

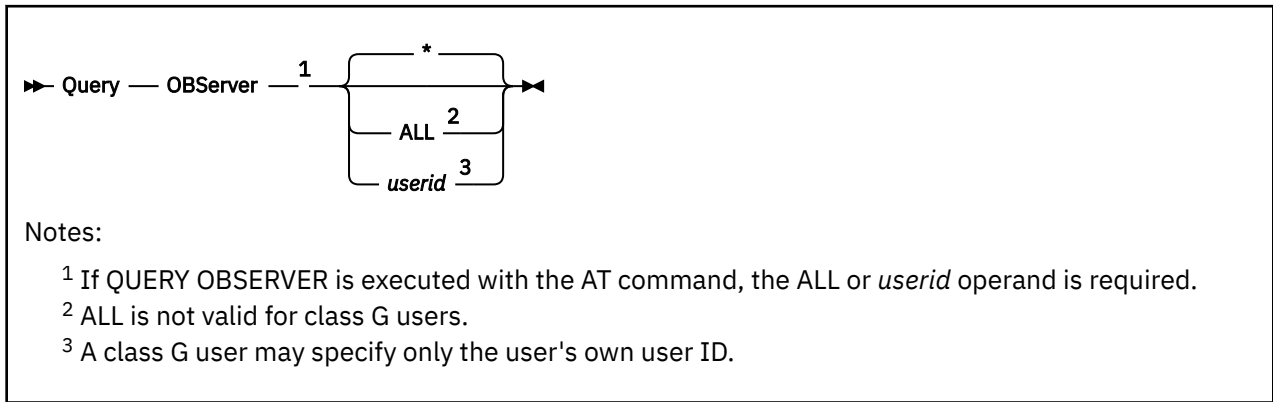

**rdev**

is the real device number of a device in the subsystem.

## Messages

- HCP006E Invalid device type - {rdev/vdev/ldev}
- HCP009E Invalid range - range
- HCP020E Userid missing or invalid
- HCP021E A real device number was not supplied or it is invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {rdev/vdev/ldev} does not exist
- HCP046E type rdev offline
- HCP319E Error processing subsystem command - cmd for DASD rdev
- HCP332E Invalid control unit type - rdev

## QUERY OBSERVER

### Authorization

Privilege Class: A, B, C, G

### Purpose

Use QUERY OBSERVER to determine the observer setting for a virtual machine. CP displays the identity and status of the observer. If you are a class G user, you can display the observer setting for your own virtual machine. If you are a class A, B, or C user, you can display the observer setting for any virtual machine or for all local virtual machines that have observers defined.

### Operands

**\***

displays the observer setting for the user who issues the command. This is the default.

**ALL**

displays the observer setting for all local users that have observers defined.

***userid***

identifies the user whose observer setting is to be displayed.

### Usage Notes

1. The initial setting for your observer is determined by the CONSOLE statement in your user directory entry.
2. A virtual machine cannot have both an observer and a secondary user defined by any combination of the SET OBSERVER and SET SECUSER commands and the CONSOLE directory statement.
3. In an SSI cluster, the observer and the target (observed) user can be logged on to different member systems.

If either user is a multiconfiguration virtual machine, the observer will function in that capacity only when it is local (logged on to the same member as the observed user). If the observed user is a multiconfiguration virtual machine, the observer must be logged on to the same member as the instance of the observed user for which the observer setting was established:

- If the setting was established by a CONSOLE statement in the identity entry in the observed user's virtual machine definition, a potential observer relationship exists for every member instance of the observed user.

- If the setting was established by a CONSOLE statement in a subconfiguration entry in the observed user's virtual machine definition, a potential observer relationship exists for that member instance of the observed user.
- If the setting was established by a SET OBSERVER command, a potential observer relationship exists for the member on which the SET OBSERVER command was issued.

## Responses

Responses 1 through 5 are returned if you issue the QUERY OBSERVER command without any additional operands.

Response 1:

```
OBSERVER userid IS DISCONNECTED
```

is returned if an observer is defined for your virtual machine (on the CONSOLE statement in your virtual machine definition or on a SET OBSERVER command), and that user is disconnected.

If the observer reconnects, it can provide the observer function for your virtual machine.

Response 2:

```
OBSERVER userid IS NOT LOGGED ON
```

is returned if an observer is defined for your virtual machine (on the CONSOLE statement in your virtual machine definition or on a SET OBSERVER command), and that user is not logged on.

If the observer logs on, it can provide the observer function for your virtual machine.

Response 3:

```
OBSERVER userid IS LOGGED ON
```

is returned if an observer is defined for your virtual machine (on the CONSOLE statement in your virtual machine definition or on a SET OBSERVER command), and that user is logged on.

Response 4:

```
OBSERVER IS UNDEFINED
```

is returned if an observer is not defined for your virtual machine.

Response 5:

```
OBSERVER IS NOT LOGGED ON LOCALLY
```

is returned if all of the following conditions are true:

- This system is a member of an SSI cluster.
- You, the observed user, are defined as a multiconfiguration virtual machine.
- An observer is defined for your virtual machine on this member of the cluster (on a CONSOLE statement in the subconfiguration entry for this member in your virtual machine definition, or on a SET OBSERVER command issued on this member).
- That user is not logged on to this member of the cluster. (The user might be logged on to another member.)

Response 6:

```
FAILED MAC CHECK
```

is returned if security label checking by an external security manager (ESM) is active and the observed/observer user relationship fails the mandatory access control checks.

## QUERY OBSERVER

**Response 7:** If you issue the QUERY OBSERVER command with an additional option and the observer is disconnected, CP responds with a display that looks like this:

Userid	Observer	Status
MAINT	DAVID	disconnected

The Status column in the display might also contain "not logged on", "logged on", "not defined", "not logged on locally", or "failed MAC check".

**Response 8:** If a class A, B, or C user issues QUERY OBSERVER ALL, CP displays the current observer settings for all users that are currently logged on or disconnected. If no currently logged on users have an observer defined, CP issues the following response:

No observers defined or active.

### Messages

- HCP003E Invalid option - *option*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP045E *userid* not logged on
- HCP1149E Error communicating with another SSI member. It cannot be determined if *command* executed remotely.

## QUERY OSA

### Authorization

Privilege Class: B

### Purpose

Use QUERY OSA to display the status of real Open Systems Adapter devices.

### Operands

#### ACTive

indicates active Open Systems Adapter devices. An active device is one that is in use by a user or the system and is specified as neither FREE nor OFFLINE nor SYSTEM.

#### ALL

indicates all Open Systems Adapter devices attached to the system. The status is displayed in the order of ACTIVE, SYSTEM, FREE, OFFLINE, and AGENT. You receive the same response as you would receive if you entered all of the following commands:

```

query osa active
query osa system
query osa free
query osa offline
query osa agent
  
```

#### ATTach *userid*

indicates the OSA devices that are dedicated to a user on the system. If you specify *userid*, only OSA devices attached to that user's virtual machine are indicated. If you do not specify *userid*, you receive the status of all OSA devices dedicated to any user on the system. Attached devices are always active.

#### BOXed

indicates the OSA devices that are unavailable (usually because of a hardware condition). A boxed device can also be active, free, or offline.

## QUERY OSA

### **FREe**

indicates all free OSA devices. A free OSA device is one that is not currently in use by a user or the system and is specified as neither ACTIVE nor OFFLINE.

### **OFFline**

indicates all offline OSA devices. An offline OSA device is one that is specified as neither ACTIVE nor FREE.

### **AGEnt**

indicates all Open Systems Adapter Agent devices. OSA Agent devices are used to control the OSA configuration.

### **SYStem**

indicates all OSA devices reserved for system use. An OSA device that is reserved for system use is associated with an OSA adapter that is in use on a shared port group.

### **TYpe**

indicates the type of OSA devices to be displayed. For each device, the display includes the type of device, the channel-path identifier (CHPID), and the type of channel path.

### **ALL**

indicates that all types of OSA devices are to be displayed. This is the default value.

### **HIPersockets**

indicates that HiperSockets devices are to be displayed. HiperSockets devices are used for communication between logical partitions and/or virtual machines, and are associated with internal-queued-direct-communication (IQD) channel paths. The displayed devices will include device types of HIPER as well as HIPER-BRDG. HIPER-BRDG indicates the EXTERNAL\_BRIDGED channel parameter was configured for the channel path.

### **OSA**

indicates that OSA devices are to be displayed. OSA devices are used for communication through a network, and are associated with Open Systems Adapter (OSA) channel paths, OSA-Express (OSE) channel paths, or OSA Direct Express (OSD) channel paths.

### **OSN**

indicates that OSN devices are to be displayed. OSA NCP (OSN) devices are used by the Communication Controller for Linux (CCL) when running the Network Control Program (NCP) in a logical partition or virtual machine. OSN devices are associated with OSN channel paths and communicate with one or more emulated 3745 device types on the same OSN channel path.

## Usage Notes

1. A VIRTUAL version of this command, QUERY VIRTUAL OSA, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL OSA” on page 1316](#).

## Responses

If the system is using an OSA device that is in an intervention-required state and you enter QUERY OSA, you see a response like this:

```
OSA 0300 has intervention required.
```

0300 is the real device number of the OSA device that needs the operator's intervention.

**Note:** This response will be preceded by one of the following.

Response 1:

If you enter QUERY OSA, QUERY OSA ACTIVE, or QUERY OSA ATTACHED and there is an OSA device attached to the system, you see something like this:

```
q osa active
OSA 0480 ATTACHED TO PVM      0480 DEVTYPE HIPER      CHPID 80 IQD
```

```
OSA 0481 ATTACHED TO PVM      0481 DEVTYPE HIPER      CHPID 80 IQD
OSA 0482 ATTACHED TO PVM      0482 DEVTYPE HIPER      CHPID 80 IQD
OSA 0888 ATTACHED TO RSCS     0888 DEVTYPE OSA        CHPID A0 OSD
OSA 0889 ATTACHED TO RSCS     0889 DEVTYPE OSA        CHPID A0 OSD
OSA 088A ATTACHED TO RSCS     088A DEVTYPE OSA        CHPID A0 OSD
OSA 1700 ATTACHED TO VTAM     0500 DEVTYPE OSN        CHPID E0 OSN
```

Ready;

The first number is the real device number of the OSA device. The ATTACHED operand might also read BOX/ATTC, which means that although the device is attached and dedicated to a user, it is unavailable. PVM, RSCS, TCPIP, and VTAM are user IDs to which the OSA devices are dedicated. The next number is the virtual device number used by a virtual machine to refer to the specified OSA device. Following the virtual device number is the type of the device, the channel path identifier (CHPID) associated with the device, and the channel-path type.

Response 2:

If you enter a QUERY OSA FREE command and there is a free OSA device attached to the system, you see something like this:

```
q osa free
OSA 0487 FREE      , OSA 04A1 FREE      , OSA 04A2 FREE      , OSA 04A3 FREE
OSA 04A4 FREE      , OSA 04A5 FREE      , OSA 04A9 FREE      , OSA 04AA FREE
OSA 04AB FREE      , OSA 04BC FREE      , OSA 04BD FREE      , OSA 04BE FREE
OSA 04BF FREE
Ready;
```

This response shows the real device number for each free OSA device.

The response for a QUERY OSA OFFLINE or QUERY OSA BOXED command is in the same format as the response for a QUERY OSA FREE command.

Response 3:

When you enter a QUERY OSA AGENT command and there is an OSA AGENT attached to the system, you see something like this:

```
q osa agent
OSA 0280 is an OSA Agent
```

Response 4:

When you enter a QUERY OSA ALL command, CP displays the same responses as it would display if you had entered the QUERY OSA ACTIVE, QUERY OSA SYSTEM, QUERY OSA FREE, QUERY OSA OFFLINE, and QUERY OSA AGENT commands.

Response 5:

If you enter QUERY OSA TYPE ALL, you will see something like this:

```
q osa type all
OSA 0480 ATTACHED TO TCPIP     0100 DEVTYPE HIPER      CHPID 80 IQD
OSA 0481 BOX/ATTC TO TCPIP     0101 DEVTYPE HIPER      CHPID 80 IQD
OSA 0482 ATTACHED TO TCPIP     0102 DEVTYPE HIPER      CHPID 80 IQD
OSA 7240 SYSTEM
OSA 7241 SYSTEM
OSA 7242 SYSTEM
OSA 0484 FREE                  DEVTYPE OSA             CHPID C0 OSE
OSA 0485 FREE                  DEVTYPE OSA             CHPID C0 OSE
OSA 0486 FREE                  DEVTYPE OSA             CHPID D0 OSA
OSA 0487 FREE                  DEVTYPE OSA             CHPID D0 OSA
OSA 04A1 OFFLINE              DEVTYPE OSA             CHPID D1 OSD
OSA 04A2 OFFLINE              DEVTYPE OSA             CHPID D1 OSD
OSA 04A3 OFFLINE              DEVTYPE OSA             CHPID D1 OSD
OSA 04A4 OFFLINE              DEVTYPE OSA             CHPID D1 OSD
OSA 04A5 OFFLINE              DEVTYPE OSA             CHPID D1 OSD
OSA 04A9 OFFLINE              DEVTYPE OSA             CHPID D1 OSD
OSA 04AA OFFLINE              DEVTYPE OSA             CHPID D1 OSD
OSA 04AB BOXED                DEVTYPE OSA             CHPID D1 OSD
OSA 04BC FREE                 DEVTYPE OSA             CHPID D1 OSD
OSA 04BD FREE                 DEVTYPE OSA             CHPID D1 OSD
OSA 048E FREE                 DEVTYPE OSA             CHPID D1 OSD
```

## QUERY OSA

```
OSA 04BF FREE          DEVTYP OSA          CHPID D1 OSD
OSA 0700 FREE          DEVTYP OSN          CHPID E0 OSN
OSA 0701 FREE          DEVTYP OSN          CHPID E0 OSN

OSA 1818 OFFLINE      DEVTYP INMN         CHPID F1 OSM
OSA 1819 OFFLINE      DEVTYP INMN         CHPID F1 OSM
OSA 181A OFFLINE      DEVTYP INMN         CHPID F1 OSM
OSA 3F00 OFFLINE      DEVTYP IEDN         CHPID F6 OSX
OSA 3F01 OFFLINE      DEVTYP IEDN         CHPID F6 OSX
OSA 3F02 OFFLINE      DEVTYP IEDN         CHPID F6 OSX
Ready;
```

This response shows the real device number of the OSA device with its current status, followed by the device type, the associated channel-path identifier, and the channel-path type. The following device status may be returned:

ATTACHED TO userID vdev	Attached and dedicated to the specified userID as virtual device vdev
BOX/ATTC TO userID vdev	Attached and dedicated to the specified userID as virtual device vdev, but is not available
BOXED	Device is not available
OFFLINE	Device is OFFLINE
FREE	Device is ONLINE and available to use
SYSTEM	Device is reserved for system use

Response 6:

If you enter QUERY OSA TYPE HIP, you will see something like this:

```
q osa type hip
OSA 0480 ATTACHED TO PVM          0480 DEVTYP HIPER          CHPID 80 IQD
OSA 0481 ATTACHED TO PVM          0481 DEVTYP HIPER          CHPID 80 IQD
OSA FD00 ATTACHED TO DTCVSW1     FD00 DEVTYP HIPER-BRDG     CHPID FD IQD
OSA FD01 ATTACHED TO DTCVSW1     FD01 DEVTYP HIPER-BRDG     CHPID FD IQD
OSA FD02 ATTACHED TO DTCVSW1     FD02 DEVTYP HIPER-BRDG     CHPID FD IQD
Ready;
```

This response shows the real device number of each HiperSockets device with its status, followed by the device type, the associated channel-path identifier, and the channel-path type. A device type of HIPER-BRDG indicates the EXTERNAL\_BRIDGED channel parameter was configured for the channel path.

Response 7:

If you specify the *type* parameter and CP cannot find an OSA device of the type you specify, you see a message like this:

```
q osa type osn
An OSA was not found for the specified type.
Ready;
```

Response 8:

If CP cannot find an OSA device for the query you specify, you see a message like this:

```
q osa boxed
A BOXED OSA was not found.
Ready;
```

In this response, BOXED may be replaced with *active*, *attached*, *offline*, *system*, or *free*, depending on what you specified on the command. The BOXED OSA would be replaced by OSA AGENT in this response if agent was specified on the command.

## Messages

- HCP007E Invalid userid - *userid*
- HCP263E Too many operands were supplied for this command.

## QUERY PAGING

► Query — PAGING ◄

### Authorization

Privilege Class: B, E

### Purpose

Use the QUERY PAGING command to display settings for the paging subsystem.

### Usage Notes

1. Use the PAGING statement in the system configuration file to define the paging subsystem's settings at IPL.  
For compatibility, the Alias and HPF settings can also be specified on the FEATURES statement in the system configuration file, using the PAGING\_ALIAS and PAGING\_HPF operands. However, it is recommended that you consolidate your paging options on the PAGING statement.  
You can use the SET PAGING command after IPL to alter the paging subsystem's settings.
2. HyperPAV aliases allow concurrent I/O requests to the same physical volume by using alias devices. Aliases do not have associated storage and can be bound dynamically to base volumes. Using HyperPAV can increase throughput by reducing queuing at the device level.
3. High Performance FICON improves paging efficiency through its support for transport mode channel program format. With transport mode, less overhead occurs between the channel subsystem and the FICON adapter than with traditional command-mode I/O. This results in higher I/O rates and less CPU overhead.
4. The warning value is also used by the SET STORAGE command to make sure that a storage removal does not cause paging volumes to exceed this level of allocation. For more information, see [“SET STORAGE”](#) on page 1722.

### Responses

Response 1:

```
PAGING_ALIAS: {ON}          PAGING_HPF= {ON}          WARNING: nnn%
               {OFF}         {OFF}
```

#### PAGING\_ALIAS

indicates the state of the HyperPAV alias feature of the paging subsystem.

#### PAGING\_HPF

indicates the state of the HPF feature of the paging subsystem.

##### ON

the feature is active

##### OFF

the feature is not active

#### Warning *nnn%*

is the allocation warning level for paging volumes, as specified on a PAGING system configuration statement or a previous SET PAGING command. The *nnn* value is a decimal integer in the range of 0 to 100. If no WARNING value has been specified, this value is 90%. If the number of allocated paging slots reaches this percentage of total slots on all paging volumes, message HCP401I is issued

to alert the system operator. This value also serves as the default MAXPAGEFULL setting for a SET STORAGE command to ensure a storage removal does not cause paging volumes to exceed this level of allocation. See [“SET STORAGE” on page 1722](#) for more information.

## Messages

- HCP003E Invalid option - *{option | command contains extra option(s) starting with option}*

## QUERY PASSWORD

### Authorization

Privilege Class: G

### Purpose

Use QUERY PASSWORD to determine whether you can include a password on the command line for the AUTOLOG, LINK, LOGON, or XAUTOLOG command.

### Operands

#### AUTOLOG

displays whether you must include a password on the AUTOLOG command line.

#### LINK

displays whether you can include a password on the LINK command line.

#### LOGON

displays whether you can include a password on the LOGON command line.

#### XAUTOLOG

displays whether you can include a password on the XAUTOLOG command line.

### Usage Notes

1. For security reasons, the password suppression facility permits your installation to require that issuers of commands that require passwords do not include the password in the command line. Instead, after the user enters the command without the password, the system prompts the user to enter the password, and the input field is masked.
2. See [“SET PASSWORD” on page 1598](#) for an explanation of how to set password suppression for the AUTOLOG, LINK, LOGON, and XAUTOLOG commands.
3. If you enter QUERY PASSWORD using DIAGNOSE code X'08', you receive one of the following return codes in your R<sub>y</sub> register:

#### RC

##### Meaning

0

Indicates that you may (must, for AUTOLOG) enter a password on the command line.

4

Indicates that you cannot enter a password on the command line.

8

Error—the operands following on the command line are not valid.

4. System programmers responsible for z/VM security should examine the usage notes for the PASSWORDS\_ON\_CMDs operand of the FEATURES system configuration statement. See the [FEATURES Statement in z/VM: CP Planning and Administration](#).

## Responses

Response 1:

```
{ AUTOLOG } PASSWORD MUST BE ENTERED SEPARATELY  
{ LINK }  
{ LOGON }  
{ XAUTOLOG }
```

indicates that you *cannot* enter the access mode password on the command line.

Response 2:

```
{ LINK } PASSWORD MAY BE INCLUDED ON THE COMMAND LINE  
{ LOGON }  
{ XAUTOLOG }
```

indicates that you *can* enter the access mode password on the command line.

Response 3:

```
{ AUTOLOG } PASSWORD MUST BE INCLUDED ON THE COMMAND LINE
```

indicates that you *must* enter the access mode password on the command line.

## Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid

## QUERY PATHS

### Authorization

Privilege Class: B, E

### Purpose

Use QUERY PATHS to display:

- All paths installed to a specific device or range of devices
- Installed path status

### Operands

*rdev*

*rdev1-rdev2*

**TO** *rdev*

**TO** *rdev1-rdev2*

is the real device number or range of real device numbers whose path allocation information you want. Each *rdev* in the active configuration can be entered as a 4-digit hexadecimal number between X'0000' and X'FFFF'. For a device in the active or standby configuration, the device number can be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is configured. You can specify a single device address, a range of device addresses, or any combination thereof. A range of devices cannot span subchannel sets.

### Usage Notes

1. The standard response lines for QUERY PATHS are shown in the following example. They are called standard because they will always be displayed for a device that has installed paths.

```
Device 0291, Status ONLINE
CHPIDs to Device 0291 (PIM) : 19 1B 2E 2F
Physically Available (PAM) : + + + +
Online (LPM) : + + + +

Legend      + Yes - No
```

2. The query response reflects the current hardware information for paths that are physically installed and physically available. The logical path information you see represents a snapshot of what CP knows based on information in the RDEV.
3. For information about the devices associated with a specific channel path, see [“QUERY CHPID” on page 791](#).
4. Error messages produced for this command may vary depending on how the device was specified on the command line. When a single device is listed on the command line, an error will be reported if there is no query information available for that single device. For example:

```
query paths to 102
HCPQPA0040E Device 0102 does not exist
Ready(00040);
```

When a range of devices is listed on the command line, only devices that have query information available are shown. Errors messages are not issued for individual devices within the range. For example:

```
query paths to 100-105
Device 0105, Status OFFLINE
CHPIDs to Device 0105 (PIM) : 19 1B 2E 2F
  Physically Available (PAM) : + + + +
  Online (LPM) : + + + +

Legend + Yes - No
Ready;
```

If query information is not available for at least one device in a range, then a generic error message will be issued. For example:

```
query paths to 100-102
HCPQPA1003E 0100-0102 was not found.
Ready(01003);
```

## Responses

Response 1 (Generic):

The following is the full, generic response to the QUERY PATHS command. Normally, you will see only pieces of this response, as CP displays only the lines that have data. For example, if the device does not have any offline channel paths, CP would not display lines 6 through 10. The maximum number of channel paths is 8, as shown in the example. CP displays only the number of channel paths attached to the device. The responses that follow this generic one will show examples of these shortened responses.

```
1 Device rdev, Status status
2 CHPIDs to Device rdev (PIM) : chpid1 ..... chpid8
3 Physically Available (PAM) : +/- ..... +/-
4 Online (LPM) : +/- ..... +/-
5 Preferred : +/- ..... +/-
6 Offline by Authorized User : +/- ..... +/-
7 Offline by ESCON Manager : +/- ..... +/-
8 Out of Path Group by Guest : +/- ..... +/-
9 Offline by Control Unit : +/- ..... +/-
10 Offline, Wrong CU Connection: +/- ..... +/-
11 Transport Mode Supported : +/- ..... +/-
12 Encrypted Link : +/- ..... +/-
13 Authenticated Link : +/- ..... +/-
14 Legend + Yes - No
```

### Line

#### Explanations

1

tells you the real device number of the device and its status. The status field can contain the following:

**BOXED**

device is not available to CP, usually because of a hardware condition

**DISABLE**

device is disabled

**ENABLE**

device is enabled

**OFFLINE**

device is offline

**ONLINE**

device is online

**QUIESCED**

device is offline for maintenance

### **SUBCHOFF**

device is subchannel disabled, see [“VARY SUBCHANNEL”](#) on page 2067.

### **TEST-ONL**

device has been forced online in test mode, see [“VARY \(Real Device\)”](#) on page 2063.

**2**

identifies the real device number and the channel path identifiers (CHPIDs) of all paths physically installed to that device. This is also known as the path installed mask (PIM).

**3**

identifies the paths that are physically available to the device. This is also known as the path available mask (PAM).

**4**

identifies the paths that are logically online to the device. This is also known as the logical path mask (LPM).

**5**

identifies the preferred paths to the device, if applicable.

**6**

identifies the paths that are logically offline because the VARY PATH command was issued by an authorized user.

**7**

identifies the paths that are logically offline because the ESCON configuration program has taken them offline.

**8**

identifies the paths removed from the path group by a guest that is managing the paths to a device.

**9**

identifies the channel paths that are unavailable to the device and locked offline while service is applied to this channel path. Once service on this channel path is completed, a corresponding resume issued by the Service Representative (SR) will cause this channel path to be varied online to the device. If for some reason the resume request did not vary this channel path back online, the FORCE option on the VARY PATH command can be used to override the quiesced path and vary the channel path online to the device. The FORCE option should only be used when the SR indicates that service is complete and a resume was issued but did not vary the channel path online.

**10**

identifies the paths that are logically offline because the wrong control unit connection was detected. This could happen as a result of a cable swap, for example.

**11**

indicates whether CHPIDs are enabled for Transport Mode. Use of High Performance FICON for IBM Z (zHPF) requires channel paths capable of Transport Mode. Moreover, a guest with the CHPIDVIRTUALIZATION ONE directory option can use zHPF only if Transport Mode is supported on all FICON channels in the system, or, in an SSI cluster, on all systems in the guest's assigned relocation domain.

**12**

identifies the paths that are encrypted.

**13**

identifies the paths that are authenticated.

**14**

identifies the legend information.

Response 2 (Path Status):

The following is an example of a query response you may see after an operator has issued the VARY PATH command:

```
Device 0291, Status ONLINE
CHPIDs to Device 0291 (PIM) : 19 1B 2E 2F
Physically Available (PAM) : + + + +
```

```

Online          (LPM) : - - - +
Offline by Authorized User : + + + -
Legend          + Yes - No
    
```

This example shows:

- device 291 is online and there are 4 paths physically installed to the device (19,1B,2E,2F)
- 1 path (2F) is logically online
- 3 paths (19,1B,2E) are logically offline because someone issued the VARY PATH command.

Response 3:

The following is an example of a query response you may see for a device that has never been online (for example, the device may have been listed in the DEVICES statement in the configuration file as NOTINITIALIZED\_at\_jpl):

```

Device 019E, Status SUBCHOFF
CHPIDs to Device 019E (PIM) : 19 1B 2E 2F
Physically Available (PAM) : + + + +
Online          (LPM) : - - - -
Legend          + Yes - No
    
```

This example shows:

- device 19E is in the subchannel disable state and has 4 paths physically installed to the device (19,1B,2E,2F)
- all paths are logically offline

Response 4:

The following is an example of a query response you may see when several paths are offline for different reasons:

```

Device 0192, Status ONLINE
CHPIDs to Device 0192 (PIM) : 11 12 1A 22 30 40
Physically Available (PAM) : + + + + + +
Online          (LPM) : - - + + + -
Offline by Authorized User : + - - - - -
Offline by Control Unit   : - + - - - +
Legend          + Yes - No
    
```

This example shows:

- device 192 is in the online state and has 6 paths physically installed to the device (11,12,1A,22,30,40)
- 3 paths (1A,22,30) are logically online to the device
- 3 paths (11,12,40) are logically offline to the device
- 1 path (11) is logically offline because someone issued the VARY PATH command.
- 2 paths (12,40) are logically offline because someone has issued a command at the control unit in order to service the device

## Messages

## QUERY PAV

### Authorization

Privilege Class: B

### Purpose

Use QUERY PAV to display the following:

- A list of all Parallel Access Volume (PAV) DASD and HyperParallel Access Volume (HyperPAV) DASD. This includes each PAV base device and its associated PAV alias devices, each HyperPAV base device, and each HyperPAV alias device.
- The PAV and/or HyperPAV information for one or more real devices. This includes all base and alias information that is associated with the specified device or devices.

### Operands

#### ALL

tells CP to display a list of all PAV and HyperPAV devices.

#### rdev

#### rdev1-rdev2

is the real device address of the device for which you want PAV or HyperPAV information. You can specify a single device address, a range of device addresses, or any combination.

### Responses

Response 1:

If you enter QUERY PAV ALL, you see a response like this:

```
Device 0190 is a base Parallel Access Volume device with the following
aliases: 0192 0194 0196 0198
Device 0192 is an alias Parallel Access Volume device whose base device
is 0190
Device 0194 is an alias Parallel Access Volume device whose base device
is 0190
Device 0196 is an alias Parallel Access Volume device whose base device
is 0190
Device 0198 is an alias Parallel Access Volume device whose base device
is 0190
Device 01A0 is a base Parallel Access Volume device with the following
aliases: 01A4 01A8
Device 01A4 is an alias Parallel Access Volume device whose base device
is 01A0
Device 01A8 is an alias Parallel Access Volume device whose base device
is 01A0
Device 01D2 is a base Parallel Access Volume device with the following
aliases: 01D3 01E6 01EA
Device 01D3 is an alias Parallel Access Volume device whose base device
is 01D2
Device 01E6 is an alias Parallel Access Volume device whose base device
is 01D2
```

```

Device 01EA is an alias Parallel Access Volume device whose base device
is 01D2
Device 4300 is a base HyperParallel Access Volume device in Pool 2
Device 4341 is an alias HyperParallel Access Volume device in Pool 2
Device 4342 is an alias HyperParallel Access Volume device in Pool 2
Device 4343 is an alias HyperParallel Access Volume device in Pool 2
Device 4344 is an alias HyperParallel Access Volume device in Pool 2
Device 4345 is an alias HyperParallel Access Volume device in Pool 2
Device 8300 is a base HyperParallel Access Volume device in Pool 6
Device 8341 is an alias HyperParallel Access Volume device in Pool 6
Device 8342 is an alias HyperParallel Access Volume device in Pool 6
Device 8343 is an alias HyperParallel Access Volume device in Pool 6
Device 8344 is an alias HyperParallel Access Volume device in Pool 6
Device 8345 is an alias HyperParallel Access Volume device in Pool 6

```

#### Response 2:

If you enter QUERY PAV ALL when no PAV or HyperPav devices exist, you see a response like this:

```
There are no Parallel Access Volume devices known to this system
```

#### Response 3:

If you enter QUERY PAV *rdev* for a PAV alias device, you see a response like this:

```
Device rdev is an alias Parallel Access Volume device whose
base device is base_rdev
```

#### Response 4:

If you enter QUERY PAV *rdev* for a HyperPAV alias device, you see a response like this:

```
Device rdev is an alias HyperParallel Access Volume device in Pool nnnnn
```

#### Response 5:

If you enter QUERY PAV *rdev* for a PAV base device, you see a response like this:

```
Device rdev is a base Parallel Access Volume device with the
following aliases: alias1_rdev alias2_rdev
```

#### Response 6:

If you enter QUERY PAV *rdev* for a HyperPAV base device, you see a response like this:

```
Device rdev is a base HyperParallel Access Volume device in Pool nnnnn
```

#### Response 7:

If you enter QUERY PAV *rdev* for a device that is not a PAV or HyperPAV device, you see a response like this:

```
Device rdev is not a Parallel Access Volume device
```

## Usage Notes

1. A VIRTUAL version of this command, QUERY VIRTUAL PAV, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL PAV” on page 1319](#).

## Messages

- HCP003E Invalid option - *{option | command contains extra option(s) starting with option}*
- HCP026E Operand missing or invalid
- HCP040E Device *rdev* does not exist

## QUERY PCIFUNCTION

### Authorization

Privilege Class: B

### Purpose

Use QUERY PCIFUNCTION to display the status of real PCI functions.

### Operands

#### ALL

indicates all real PCI functions. This is the default.

#### ATTach

indicates real PCI functions that are attached to a user or the system.

#### ATTach *userid*

indicates real PCI functions that are attached to a user. If you specify *userid*, only functions attached to that user's virtual machine are indicated. If you do not specify *userid*, you receive the status of all functions attached to any user on the system.

#### ATTach SYSTEM

indicates real PCI functions that are attached to the system.

#### DETAILS *rpfid*

#### DETAILS *rpfid1-rpfid2*

displays detailed information about real PCI functions.

#### *rpfid*

#### *rpfid1-rpfid2*

is a real PCI function ID or a range of real PCI function IDs whose status is to be queried. Specify a PCI function ID as 8 hexadecimal digits. You may omit leading zeros. The total number of real PCI functions specified cannot exceed 256.

#### FREe

indicates all real PCI functions that are available for use by the configuration and are not currently attached to a user or the system.

#### STANdby

indicates all real PCI functions currently in the standby state.

## Usage Notes

1. A VIRTUAL version of this command, QUERY VIRTUAL PCIFUNCTION, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL PCIFUNCTION”](#) on page 1322.

## Responses

Response 1:

If you enter QUERY PCIFUNCTION with the ATTACH operand, you will see something like:

```
PCIF 00000021 ATTACHED TO USER01 00000021 DISABLED 10GbE RoCE
PCIF 00000029 ATTACHED TO USER02 00000003 ENABLED 10GbE RoCE
```

The first number is the real PCI function ID. USER01 and USER02 are user IDs to which the PCI functions are attached. The next number is the virtual PCI function ID used by a virtual machine to refer to the PCI function. Following the virtual PCI function ID is the state of the PCI function and the type of PCI function.

The state of the function is one of the following:

### BLOCKED

PCI function blocked

### DISABLED

The indicated PCI function has not been initialized.

### ENABLED

The indicated PCI function has been detected and initialized by the guest.

### ERROR

Error detected by z/PCI facility

### PERMERR

Error recovery for PCI function unsuccessful

### STANDBY

PCI function not available to the configuration

Response 2:

If you enter QUERY PCIFUNCTION with the FREE operand, you will see something like:

```
PCIF 00000021 FREE DISABLED 10GbE RoCE
PCIF 00000029 FREE DISABLED 10GbE RoCE
```

The number is the real PCI function ID followed by FREE, the state of the PCI function and the type of PCI function.

Response 3:

If you enter QUERY PCIFUNCTION with the STANDBY operand, you will see something like:

```
PCIF 00000021 NOT CONFIGURED STANDBY 10GbE RoCE
PCIF 00000029 NOT CONFIGURED STANDBY 10GbE RoCE
```

The number is the real PCI function ID followed by NOT CONFIGURED, the state of the PCI function and the type of PCI function.

Response 4:

If you enter QUERY PCIFUNCTION with the ALL operand or a real PCI function ID or range of real PCI function IDs, you will see something like:

```
PCIF 00000003 ATTACHED TO USER01 00000001 DISABLED 10GbE RoCE
PCIF 00000004 FREE DISABLED 10GbE RoCE
PCIF 00000021 NOT CONFIGURED STANDBY 10GbE RoCE
PCIF 00000026 NOT CONFIGURED STANDBY 10GbE RoCE
PCIF 00000029 FREE DISABLED 10GbE RoCE
```

## QUERY PCIFUNCTION

```
PCIF 00000032 ATTACHED TO USER02 00000032 ENABLED 10GbE RoCE
PCIF 00000033 FREE ERROR 10GbE RoCE
```

Response 5:

If you enter QUERY PCIFUNCTION with the DETAILS operand, you will see something like:

```
PCIF 00000003, TYPE = 10GbE RoCE
PCHID = 3C0, VFN = 02, UID = 00001 PORT = --
NETID = NETIDPort1 NETIDPort2 -----
```

The first line of the response tells you the real PCI function ID and the type of PCI function. The lines that follow contain the details.

Details	Meaning
PCHID	physical channel identifier
VFN	virtual function number
UID	user-defined identifier value for a particular PCI function
PORT	port number
NETID	asserted physical-network identifiers corresponding to the order of the ports of the adapter. Dashes indicate no network ID has been assigned to the port.

Response 6:

If you enter QUERY PCIFUNCTION with the ALL operand and there are no PCI functions in the LPAR, you will receive the following response:

```
A PCI function was not found.
```

Response 7:

If you enter QUERY PCIFUNCTION for a PCI function that is associated with an NVMe EDEVICE, you will receive a response that is similar to the following example:

```
PCIF 00000071 ATTACHED TO SYSTEM EDEV 0F80 ENABLED NVMe
```

The first number (00000071) is the real PCI function ID, and it is attached to SYSTEM. The next number (0F80) is the address of the initial EDEVICE that is associated with the function. The PCI function state is ENABLED and its type is NVMe. A similar line would appear in the response to QUERY PCIFUNCTION with the ATTACH, ATTACH SYSTEM, or ALL operand. If the NVMe function is removed from the configuration, then the function state becomes STANDBY. If the function is subsequently added to the configuration, then the function state becomes DISABLED and the associated EDEVICES must be deleted and redefined to restore access to the EDEVICES.

If you enter QUERY PCIFUNCTION with the DETAILS option for an NVMe function that is associated with an EDEVICE, then additional details are provided unless any of the following conditions are true:

- The PCIe function was deconfigured or deleted.
- The PCIe function encountered a permanent error.
- The PCIe function reported a fatal status error.

The DETAILS response contains information about the device configuration, capacity, and health, and might look like the following example.

```
PCIF 00000071, TYPE = NVMe
PCHID = 0330, VFN = ---, UID = 00000, PORT = --
NETID = -----
Model Number: INTEL SSDPE2KX040T8
Serial Number: BTLJ906003YL4P0DGN
Firmware Version: VDV10131
PCI Vendor/Subsystem ID: 0x8086
```

```

## Messages

- HCP002E Invalid operand - *operand*
- HCP009E Invalid range - *range*
- HCP021E A real PCI function ID was not supplied or it is invalid.
- HCP040E PCI function *rpfid* does not exist
- HCP1003E *rpfid* not found.
- HCP5780E Adjunct does not support the *command subcommand* command
- HCP6000E The range of PCI function ids cannot exceed 256.

## QUERY PENDING COMMANDS

### Authorization

Privilege Class: B

### Purpose

Use QUERY PENDING COMMANDS to display the commands that you have entered and, optionally, that others have entered for which the associated asynchronous function has not yet completed.

### Operands

#### ALLUSERS

is an optional keyword that indicates that all pending commands for the specified devices are to be displayed, including pending commands that were not issued by you.

#### ALL

indicates that pending commands for all devices are to be displayed.

#### *rdev*

#### *rdev1-rdev2*

is the real device number, a list of real device numbers, or a range of real device numbers of devices in the subsystems being queried.

### Usage Notes

1. Many CP commands associated with DASD subsystems result in a channel program being issued to a device or subsystem. In most cases, these operations complete in a very short time, and the command response is presented to the operator immediately. However, for some cached DASD subsystems, some of these operations do not complete immediately. Use the QUERY PENDING COMMANDS command to display those commands that you have issued that have not yet completed. See [“Delayed Responses to CP Commands”](#) on page 7 for further information and an example.

### Responses

Response 1:

```
No pending commands exist.
```

This response is displayed if QUERY PENDING COMMANDS ALL is issued and there are no pending commands.

Response 2:

```
No pending commands exist for rdev.
```

This response is displayed if there are no pending commands for the indicated device.

**rdev**

is the real device number of a device being queried.

Response 3:

```
Command pending:  command rdev.
```

This response is repeated for each pending command for each specified device.

**command**

is the command for which the associated asynchronous function is not yet complete.

**rdev**

is the real device number of a device being queried.

Response 4:

```
Command pending for userid:  command rdev.
```

This response is repeated for each pending command for each specified device for commands not issued by you.

**userid**

is the ID of the user who issued the command.

**command**

is the command for which the associated asynchronous function is not yet complete.

**rdev**

is the real device number of a device being queried.

**Messages**

- HCP009E Invalid range - *range*
- HCP021E A real device number was not supplied or it is invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {*rdev/vdev/ldev*} does not exist

## QUERY PER

---

### **Authorization**

Privilege Class: G

### **Purpose**

QUERY PER is recognized as a synonym for QUERY TRACE.

Within VM, TRACE monitors events that occur in your virtual machine. Please refer to the CP QUERY TRACE command.

## QUERY PFnn

### Authorization

Privilege Class: G

### Purpose

Use QUERY PFnn to display the program function key assignments.

### Operands

**PF**

**PFnn**

requests a display of the program function command lines associated with the program function key you designate by the value *nn*. The value *nn* is a number from 1 (or 01) through 24. If you do not specify a value for *nn*, all program function keys and their associated data lines are displayed.

### Usage Notes

1. See [“SET PFnn” on page 1602](#) for an explanation of the way to define and use program function keys.

### Responses

Response 1:

```
PFnn [SUBSTITU]{DELAY } pfdata
           {IMMED }
           {NODISP}
```

**PFnn**

is the program function key number.

**SUBSTITU**

indicates that tokens from the input are substituted in *pfdata* when the PF key is pressed. Otherwise, no substitution takes place.

**DELAY**

**IMMED**

**NODISP**

indicates when the program function is to be run. IMMED means the program function is run when you press the PF key. DELAY means the program function is displayed in the input area when you press the PF key. NODISP means the program function is executed when you press the PF key, but the function is not redisplayed on the terminal.

***pfdata***

is the program function command line associated with the key.

Response 2:

If the program function key has been set to retrieve prior commands, you can receive these responses:

```
PFnn RETRIEVE BACKWARD
PFnn RETRIEVE FORWARD
```

## QUERY PFnn

```
PFnn RETRIEVE BACKWARD n  
PFnn RETRIEVE FORWARD n
```

Response 3:

If there is no function defined for the program function key, you see the following:

```
PFnn UNDEFINED
```

### Messages

- HCP003E Invalid option - *option*
- HCP263E Too many operands were supplied for this command.

## QUERY PINNED

### Authorization

Privilege Class: B

### Purpose

Use QUERY PINNED to display the data tracks of one or more DASD that have become pinned in subsystem storage (cache) or nonvolatile storage.

This command may also be used to determine the total amount of subsystem storage (cache) or nonvolatile storage that contains pinned data.

### Operands

#### DEVICE

indicates that pinned tracks for the specified devices are to be displayed. This is the default value.

#### SUBSYSTEM

indicates that the total amount of subsystem cache and nonvolatile storage containing pinned data is to be displayed.

#### *rdev*

#### *rdev1-rdev2*

is the real device number, a list of real device numbers, or a range of real device numbers of devices in the subsystems being queried.

### Usage Notes

1. This command may be issued to offline devices.

### Responses

Response 1:

The following response is displayed for each specified device that does not have any pinned tracks when you enter QUERY PINNED DEVICE:

```
rdev No pinned tracks exist for this device.
```

#### *rdev*

is the real device number of a device being queried.

Response 2:

The following response is displayed for each specified device when you enter QUERY PINNED DEVICE:

```
rdev Pinned track data:
tt-cccchh tt-cccchh tt-cccchh tt-cccchh
tt-cccchh tt-cccchh tt-cccchh tt-cccchh
```

## QUERY PINNED

### **rdev**

is the real device number of a device being queried.

### **tt**

is the type of pinned track.

### **01**

indicates that the operation can be retried when the hardware is repaired.

### **02**

indicates that the operation cannot be retried because of a format error.

### **04**

indicates that the data is pinned in NVS, the operation can be retried.

### **08**

indicates that the cache copy of the data is defective.

### **cccchh**

is the address (cylinder, head) of a data track pinned in subsystem cache or nonvolatile storage.

Response 3:

This response is repeated for each *unique subsystem* identified by the devices specified on the command line when you enter QUERY PINNED SUBSYSTEM:

```
rdev Pinned subsystem data:  
cccccccK Bytes are in cache.  
nnnnnnnK Bytes are in non-volatile storage.
```

### **rdev**

is the real device number of one of the specified devices in a subsystem being queried.

### **ccccccc**

is the total amount of cache storage containing pinned data.

### **nnnnnnnn**

is the total amount of nonvolatile storage containing pinned data.

Response 4:

This response is repeated for each *unique subsystem* identified by the devices specified on the command line when you enter QUERY PINNED SUBSYSTEM if the amount of pinned data in nonvolatile storage cannot be determined.

```
rdev Pinned subsystem data:  
cccccccK Bytes are in cache.  
          Bytes in non-volatile storage cannot be determined.
```

### **rdev**

is the real device number of one of the specified devices in a subsystem being queried.

### **ccccccc**

is the total amount of cache storage containing pinned data.

## Messages

- HCP006E Invalid device type - {rdev/vdev/ldev}
- HCP009E Invalid range - range
- HCP020E Userid missing or invalid
- HCP021E A real device number was not supplied or it is invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {rdev/vdev/ldev} does not exist
- HCP319E Error processing subsystem command - cmd for DASD rdev
- HCP332E Invalid control unit type - rdev

- HCP1109E The *command* command cannot be processed for device *rdev* because the device is the secondary in a duplex pair.
- HCP1120E The requested [command|DETACH|GIVE] for device [*ldev*|*rdev*] did not complete in the allotted time.

## QUERY PORT

### Authorization

Privilege Class: B

### Purpose

Use the QUERY PORT command to display information about link aggregation groups or devices that have been defined for virtual switches on the system.

### Operands

#### GROUP ALL

indicates a request for all active port groups defined in the system. This is the default when an explicit GROUP *groupname* is omitted.

#### ACTive

indicates a request to return only those groups that have been associated with an active virtual switch.

#### INActive

indicates a request to return only those groups that have not been associated with a virtual switch.

#### GROUP *groupname*

indicates a request for the specified *groupname*.

#### GROUP *groupname.instance*

indicates a request for the specific instance (0-3) of a *groupname*. This format can be used to display a specific instance of a shared port group when it is configured to a global virtual switch on a system.

#### RDEV *rdev*

indicates a request for the specified real device.

#### DETAils

indicates a request for full information about the groups or device specified. This will include Link Aggregation Control Protocol (LACP) information for the selected group or device. For shared port groups, the display includes information about how each copy of the shared port group is configured on each IVL domain member.

### Examples

1. QUERY PORT GROUP *groupname*:

Display a list of information about a group and the associated devices that have been defined for the group where the group has not been associated with a virtual switch:

```
cp q port gro prodgrp

Group: PRODGRP   Inactive   LACP Mode: Active   Exclusive
VSWITCH <none>                               ifIndex: 1
Load Balancing: Independent   Interval: 300
RDEV: 3300.P00   Adapter ID: 29640007E386.0250
RDEV: 3400.P00   Adapter ID: 29640007E386.0251
RDEV: 3500.P00   Adapter ID: 29640007E386.0252
RDEV: 3600.P00   Adapter ID: 29640007E386.0254
```

## 2. QUERY PORT GROUP *groupname*:

Display a list of information about a group and the associated devices that have been defined for the group where the group has been associated with an active virtual switch:

```
cp query port gro ethgrp

Group: ETHGRP   Active   LACP Mode: Active   Exclusive
VSWITCH SYSTEM ETH1                               ifIndex: 1
Load Balancing: Independent   Interval: 300
RDEV: 9C00.P00 VDEV: 9C00 Controller: DTCVSW1   ACTIVE
Adapter ID: 29640007E386.0260
Uplink Port Connection:
Data Counters Cleared: 11/12/15   13:54:00

Device: 9D02 Unit: 002 Role: DATA Port: 0002
Partner Switch Capabilities: No_Reflective_Relay
LAG Port Controller: Active
```

## 3. QUERY PORT RDEV *rdev*:

Display information about a device that has been associated with an active virtual switch:

```
cp query port rdev 9d00

Group: ETHGRP   Active   LACP Mode: Active   Exclusive
VSWITCH SYSTEM ETH1                               ifIndex: 1
Load Balancing: Independent   Interval: 300
RDEV: 9D00.P01 VDEV: 9D00 Controller: DTCVSW1   ACTIVE
Adapter ID: 29640007E386.0560
Uplink Port Connection:
MAC address: 02-22-90-00-00-06
RX Packets: 19   Discarded: 0   Errors: 0
TX Packets: 9   Discarded: 0   Errors: 0
RX Bytes: 152   TX Bytes: 1440
Device: 9D02 Unit: 002 Role: DATA Port: 0002
Partner Switch Capabilities: No_Reflective_Relay
LAG Port Controller: Active
```

## 4. QUERY PORT GROUP *groupname* DETAILS:

## QUERY PORT

Display a list of detailed information including LACP activity about a group and the associated devices that have been defined for the group.

```
q port group ethgrp details

```

## 6. QUERY PORT GROUP ALL ACTIVE

Display a list of information for all active port groups. For shared port group, all instances will be displayed.

```

cp query port group all active

Group: BLUE.0 Active LACP Mode: Active Shared
VSWITCH CASEY.RICK ifIndex: 2112
Load Balancing: Collaborative Interval: 300
RDEV: 7240.P00 VDEV: 7240 Controller: DTCVSW1 ACTIVE
Adapter ID: 29640007E386.0260
Group: BLUE.1 Active LACP Mode: Active Shared
VSWITCH CASEY.SUE ifIndex: 2112
Load Balancing: Collaborative Interval: 300
RDEV: 7243.P00 VDEV: 7243 Controller: DTCVSW1 ACTIVE
Adapter ID: 29640007E386.0260

```

## QUERY PORT

```
Group: BLUE.2 Active LACP Mode: Active Shared  
VSWITCH CASEY.SAM ifIndex: 2112  
Load Balancing: Collaborative Interval: 300  
RDEV: 7246.P00 VDEV: 7246 Controller: DTCVSW1 ACTIVE  
Adapter ID: 29640007E386.0260
```

### Responses

Response 1: The QUERY PORT response includes optional lines. The general format is:

#### **Group *groupname* [*instance*]**

*groupname* identifies the link aggregation group. When a shared port group is in use on a global virtual switch, the group name is displayed with an instance number in the format *groupname.instance*. This is most useful when the shared port group is in use by more than one global virtual switch on a single system. For example, when RICK and SAM are global virtual switches defined on the same system and both are configured to use shared port group Blue, BLUE.0 is displayed for the line describing RICK and BLUE.1 is displayed for the line describing SAM.

#### **LACP Mode**

identifies whether the Link Aggregation Control Protocol (LACP) mode is Active or Inactive.

#### **VSWITCH <none> | SYSTEM *switchname systemname.switchname***

identifies the virtual switch that has been associated with the group. If <none> is listed, an association has not been made. For GLOBAL virtual switches, *systemname.switchname* is shown in place of SYSTEM *switchname* where *systemname* identifies the 8 byte EBCDIC z/VM System Identifier of the system where a copy of the shared port group exists and is in use on a global virtual switch.

#### **Interval**

*nnnn* indicates the length in time in seconds between load balancing intervals.

#### **ifIndex**

*nnnn* is the ifIndex representing the aggregator for the port group.

#### **Load Balancing**

displays information about load balancing.

##### **Independent**

Each VSwitch sharing the same LAG will only balance the workload on its VSwitch. There is no consideration for the other VSwitches also sharing the same LAG.

##### **Forced Independent**

The port group is configured to use the Collaborative Load Balance management method, but is being forced by z/VM to use the Independent Load Balance management method. All z/VM Systems currently connected to the same IVL are not capable or are not able to functionally support Collaborative Load Balance.

##### **Collaborative**

All VSwitches sharing the same LAG will collaborate with each other to balance the LAG's workload.

##### **Interval**

*nnnn* indicates the length in time in seconds between load balancing intervals.

#### **RDEV**

*nnnn.Pnn* indicates the base real device number of a QDIO device defined for the virtual switch. The base number is the first of three consecutive device numbers and OSA-Express port number used to establish a QDIO connection.

#### **VDEV**

*nnnn* indicates the base virtual device number used by the virtual switch controller for the RDEV.

#### **Controller**

is the user ID of the TCP/IP virtual machine acting as a controller for the RDEV.

#### **Adapter ID**

describes the OSA-Express port in use on system *systemname*. The format is:

```
cccccccccccc.pchid
```

**cccccccccccc**

represents the 12 bytes of text character and hexadecimal information that uniquely identifies the processor.

**pchid**

identifies the Physical Channel ID representing the OSA-Express feature.

**Status**

indicates the status of the RDEV. If the field is blank, the device is operating in the ACTIVE state and operating normally. Possible states are:

**ACTIVE (displayed as blank)**

The port is currently available and in use within the link aggregation group.

**Waiting**

The port is available but is not currently being used within the link aggregation group.

**Suspended**

All data transmissions are suspended until pending requests are complete or they can be moved to another port within the link aggregation group.

**Error**

The port is not available to the link aggregation group. The reason for the error is listed in the response.

**Reason**

Possible error reasons are:

**Pending QDIO Activation**

The device has been assigned to a controller and is completing initialization.

**Pending Routing Assignment**

The device is being activated and will become available during the next cycle.

**Port inoperable**

The device is suspended.

**ABEND occurred**

An abend occurred while processing data for this device.

**Pending fallback**

The device is failing back to the link aggregation group.

**LACP negotiation**

The device is waiting for LACP port negotiation to add this port to the group. Inbound datagrams are accepted.

**Partner LACP information mismatch**

The partner system ID and/or key do not match the virtual switch information.

**Inoperable by LACP**

The partner has indicated the device is not part of the group.

**LACP not enabled on partner**

LACP is not currently enabled on the partner switch.

Response 2: In addition to the lines displayed in response 1, the QUERY PORT GROUP response will include the following lines when DETAILS are requested for a shared port group.

**Member: *systemname***

identifies the 8 byte EBCDIC z/VM system identifier of the domain member.

**Scope****Synchronized**

The local system's view of the shared port group matches the port group configuration on other IVL domain members.

**Pending Synchronized**

The local system is checking to make sure that configuration of the shared port group matches the existing configuration on all systems in the IVL domain.

### **Not Synchronized**

The local system's view of the shared port group does not match the configuration on other IVL domain members.

### **Error [msgno]**

The local system has identified a configuration mismatch with the way the shared port group is configured on another system in the IVL domain.

A message number may also be displayed to identify a specific synchronization problem.

### **LAG Synchronization Token**

A token representing the most recent update made to the shared port group. This token is for use by IBM personnel for diagnosing synchronization problems.

### **Mode: [Connected | Inactive]**

Connected indicates the port group is associated with a global VSwitch and the global VSwitch is connected. Inactive indicates the port group is not associated with a global VSwitch or the associated global VSwitch is not connected.

### **Take-over Status Member: *systemname* MAC address: *mac***

An additional line(s) shows take over status when the shared port group is involved in MAC address takeover to maintain connectivity following a failure.

A different global VSwitch member had an UPLINK port failure, and its MAC addresses are now assigned to one of the local OSAs on this global VSwitch member. The member name may be omitted if it cannot be obtained (for example if the member left the IVL domain). This is followed by a list of MAC Addresses.

## **Messages**

- HCP2837E No {active|inactive} groups found.
- HCP2783E GROUP *groupname* does not exist.
- HCP2783E RDEV *vdev* does not exist.
- HCP3185I The displayed response may be incomplete. The system is not joined with the IVL Domain.

## QUERY (Printer ID)

---

► Query — *ptid* ◄

### Authorization

Privilege Class: B

### Purpose

Use QUERY (Printer ID) to display the status of a virtual machine that controls a print server printer. The operand *ptid* is 1- to 8- alphanumeric characters. If you specify *ptid* as 4 or fewer characters, it must not contain only hexadecimal characters; because CP interprets *ptid* as *rdev*.

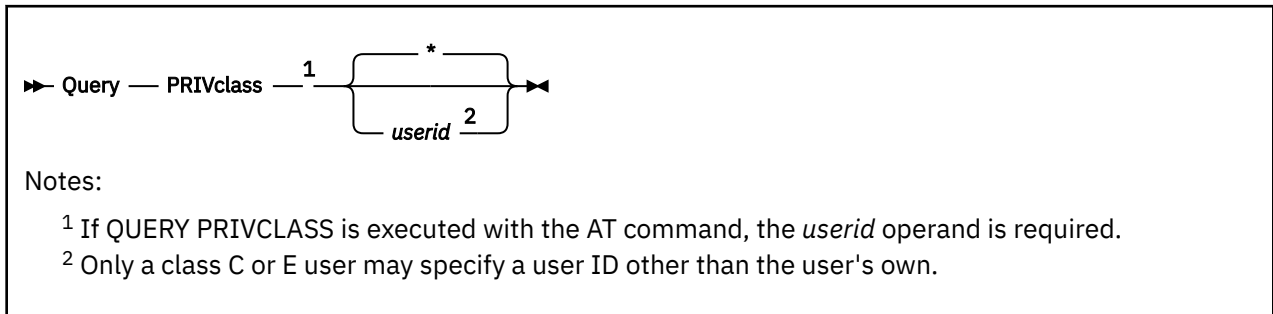

### Responses

The virtual machine controlling the printer issues responses to this command, not CP.

### Messages

None.

## QUERY PRIVCLASS

### Authorization

Privilege Class: Any, C, E

### Purpose

Use QUERY PRIVCLASS to display the current and directory-specified privilege classes available to a virtual machine. If you are a class C or E user, you can display the privilege classes for any virtual machine. If you are not a class C or E user, you can display the privilege classes only for your own virtual machine.

### Operands

\*

displays the privilege classes of the user who issues the command. This is the default.

*userid*

identifies the user whose privilege classes are to be displayed.

### Usage Notes

1. When you log on, CP sets your user ID's privilege classes to the privilege classes granted to you in your user directory entry.
2. If a privileged DirMaint user updates your directory entry by adding additional privilege classes while you are logged on, you can put those new privilege classes into effect by issuing the SET PRIVCLASS \* RESET command.

For more information, see [“SET PRIVCLASS” on page 1616](#).

### Responses

Response 1:

If you enter a QUERY PRIVCLASS command, you will see something like this:

```
Privilege classes for user MINNIE
  Currently: BCEG
  Directory: ABCDEFG
The privilege classes are not locked against changes.
```

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *operand*
- HCP007E Invalid *userid* - *userid*
- HCP045E *userid* not logged on

- HCP052E Error in CP directory
- HCP053E *userid* not in CP directory

## QUERY PROCESSORS

### Authorization

Privilege Class: A, B, C, E

### Purpose

Use QUERY PROCESSORS to display a list of all real processors, and indicate the way in which each processor is being used. It also can be used to display the mode of the logical partition.

Use QUERY PROCESSORS TOPOLOGY to display the CPU topology. The topology is a tree representation that contains information about the specific logical CPUs that have affinity within the corresponding part of the real machine.

When multithreading is enabled, these commands also show the relationship between CPUs (threads) and the cores on which they reside.

### Operands

#### EXPanded

requests an expanded response.

#### TOPOlogy

requests current topology.

### Usage Notes

1. A primary processor is a processor with a CPU type that matches the type of the IPL processor. In an all-IFL configuration, each IFL processor is a primary processor. In all other configurations, primary processors are type CP. A secondary processor is a processor with a type that does not match the type of the IPL processor.
2. A PARKED processor can exist in vertical-polarization mode only.
3. When VM is running second-level, the CPU topology is not available.
4. When multithreading is enabled, gaps might occur in the sequence of processor addresses for cores that have less than the maximum number of activated threads. For an example, see [“QUERY MULTITHREAD”](#) on page 1026.
5. Unlike QUERY PROCESSORS and QUERY PROCESSORS EXPANDED, QUERY PROCESSORS TOPOLOGY does not include information on standby processors because they do not have an assigned placement within the topology.
6. Processors defined to the partition but outside the addressable range (0000 - 004F) might appear in monitor output, but will not appear in the QUERY PROCESSORS display.

### Responses

Response 1:

This is the response format when *no* operands are specified. Each processor's information is displayed as one of the following lines.

```
PROCESSOR nnnn MASTER type [CORE cccc]
PROCESSOR nnnn ALTERNATE type [CORE cccc]

PROCESSOR nnnn PARKED type [CORE cccc]
PROCESSOR nnnn STANDBY type [CORE cccc]
```

***nnnn***

is the logical processor number.

**MASTER**

indicates the master processor.

**ALTERNATE**

indicates an alternate processor (a nonparked processor other than the master).

**PARKED**

indicates a processor that is online, but CP has chosen not to run any work on it. A processor can be parked in vertical-polarization mode only.

**STANDBY**

indicates a processor that is part of the configuration but is not online. A STANDBY processor can be brought online by using the VARY PROCESSOR command.

***type***

indicates the type of the real processor. Type can be as follows:

**CP**

indicates the processor is a central processor (that is, a general-purpose processor).

**IFL**

indicates the processor is an IBM Integrated Facility for Linux processor.

**ZIIP**

indicates the processor is an IBM z Integrated Information Processor.

**ICF**

indicates the processor is an Internal Coupling Facility processor.

**CORE *cccc***

when multithreading is enabled, identifies the core ID of the logical core that contains the specified logical processor.

***userid***

is the user who owns the virtual CPU.

***mm***

is the virtual address of the virtual CPU.

Response 2:

This is the response format when the EXPANDED operand is specified. Each processor's information is displayed as one of the following first four lines.

```
PROCESSOR nnnn MASTER type [CORE cccc]
PROCESSOR nnnn ALTERNATE type [CORE cccc]

PROCESSOR nnnn PARKED type [CORE cccc]
PROCESSOR nnnn STANDBY type [CORE cccc]
PARTITION MODE {ESA/390 }
                {GENERAL }
                {LINUX-ONLY}
                {Z/VM }
```

where PARTITION MODE is the mode of the logical partition as specified in the image profile and the other fields are as described in Response 1.

Response 3:

## QUERY PROCESSORS

This is the response format when the TOPOLOGY operand is specified. Depending on the machine, one or two nesting levels might be displayed. The PROCESSOR line is repeated for each processor within the nesting level.

```
TOPOLOGY
NESTING LEVEL: nl ID: id
NESTING LEVEL: nl ID: id
PROCESSOR nnnn proctype type pe dv [CORE cccc]
PROCESSOR nnnn proctype type pe dv [CORE cccc]
```

### ***nl***

is the nesting level.

### ***id***

is the identifier for the nesting level.

### ***nnnn***

is the logical processor number.

### ***proctype***

can be MASTER, ALTERNATE, or PARKED, as described in Response 1.

### ***type***

indicates the type of the real processor, as described in Response 1.

### ***pe***

indicates the polarization and entitlement of a CPU.

### **HZ**

indicates that the CPU is polarized horizontally. Horizontally-polarized CPUs (of a given CPU type) receive approximately equal access to CPU resources.

### **VL**

indicates that the CPU is polarized vertically with low entitlement. Vertical-low CPUs are not entitled to any CPU resource and consume spare cycles only, if they are available.

### **VM**

indicates that the CPU is polarized vertically with medium entitlement. Vertical-medium CPUs are entitled to a fraction of a real CPU, but can consume more than this if there are spare cycles on the machine.

### **VH**

indicates that the CPU is polarized vertically with high entitlement. Vertical-high CPUs are entitled to an entire real CPU.

### ***dv***

identifies the four-digit decimal dispatch vector (work queue) membership of the processor. When two or more processors have the same *dv* value, they are selecting work from the same queue.

### **CORE *cccc***

when multithreading is enabled, identifies the core ID of the core that contains the specified processor.

Response 4:

This is the response format when the TOPOLOGY operand is specified and topology information is not available.

```
CPU topology is not available.
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP013E Conflicting option - *option*
- HCP263E Too many operands were supplied for this command.

## QUERY PRODUCT

### Authorization

Privilege Class: C, E

### Purpose

Use QUERY PRODUCT to display information regarding the PRODUCT statements defined to the system in the system configuration file at IPL and defined using the SET PRODUCT command.

### Operands

#### PRODIG ALL

tells CP to display information about all product IDs defined to the system. This is the default.

#### PRODIG *vmses\_prodid*

is the identifier used by VMSES/E to install and service the given product. *vmses\_prodid* must be a 7 or 8 character identifier.

#### STATE ALL

tells the system to display the associated product information regardless of the current state. This is the default.

#### STATE ENABLED

displays information about the product IDs that are enabled on the system.

#### STATE DISABLED

displays information about product IDs that are explicitly disabled on the system.

### Usage Notes

1. QUERY PRODUCT commands gathers information about the current PRODUCT statements defined to the system. Although this information may be contained in the system configuration file, it may have been changed with a SET PRODUCT command since that time.
2. The output from QUERY PRODUCT is sorted by product ID from lowest to highest.
3. QUERY PRODUCT is not intended to be a programming interface. Programs requiring enablement data should use DIAGNOSE code X'27C'.

## QUERY PRODUCT

### Responses

Response 1:

To query a single product ID (5735FALQ), enter the following command:

```
QUERY PRODUCT 5735FALQ
```

```
Product State Description
5735FALQ Enabled TCP/IP LEVEL 310 - TCP/IP FEATURE (BASE)
```

Response 2:

To query ONLY enabled product IDs on the system, enter the following command:

```
QUERY PRODUCT STATE ENABLED
```

```
Product State Description
5735FALQ Enabled TCP/IP LEVEL 310 - TCP/IP FEATURE (BASE)
5877-00 Enabled Product ABC
```

### Messages

## QUERY PROMPT

### Authorization

Privilege Class: B

### Purpose

Use QUERY PROMPT to display whether CP will prompt the operator for startup information following a CP restart after an abend or a shutdown REIPL.

### Operands

#### AFTER\_REStart

specifies to display whether CP will prompt the operator for startup information after a CP restart after an abend or not.

#### AFTER\_SHUTDOWN\_REIPL

specifies to display whether CP will prompt the operator for startup information after a shutdown REIPL or not.

### Usage Notes

1. Use the SET PROMPT command to change the settings of the prompt operands.
2. Use the FEATURES ENABLE/DISABLE PROMPT configuration file statement to initialize the settings of the prompt operands at IPL time.
3. If the SET PROMPT command was not used or the FEATURES ENABLE PROMPT statement was not specified in the configuration file, the operator will not be prompted for start up information after a system restart or a shutdown REIPL.

### Responses

Response 1:

To query the settings of the prompt after\_restart operand enter the following:

```

q prompt after_restart
The system will not prompt for startup information after restart
Ready;
  
```

To query the settings of the prompt after\_shutdown\_reipl operand enter the following:

```

q prompt after_shutdown_reipl
The system will not prompt for startup information after a
shutdown reipl
Ready;
  
```

### Messages

## QUERY PROMPT

- HCP6706E Invalid string - *string*

# QUERY PSWTRANS

► Query — PSWTRANS ◄

## Authorization

Privilege Class: G

## Purpose

Use QUERY PSWTRANS to determine if the PSW option will be accepted on the DISPLAY, DUMP and STORE commands to display or manipulate 64-bit ESA/390 PSWs when the virtual machine is in z/Architecture mode.

## Usage Notes

1. To change the PSWTRANS option, enter the SET PSWTRANS command.

## Responses

Response 1:

```
PSWTRANS {ON      }
          {OFF     }
          {ALL     }
          {DISPLAY }
          {STORE  }
```

### ON

indicates that the PSW option is allowed for the DISPLAY, DUMP or STORE commands when the virtual machine is in z/Architecture mode.

### OFF

indicates that the PSW option is not allowed for the DISPLAY, DUMP or STORE commands when the virtual machine is in z/Architecture mode.

### ALL

indicates that the PSW option will be accepted for the DISPLAY, DUMP and STORE commands to reference or change PSW data in the 64-bit ESA/390 format when the virtual machine is in z/Architecture mode (64-bit PSW displayed and 64-bits accepted on STORE).

### DISPLAY

indicates that the PSW option will be accepted for the DISPLAY and DUMP commands (but not STORE) to reference PSW data in the 64-bit ESA/390 format when the virtual machine is in z/Architecture mode.

### STORE

indicates that the PSW option will be accepted for the STORE command (but not DISPLAY or DUMP) to change PSW data in the 64-bit ESA/390 format when the virtual machine is in z/Architecture mode.

## Messages

- HCP003E Invalid operand - *operand*

## QUERY QIOASSIST

### Authorization

Privilege Class: B, G

### Purpose

Use QUERY QIOASSIST to determine the current status of the queue-I/O assist for a virtual machine. The setting for queue-I/O assist is controlled by the SET QIOASSIST command.

### Operands

#### USER *userid*

\*

specifies an individual user for which the queue-I/O assist status is to be reported.

An asterisk (\*), which is the default, specifies the virtual machine (user ID) from which the command is issued.

### Usage Notes

1. When the setting for all users is OFF, eligibility for queue-I/O assist is disabled for all virtual machines, including any new users that may logon, regardless of the individual setting.

When the setting for all users is ON, then the individual user setting determines whether queue-I/O assist is allowed or disallowed for the requested user ID.

### Responses

The response displays the setting for all users, followed, if appropriate, by the individual user setting and status, which is one of the following:

#### ACTIVE

the specified *userid* is currently enabled to use the queue-I/O assist for devices that support the queued-I/O protocols.

#### PENDING ACTIVE

the specified *userid* is in the process of being enabled to use the queue-I/O assist.

#### PENDING INACTIVE

the specified *userid* is in the process of being disabled from using the queue-I/O assist.

#### INACTIVE

the specified *userid* is currently not using the queue-I/O assist.

#### NOT AVAILABLE

the queue-I/O assist is not available to the virtual machine. See [“SET QIOASSIST” on page 1623](#).

**USER DISABLED**

the virtual machine was made ineligible to use the queue-I/O assist by the SET QIOASSIST OFF command for the userid.

**CP DISABLED**

the virtual machine cannot use the queue-I/O assist because of special conditions in the virtual machine environment. For example, if the user enabled the tracing of I/O interruptions via the TRACE I/O or TRACE AIF CP commands, the queue-I/O assist is disabled in order to trace the events.

**Messages**

- HCP003E Invalid operand - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on
- HCP263E Too many operands were supplied for this command

## QUERY QUICKDSP

---

►► Query — QUICKDSP — *userid* ◄◄

### Authorization

Privilege Class: A, E

### Purpose

Use QUERY QUICKDSP to display the QUICKDSP attribute (on or off).

### Operands

#### *userid*

is the virtual machine whose QUICKDSP setting you want displayed.

### Responses

Response 1:

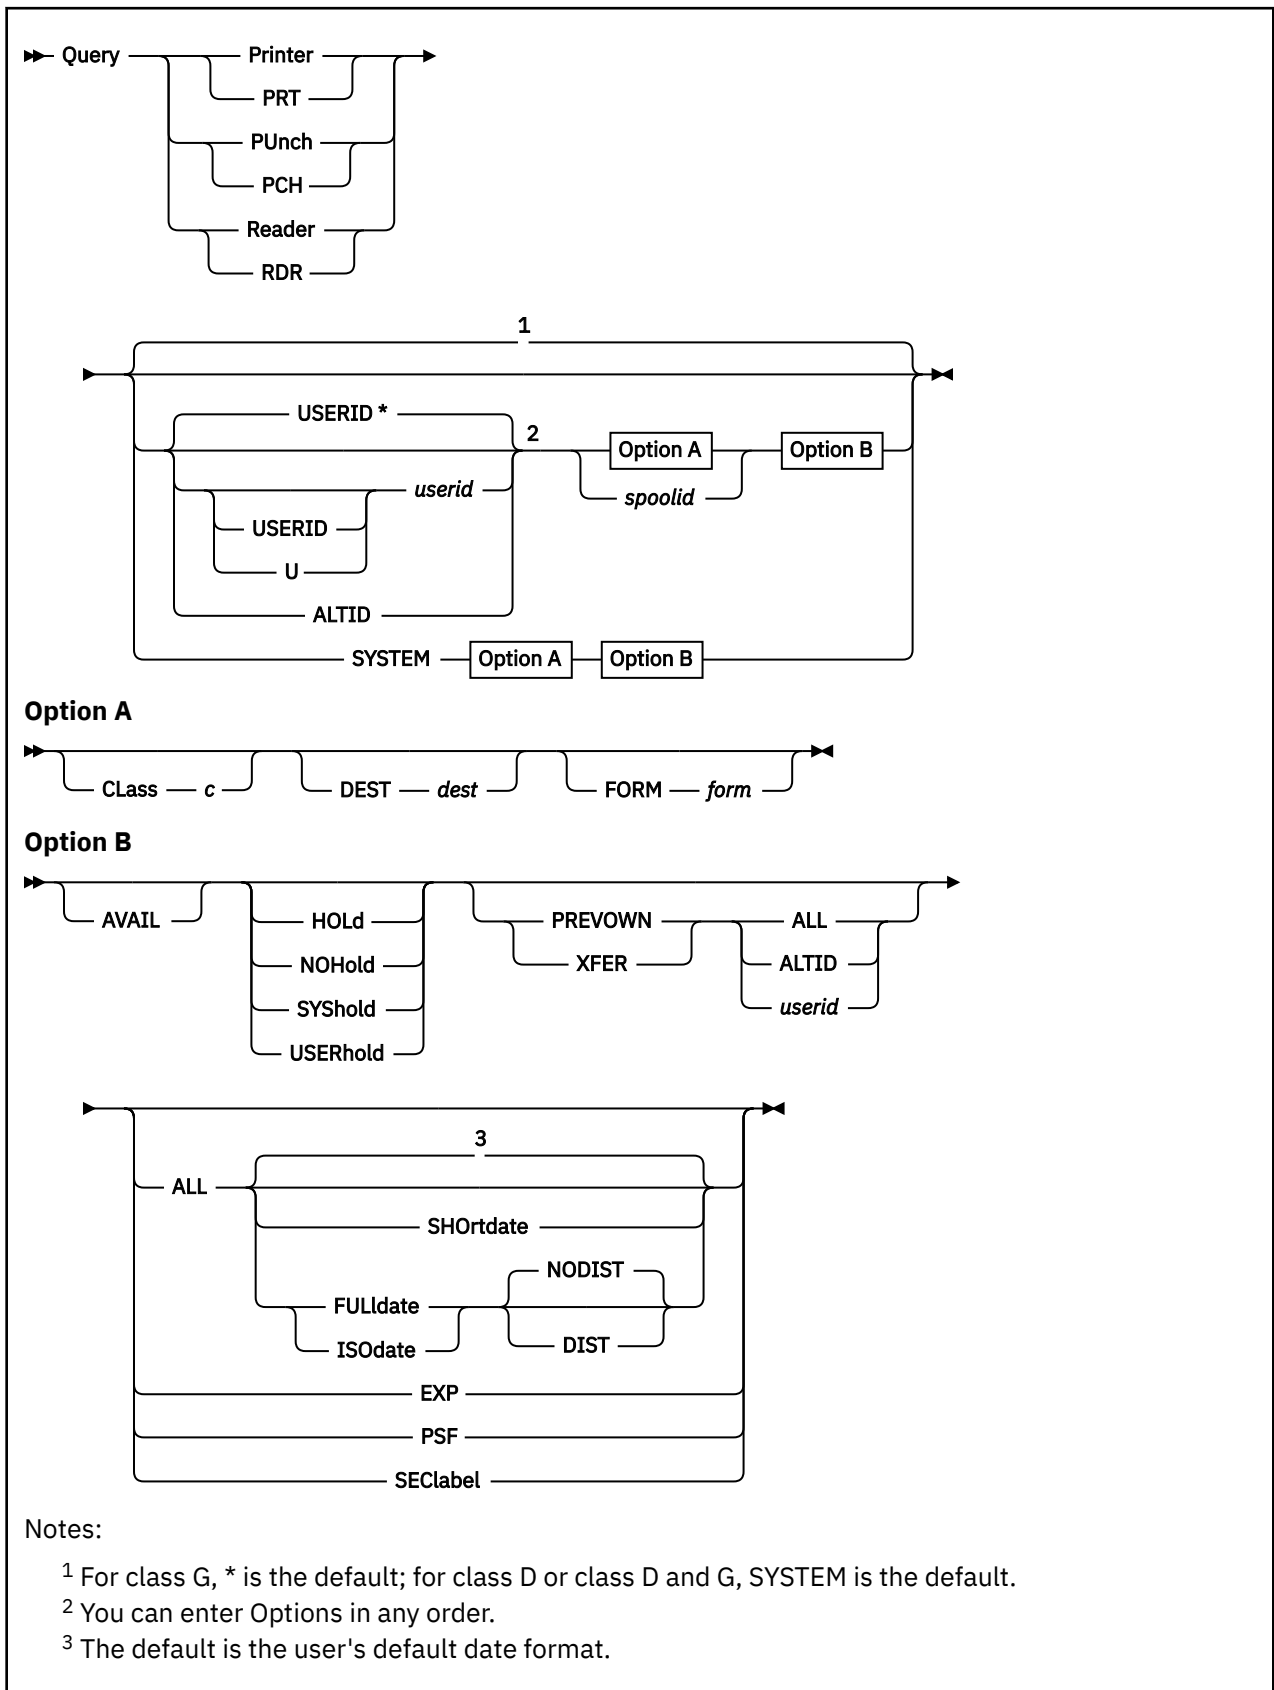

```
USER userid: QUICKDSP={ON }  
                {OFF }
```

is returned to the QUERY QUICKDSP command issuer.

### Messages

- HCP007E Invalid *userid* - *userid*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on

# QUERY READER/PRINTER/PUNCH

## Authorization

Privilege Class: D, G

## Purpose

Use QUERY READER/PRINTER/PUNCH to display detailed information about one or more spool files of the specified type. The display includes files that are:

- Open on virtual devices
- Closed and on the device queue
- Being processed on real printers, punches, or readers.

Spool files are displayed in the order in which they are processed.

Class G users can obtain information about reader, printer, or punch files that they own, that they created, or that are owned by their alternate user ID.

Class D users can obtain information about all spool files in the system, or spool files belonging to any user on the system.

## Operands

### Printer

**PRT**

### PUnch

**PCH**

### Reader

**RDR**

displays the following information about your reader, printer, or punch files:

- The *userid* of the file creator
- The spool file identification
- The spool file's class and type of device where originated
- The number of logical records in the file
- The number of copies specified for the file
- The file HOLD, KEEP, and MSG status
- The form name.

### USERID

**U**

indicates that the next parameter is a userid. Class G users can specify only an asterisk (\*) following USERID or U. U is the only abbreviation allowed for USERID.

**\***

### *userid*

**ALTID**

identifies the user whose spool files are to be queried. You can specify an asterisk (\*) to query your own files; an asterisk (\*) is the default for the class G user. You can specify ALTID to query files belonging to your alternate user ID. Class G users cannot specify *userid*.

Class D users can obtain information about reader, printer, or punch spool files that are owned by any user of the system by specifying that user's *userid*. If class D users want to obtain a display about their own spool files, they must enter their own *userid* or an asterisk (\*) on the command line. A class D user issuing the QUERY command for a one-to-four digit, all numeric *userid*, will cause unpredictable results because of the one-to-four digit, all numeric spoolid parameter.

**SYSTEM**

allows only the class D user to obtain information about all files in the system, regardless of ownership. This system is not allowed with the *spoolid* option. SYSTEM is the default for the class D user.

***spoolid***

is the system-assigned number of the spool file that is to be queried. This option is not valid with the SYSTEM keyword.

**Options****Class *c***

designates an existing spool file class. The operand *c* is a 1-character alphanumeric field that may be from A to Z, or 0 to 9.

**DEST *dest***

indicates that you want to obtain information for files with the specified destination value; *dest* is a 1- to 8-character value.

**FORM *form***

indicates that you want to obtain spool file information for files with the specified form; *form* is one to eight characters long. For the class G user, *form* is the user form name. For the class D operator, *form* is the user form name when you specify asterisk (\*). Otherwise, *form* is the operator form number.

**AVAIL**

displays only available files, not those files which are open or in use.

**HOLD****NOHold****SYShold****USERhold**

identifies the status of the files to be queried.

- Specify HOLD to query files that are in user or system hold. A file that is in HOLD status cannot be processed by the spooling device. If you are a class G user, you can change a file's user hold status by using the CHANGE command; if you are a class D user, you can also change the system hold status by using the CHANGE command.
- Specify NOHOLD to query files that are not in user or system HOLD.
- Specify SYSHOLD to query files that only have system HOLD in effect.
- Specify USERHOLD to query files that only have user HOLD in effect.

**ALL**

displays additional information for spool files. In addition to the information normally displayed for the reader, printer, or punch files, the following is also displayed:

- The date and time the file was created
- The file name and file type of file (if any)
- The distribution code of the file. If FULLDATE or ISODATE is specified, the distribution code is displayed only if DIST is also specified. See the DIST/NODIST option for details.

**Note:** The form name is not displayed when you use the ALL option.

**EXP**

displays expanded information for spool files.

The information displayed is:

- The user form name and operator form number
- The forms control buffer (FCB)
- The name and number of the copy modification module
- The flash name

- The number of copies to be flashed (flash count)
- The position of the 3800 LOAD CCWs within the spool file
- The name of the character set or sets
- The size of the file. This is the number of 4096-byte blocks in the file.

TBL is accepted as a substitute for the EXP option.

### **PSF**

displays additional information for spool files. This additional information is returned under the following headings:

### **DEST**

identifies which printers are to process the file.

### **CONVERSION**

indicates whether PSF has done preliminary processing on the file.

### **SPECIAL**

indicates whether the file contains X'5A' CCWs inserted by CP. The presence of X'5A' CCWs indicates that PSF control information has been added to the file.

### **PURGE**

indicates whether the file has been purged from CP and is waiting for PSF to recognize this state.

### **SEClabel**

displays the security label associated with each spool file.

### **PREVOWN *userid*|ALL|ALTID**

displays information about files previously owned by the specified user ID or ALTID and owned by the issuing user ID. Class D users may use the SYSTEM option to display previous owner information about any files in the system. PREVOWN *userid* displays information about spool files transferred by the specified user ID or ALTID and owned by the query issuer. Files transferred back to the generator are not displayed. PREVOWN ALTID displays information about files generated by the ALTID owned by the issuing user ID. PREVOWN ALL displays information about files not generated by the issuing user ID or ALTID that are owned by the issuing user ID.

### **XFER *userid*|ALL|ALTID**

displays information about spool files generated by the specified user ID or ALTID and owned by another user ID. Class D users may use the SYSTEM option to display information about any files in the system owned by a user ID other than the originating user ID. XFER *userid2* displays information about spool files generated by the specified user ID or ALTID and owned by the user specified as *userid2*. Files generated and owned by the same user are not displayed. XFER ALTID displays information about files generated by the specified *userid* and owned by ALTID. XFER ALL displays information about files generated by the specified *userid* or ALTID and owned by another *userid*.

### **SHOrtdate**

specifies that dates in the response to this command will be displayed in *mm/dd* format, where *mm* is the month and *dd* is the day of the month.

### **FULLdate**

specifies that dates in the response to this command will be displayed in *mm/dd/yyyy* format, where *mm* is the month, *dd* is the day of the month, and *yyyy* is the 4-digit year.

### **ISOdate**

specifies that dates in the response to this command will be displayed in *yyyy-mm-dd* format, where *yyyy* is the 4-digit year, *mm* is the month, and *dd* is the day of the month.

### **NODIST**

### **DIST**

Specifies whether or not to display a distribution code when FULLDATE or ISODATE has been specified. The default is NODIST so each output record fits within an 80-character buffer.

## **Usage Notes**

1. TBL is an acceptable substitute for the EXP option. The response has the same wording.

2. If the *userid* option is used with the XFER option, the *userid* option is treated as the origin ID of the files. The result is information about the files generated by the first user and which are owned by the user specified after the XFER option.
 

If a Class D user enters QUERY PRT USER1, the user receives information about the printer files that USER1 owns.

If a Class D user enters QUERY PRT XFER USER2, the user receives information about the printer files that USER2 owns but did not originate.

If a Class D user enters QUERY PRT USER1 XFER USER2, the user receives information about the printer files generated by USER1 but owned by USER2.
3. For Class D Users:
  - The *userid* and SYSTEM options are permitted for class D users only.
  - If you use a one-to-four digit, all-numeric *userid*, the QUERY command produces unpredictable results because it also has a one-to-four digit, all-numeric *spoolid* parameter.
  - If you specify *spoolid*, you must also specify *userid* or an asterisk (\*).
4. If DEST is not specified on a command that can select files by DEST, the destination value of the file is ignored. The AVAIL option limits the files displayed to include only those files which are currently available to the virtual machine. When the virtual machine issues a read to the virtual card reader and a reader file is not already open, the first file which is available is selected. It is possible for a file not currently available to be on the chain ahead of another which is available (that is, CP is checkpointing the file). And it is possible that this file can become available between the time that this QUERY command is issued and the time that the virtual machine actually issues a read. If it is important that a particular file be selected on the read, then that file should be placed at the beginning of the queue with the ORDER command before the read is issued. An alternative for use in a program is Diagnose X'14' subcode X'2C'. This function allows a program to choose a particular reader file, order it, and read the first record all in one operation.
5. The SECLABEL option is valid only when an external security manager (ESM) is installed and security label checking is enabled.
6. When security label checking is enabled, the ESM is called to verify the user's access to each file. If the user is denied access to a specific file, some of the information about that file must be hidden from the user. The only fields of the response that will contain information are ORIGINID, FILE, CLASS, HOLD, DATE and TIME. All other fields contain asterisks. If a security label is not assigned to the file, the SECLABEL field contains the word NONE.
7. The default date format for certain CP and CMS commands can be set on a system-wide basis and also for the individual user. The system-wide default date format is set with the SYSTEM\_DATEFORMAT system configuration statement. The user's default date format is set with the DATEFORMAT directory statement. The system-wide default and the user's default can also be set with the CP SET DATEFORMAT command. The user's default date format defaults to the system-wide default. The system-wide and user settings can be queried with the CP QUERY DATEFORMAT command. The hierarchy of possible date format settings for the QUERY RDR/PRT/PUN command, from highest priority to lowest, is:
  - QUERY RDR/PRT/PUN command option
  - User default
  - System-wide default
8. The separate commands QUERY VIRTUAL READER, QUERY VIRTUAL PRINTER, and QUERY VIRTUAL PUNCH do not facilitate per-*userid* versions of this data request. They display the status of the virtual devices themselves, whereas this command details information about one or more spool files of the specified type.

## Responses

The column heads and variables used in the following responses are displayed at the end of this section under [Explanation of Response Contents](#).

## QUERY READER/PRINTER/PUNCH

Response 1:

The following response is issued when you specify QUERY RDR/PRT/PUN without the ALL option:

*For the Class G user*

```
ORIGINID FILE CLASS RECORDS  CPY HOLD FORM      DEST KEEP MSG
userid  spid a typ nnnnnnnn  nnn NONE formname dest ON  ON
                    *nnn USER          OFF OFF
                    SYS
                    USYS
```

*For the Class D user*

```
OWNERID FILE CLASS RECORDS  CPY HOLD USERFORM OPERFORM DEST KEEP MSG
userid  spid a typ nnnnnnnn  nnn NONE userform operform dest ON  ON
                    *nnn USER          OFF OFF
                    SYS
                    USYS
```

Response 2:

The following response is issued when you specify QUERY RDR/PRT/PUN with the ALL and SHORTDATE option, or if the user's default date format setting is SHORTDATE:

```
ORIGINID FILE CLASS RECORDS  CPY HOLD DATE  TIME      NAME      TYPE      DIST
userid  spid c typ nnnnnnnn  nnn NONE mm/dd hh:mm:ss filename
                    *nnn USER
                    SYS
                    USYS

filetype distcode
```

Response 3:

If you use the EXP option, you receive the following response:

```
ORIGINID FILE CLASS RECORDS  FLASH FCB MDFY  FLSHC LOAD CHARS      SIZE
userid  spid c typ nnnnnnnn  name fcb mod n ccc NO name name name name size
BEG
ANY
```

**Note:** If the size is greater than 9999, then sssK will be shown, and if the size is greater than 999499, then sssM is shown. "K" means 1000 and "M" means 1,000,000.

Response 4:

If the file is open (being created or read) on a virtual device, then the OPEN status and the virtual device number (*vdev*) are displayed in place of the DATE and TIME fields.

```
ORIGINID FILE CLASS RECORDS  CPY HOLD DATE  TIME NAME
userid  spid c typ nnnnnnnn  nnn NONE OPEN- vdev filename
                    *nnn USER
                    SYS
                    USYS

TYPE      DIST
filetype distcode
```

Response 5:

If a closed spool file is in the process of being printed or punched on a real output device, the PRT or PUN status and the number of records remaining to be printed in the current copy are displayed in the DATE and TIME fields.

```
ORIGINID FILE CLASS RECORDS  CPY HOLD DATE  TIME NAME
userid  spid c typ nnnnnnnn  nnn NONE PRT-  nnnn filename
                    *nnn USER PUN-  nnnK
                    SYS      nnnM
                    USYS

TYPE      DIST
filetype distcode
```

**Note:** If the number of records remaining to be printed is greater than 9999, *nnnK* is shown, and if the number of records remaining is greater than 999499 then *nnnM* is shown. "K" means 1000 and "M" means 1,000,000.

Response 6:

If a spool file is open (being read) on a real card reader, the OPEN status and the real device number (*rdev*) are displayed in place of the DATE and TIME fields.

```

ORIGINID FILE CLASS RECORDS  CPY HOLD DATE  TIME NAME
userid  spid c typ nnnnnnnn  nnn NONE OPEN- rdev filename
                    *nnn USER
                    SYS
                    USYS

TYPE      DIST
filetype distcode
    
```

Response 7:

The following response is issued when you specify QUERY RDR/PRT/PUN with the PSF option:

```

ORIGINID FILE CLASS RECORDS  FORM      DEST CONVERSION SPECIAL PURGE
userid  spid c typ nnnnnnnn  formname dest constat  YES   YES
                    NO      NO
    
```

Response 8:

The following response issued by QUERY PRINT for a file that has been purged.

```

ORIGINID FILE CLASS RECORDS  CPY HOLD **PURGED** NAME
userid  spid c typ nnnnnnnn  nnn NONE          filename
                    *nnn USER
                    SYS
                    USYS

TYPE      DIST
filetype distcode
    
```

The response indicates that PURGE processing is not complete for the file. This is a temporary state. If a printer spool file remains in this state for an extended period of time, it may indicate that the file has been selected for printing, but that intervention is required on the printer, or it may indicate that there is a problem with the printer server virtual machine.

Response 9: (QUERY PRINTER only)

When CP manages a real 3800 system printer, it maintains a delayed purge queue for each 3800 system printer. If the files have already been printed, but are being held in this delayed purge queue, the text **\*\*PRINTED\*\*** will be displayed in the column that usually contains the date and time.

```

ORIGINID FILE CLASS RECORDS  CPY HOLD DATE  TIME  NAME
userid  spid c typ nnnnnnnn  nnn SYS  **PRINTED** filename

TYPE      DIST
filetype distcode
    
```

The delayed purge queue for each printer is limited, so this file should eventually be purged by the system when it gets 'pushed' off the queue by subsequent print jobs. A file marked **\*\*PRINTED\*\*** cannot be changed, transferred, ordered, tagged, or dumped by SPXTAPE. It can be deleted by the PURGE command, which can be issued by the operator, or by the owner of the file.

These files may become detached from the delayed purge queue by events like an abnormal system shutdown. When this happens, the file will not be automatically deleted by the system. It should be deleted by the operator or the owner of the file.

Response 10:

If no files of the specified type exist, one of the following responses is given, corresponding to the specified file type:

```
NO RDR FILES
```

- or -

NO PRT FILES

- or -

NO PUN FILES

Response 11:

In an SSI cluster, the response for QUERY RDR/PRT/PUN ALL shows whether a file is unavailable for processing.

LOCK- *sysname* means the file is locked by (another) system, *sysname*. When a spool file is requested and the file is unavailable to the inquiring system because it is in use by another system, a status of LOCK appears under DATE, and the system that is using the spool file appears under TIME. For example:

```
ORIGINID FILE CLASS RECORDS  CPY HOLD DATE  TIME  NAME TYPE DIST
userid   spid c typ nnnnnnnn  nnn NONE LOCK-  sysname fnft distcode
```

COPY- *sysname* means this system's SPFBK is a copy, and the lock cannot be obtained because communication is not available to the system that owns the original. When the requested spool file is a copy and the file cannot be processed because communications with the owning system are impossible, a status of COPY appears under DATE, and the system that owns the spool file appears under TIME. For example,

```
ORIGINID FILE CLASS RECORDS  CPY HOLD DATE  TIME  NAME TYPE DIST
userid   spid c typ nnnnnnnn  nnn NONE COPY-  sysname fnft distcode
```

In these circumstances, a reader file may be read using the PEEK or RECEIVE commands, but it cannot be manipulated by the CHANGE or TRANSFER commands.

In all other cases, the response to this command in an SSI cluster is the same as the response when not in an SSI cluster.

Response 12:

The following response is issued when you specify QUERY RDR/PRT/PUN with the SECLABEL option:

*For a class G user*

```
ORIGINID FILE CLASS RECORDS  CPY HOLD FORM      DEST      SECLABEL
userid   spid a typ nnnnnnnn  nnn NONE formname dest  ssssssss
                *nnn  USER
                SYS
                USYS
```

*For a class D user*

```
OWNERID  FILE CLASS RECORDS  CPY HOLD USERFORM
userid   spid a typ nnnnnnnn  nnn NONE userform
                *nnn  USER
                SYS
                USYS

OPERFORM DEST      SECLABEL
operform dest  ssssssss
```

Response 13:

When security label checking is enabled, some fields must be hidden from the user if access to the file is denied. This example shows the response that is issued when you specified QUERY RDR/PRT/PUN with the SECLABEL option, and you were denied access to the file:

*For a class G user*

```
ORIGINID FILE CLASS RECORDS  CPY HOLD FORM      DEST      SECLABEL
userid   spid a typ *****  *** NONE *****  ****  *****
                ****  USER
```

```
SYS
USYS
```

Response 14:

If the spool file that was printing has been suspended, the number of records left to be printed is displayed in place of the DATE and TIME fields.

```
ORIGINID FILE CLASS RECORDS  CPY HOLD DATE  TIME NAME
userid  spid c typ nnnnnnnn  nnn nnnn nnnn  rdev filename
                                *nnn USER
                                SYS
                                USYS

TYPE      DIST
filetype distcode
```

Response 15:

The following response is issued when you specify QUERY RDR/PRT/PUN with the ALL, FULLDATE, and NODIST options:

```
ORIGINID FILE CLASS RECORDS  CPY HOLD DATE      TIME  NAME
userid  spid c typ nnnnnnnn  nnn NONE mm/dd/yyyy hh:mm:ss
filename
                                *nnn USER
                                SYS
                                USYS

TYPE
filetype
```

Response 16:

The following response is issued when you specify QUERY RDR/PRT/PUN with the ALL, ISODATE, and DIST options:

```
ORIGINID FILE CLASS RECORDS  CPY HOLD DATE      TIME  NAME
userid  spid c typ nnnnnnnn  nnn NONE yyyy-mm-dd hh:mm:ss
filename
                                *nnn USER
                                SYS
                                USYS

TYPE      DIST
filetype distcode
```

Explanation of Response Contents:

**CHARS name**

is the name of the character set or sets used to generate output if printed on a 3800 printer.

**CONVERSION convstat**

is the conversion status of the file, which can be any of the following:

Status	Meaning
<b>ACTIVE</b>	The print server is converting the file to a CMS file containing the actual data and the print controls used to print the file.
<b>COMPLETE</b>	The file is converted.
<b>NOTCONV</b>	The file is not yet been converted.

**DEST dest**

specifies the destination value assigned to the spool file.

**distcode**

is the distribution code of the file.

**FCB fcb**

is the name of the FCB module used in the vertical formatting of a page.

**filename**

is the file name assigned to the file (if any).

**filetype**

is the file type assigned to the file (if any).

**FLASH name**

is the name of the forms overlay frame to be superimposed on the output if printed on a 3800 printer.

**FLSHC ccc**

is the number of copies that are printed while the forms overlay frame is in place if printed on a 3800 printer.

**FORM name**

is the name of the paper type as understood by the user (displayed for a class G user).

**hh:mm:ss**

is the time when the file was created in hours, minutes, and seconds.

**KEEP ON****KEEP OFF**

indicates whether the file is retained after being processed. ON indicates that KEEP is in effect and the file is retained after processing, and OFF indicates that KEEP is not in effect.

**LOAD NO****LOAD BEG****LOAD ANY**

is where the 3800 LOAD CCWs are positioned within the spool file—not at all (NO), at the beginning (BEG), or interspersed throughout the spool file (ANY).

**MDFY mod**

is the name of the copy modification module used to alter output text if printed on a 3800 printer.

**mm/dd****mm/dd/yyyy****yyyy-mm-dd**

is the date the file was created. The format of the date is determined by the SHORTDATE, FULLDATE, or ISODATE option. If no date format option is specified, the user's default date format setting is used.

**MSG ON****MSG OFF**

indicates whether messages about the file printing or punching are displayed. ON indicates these messages are displayed; OFF indicates they are not.

**n**

is the copy modification character set number.

**nnn****\*nnn**

is the number of copies requested for the spool file. This is shown as a 3-digit number (*nnn*). The asterisk (\*) indicates that the 3800 printer should print each page from the spooled output files *nnn* times before going on to the next page.

**nnnnnnnn**

is the number of logical records contained in the file.

**NONE****USER****SYS****USYS**

represents the file's HOLD status. NONE indicates there are no holds on the file, USER indicates the file is in user hold status, SYS indicates the file is in system hold, and USYS indicates the file is in both user and system hold.

**operform**

is the name of the paper type as understood by the operator (displayed for a class D user).

**ORIGINID****OWNERID**

ORIGINID heading the title line for the spool file data is altered to OWNERID when *userid* or the XFER operand is used, or when a class D user is defaulting to, or specifying, SYSTEM. In that event, OWNERID represents the owner of the file.

**PURGE (YES/NO)**

YES indicates that a file has been converted and subsequently changed, transferred, or purged. A new and unconverted file was created to reflect the altered attributes while retaining the original file data.

When the print server selects a file with PURGE=YES, it cancels further processing and deletes the old file.

**SECLABEL ssssssss**

identifies the security label (SECLABEL) associated with each file. The SECLABEL value is displayed as a 1- to 8-character alphanumeric value.

**SIZE size**

is the number of 4 KB DASD blocks allocated for data for the file.

**SPECIAL (YES/NO)**

indicates whether the file contains any records with X'5A' CCWs. The presence of X'5A' CCWs indicates that CP has added PSF control information to the file.

**spid**

is a system-assigned number used by the system to identify the file.

**typ**

identifies the device type that originally produced the spool file. The type can be RDR, PRT, PUN, CON, DMP or SYS.

**userform**

is the name of the paper type as understood by the user (displayed for a class D user).

**Messages**

- HCP003E Invalid option - *{option|command}* contains extra option(s) starting with *option*
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP413E Command processing cannot complete due to a spool paging error.
- HCP422E The same option was specified twice.
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP848E SYSTEM parameter is invalid with the spoolid option
- HCP849E A *userid* must be specified with the spoolid
- HCP1558E Command processing cannot complete.

## QUERY (Real Device)

### Authorization

Privilege Class: B

### Purpose

Use QUERY (Real Device) to display the status of real devices.

### Operands

#### ID

displays the device and control unit information from the sense ID data for a specified device address if they are known. It also displays the device equivalency ID (EQID) if one exists for the device.

#### *rdev*

#### *rdev1-rdev2*

displays the kind of real device at a specified device address. The status presented indicates whether the device is operational, has an equipment check, has a channel error, or is offline. You can enter a single *rdev*, a series (*rdev rdev*), or a range (*rdev1-rdev2*). Each *rdev* in the active configuration can be entered as a 4-digit hexadecimal device number between X'0000' and X'FFFF'. For an *rdev* in the active or standby configuration, the device can be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is defined. A range of devices cannot span subchannel sets.

#### STATUS

displays the status of a real DASD. The status indicates whether the device is operational, has an equipment check, has a channel error, or is offline.

### Usage Notes

1. If you are authorized for some options of this command but not for others and you enter an unauthorized option, CP interprets your command in the formats for which you are authorized. This might cause the command to run in an unexpected fashion, or reflect an unexpected message.
2. If the ID option is specified, but sense ID data is not available, the information is displayed as a dash (-).

### Responses

Response with ID:

```
type rdev dddd-mm CU: cccc-nn
    rdev EQID: qqqqqqqq
```

**type**

is the device type

**rdev**

is the real device number

**dddd**

is the device identifier

**mm**

is the device model number in hexadecimal

**cccc**

is the control unit identifier

**nn**

is the control unit model number in hexadecimal

**qqqqqqqq**

is the 1–8 character user-defined device equivalency ID (EQID) or the 50 character system-generated EQID.

**Note:** If the device identifier is unknown, the *dddd* and *mm* fields are blank. If the control unit identifier is unknown, the *cccc* and *nn* fields are blank. If the device has no EQID, the *qqqqqqqq* field is blank.

Responses with STATUS:

**Note:** In all of the following responses, *rdev* is the real device number for which the user refers to the device.

When the device is ready and available, you see a response like this:

```
DEVICE rdev OPERATIONAL
```

When the device is either disabled or not connected to the channel subsystem, you see a response like this:

```
DEVICE rdev NOT OPERATIONAL
```

When the device sense data indicates an equipment check, you see a response like this:

```
DEVICE rdev EQUIPMENT CHECK
```

When the device has indicated it has hardware problems, you see a response like this:

```
rdev CHANNEL ERROR
```

When the device is unavailable (boxed), you see a response like this:

```
DASD rdev BOXED
```

When the device is unavailable to CP, you see a response like this:

```
DASD rdev OFFLINE
```

When the device is in a state-change-pending condition, during which it cannot service I/O requests, you see a response like this:

```
DASD rdev STATE CHANGE IS PENDING
```

When the subchannel for the device has been varied offline you see a response like this:

```
DASD rdev SUBCHOFF
```

When the device has been taken offline for maintenance, you see a response like this:

## QUERY (Real Device)

```
DASD rdev QUIESCED
```

Response for Devices Needing Intervention:

If the system is using a device that is in an intervention-required state when you enter QUERY (Real Device), you receive a response that looks like this:

```
DASD 1801 has intervention required.
```

DASD is the real device type. It can be replaced by one of the following, depending on the type of device at the specified address:

<b>Type</b>	<b>Meaning</b>
TAPE	Magnetic tape
RDR	Card reader
PRT	Printer
PUN	Card punch
GRAF	Display device
LINE	Communication line
CTCA	Channel-to-channel adapter
FCP	SCSI Device Adapter
OSA	Open Systems Adapter
CTLR	3745 Communications Controller
MSC	Mass Storage Controller
SWCH	Dynamic Switching device
DEV	Any other device.
KBD	Keyboard

1801 is the real device number of the device that needs the operator's intervention.

**Note:** This response is preceded by one of the following.

Responses from Real Channel-to-Channel Adapters:

If there are channel-to-channel adapters attached to the system at the addresses specified, you see something like this:

```
q 480-486
DEV 0480 OFFLINE , DEV 0481 OFFLINE , CTCA 0482 FREE
CTCA 0483 ATTACHED TO RSCS 0483
CTCA 0484 FREE
CTCA 0485 ATTACHED TO PVM 0484
CTCA 0486 ATTACHED TO VTAM 0486
Ready;
```

The first number is the real device number of the channel-to-channel adapter. The ATTACHED operand might also read BOX/ATTC, meaning that although the device is attached and dedicated to a user, it is unavailable. PVM, RSCS, VTAM are user IDs to which the CTCAs are dedicated. The last number is the virtual device number which each virtual machine uses to refer to a CTCA. Any free, boxed, or offline devices within the device range are also included in the response.

Specifying the ID option for a single device may display the following sense ID and control unit information:

```
q 7e0 id
CTCA 7E0 - CU: 3088-08
Ready;
```

**Note:** Use the QUERY CTCA command to restrict responses to include only those CTCA devices in a specific state, such as free, boxed, or offline.

Responses from Real DASD:

You see responses like the following if real DASDs are attached to the system for access as user minidisks or for system paging, spooling, or temporary disk space.

```
q 280-285
DASD 0280 CP SYSTEM XAUSR1 49
DASD 0281 CP SYSTEM XAUSR2 24
DASD 0282 CP SYSTEM XAUSR3 49
DASD 0283 CP SYSTEM XAUSR4 34
DASD 0284 CP SYSTEM XAUSR5 42
DASD 0285 CP SYSTEM XAUSR6 20
Ready;
```

The first number listed is the real device number of the DASD. SYSTEM indicates the device is allocated to the system for use as users' minidisks. OWNED indicates the device is used by the system for paging and spooling activity. XAUSR1 and the rest are volume labels of the devices. The last number indicates the number of links to minidisks contained on the volume.

The following response is also displayed if real DASDs are attached to the system for access as user minidisks or for system paging, spooling, or temporary disk space. This response is longer than the response above because the device may be reserved (shared option is on), it may have a reserve pending, or it is currently reserved.

```
q 181a-181c
DASD 181A CP SYSTEM ESAP2C SHARED
DASD 181B CP OWNED ESAP2F RESERVE PENDING FOR USER DAVID
DASD 181C CP OWNED ESAP30 RESERVED BY SYSTEM
Ready;
```

If a DASD at the specified address is dedicated to a user, you will see a message like this:

```
q 820
DASD 0820 ATTACHED TO OLIVER 01FC R/O XAUSR4
Ready;
```

This means that the DASD at the real device number 0820 is attached to OLIVER's virtual machine as the virtual device 01FC. The DASD's volume identifier is XAUSR4. R/O means that the user OLIVER has read-only access to the DASD. R/O might also read R/W, which would mean that the user had read-write access. ATTACHED may be replaced with BOX/ATTC, which means that although the device is dedicated to a user, it is unavailable (usually because of a hardware condition).

If the device was defined by the DEVNO option on the MDISK statement, you see a response like this:

```
QUERY F8A3
DASD F8A3 CP SYSTEM DEVNO 13
```

The first number listed is the real device number of the DASD. SYSTEM indicates the device is allocated for use as a minidisk. DEVNO indicates that this device was defined by the DEVNO option on the MDISK statement. The last number indicates the number of links to the full-pack minidisk.

There must be at least one link, either by the owner of the disk or another user, to get the DEVNO response. One cannot link to a DEVNO mdisk attached to the system, it must be a free device. Even when linked, a DEVNO device is not attached to the system.

The volser for a DEVNO device is available from QUERY SYSTEM rdev.

Responses from Real Graphic Display Devices:

## QUERY (Real Device)

If a real graphic display at the specified address is dedicated to a virtual machine, you see something like this:

```
q 0bcd
GRAF 0BCD ATTACHED TO OLIVER 0010
Ready;
```

This message means the graphic display device at the real device number 0BCD is attached to OLIVER's virtual machine as the virtual device 0010. ATTACHED may be replaced with BOX/ATTC, which means that although the device is dedicated to a user, it is unavailable (usually because of a hardware condition).

If a graphic display device has a user logged on or dialed through it, you see something like this:

```
q 08e0
GRAF 08E0 LOGON AS SVCDIR 0009
Ready;
```

This response tells you that the user SVCDIR is logged on through the graphic display device at 08E0. The number 0009 is SVCDIR's virtual console device number.

If there are free graphic display devices at the specified addresses, you see something like this:

```
q 08e1-08e7
GRAF 08E1 ENABLED, GRAF 08E2 ENABLED, GRAF 08E3 ENABLED,
GRAF 08E4 LOGON AS OPERATOR 0009
GRAF 08E5 OFFLINE, GRAF 08E6 ENABLED, PRT 08E7 ENABLED
Ready;
```

**Note:** Use the QUERY GRAF command to restrict responses to include only those GRAF devices in a specific state, such as free, boxed, or offline.

Responses from Real Communication Lines:

If a real communication line is dedicated to a user, you see something like this:

```
q f0
LINE 00F0 ATTACHED TO OLIVER 0010
Ready;
```

This response means that the communication line with the real device number 00F0 is attached to OLIVER's virtual machine as the virtual device 0010. ATTACHED may be replaced with BOX/ATTC, which means that although the device is dedicated to a user, it is unavailable (usually because of a hardware condition).

If there are communication lines that have users logged on at them or dialed through them, you see something like this:

```
q fa fc
LINE 00FA LOGON AS DAVID 0009
LINE 00FB DIALED TO PVM 00F9
LINE 00FC FREE
Ready;
```

This response tells you that the user DAVID is logged on through the communication line at 00FA. The number 0009 is the virtual device number of the virtual console where DAVID is logged on. The second line tells you that the terminal connected to communications line 00FB is dialed to PVM's virtual device number 00F9.

**Note:** Use the QUERY LINE command to restrict responses to include only those LINE devices in a specific state, such as free, boxed, or offline.

Responses from FCP Adapter Devices:

If there are FCP devices attached to the system at the addresses specified, you see something like this:

```
q 480-487
FCP 0480 ATTACHED TO LINUX1 0480 CHPID F1
FCP 0481 ATTACHED TO LINUX1 0481 CHPID F1
FCP 0482 ATTACHED TO LINUX2 0482 CHPID F1
```

```
FCP 0483 FREE, FCP 0484 FREE
FCP 0485 ATTACHED TO LINUX3 0485 CHPID F1
FCP 0486 ATTACHED TO TEST1 0486 CHPID F1
FCP 0487 FREE
Ready;
```

The first number is the real device number of the FCP adapter device. The ATTACHED operand might also read BOX/ATTC, meaning that although the device is attached and dedicated to a user, it is unavailable. LINUX1, LINUX2, LINUX3, and TEST1 are user IDs to which the FCP devices are dedicated. The next number is the virtual device number which each virtual machine uses to refer to an FCP device. The last number is the CHPID number (channel path) associated with the device number. Any free, boxed, or offline devices within the device range are also included in the response.

**Note:** Use the QUERY FCP command to restrict responses to include only those FCP devices in a specific state, such as free, boxed, or offline.

Responses from Open Systems Adapter Devices:

If there are Open Systems Adapter devices attached to the system at the addresses specified, you see something like this:

```
q 480-48B
OSA 0480 ATTACHED TO PVM 0480
OSA 0481 ATTACHED TO PVM 0481
OSA 0482 ATTACHED TO RSCS 0482
OSA 0483 ATTACHED TO RSCS 0483
OSA 0484 OFFLINE, OSA 0485 OFFLINE, OSA 0486 FREE , OSA 0487 FREE
OSA 0488 FREE OSA 0489 FREE , OSA 048A FREE , OSA 048B FREE
Ready;
```

The first number is the real device number of the Open Systems Adapter devices. The ATTACHED operand might also read BOX/ATTC, meaning that although the device is attached and dedicated to a user, it is unavailable. PVM, RSCS, TCPIP, and VMNET are user IDs to which the OSA devices are dedicated. The last number is the virtual device number which each virtual machine uses to refer to an OSA device. Any free, boxed, or offline devices within the device range are also included in the response.

Specifying the ID option for a single device may display the following sense ID and control unit information:

```
q 4a1 id
OSA 4A1 1732-05 CU: 1731-05
Ready;
```

**Note:** Use the QUERY OSA command to restrict responses to include only those OSA devices in a specific state, such as free, boxed, offline, or system.

Responses from Real Dynamic Switching Devices:

If there is a dynamic switching device dedicated to a user, you see something like this:

```
q 0cd5
SWCH 0CD5 ATTACHED TO EMILY 0012
Ready;
```

This means that the switching device at the real device number OCD5 is attached to EMILY's virtual machine as the virtual device number 0012. ATTACHED may be replaced by BOX/ATTC, which indicates the dedicated switching device is not available (usually because of a hardware condition).

**Note:** Use the QUERY SWCH command to restrict responses to include only those SWITCH devices in a specific state, such as free, boxed, or offline.

Responses from Real Magnetic Tape Drives:

If there is a tape drive dedicated to a user, you see something like this:

```
q 102
TAPE 0102 ATTACHED TO RALPH 0236 R/W
Ready;
```

## QUERY (Real Device)

This means that the magnetic tape drive at the address 0102 is attached to RALPH's virtual machine as the virtual device number 0236. R/W means that the user RALPH has read-write access to the tape drive. R/W might also read R/O, which would mean that the user had read-only access. R/W and R/O represent the software's point of view, the hardware access control status may differ.

If the tape drive is currently being used by the TRSAVE command, you see something like this:

```
q 242
TAPE 0242 ASSIGNED SYSTEM TRSAVE
Ready;
```

If a tape that is not dedicated to a user is not available (boxed), you see something like this:

```
q 0244
TAPE 0244 BOXED
Ready;
```

If the tape drive is currently being unloaded following a DETACH command, or if CP is in the process of determining whether rewind is possible, you will see something like this:

```
q 246
TAPE 0246 UNLOADING
Ready;
```

If a tape drive has been attached MULTIUSER to one or more users, you see something like this:

```
q 2100
TAPE 2100 ATTACHED TO USER1    0181 R/W  NOASSIGN MULTIUSER
TAPE 2100 ATTACHED TO USER2    0181 R/W  NOASSIGN MULTIUSER
Ready;
```

This means that the tape drive at real address 2100 is attached to USER1 and USER2 at virtual device address 0181. MULTIUSER indicates that the tape drive is shared by both users, and NOASSIGN states that the users must manage the assignment of the tape drive by using assign and unassign I/O.

**Note:** Use the QUERY TAPES command to restrict responses to include only those tape devices in a specific state, such as free, boxed, or offline.

Responses from Real Unit Record Devices:

If a unit record device is dedicated to a user, you see something like this:

```
q 000c
RDR 000C ATTACHED TO JAMES 02F0
Ready;
```

This response means that the real card reader at the device number 000C is dedicated to JAMES's virtual machine at the virtual device number 02F0. RDR might be replaced by PRT or PUN, depending on the kind of unit record device. ATTACHED might be replaced by BOX/ATTC, which indicates that the device is attached to the virtual machine but is unavailable (usually because of a hardware problem).

*Responses from Active Readers:* If a reader is assigned to the system for spooling activity and it is currently active with a spool file, you see a message like this:

```
q 000C
RDR 000C STARTED SYSTEM
RDR 000C READING PERCY FILE 0021
Ready;
```

000C is the real device number of the card reader. STARTED indicates that the device is available for spooling activity. SYSTEM means that the device is available for input with user identification cards. STARTED might be replaced by any of the following:

- DRAINING, which means that the device would be unavailable for spooling activity as soon as it finished processing the current file.
- DRAINED, which means that the device was unavailable for spooling activity; you could enter the CP START command to restart it.

- INT REQ, which means that the device was not ready and required manual intervention before spool file processing could resume.

**Note:** If STARTED were replaced by any of the above options except DRAINING, the second line of the response would not appear.

SYSTEM might be replaced by a user ID, which means that the device was available for input without user identification cards. All input decks would be assigned to the user ID specified.

The second line of the response means that the card reader is currently active with a spool file. In this example, the reader at the real device number 000C is reading a card deck and creating a file that will be the user PERCY's spool file 0021.

*Responses from Active Printers:* If there is an impact printer in use as a system spooling device, you see a response like this:

```
q 0e0e
PRT 0E0E STARTED      SYSTEM CLASS 1          SEC JOBARO
PRT 0E0E FORM STANDARD MANUAL SEP  N03800  DEFFCB  LIMIT NONE
PRT 0E0E FOLD  IMAGE IMAG4248 CHARS      FCB FCB8      LPP 068
PRT 0E0E DEST OFF      DEST - NONE - DEST - NONE - DEST - NONE -
PRT 0E0E NOAFP
Ready;
```

This response tells you the following about the impact printer at the real device number 0E0E. The first line tells you that the printer will:

- Be available for spooling activity
- Process files for any user ID
- Select only class 1 spool files for processing
- Print files with a security label (SEC) of JOBARO.

**Note:** The security label field is displayed only when an external security manager is installed and security label checking is enabled.

The second line tells you that it will:

- Select files requesting the STANDARD form
- Wait for the operator to schedule forms output
- Generate a separator page for output files
- Not accept spool files that contain 3800 load CCWs
- Use the default forms control buffer that was loaded into it
- Process spool files regardless of their length.

The third line tells you that it will:

- Translate (fold) lower case characters into upper case
- Use the system image library file IMAG4248
- Not use a character set
- Use the forms control buffer FCB8.
- Print separator pages with 68 lines per page.

The fourth line tells you that the printer will not use destination values as a criterion for selecting files.

The fifth line tells you that the printer will not process files with advanced function printer (AFP) characteristics, that is, files that contain X'5A' CCWs or an extended attributes buffer (XAB). For more information about each line of the response, see the tables below.

You see a response like the following if there is a 3800 printer in use as a system spooling device and that printer is currently active with a spool file:

```
q 0f10
PRT 0F10 STARTED      SYSTEM CLASS *          SEC JOBARO
```

## QUERY (Real Device)

```
PRT 0F10 FORM STANDARD AUTO SEP ANY3800 LIMIT NONE
PRT 0F10 FLASH 0987 IMAGE IMAG3800 CHARS GF10 FCB 6 HOLD LPP 060
PRT 0F10 DEST OFF DEST - NONE - DEST - NONE - DEST - NONE -
PRT 0F10 AFP MARK
PRT 0F10 PRINTING DAVID FILE 0002 RECS 130K COPY 005 SEQ 001
Ready;
```

This response tells you the following about the printer at the real device number 0F10. The first line means that the printer will:

- Be available for spooling activity
- Process files for any user ID
- Select spool files regardless of class
- Print files with a security label (SEC) of JOBARO.

**Note:** The security label field is displayed only when an external security manager is installed and security label checking is enabled.

The second line tells you that the printer will:

- Select files requesting the STANDARD form
- Automatically schedule forms output
- Generate a separator page for output files
- Accept spool files that contain 3800 load CCWs
- Process spool files regardless of their length.

The third line tells you that the printer will:

- Use the forms overlay negative called 0987
- Use the system image library file IMAG3800
- Use the character set GF10
- Print six lines per inch
- Put spool files causing 3800 load checks into system HOLD status.
- Print separator pages with 60 lines per page.

The fourth line tells you that the printer will not use destination values as a criterion for selecting files.

The fifth line tells you that the printer will:

- Process files with advanced function printer (AFP) characteristics, that is, files that contain X'5A' CCWs or an extended attributes buffer (XAB).
- Mark separator trailer pages with separator bars.

The last line tells you the following:

- The printer is active with the spool file 0002, owned by the user DAVID.
- The number of records remaining for output in the file is 130K, where K is the number of records in thousands rounded to the nearest 1000. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines in millions rounded to the nearest million.
- There are five copies remaining for output.
- The sequence for the file on the printer is 001.

The parts of the first line of the response for impact printers and 3800 printers can also be:

Category	Possible Values	Meaning
Status	STARTED	Device is available for spooling activity.
	DRAINING	Device is processing a file, but will be drained after the file has printed.
	DRAINED	Device is not available for spooling activity. Issue the CP START command to activate the device.
	INT REQ	Device is not available; it needs manual intervention before it can continue to process spool files.
	SETUP REQ	Printer is ready to print an alignment page so that the operator can align the forms properly on an impact printer. The operator must press the STOP and START buttons to print another alignment page, or enter the START command to begin printing the entire file.
	MOUNT REQ	Printer is waiting for the operator to mount a new form.
User ID	SYSTEM	Device processes files for any user ID.
	<i>userid</i>	Device processes files only for the specified user ID.
Spool file class	CLASS <i>cl</i>	Device services spool files of the specified classes, in the specified order. An output device can service as many as 8 output classes.
Security Label	<i>seclabel</i>	Printer will print only those spool files with the specified security label (SEC). The ESM-authorized operator uses the START command to change the security label for a printer.
	NONE	Printer was not assigned a security label. No files can be printed until the printer is started with a valid security label. For more information, contact your security administrator.  <b>Note:</b> NONE and <i>seclabel</i> only appear if an external security manager (ESM) is installed and security label checking is enabled.

The parts of the second line of the response can be:

Category	Possible Values	Meaning
Form	FORM <i>form</i>	Device services the specified 1- to 8-character operator form number.

Category	Possible Values	Meaning
Scheduling	MANUAL	Operator schedules forms output. Only spool files with the form currently active on the device are processed. When the last spool file with the current form is printed, the printer stops.
	AUTO	Operator wants CP to schedule forms output. The form that is currently active is processed first. When all files with the current form have been printed, CP selects a new form for the device.
	SETUP	<p>Operator wants CP to print a page for forms alignment verification. (Only valid for impact printers.) The operator receives a message to set up the form. After setting up the form, the operator must press the STOP button, then the START button. An alignment page prints with letters replaced by X's and numbers replaced by 9's on the first page of the file.</p> <p>Each time the operator presses STOP and START after a full alignment page is printed, another alignment page prints. After aligning the forms, the operator enters the START command for the device. The printer then returns to its previous mode (AUTO or MANUAL), and the file prints in its entirety.</p> <p><b>Note:</b> If neither MANUAL, AUTO, nor SETUP is specified and the printer is currently in SETUP mode, it returns to the previous mode, AUTO or MANUAL. The default forms output is MANUAL.</p>
File separator	SEP	File separator prints between output files.
	NOSEP	File separator does not print between output files.
3800 load CCWs	NO3800	Printer does not print any spool files containing 3800 load CCWs. This option ensures a fast output queue, because load CCWs issued to 3800 printers can take a lot of time.
	BEG3800	Only spool files without 3800 load CCWs, or spool files with 3800 load CCWs only at the beginning of the file, print on this device. This allows the user an initial setup with which the entire file can be printed.
	ANY3800	Output device will process spool files regardless of whether they contain 3800 load CCWs. This option may cause a slower output queue, based on the number of 3800 load CCWs issued by the spool files.
Default FCB	DEFFCB	Printer uses the default FCB with which it was loaded. CP does not send imbedded LOAD FCB CCWs to the printer. The LOADBUF command specifies the default FCB.
	FILEFCB	<p>CP sends FCBs to the real printer. File FCBs are LOAD FCB CCWs imbedded in the spool file. This is the default when you start the printer after a cold start.</p> <p><b>Note:</b> DEFFCB and FILEFCB only appear for non-1403 impact printers.</p>

Category	Possible Values	Meaning
Length limit	LIMIT NONE	CP selects files for printing regardless of the number of records.
	LIMIT <i>nnnnnnnnnn</i>	CP only selects spool files for printing that are less than or equal to the specified number of records. The spool file record number is the number of copies multiplied by the size of the file.

The parts of the third line of the response can be:

Category	Possible Values	Meaning
Folding into upper case	FOLD	CP translates (folds) lower case characters into upper case.
	NOFOLD	CP does not translate lower case characters into upper case. <b>Note:</b> FOLD and NOFOLD only appear for impact printers.
Forms overlay negative	FLASH <i>name</i>	Printer uses the specified forms overlay negative, which is from 1 to 4 characters long. <b>Note:</b> FLASH only appears for 3800 printers.
Image library	IMAGE <i>imagelib</i>	Printer uses the specified system image library file, which contains the load images (character sets, FCBs, graphic character modifications, or copy modifications) used for printing files and separator pages.
Character set	CHARS <i>chars</i>	Printer uses the specified character set, which is from 1 to 4 characters long, when printing the separator page.
FCB	FCB <i>name</i>	For impact printers: printer uses the specified FCB when printing the file or the separator page. For 3800 printers: the FCB is the number of lines per inch. <b>Note:</b> FCB does not appear for 1403-type printers.
3800 load checks	HOLD	Printer puts spool files causing 3800 load checks in system HOLD status.
	PURGE	Printer deletes spool files causing 3800 load checks. <b>Note:</b> HOLD and PURGE only appear for 3800 printers.
Lines per page	LPP	Defines the number of lines for file separator pages on the printer.

The parts of the next-to-last line of this response can be:

Category	Possible Values	Meaning
Destination	DEST	Printer services the specified destination values. The printer can service up to 4 destination values. The first value for the device is always OFF if it was not specifically set by either a START command, or at initialization with the RDEVICE statement in the system configuration file. If it was set, the specified destination is shown. If the remaining destination values were not specified, the values are null and are shown as – NONE –. If they were specified, the specified value is shown.
AFP characteristics	AFP	Printer processes files with advanced function printer (AFP) characteristics, that is, files that contain X'5A' CCWs or an extended attributes buffer (XAB).
	NOAFP	Printer does not process files with AFP characteristics.
Mark separator trailer pages	MARK	Printer marks 3800 trailer pages with separator bars.
	NOMARK	Printer does not mark 3800 trailer pages with separator bars.

**Note:** MARK and NOMARK only appear for 3800 printers.

*Responses from Active Card Punches*

If a punch is attached to a user and is currently active with a spool file, you see a message like:

```
q 1f30
PUN 1F30 STARTED SYSTEM CLASS 1
PUN 1F30 FORM STANDARD AUTO NOSEP LIMIT NONE
PUN 1F30 DEST OFF DEST - NONE - DEST - NONE - DEST - NONE -
PUN 1F30 PUNCHING JAMES FILE 0042 RECS 012K COPY 002 SEQ 001
Ready;
```

This response tells you the following about the card punch at the real device number 1F30. The first line means that the punch will:

- Be available for spooling activity
- Process files for any user ID
- Select class 1 spool files.

The second line tells you that the punch will:

- Select files requesting STANDARD form
- Automatically schedule forms output
- Not generate a separator page for output files.

The third line tells you that the punch will not use destination values as a criterion for selecting files. The parts of the first line of the response can also be:

Category	Possible Values	Meaning
Status	STARTED	Device is available for spooling activity.
	DRAINING	Device is processing a file, but will be drained when the file is finished.
	DRAINED	Device is not available for spooling activity. Issue the CP START command to activate the device.
	INT REQ	Device is not available; it needs manual intervention before it can continue to process spool files.
	SETUP REQ	Punch is ready to generate an alignment page to let the operator align the forms properly on an impact printer. The operator must press the STOP and START buttons to print another alignment page, or enter the START command to begin printing the entire file.
	MOUNT REQ	Punch is waiting for the operator to mount a new form.
User ID	SYSTEM	Device processes files for any user ID.
	<i>userid</i>	Device processes files only for the specified user ID.
Spool file class	CLASS <i>cl</i>	Device services spool files of the specified classes, in the specified order. An output device can service as many as 8 output classes.

The options for the second line of the response can be:

Category	Possible Values	Meaning
Form	FORM <i>form</i>	Device services the specified 1- to 8-character operator form number.
Scheduling	MANUAL	Operator schedules forms output. Only spool files with the form currently active on the device are processed. When the last spool file with the current form is punched, the punch stops.
	AUTO	Operator wants CP to schedule forms output. The form that is currently active is processed first. After punching all files with the current form, CP selects a new form for the device.
File separator	SEP	File separator prints between output files.
	NOSEP	File separator does not print between output files.
Length limit	LIMIT NONE	CP selects files for punching regardless of the number of records.
	LIMIT <i>nnnnnnnnnn</i>	CP only selects spool files for punching that are less than or equal to the specified number of records. The spool file record number is the number of copies multiplied by the size of the file.

The options for the third line of the response can be:

Category	Possible Values	Meaning
Destination	DEST	Printer services the specified destination values. The printer can service up to 4 destination values. The first value for the device is always OFF if it was not specifically set by either a START command, or at initialization with the RDEVICE statement in the system configuration file. If it was set, the specified destination is shown. If the remaining destination values were not specified, the values are null and are shown as – NONE –. If they were specified, the specified value is shown.

The last line of this response only appears if there is a file active on the card punch. The line in the example above tells you that the punch at the real device number 1F30 is punching the spool file 0042, owned by the user JAMES. The number of records remaining for output in the file is 12K, where K is the number of records in thousands rounded to the nearest 1000. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines in millions rounded to the nearest million. There are two copies remaining for output. The sequence for the file on the punch is 001.

*Response from Boxed Unit Record Devices:* If a unit record that is not dedicated to a user is unavailable, you see a message like:

```
q 000F
RDR 000F BOXED
Ready;
```

000F is the real device number of the card reader that is unavailable. RDR might be replaced by PRT or PUN.

# QUERY RECORDING

## Authorization

Privilege Class: A, B, C, E, F

## Purpose

Use QUERY RECORDING to determine the status of:

- CP data collection for these records:
  - Accounting
  - EREP
- CP data collection for symptom records
- Active retrieval of these records.

## Operands

### REcording

requests the status of data collection for ACCOUNTING, SYMPTOM, CONFIG, and EREP records.

## Usage Notes

1. User IDs displayed in the output have previously connected successfully to the CP system service which supports the type of record being collected (\*ACCOUNT must be specified for ACCOUNT records, \*LOGREC for EREP records, and \*SYMPTOM for SYMPTOM records). The association to the recording function will remain until a cold start of the system is performed.
2. If the PENDING indication is ON and the record count has not decreased, an error has probably occurred, and data retrieval is not proceeding normally. The virtual machine retrieving the records should enter a SYSTEM RESET command and reinitiate data retrieval.
3. Class A and B users receive the status of all recording functions. Other users receive the status of the recording functions for which they are eligible to retrieve data records.

## Responses

Response 1:

RECORDING	COUNT	LMT	USERID	COMMUNICATION
function {ON } {OFF}	nnnnnnnn	mmm	userid	{INACTIVE } {ACTIVE [PENDING]}

### RECORDING

identifies the name of the recording function. ACCOUNT is the name used for accounting records, SYMPTOM is the name used for symptom records, CONFIG is the name used for configuration records, and EREP is used for error recording (for example, LOGREC records).

### ON

### OFF

identifies whether records are being saved for or sent to the userid specified.

**COUNT**

identifies the number of records pending in storage. If the count exceeds 99999999, this will be indicated by 99999999+ in the output.

**LMT**

identifies the threshold limit used to calculate when the system operator and retrieving virtual machine are notified that uncollected records are accumulating.

**USERID**

identifies the virtual machine eligible to retrieve the associated records. This user can alter selected fields in the CP recording table by using the RECORDING command.

**COMMUNICATION**

is the status of the virtual machine's communication with CP for record retrieval. INACTIVE means that the user must start communication with CP to begin record retrieval. ACTIVE means that the user has already initiated the communication. PENDING means that CP-to-virtual machine communication was initiated and CP sent a record to the virtual machine for retrieval.

**Messages**

- HCP003E Invalid option - *{option|command contains extra option(s) starting with option}*

## QUERY RELODOMAIN

### Authorization

Privilege Class: A, B, C, E

### Purpose

Use QUERY RELODOMAIN to list the members of one or more relocation domains. The command will display the SSI members to which a guest with the specified relocation domain may be relocated or will display all of the possible relocation domains and the members of each.

### Operands

#### ALL

specifies that the membership of all domains defined within the SSI cluster be listed. The list will include those implicitly defined domains such as the SSI domain and the domains that contain each single member (singleton domains).

#### SSI

specifies that membership of the SSI relocation domain is to be displayed. The SSI domain contains all members of the SSI cluster.

#### *domain\_name*

is the 1- to 8-character name of the relocation domain whose members are to be displayed.

### Usage Notes

1. The DEFINE RELODOMAIN command can be used to create installation-defined relocation domains.
2. For information about [Using Relocation Domains](#), see *z/VM: CP Planning and Administration*.

### Responses

Responses issued by QUERY RELODOMAIN

```
Domain domain_name members: mem1 mem2 mem3 mem4
This system is not a member of an SSI cluster.
```

This response can be issued with no members listed if the domain is a singleton domain for a member that has been deleted by a SET SSI SLOT *n* AVAILABLE command. No new virtual machines can be assigned to this domain.

### Messages

- HCP0002E Invalid operand - *operand*
- HCP0003E Invalid option - *option*
- HCP0013E Conflicting option - *option*
- HCP0026E Operand missing or invalid
- HCP1821E Relocation domain *domain\_name* does not exist

- HCP6706E Invalid string - *string*

## QUERY REORDER

### Authorization

Privilege Class: B, E

### Purpose

With the introduction of z/VM memory scalability up to 1T of real memory, the reorder process is no longer supported. The QUERY REORDER command remains for compatibility purposes but issuance of the command always indicates reorder is off.

### Operands

#### FOR USER

are optional keywords to aid in readability of the command.

#### *userid*

displays the reorder setting for the specified virtual machine.

#### \*

displays the reorder setting for the command issuer's virtual machine.

#### SYSTEM

displays the default system-wide setting.

### Usage Notes

1. The SYSTEM setting applies to the Shared Frame Owned list and the User Frame Owned list of every virtual machine in the system with the exception of those virtual machines for which a SET REORDER command was issued to override the SYSTEM default. Issue the QUERY REORDER *userid* command to see the setting for a specific virtual machine.

### Responses

Reorder is ON|OFF for user *userid*

Reorder default is ON|OFF for SYSTEM

### Messages

- HCP002E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP045E User not logged on

## QUERY RESERVED

### Authorization

Privilege Class: A, E

### Purpose

Use QUERY RESERVED to display the amount of reserved storage, along with the current resident storage and instantiated storage for a virtual machine, Named Saved Systems (NSS), or Discontiguous Saved Segment (DCSS) having a reserved storage setting.

### Operands

#### ALL

displays the reserved settings for all virtual machines, NSSs, and DCSSs, as well as the total for the system. This is the default.

#### USER

an optional keyword you can use when specifying a userid.

#### *userid*

\*

identifies the virtual machine whose reserved storage is to be displayed. To specify your own virtual machine, you may use an asterisk.

#### **NSS filename**

identifies a system data file containing an available NSS.

#### **DCSS filename**

identifies a system data file containing an available DCSS.

#### **SPOOLID spoolid**

identifies a system data file containing an available or pending purge NSS or DCSS.

#### **SYSMAX**

indicates the reserved storage system maximum should be displayed.

### Usage Notes

1. To avoid confusion with the CMS QUERY RESERVED command, you should enter the QUERY RESERVED command with the CP prefix (for example, cp query reserved all) or you should be in CP Read mode when you enter the command.

## QUERY RESERVED

- For readability, the storage values within a single line of the command response are displayed with the same storage unit. The values for the resident and instantiated storage may be rounded to accommodate the unit specification of the reserved setting. The reserved setting will never be rounded although it may be shown in a smaller unit than entered, when the resident or instantiated storage size is less than the reserved setting, in order to maintain the same storage unit across the line.

If you want precise values for the resident and instantiated counts, you should use the INDICATE USER or INDICATE NSS commands.

## Responses

Response 1:

The response to QUERY RESERVED ALL shows all existing reserved storage settings, along with the amount of storage resident and instantiated for those users, NSSs, and DCSSs having a reserved setting.

Resource	Type	SPID	Reserved	Resident	Instantiated
<i>userid1</i>	USER	----	<i>rsvstorU</i>	<i>resstorU</i>	<i>instanstorU</i>
<i>userid2</i>	USER	----	<i>rsvstorU</i>	<i>resstorU</i>	<i>instanstorU</i>
...					
<i>filename1</i>	NSS	<i>spid</i>	<i>rsvstorU</i>	<i>resstorU</i>	<i>instanstorU</i>
<i>filename2</i>	DCSS	<i>spid</i>	<i>rsvstorU</i>	<i>resstorU</i>	<i>instanstorU</i>
...					
	Totals		<i>rsvstorU</i>	<i>resstorU</i>	<i>instanstorU</i>

where:

### ***useridn***

identifies the virtual machine.

### ***filenamem***

identifies the Named Saved System or Discontiguous Saved Segment by name.

### **USER**

### **NSS**

### **DCSS|DCSSG**

identifies the type of resource as a virtual machine, Named Saved System, or Discontiguous Saved Segment.

----

four dashes are displayed to indicate a spool id is not applicable when Type=USER.

### ***rsvstorU***

is the reserved storage setting for this userid in storage units (K,M,G,T,P,E).

If the reserved value was specified as a count of frames on the SET RESERVED command, the value may be rounded to fit within 7-decimal digits plus a storage unit suffix.

### ***resstorU***

is the current resident storage size for this user, NSS, or DCSS in storage units (K,M,G,T,P,E) at the time the command is issued. This value may be rounded.

### ***instanstorU***

is the current instantiated storage size for this user, NSS, or DCSS in storage units (K,M,G,T,P,E) at the time the command is issued. This value may be rounded. Since guest pages can exist in multiple levels of the storage hierarchy (for example, in real storage and in auxiliary storage), the instantiated storage may be less than the storage size calculated by summing the page counts for real and auxiliary storage as shown in response to the INDICATE USER or INDICATE NSS command.

Response 2:

The response to QUERY RESERVED USER shows the reserved setting along with the amount of storage resident and instantiated for a single user.

Resource	Type	SPID	Reserved	Resident	Instantiated
<i>userid</i>	USER	----	<i>rsvstorU</i>	<i>resstorU</i>	<i>instanstorU</i>

Response 3:

The response to QUERY RESERVED NSS | DCSS | SPOOLID shows the reserved setting along with the amount of storage resident and instantiated for an NSS or DCSS.

Resource	Type	SPID	Reserved	Resident	Instantiated
<i>filename</i>	<i>type</i>	<i>spid</i>	<i>rsustorU</i>	<i>resstorU</i>	<i>instanstorU</i>

Response 4:

The response to QUERY RESERVED SYSMAX shows the maximum allowed reserved storage size along with the system maximum as a percentage of DPA and real online storage:

```
SYSMAX = nU    xxx% of pageable storage    yyy% of online storage
```

where:

**nU**

identifies the total maximum allowable amount of reserved storage for all users, NSSs, and DCSSs in storage units (K,M,G,T,P,E).

**xxx%**

specifies the system maximum as an approximate percentage of the Dynamic Paging Area (DPA). The percent value is rounded to the nearest whole percent. When the value is less than .5%, it is shown as <1%.

The size of the DPA varies over time. It includes available frames and those that are pageable at the time the command is issued. A system maximum near the size of DPA can have undesirable effects on performance.

**yyy%**

specifies the system maximum as an approximate percentage of real online storage. The percent value is rounded to the nearest whole percent. When the value is less than .5%, it is shown as <1%.

Response 5:

If a user, NSS, or DCSS does not have a reserved setting, the following is displayed:

```
RESERVED is OFF for userid|filename|SYSMAX
```

or

```
RESERVED is OFF for spoolid spoolid
```

Response 6:

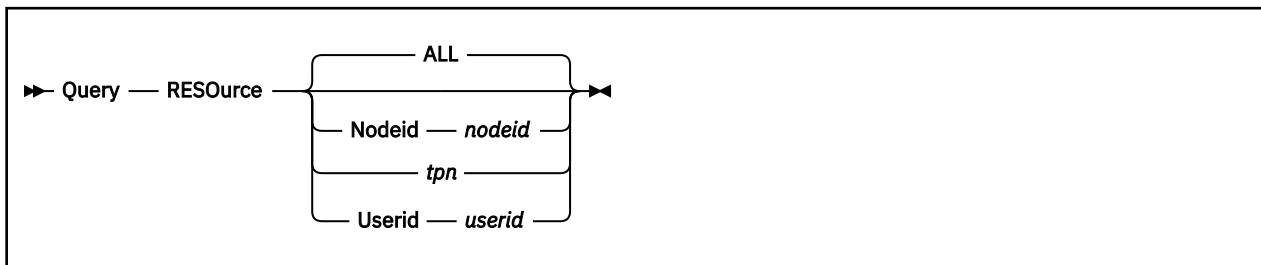

If there are no reserved frames, the following is displayed in response to the QUERY RESERVED ALL command:

```
There are no reserved frames.
```

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *{option|command}* contains extra option(s) starting with *option*
- HCP045E *userid* not logged on
- HCP2549E {NSS | DCSS} with {*spoolid spoolid* | *filename filename*} could not be found.
- HCP6704E Missing token at end of line.

## QUERY RESOURCE

### Authorization

Privilege Class: G

### Purpose

Use QUERY RESOURCE to display information about:

- Local, global, and system resources defined on the local z/VM system
- Global resources defined at the other domains in the Communication Services (CS) collection.

### Operands

#### ALL

displays information for all local, global, system resources defined on the local system and the global resources defined in the CS collection.

#### Nodeid *nodeid*

displays information for the global resources that are located at the node *nodeid*.

#### *tpn*

displays information for the specified global resource (transaction program).

#### Userid *userid*

displays information about resources owned by *userid* that are located on the local VM node.

### Responses

Response 1:

```
{Resource: resid} Type: Global Owing Nodeid: nodeid [via tnode]
{Service: stpn }
```

#### *resid*

specifies the resource ID of the global resource known in the CS collection.

#### *stpn*

specifies the hexadecimal name of a service transaction program.

#### *nodeid*

specifies the node ID of the system in the CS collection that owns the resource.

#### *tnode*

is the node through which the resource is known.

Response 2:

```
{Resource: resid} Type: restype Owing Userid: userid
{Service: stpn }
```

**resid**

specifies the resource ID of the local, global, or system resource defined at the local z/VM system.

**stpn**

specifies the hexadecimal name of a service transaction program.

**restype**

indicates if this is a local, global, or system resource.

**userid**

is the user ID on the local system that owns the resource.

Response 3:

```
Status: status.
```

**status**

indicates if an identify or a revoke is pending for the resource. This response is suppressed if the resource is identified.

Response 4:

```
No resources identified.
```

Response 5:

```
No resources identified by node nodeid.
```

**nodeid**

specifies the node ID that has no resources identified.

Response 6:

```
No resources identified by user userid.
```

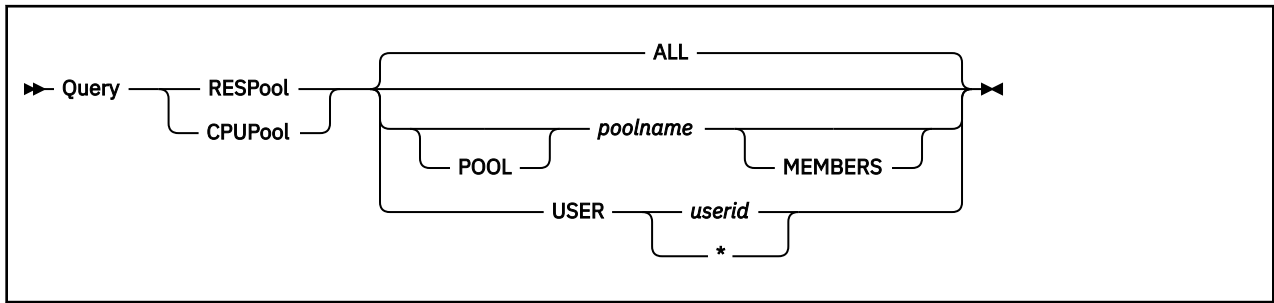

**userid**

is the user ID that has no resources identified.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid
- HCP2724E Resource *tpn* is undefined.

## QUERY RESPOOL

### Authorization

Privilege Class: A, E

### Purpose

Use QUERY RESPOOL to display information about resource pools that are defined on the system. For compatibility with prior releases, CPUPOOL is accepted as a synonym for RESPOOL.

### Operands

#### ALL

displays information about all resource pools defined on the system. This is the default.

#### *poolname*

#### **POOL** *poolname*

displays the definition of the specified resource pool, which includes the name of the pool, the pool resource limits, the type of CPU resource that is limited, and the number of users assigned to the pool.

#### **MEMBERS**

displays the names of the users assigned to the resource pool.

#### **USER** *userid*

#### **USER** \*

displays the name of the resource pool to which the specified user is assigned. If an asterisk (\*) is specified, the name of the resource pool for the user issuing the command is displayed.

### Usage Notes

1. Because the scope of a resource pool is a single z/VM system, the QUERY RESPOOL command returns information only about the system on which the command was issued. To obtain resource pool information for another z/VM system in an SSI cluster, use the AT command. For example, to display information about all of the resource pools on member VMSYS2 in the SSI cluster, issue the command:

```
at vmsys2 cmd query respool
```

2. If CPU affinity is suppressed for IFL processors and a resource pool in the response has a TYPE of IFL, the QUERY RESPOOL command response will include the following last line:

```
CPU Affinity is suppressed for CPU type IFL
```

3. Because the scope of a resource pool is a single z/VM system, guest relocation essentially removes the user from the resource pool on the source system and assigns the user to the resource pool on the destination system. From the time a VMRELOCATE MOVE command starts until the user is moved to the destination system and can consume its resources, the user is reported on the destination system as an "incoming user" in QUERY responses. The count of resource pool members includes

these incoming users, so the resource pool cannot be deleted. However, the names of incoming users are not displayed in the response to a QUERY RESPOOL *poolname* MEMBERS command because they are not yet consuming or being limited by pool resources. After an incoming user can consume pool resources, its name is included in the QUERY response. There is a short period of time when that user ID will be a skeleton LOGNMxxx ID.

## Responses

Response 1:

The following response is displayed for QUERY RESPOOL ALL if no resource pools are defined:

```
No resource pools exist
```

Response 2:

The following example shows the format of the response to QUERY RESPOOL ALL when resource pools are defined. Each line under the heading contains the definition of a resource pool, which includes the name of the pool, the pool limits, the type of CPU resource that is limited, and the number of users assigned to the pool.

Pool name	CPU	Type	Storage	Trim	Members
LINUXP2	8.00 Cores	IFL	NoLimit	----	0
LINUXP1	NoLimit	IFL	NoLimit	----	6
CPPOOL10	12 %	CP	NoLimit	----	8
LINUXP3	30 %	IFL	NoLimit	----	20

In this example there are four resource pools. Resource pool LINUXP2 has a CAPACITY limit for IFL processors and no storage limit. Resource pool LINUXP1 has no CPU limit and no storage limit. Resource pool CPPOOL10 has a LIMITHARD limit for CP processors and no storage limit. Resource pool LINUXP3 has a LIMITHARD limit for IFL processors and no storage limit.

If a defined resource pool is of type IFL and there are no IFL processors on the system, the following is displayed as the last line of the response:

```
CPU Affinity is suppressed for CPU type IFL
```

Response 3:

The response to QUERY RESPOOL *poolname* displays the definition of the specified resource pool, as in this example:

Pool name	CPU	Type	Storage	Trim	Members
LINUXP1	NoLimit	IFL	NoLimit	----	6

Response 4:

The response to QUERY RESPOOL *poolname* MEMBERS displays the definition of the specified resource pool and lists the members of the pool, five per line, as in this example:

Pool name	CPU	Type	Storage	Trim	Members
LINUXP1	NoLimit	IFL	NoLimit	----	6
The following users are members of resource pool LINUXP1:					
D70LIN12	D79LIN03	D79ADM	D79LIN10	D79LIN07	
D79LIN04					

If there are no IFL processors on the system, the following is displayed as the last line of the response:

```
CPU Affinity is suppressed for CPU type IFL
```

Response 5:

## QUERY RESPOOL

The following example shows the response to `QUERY RESPOOL poolname MEMBERS` if the specified resource pool has no members:

```
Pool name      CPU    Type  Storage Trim Members
LINUXP2      8.00 Cores  IFL  NoLimit ----      0
Resource pool LINUXP2 has no members
```

Response 6:

The following example shows the response to `QUERY RESPOOL poolname MEMBERS` if the specified resource pool has two members that are being relocated from another system. One member has a relocation skeleton user ID (LOGNM012) and can consume pool resources, whereas the other is still incoming.

```
Pool name      CPU    Type  Storage Trim Members
LINUXP4      8.00 Cores  IFL  NoLimit ----      2
Resource pool LINUXP4 has incoming members
The following users are members of resource pool LINUXP4:
LOGNM012
```

Response 7:

The following response to `QUERY RESPOOL USER userid` is displayed if the specified user is assigned to a resource pool:

```
User userid is in resource pool poolname
```

Response 8:

The following response to `QUERY RESPOOL USER userid` is displayed if the specified user is not assigned to any resource pool:

```
User userid is not in a resource pool
```

## Messages

- HCP002E Invalid operand — *operand*

## QUERY RETRIEVE

### Authorization

Privilege Class: G

### Purpose

Use QUERY RETRIEVE to display the number of program function (PF) key RETRIEVE buffers available to your virtual machine and the maximum number of program function key RETRIEVE buffers available to users on the system. You can also use QUERY RETRIEVE to display the contents of the program function key RETRIEVE buffers.

### Operands

#### COUnts

displays the number of program function (PF) key RETRIEVE buffers available to your virtual machine and the maximum number of program function key RETRIEVE buffers available to users on the system. COUNTS is the default.

#### BUffers

displays the contents of the program function key RETRIEVE buffers.

### Usage Notes

1. CP initially sets the number of buffers available to your virtual machine to the system default, which is defined in the system configuration file with the FEATURES statement. If a default has not been specified in the system configuration file, CP allocates seven RETRIEVE buffers for your virtual machine. For more information on the system configuration file, see the [FEATURES Statement](#) in *z/VM: CP Planning and Administration*.
2. Use the SET RETRIEVE command to request a certain number of PF key RETRIEVE buffers. If you are a class C or class E user, you can use the SET RETRIEVE command to change the maximum number of PF key RETRIEVE buffers available to all users.

For more information, see [“SET RETRIEVE”](#) on page 1681.

3. It is possible that the number of PF key RETRIEVE buffers allocated for your virtual machine may exceed the maximum number established for other users on the system. When the maximum number of PF key RETRIEVE buffers available to users is decreased, buffers already allocated to users are not deleted.

### Responses

Response 1:

If you enter QUERY RETRIEVE COUNTS, you receive the following response:

```
nnn buffers available. Maximum of mmm buffers may be selected.
```

The number of buffers available to your virtual machine will be zero if you have not set a PF key for the retrieve function or defined a value with the SET RETRIEVE command.

## QUERY RETRIEVE

Response 2:

If you enter QUERY RETRIEVE BUFFERS, you receive the following response:

Position	Contents....
7	<i>cmd7</i>
6	<i>cmd6</i>
5	<i>cmd5</i>
4	<i>cmd4</i>
3	<i>cmd3</i>
2	<i>cmd2</i>
1	<i>cmd1</i>

The most recent command is displayed last.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *operand*

## QUERY RSAW

### Authorization

Privilege Class: B

### Purpose

Use QUERY RSAW to generate and display the remote service access word (RSAW) for storage clusters in the DASD subsystem.

### Operands

**CLUSTER ALL**

**CLUSTER 1**

**CLUSTER 0**

indicates the storage clusters from which the remote service access word is to be fetched. ALL is the default.

**rdev**

is the real device number of one of the devices in the subsystem.

### Usage Notes

1. The Storage Subsystem Support Facility supports subsystem error recovery, maintenance, diskette drive operations, and the operator panel. The remote service access word is generated by the Support Facility and is recognized by that Support Facility to allow remote maintenance attachment.
2. This command may be issued to offline devices.

### Responses

Response 1:

```
rdev RSAW is nnnn for cluster n, serial number sssss.
```

This response is repeated for each storage cluster if CLUSTER ALL is specified.

**rdev**

is the real device number specified in the command.

**nnnn**

is the requested remote service access word.

**n**

is the storage cluster number. Storage clusters contain storage directors and storage paths.

**sssss**

is the storage control unit serial number.

Response 2:

```
rdev Subsystem support facility is unavailable.
```

This response is repeated for each storage cluster if CLUSTER ALL is specified.

***rdev***

is the real device number specified in the command.

Response 3:

```
rdev Remote service is not enabled.
```

This response is repeated for each storage cluster if CLUSTER ALL is specified.

***rdev***

is the real device number specified in the command.

### Messages

- HCP006E Invalid device type - {*rdev/vdev/ldev*}
- HCP009E Invalid range - *range*

- HCP1109E The *command* command cannot be processed for device *rdev* because the device is the secondary in a duplex pair.

## QUERY SCMBKS

► Query — SCMBKS ◄

### Authorization

Privilege Class: B, E

### Purpose

Use QUERY SCMBKS to display the:

- Total number of subchannel measurement blocks (SCMBKs) that CP allocated, and
- Number (and percentage) of SCMBKs that are not currently being used.

### Usage Notes

**Format-1 measurement blocks:** When format-1 measurement blocks are being used, measurement blocks are allocated dynamically.

1. SCMBKs are used to accumulate data about a subchannel, such as rate and utilization information. This subchannel measurement data, which CP Monitor collects in various monitor records, can be useful for analyzing the I/O performance characteristics of a real device.

**Format-0 measurement blocks:** See the notes below.

1. During initialization, CP allocates 1 SCMBK for every subchannel on the system and rounds the amount of storage up to the nearest page boundary. Thus, you have enough SCMBK space for every real device on your system plus some free SCMBK space. How much free SCMBK space you have will vary, depending upon how many real devices you have on your system.
2. You should plan for additional SCMBK space if you intend to dynamically add new real devices to your running system. At initialization, you can allocate more free SCMBK space than CP would normally allocate using the SCMBK operand of the STORAGE statement in the system configuration file. For more information, see [STORAGE Statement](#) in *z/VM: CP Planning and Administration*.
3. If you run out of free SCMBK space on a running system and you need to measure additional real devices, you have two choices:
  - a. Re-IPL and specify more free SCMBK space using the SCMBK operand, or
  - b. Stop collecting subchannel measurement data for one or more devices. When you use one of the following commands:
    - DELETE DEVICE (see [“DELETE DEVICE / IODEVICE”](#) on page 265)
    - DELETE IODEVICE (see [“DELETE DEVICE / IODEVICE”](#) on page 265)
    - DELETE RDEVICE (see [“DELETE RDEVICE”](#) on page 274)
    - SET SCMEASURE OFF (see [“SET SCMEASURE”](#) on page 1685)

CP returns the SCMBK assigned to that device (or devices) to the pool of available SCMBKs. It is then available to be used to collect subchannel measurement data for another device.

### Responses

To see information about the number of SCMBKs that CP allocated and information about the free SCMBK space, enter the following QUERY SCMBKS command:

## QUERY SCMBKS

Response 1:

```
query scmbks
Total SCMBKs= 1024 (pages= 8), Free SCMBKs= 77 (7%)
Ready;
```

This response tells you that CP allocated 1024 SCMBKs (which takes up 8 pages of storage) and all but 77 of the SCMBKs are in use, which is roughly 7% of the total SCMBK space.

Response 2:

```
query scmbks
Total SCMBKs= 31 (pages= 1), Free SCMBKs= 0 (0%) dynamically allocated
Ready;
```

This response tells you that CP allocated 31 SCMBKs (which took up 1 page of storage). Dynamically allocated means format-1 measurement blocks are being used. In this case, free SCMBKs will always be zero.

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with - *option*

## QUERY SCMEASURE

### Authorization

Privilege Class: B, E

### Purpose

Use QUERY SCMEASURE to display whether subchannel measurement data is being collected for a specific device or range of devices.

### Operands

**rdev**

**rdev1-rdev2**

is the real device number (or numbers) of the device for which you want to display subchannel measuring status. The variable *rdev* must be a hexadecimal number between X'0000' and X'FFFF'. You can specify a single device address, a range of device addresses, or any combination thereof.

### Usage Notes

1. Subchannel measurement blocks (SCMBKS) are used to accumulate data about a subchannel, such as rate and utilization information. This subchannel measurement data, which CP Monitor collects in various monitor records, can be useful for analyzing the I/O performance characteristics of a real device.
2. To enable or disable the collecting of subchannel measurement data for one or more devices, use the SET SCMEASURE command (see [“SET SCMEASURE” on page 1685](#)).
3. When a device is first initialized, the default is to enable it for collecting subchannel measurements. To change this initial default, use the SCMEASURED or NOTSCMEASURED operands of the DEVICES statement in the system configuration file. For more information about the [DEVICES Statement](#), see *z/VM: CP Planning and Administration*.
4. Error messages produced for this command may vary depending on how the device was specified on the command line.

When a single device is listed on the command line, an error will be reported if there is no query information available for the single device. For example:

```
query scmeasure 102
Device 0102 does not exist
Ready(00040);
```

When a range of devices is listed on the command line, only devices that have query information available are shown. Error messages are not issued for individual devices within the range. For example:

```
query scmeasure 100-105
Subchannel measuring for device 103 is on
Subchannel measuring for device 104 is off
Ready;
```

## QUERY SCMEASURE

If query information is not available for at least one device in a range, then a generic error message will be issued. For example:

```
query scmeasure 100-102
HCPCHC1003E 0100-0102 was not found
Ready (01003);
```

## Responses

Response 1:

To find out whether CP is collecting subchannel measurement data for device 131, enter the following QUERY SCMEASURE command:

```
query scmeasure 131
Subchannel measuring for device 0131 is on
Ready;
```

Response 2:

To find out which devices CP is collecting subchannel measurement data for in the device range 750 through 759, enter the following QUERY SCMEASURE command:

```
query scmeasure 750-759
Subchannel measuring for device 0750 is off
Subchannel measuring for device 0751 is off
Subchannel measuring for device 0752 is on
Subchannel measuring for device 0753 is on
Subchannel measuring for device 0754 is on
Subchannel measuring for device 0755 is off
Subchannel measuring for device 0756 is on
Subchannel measuring for device 0757 is on
Ready;
```

This example shows that:

- CP is not collecting subchannel measurement data for devices 750, 751, and 755
- CP is collecting subchannel measurement data for devices 752, 753, 754, 756, and 757

## Messages

- HCP003E Invalid option - *option*
- HCP009E Invalid range - *rdev-rdev*
- HCP021E A real device number was not supplied or it is invalid.
- HCP040E Device *rdev* does not exist

- HCP6706E Invalid RDEV - *rdev*. RDEV not initialized

## QUERY SCREEN

► Query — SCReen ◄

### Authorization

Privilege Class: G

### Purpose

Use QUERY SCREEN to display the extended color and highlight values governing your console.

### Usage Notes

1. The extended color and highlighting values are set either by the SCREEN statement in your directory entry or when you enter the SCREEN command.
2. If you do not have a SCREEN directory statement in your directory entry and you have not issued the SCREEN command during the current session, the response to the QUERY SCREEN command is DEFAULT for the color value and NONE for the extended highlight value.

### Responses

Response 1:

CPOUT	<i>color</i>	<i>exthilight</i>	VMOUT	<i>color</i>	<i>exthilight</i>
INREDISP	<i>color</i>	<i>exthilight</i>	INAREA	<i>color</i>	<i>exthilight</i>
STATAREA	<i>color</i>	<i>exthilight</i>			

#### ***color***

identifies the color value currently in effect for your virtual console.

#### ***exthilight***

identifies the extended highlight value currently in effect for your virtual console.

### Messages

- HCP003E Invalid option - *{option|command}* contains extra option(s) starting with *option*

## QUERY SDF

► Query — SDF ◄

### Authorization

Privilege Class: A, B, C, D, E, G

### Purpose

Use QUERY SDF to display a count of all system data files.

### Usage Notes

1. Counts of the various types of system data files are displayed only to specific classes of users:
  - a. IMG files to class A, B, C, D, and E users
  - b. NSS files to class E users
  - c. UCR files to class A, B, and C users
  - d. NLS files to class E users
  - e. TRF files to class A, C, D, E, and G users
  - f. For a class G user, only the number of TRF files that the class G user owns is displayed.
2. QUERY SDF ALL returns the same information as QUERY SDF.

### Responses

Response 1:

```
FILES: [ {nnnn} IMG ] [ , {nnnn} NSS ] [ , {nnnn} UCR ] [ , {nnnn} TRF ] [ , {nnnn} NLS ]
       [ { NO} ] [ { NO} ] [ { NO} ] [ { NO} ] [ { NO} ]
```

#### **nnnn**

is the number of system data files of each type.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP413E Command processing cannot complete due to a spool paging error.
- HCP422E The same option was specified twice.
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP848E SYSTEM parameter is invalid with the spoolid option
- HCP849E A *userid* must be specified with the spoolid
- HCP1558E Command processing cannot complete.

## QUERY SECUSER

### Notes:

- <sup>1</sup> If QUERY SECUSER is executed with the AT command, the ALL or *userid* operand is required.
- <sup>2</sup> ALL is not valid for class G users.
- <sup>3</sup> A class G user may specify only the user's own user ID.

## Authorization

Privilege Class: A, B, C, G

## Purpose

Use QUERY SECUSER to determine the secondary user setting for a virtual machine (the primary user). CP displays the identity and status of the secondary user. If you are a class G user, you can display the secondary user setting for your own virtual machine. If you are a class A, B, or C user, you can display the secondary user setting for any virtual machine or for all local virtual machines that have secondary users defined.

## Operands

**\***

displays the secondary user setting for the user who issues the command. This is the default.

**ALL**

displays the secondary user setting for all local users currently logged on or disconnected that have secondary users defined.

***userid***

identifies the user whose secondary user setting is to be displayed.

## Usage Notes

1. The initial setting for your secondary user ID is determined by the CONSOLE statement in your user directory entry.
2. A virtual machine cannot have both a secondary user and an observer defined by any combination of the SET SECUSER and SET OBSERVER commands and the CONSOLE directory statement.
3. In an SSI cluster, the primary user and secondary user can be logged on to different member systems.

If either user is a multiconfiguration virtual machine:

- The secondary user will function in that capacity only when it is local (logged on to the same member as the primary user). If the primary user is a multiconfiguration virtual machine, the secondary user must be logged on to the same member as the instance of the primary user for which the secondary user setting was established:
  - If the setting was established by a CONSOLE statement in the identity entry in the primary user's virtual machine definition, a potential secondary user relationship exists for every member instance of the primary user.

## QUERY SECUSER

- If the setting was established by a CONSOLE statement in a subconfiguration entry in the primary user's virtual machine definition, a potential secondary user relationship exists for that member instance of the primary user.
  - If the setting was established by a SET SECUSER command, a potential secondary user relationship exists for the member on which the SET SECUSER command was issued.
  - If the secondary user is remote:
    - The secondary user can issue SEND commands to the primary user. The AT *sysname* operands are required if the primary user is a multiconfiguration virtual machine instance.
    - The secondary user will not receive responses to SEND commands or any other output from the primary user.
4. If your virtual machine requests console input while disconnected and you do not have a functional secondary user, CP waits for some installation-defined period of time (usually 15 minutes) for you to reconnect. If you do not reconnect within that time, CP logs you off the system.

### Responses

Responses 1 through 5 are returned if you issue the QUERY SECUSER command without any additional operands.

Response 1:

```
SECONDARY USER userid IS DISCONNECTED
```

is returned if a secondary user is defined for your virtual machine (on the CONSOLE statement in your virtual machine definition or on a SET SECUSER command), and that user is disconnected.

If you disconnect from the system, the result is the same as if no secondary user ID was defined, unless the secondary user's virtual machine handles console I/O through the message system service. In this case, secondary console support is provided to your disconnected virtual machine. If the secondary user reconnects, it can provide secondary console functions for your virtual machine.

Response 2:

```
SECONDARY USER userid IS NOT LOGGED ON
```

is returned if a secondary user is defined for your virtual machine (on the CONSOLE statement in your virtual machine definition or on a SET SECUSER command), and that user is not logged on.

If you disconnect from the system, the result is the same as if no secondary user ID was defined. If the secondary user logs on, it can provide secondary console functions for your virtual machine.

Response 3:

```
SECONDARY USER userid IS LOGGED ON
```

is returned if a secondary user is defined for your virtual machine (on the CONSOLE statement in your virtual machine definition or on a SET SECUSER command), and that user is capable of providing secondary console support for you.

If you, the primary user, disconnect from the system, that secondary user receives your console output until you reconnect or log off. The secondary user may provide console input to your virtual machine or to CP on your behalf by using the SEND command.

Response 4:

```
SECONDARY USER IS UNDEFINED
```

is returned if a secondary user is not defined for your virtual machine. If you disconnect from the system, your console output is lost until you reconnect. If you have spooled your console output, it is retained in your console spool file.

Response 5:

```
SECONDARY USER IS NOT LOGGED ON LOCALLY
```

is returned if all of the following conditions are true:

- This system is a member of an SSI cluster.
- You, the primary user, are defined as a multiconfiguration virtual machine.
- A secondary user is defined for your virtual machine on this member of the cluster (on a CONSOLE statement in the subconfiguration entry for this member in your virtual machine definition, or on a SET SECUSER command issued on this member).
- That user is not logged on to this member of the cluster. (The user might be logged on to another member.)

No console output from your virtual machine will be sent to the secondary user. See usage note [“3” on page 1153](#).

Response 6:

```
FAILED MAC CHECK
```

is returned if security label checking by an external security manager (ESM) is active and the primary/secondary user relationship fails the mandatory access control checks.

Response 7: If you issue the QUERY SECUSER command with an additional option and the secondary user is disconnected, CP responds with a display that looks like this:

```

Userid      Secondary
MAINT      Userid    Status
          DAVID  disconnected
    
```

The Status column in the display might also contain "not logged on", "logged on", "not defined", "not logged on locally", or "failed MAC check".

Response 8: If a class A, B, or C user issues QUERY SECUSER ALL, CP displays the current secondary user settings for all users that are currently logged on or disconnected. If no currently logged on users have a secondary user defined, CP issues the following response:

```
No secondary users defined or active.
```

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP045E *userid* not logged on
- HCP1149E Error communicating with another SSI member. It cannot be determined if *command* executed remotely.

## QUERY SET

► Query — Set ◄

### Authorization

Privilege Class: G

### Purpose

Use QUERY SET to display the status of many SET command functions.

### Operands

#### Set

requests a display of the status of the SET command functions.

### Responses

Response 1:

```

MSG {ON } , WNG {ON } , EMSG {ON } , ACNT OFF , RUN {ON }
  {OFF }      {OFF }      {OFF }      {OFF }

  {OFF }      {OFF }      {ENABLED}
  {ACTIVE }

```

#### **370ACCOM ON**

#### **370ACCOM OFF**

indicates whether 370-only CMS applications can run in XA, ESA, or XC virtual machines. Note that a guest in z/Architecture mode or z/XC mode can not have 370ACCOM on.

#### **370E OFF**

appears for compatibility purposes.

**ACNT OFF**

appears for compatibility purposes.

**AFFINITY NONE**

appears for compatibility purposes.

**ASSIST OFF**

appears for compatibility purposes.

**AUTOPOLL ON****AUTOPOLL OFF**

indicates whether CP or your virtual machine detects changes to virtual autopolling channel programs. ON specifies that your virtual machine must notify CP that a change has been made to a virtual autopolling channel program. OFF specifies that CP tests for changes to virtual autopolling channel programs.

**CCWTRAN ON**

appears for compatibility purposes.

**CONCEAL ON****CONCEAL OFF**

indicates whether the virtual machine is running in a protected application environment. ON indicates that certain error conditions and virtual machine state changes detected by CP will result in an automatic re-IPL of the virtual machine. OFF indicates that the virtual machine will stay in whatever environment it was in when the error occurred.

**CPCONIO OFF****CPCONIO IUCV**

controls the destination of any CP-generated output. OFF indicates that the output is displayed at the terminal. IUCV indicates that the output is sent to the virtual machine through IUCV if a connection to the message system service exists. If no IUCV connection exists, data is handled as if CPCONIO were set to OFF.

**DIALDROP ON****DIALDROP OFF**

indicates whether devices DIAled to your virtual machine are dropped (ON) or stay connected (OFF) when a reset occurs (for example, when an IPL or SYSTEM CLEAR command is issued). Such a device is always dropped when an explicit DETACH or RESET command is issued for the associated virtual device.

**ECMODE ON**

appears for compatibility purposes.

**EMSG ON****EMSG OFF****EMSG CODE****EMSG TEXT****EMSG IUCV**

indicates how error messages are to be edited and displayed. ON indicates that both the error code and the message text are displayed. OFF indicates that no error messages will be displayed. CODE indicates that only the error code is displayed. TEXT indicates that only the error message text are displayed. IUCV indicates that both the error code and error message text are passed to the virtual machine through IUCV if a connection to the message system service exists. If no IUCV connection exists, the error message is handled as if EMSG were set ON.

**IMSG ON****IMSG OFF****IMSG IUCV**

indicates whether informational messages associated with certain CP commands are to be displayed. ON specifies that informational responses are displayed. OFF specifies that the responses are not displayed. IUCV specifies that the informational responses are passed to the virtual machine through IUCV if a connection to the message system service exists. If no IUCV connection exists, the responses are handled as if IMSG were set ON.

## QUERY SET

### **ISAM OFF**

appears for compatibility purposes.

### **LINEDIT ON**

### **LINEDIT OFF**

indicates whether line-editing functions and symbols are to be used to edit virtual console input. ON indicates that the system line editing functions are used. OFF indicates that no character or line editing is used for the virtual machine operating system.

### **MACHINE ESA**

### **MACHINE XA**

### **MACHINE XC**

### **MACHINE Z**

indicates the architecture setting of your virtual machine:

#### **ESA**

indicates an ESA virtual machine, which simulates ESA/390 architecture. A guest can switch the virtual machine between ESA/390 and z/Architecture.

#### **XA**

indicates an XA virtual machine, which is functionally equivalent to an ESA virtual machine.

#### **XC**

indicates an XC virtual machine, which simulates ESA/XC architecture. The guest can switch the virtual machine between ESA/XC and z/XC architecture.

#### **Z**

indicates a z/Architecture virtual machine, which simulates only the z/Architecture.

**Note:** An ESA (or XA) virtual machine runs in either full ESA/390 mode or ESA/390 compatibility mode, depending on the level of ESA/390 capability available in the machine where the virtual machine is logged on or in the virtual machine's relocation domain.

### **MIH ON**

### **MIH OFF**

ON specifies that CP handles any detected missing interrupt conditions. OFF specifies that CP does *not* handle any detected missing interrupt conditions.

### **MSG ON**

### **MSG OFF**

### **MSG IUCV**

indicates whether messages sent from other users by means of the CP MESSAGE command are to be displayed. ON specifies that messages are displayed. OFF specifies that messages are not displayed. IUCV specifies that messages are passed to the virtual machine through IUCV if a connection to the message system service exists. If no IUCV connection exists, the message is handled as if MSG were set ON.

### **NOPDATA ON**

### **NOPDATA OFF**

controls whether NOP CCWs are simulated as data transfer CCWs for spooled punches and printers of your virtual machine. ON indicates that for more than one byte of data, CP attempts to transfer the data addressed by a NOP CCW to the spool file. OFF indicates that CP simulates the NOP the same way a real device and channel does.

### **NOTRAN OFF**

appears for compatibility purposes.

### **PAGEX ON**

### **PAGEX OFF**

indicates whether the pseudo page fault facility is activated for your virtual machine. ON specifies that the facility is activated. OFF specifies the facility is deactivated.

### **RUN ON**

### **RUN OFF**

indicates whether your virtual machine begins to run after you enter something from your terminal, and also indicates whether it runs when a CP READ status is showing. ON indicates that your virtual

machine runs when CP READ status is showing and switches to RUNNING following the entry. OFF specifies that your virtual machine does not run when CP READ status is showing, and will remain in CP READ status following the entry.

**SMSG ON****SMSG OFF****SMSG IUCV**

specifies whether a virtual machine is receiving special messages. OFF indicates the virtual machine cannot receive special messages. ON indicates the virtual machine can receive special messages. IUCV indicates the special messages are passed to the virtual machine through IUCV if a connection to the message system service exists. If no IUCV connection exists, the special messages are handled as if SMSG were set OFF.

**STBYPASS OFF**

appears for compatibility purposes.

**STMULTI OFF**

appears for compatibility purposes.

**SVC76 CP****SVC76 VM**

indicates how SVC 76 instructions issued by a virtual machine are processed by CP. The designation CP specifies that the virtual machine's error records are recorded by CP error recording facilities, if the virtual machine is running in supervisor state. The designation VM specifies that no errors are recorded and all SVC 76 operations are processed by the virtual machine.

**SVCACCL OFF**

appears for compatibility purposes.

**TIMEBOMB IDLE****TIMEBOMB OFF****TIMEBOMB ENABLED****TIMEBOMB ACTIVE**

displays the dynamic virtual machine time bomb setting. ENABLED means that the time bomb function is initialized but no expiration time is currently set. ACTIVE means that the time bomb function is initialized and an expiration time is currently set. IDLE means that the time bomb function is not initialized. OFF means that the time bomb function is initialized but has been disabled by a SET TIMEBOMB OFF command.

**TIMER ON****TIMER OFF****TIMER REAL**

indicates whether the virtual interval timer is to be updated. ON specifies that the virtual interval timer is updated during virtual processor run time. OFF specifies that the virtual interval timer is not updated. REAL specifies that the virtual interval timer is updated during virtual processor run time and also during virtual wait time. SET 370ACCOM must be set to ON.

**VMCONIO OFF****VMCONIO IUCV**

controls the destination of any virtual machine generated output. This includes any CMS error messages and any line mode I/O done by the virtual machine to the virtual console. OFF indicates that output is displayed at the terminal. IUCV indicates that output is sent to the virtual machine through IUCV if a connection to the message system service exists. If no IUCV connection exists, data is handled as if VMCONIO were set to OFF.

**VMSAVE OFF**

appears for compatibility purposes.

**WNG ON****WNG OFF****WNG IUCV**

indicates whether warning messages sent from an authorized user through the WARNING command are received at your display. ON specifies that warning messages are displayed. If OFF is specified, no warning messages are displayed. IUCV specifies that warning messages are passed to the virtual

## QUERY SET

machine through IUCV if a connection to the message system service exists. If no IUCV connection exists, the warning message is handled as if WNG were set ON.

### Messages

- HCP003E Invalid option - *{option|command}* contains extra option(s) starting with *option*

## QUERY SHARE

```
► Query — SHARE — userid ◄
```

### Authorization

Privilege Class: A, E

### Purpose

Use QUERY SHARE to display the type and intensity of a user's share of the system. The share values are displayed for all processor types.

### Operands

#### *userid*

is the virtual machine whose share you want to display.

### Usage Notes

- You can set a user's system-resource-access priority for each processor type with the SET SHARE command, but some of these processor types are not available in certain processor configurations. The share values are still displayed for the unavailable processor types, but they are not used.

### Responses

Response 1:

The following response is returned to the command issuer:

```
USER userid: CP   share_type SHARE = value
                MAXIMUM SHARE = option share_type value
             IFL share_type SHARE = value
                MAXIMUM SHARE = option share_type value
             ICF share_type SHARE = value
                MAXIMUM SHARE = option share_type value
             ZIIP share_type SHARE = value
                MAXIMUM SHARE = option share_type value
```

#### **ABSOLUTE SHARE = *nnn%***

appears for users with an absolute share. The operand *nnn%* specifies the percent of system resources this user is allowed to access.

#### **RELATIVE SHARE = *nnnnn***

appears for users with a relative share. The operand *nnnnn* specifies the relative priority of access to system resources, when compared to all other users with relative shares.

#### ***m* DEDICATED CPU[S]**

specifies the number of virtual CPUs of this type that this user has that have a real processor dedicated to them. This string does not appear if the user has no dedicated processors (for example, when *m* = 0). Because only processors of the primary real processor type can be dedicated, this string can only appear on the response line for virtual CPUs of type CP or IFL.

#### ***option***

either NOLIMIT, LIMITSOFT, or LIMITHARD. Note: When NOLIMIT appears, the type and value will not be shown.

## QUERY SHARE

### ***share\_type***

either RELATIVE or ABSOLUTE.

### ***value***

when *type* is RELATIVE, *value* is *nnnn*. When *type* is ABSOLUTE, *value* is *nnn%*.

## **Messages**

- HCP007E Invalid userid - *userid*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on

## QUERY SHUTDOWN

Notes:

<sup>1</sup> A user with privilege class G but not privilege class A or C can issue QUERY SHUTDOWN STATUS only.

### Authorization

Privilege Class: A, C, G

### Purpose

Use QUERY SHUTDOWN to learn more about a system shutdown that is in progress. When no operands are specified, the output of the TIME operand followed by the STATUS operand is given. Privilege class A or C is required to issue QUERY SHUTDOWN with no operands.

### Operands

#### TIME

displays the amount of time reserved for a VM SHUTDOWN to be performed. When a SHUTDOWN command is issued or the VM system shuts down automatically as the result of receiving a hardware deactivation signal, there is a time interval within which the shutdown must be completed. The SHUTDOWN TIME value specifies how much of that interval is reserved for the VM Control Program. The difference between these two values determines how much time, if any, guests are allowed to perform their own shutdown processing. Privilege class A or C is required to issue QUERY SHUTDOWN TIME.

#### STATUS

indicates whether a system shutdown is in progress. If so, return information on whether a user ID or a hardware deactivation initiated the system shutdown, the time the shutdown was started, and the amount of time left for guests or servers to shut down. Privilege class A, C, or G is required to issue QUERY SHUTDOWN STATUS.

If the system shutdown was initiated by a hardware deactivation, the message indicates that SYSTEM initiated the shutdown.

### Usage Notes

1. The QUERY SHUTDOWN TIME command displays the same output as the QUERY SHUTDOWNTIME command.
2. If the system shutdown was initiated by a SHUTDOWN command, the output indicates that the shutdown was initiated by "a user" or displays the actual user ID that issued the SHUTDOWN command based on the privilege class of the user ID issuing the QUERY command. Issuers of the QUERY command with privilege class A or C will see the user ID that issued the SHUTDOWN. Issuers without privilege class A or C will see output indicating that "a user" has initiated the shutdown. The user who initiated the system shutdown is the one who has privileges to issue commands that perform those functions.
3. The QUERY SHUTDOWN STATUS command is meant to be used by virtual machines to obtain more information when they receive a shutdown signal.

## QUERY SHUTDOWN

- The output of the QUERY SHUTDOWN STATUS command shows the status of the current system shutdown. It is a point in time and the status can change just after the command is issued. For example, if a SHUTDOWN command issued the shutdown signal, but a SHUTDOWN CANCEL was processed before the QUERY SHUTDOWN STATUS, an issuer of this command could see output indicating that "System shutdown is not in progress".

### Responses

Response 1:

```
SHUTDOWN initiated at yyyy-mm-dd hh:mm:ss by SYSTEM
Signaled users have nnnnn seconds left to shut down
```

is displayed when the QUERY SHUTDOWN STATUS command is accepted and a shutdown initiated by a hardware deactivation is in progress. The privilege class of the issuer does not affect the output. The number of seconds left is in the range 1-65535.

Response 2:

```
System shutdown time: interval seconds
SHUTDOWN initiated at yyyy-mm-dd hh:mm:ss by userid
Signaled users have nnnnn seconds left to shut down
```

is displayed when a QUERY SHUTDOWN command is accepted, a shutdown initiated by the SHUTDOWN command is in progress, and the issuer of the QUERY SHUTDOWN command has privilege class A or C. The *interval* is the amount of time reserved for VM SHUTDOWN processing. The number of seconds left is in the range 1-65535.

Response 3:

```
System shutdown time: interval seconds; previous shutdown duration:
length seconds
SHUTDOWN initiated at yyyy-mm-dd hh:mm:ss by userid
Signaled users have nnnnn seconds left to shut down
```

is displayed when a QUERY SHUTDOWN command is accepted, a shutdown initiated by the SHUTDOWN command is in progress, and the issuer of the QUERY SHUTDOWN command has privilege class A or C. The *interval* is the amount of time reserved for VM SHUTDOWN processing and *length* is the amount of time the previous VM SHUTDOWN required. The number of seconds left is in the range 1-65535.

Response 4:

```
System shutdown time: interval seconds
```

is displayed when a QUERY SHUTDOWN TIME command is accepted. The *interval* is the amount of time reserved for VM SHUTDOWN processing.

Response 5:

```
System shutdown time: interval seconds; previous shutdown duration:
length seconds
```

is displayed when a QUERY SHUTDOWN TIME command is accepted. The *interval* is the amount of time reserved for VM SHUTDOWN processing and *length* is the amount of time the previous VM SHUTDOWN required.

Response 6:

```
SHUTDOWN initiated at yyyy-mm-dd hh:mm:ss by a user
Signaled users have nnnnn seconds left to shut down
```

is displayed when the QUERY SHUTDOWN STATUS command is accepted, a shutdown initiated by the SHUTDOWN command is in progress, and the issuer of the QUERY SHUTDOWN command does not have privilege class A or C but has privilege class G. The number of seconds left is in the range 1-65535.

Response 7:

```
System shutdown is not in progress
```

is displayed when the QUERY SHUTDOWN STATUS command is accepted and no system shutdown is in progress. If the user received a shutdown signal, this response indicates that the user was told to shut down (most likely from a SIGNAL SHUTDOWN or FORCE), but the whole system is not shutting down.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP003E Invalid option - *option*
- HCP026E Operand missing or invalid

## QUERY SHUTDOWNTIME

► Query — SHUTDOWNTime ◄

### Authorization

Privilege Class: A, C

### Purpose

Use QUERY SHUTDOWNTIME to display the amount of time reserved for a VM SHUTDOWN to be performed. When a SHUTDOWN command is issued or the VM system shuts down automatically as the result of receiving a hardware deactivation signal, there is a time interval within which the shutdown must be completed. The SHUTDOWNTIME value specifies how much of that interval is reserved for the VM Control Program, and the difference between these two values determines how much time, if any, guests are allowed to perform their own shutdown processing.

### Usage Notes

1. The duration of the previous SHUTDOWN is reported only if the system has been restarted after a system failure or restarted via a SHUTDOWN REIPL command.
2. The QUERY SHUTDOWNTIME command returns the same information as the QUERY SHUTDOWN TIME command.

### Responses

Response 1:

```
System shutdown time: interval seconds
```

#### *interval*

is the amount of time reserved for VM SHUTDOWN processing.

Response 2:

```
System shutdown time: interval seconds; previous shutdown duration: length seconds
```

#### *interval*

is the amount of time reserved for VM SHUTDOWN processing.

#### *length*

is the amount of time the previous VM SHUTDOWN required.

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*

## QUERY SIGNAL

---

►► Query — SIGnal — SHUTDOWNtime ◄◄

### Authorization

Privilege Class: G

### Purpose

Use QUERY SIGNAL to display system default signal timeout interval value.

### Operands

#### SHUTDOWNtime

displays the system default shutdown signal timeout interval. If a SIGNAL, FORCE, or SHUTDOWN command is issued without specifying an interval, this value is used to determine the interval.

### Usage Notes

1. The system default signal timeout interval is set by the SET SIGNAL system configuration statement. The value can be dynamically reset for the current system IPL by the SET SIGNAL command.
2. A user is enabled for signals only when a guest operating system is running in the virtual machine and has enabled to receive these signals. To display the signal status of a user or all users, use the QUERY SIGNALS command.

### Responses

Response 1:

```
System default shutdown signal timeout: interval seconds
```

#### *interval*

is the duration of the system default shutdown signal timeout interval.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*

## QUERY SIGNALS

### Authorization

Privilege Class: B

### Purpose

Use QUERY SIGNALS to display a user's signal status or to display the signal status of all users who are enabled to receive them or are processing signals.

### Operands

#### ALL

indicates that the status of all signals is to be displayed.

#### SHUTDOWN

indicates that the status of the SHUTDOWN signal is to be displayed.

#### *userid*

identifies the user whose signal status is to be displayed. Use the keyword USER when you specify a user ID of "all".

#### ALL

indicates that the signal status of all users who are enabled to receive or have received the designated *signal* should be displayed.

### Responses

Response 1:

Userid	Signal	Signal Status	Signalled By	Timeout Remaining
<i>userid</i>	<i>signal</i>	Enabled	-	-
<i>userid</i>	<i>signal</i>	Pending	<i>issuer</i>	<i>interval</i>
<i>userid</i>	<i>signal</i>	Processing	<i>issuer</i>	<i>interval</i>
<i>userid</i>	<i>signal</i>	Not enabled	-	-
<i>userid</i>	-	Logging on/off	-	-
<i>userid</i>	-	Console wait	-	-

#### *userid*

identifies the user.

#### *signal*

identifies the signal.

#### Enabled

indicates that the virtual machine is enabled to receive the *signal*.

#### Pending

indicates that the virtual machine has the *signal* pending but it has not yet been delivered.

#### Processing

indicates that the virtual machine has had the *signal* delivered it but has not yet responded to indicate that it has completed processing it.

**Not enabled**

indicates that the virtual machine is not enabled to receive the *signal*.

**Logging on/off**

indicates that the virtual machine is in the process of logging on or off.

**Console wait**

indicates that the virtual machine's console is in a state (for example, HOLDING) such that the signal status cannot be obtained.

**issuer**

identifies the user who caused the signal to be sent to the user. If SYSTEM is specified as the issuer in the output response, the signal came from the hardware (a hardware quiesce signal, for example) rather than an actual user.

**interval**

shows the amount of time in seconds remaining in the timeout interval.

Response 2:

```
No users are enabled for signals
```

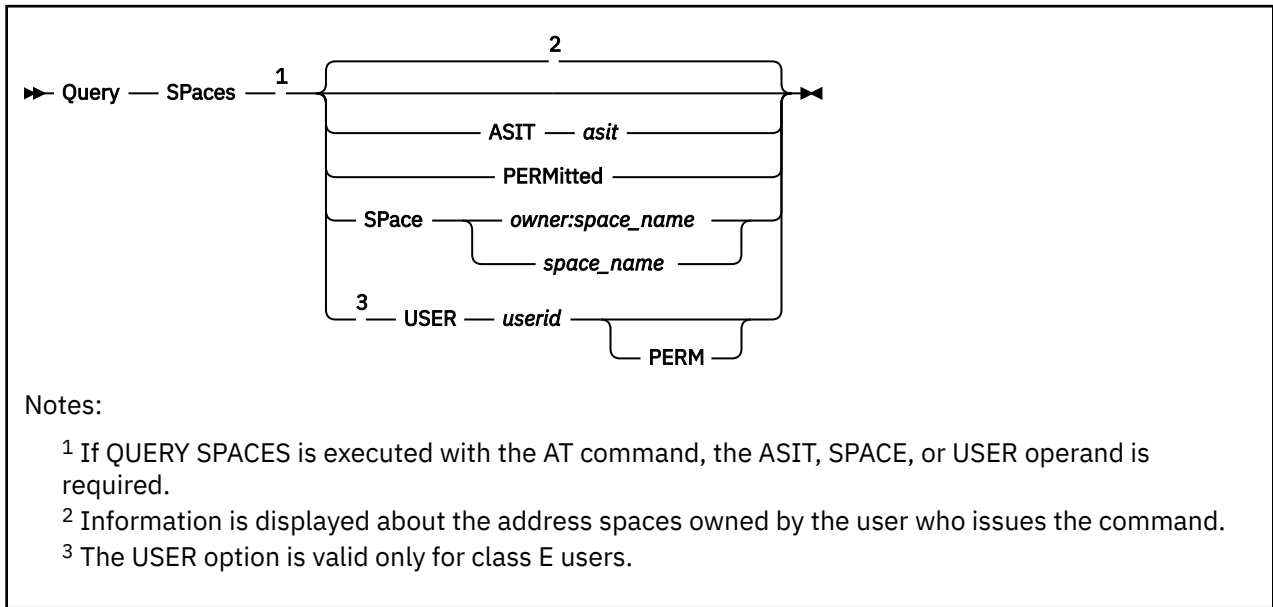

**Usage Notes**

1. A user is enabled for signals only when a guest operating system is running in the virtual machine and has enabled to receive these signals.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP007E Invalid userid - *userid*
- HCP013E Conflicting option - *option*
- HCP045E *userid* not logged on
- HCP6704E Missing token at end of line
- HCP6706E Invalid string - *string*

## QUERY SPACES

### Authorization

Privilege Class: E, G

### Purpose

Use QUERY SPACES to display information about the address spaces that a virtual machine owns or has access to. If you are a class G user, you can display information about your own address spaces. You can also display information about an address space owned by another user ID if you have permission to access it. If you are a class E user, you can display information about any address space, or all address spaces that a specific user ID owns or has access to.

### Operands

#### ASIT *asit*

returns information about the address space identified by the ASIT *asit*.

#### PERMitted

returns information about the address spaces that the command issuer has permission to access.

#### SPace *owner:space\_name*

returns information about the address space owned by user ID *owner* and named *space\_name*. The owner's user ID is optional and defaults to the ID of the user issuing the command. The space name is a 1- to 24-character string of alphanumeric and national characters.

The class G user must have permission to access the address space. The class E user can obtain the information without permission to access the space.

#### USER *userid*

returns information about the address spaces owned by *userid*.

#### PERM

returns information about the address spaces that *userid* has permission to access.

## Usage Notes

1. Programs that parse the output of this command should not depend on the ordering of the columns in the output. They should use the heading line to determine which column contains a particular piece of information.
2. If you issue QUERY SPACES with the ASIT operand and specify the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the QUERY SPACES command is rejected and error message HCPQSP6578E is issued. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value by using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:
  - SYSTEM CLEAR
  - IPL by NSS name
  - IPL by device with the CClear option
  - SET MACHine (to a different machine architecture)

## Responses

Response 1:

```

ASIT      STORAGE    P/S      ACC      SPACE IDENTIFICATION
aaa...aaa nu      {PRV}    {R/O}    sss...sss
                {SHR}    {R/W}
                {---}
    
```

### **aaa...aaa**

is the address space identification token (ASIT) for the address space (16 hexadecimal digits).

### **nu**

where *n* is the size of the address space in bytes and *u* is the unit of measure:

#### **M**

megabytes

#### **G**

gigabytes

#### **T**

terabytes

#### **P**

petabytes

#### **E**

exabytes

For the primary address space, this includes discontinuous storage (that is - NSS or saved segment storage located above the virtual machine's defined size). If discontinuous storage is used, there may be non-addressable areas within this storage.

### **PRV**

indicates that the address space is in the private state.

### **SHR**

indicates that the address space is in the shareable state.

### **sss...sss**

is the space ID for the address space (3 to 33 characters).

### **R/O**

### **R/W**

### **---**

show the degree of access permitted to the user. Three dashes are displayed when a class E user uses the ASIT or SPACE operands for a space the user does not have permission to access.

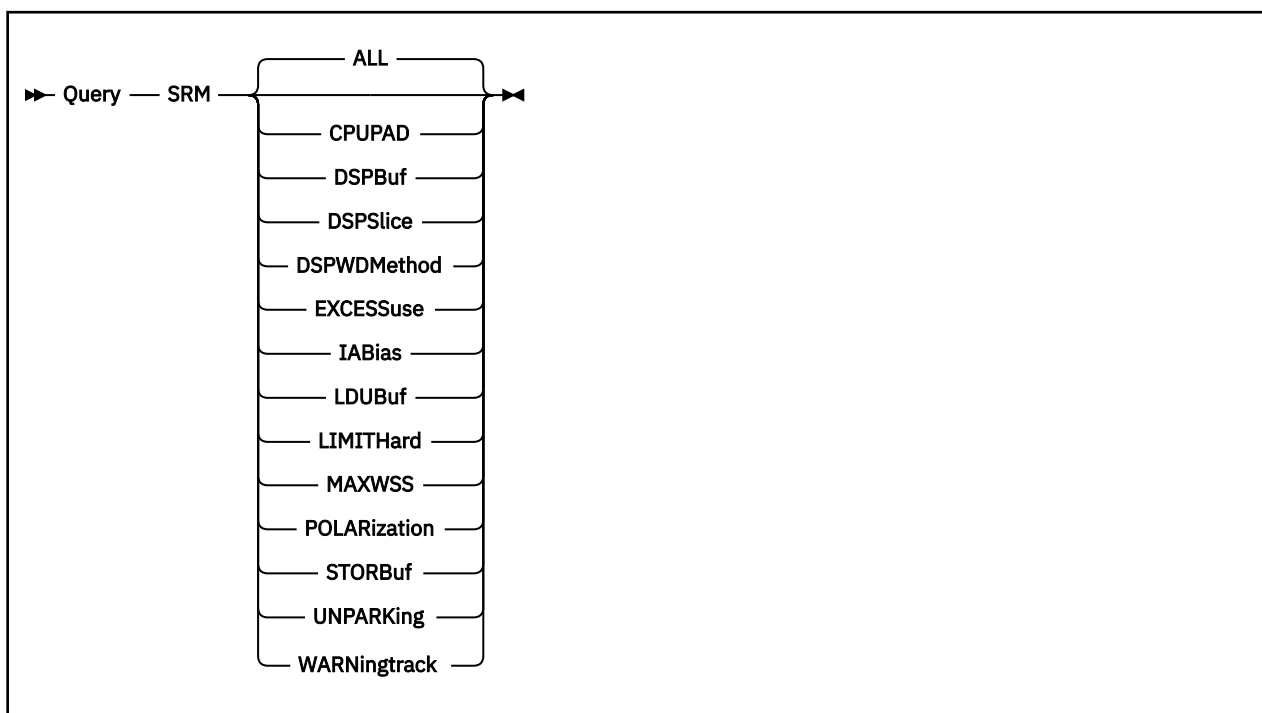

### Examples

```
q sp
ASIT          STORAGE P/S ACC SPACE IDENTIFICATION
017801800000001 32M PRV R/W OPERATOR:spacename
017802400000001  1M PRV R/W OPERATOR:spacename
017802800000001  1M PRV R/W OPERATOR:spacename
017802C00000001  1M PRV R/W OPERATOR:spacename
```

### Messages

- HCP263E Too many operands were supplied for this command.
- HCP1001E An operand is missing for *option*.
- HCP6156E {ASIT *asit*|Address space identifier SPACE\_ID} does not designate an address space to which you have the appropriate access.
- HCP6578E Invalid {access register|ASIT|address space identifier} - *option*

## QUERY SRM

### Authorization

Privilege Class: A, E

### Purpose

Use QUERY SRM (system resource manager) to display system-wide parameters used by the scheduler to set the priority of system resource access.

### Operands

#### ALL

causes a summary of the current system-wide settings. The operand displays the CPUPAD, DSPBUF, DSPSLICE, DSPWDMETHOD, EXCESSUSE, IABIAS, LDUBUF, LIMITHARD, MAXWSS, POLARIZATION, STORBUF, UNPARKING, and WARNINGTRACK settings. This operand is the default.

#### CPUPAD

displays the current CPUPAD setting for each CPU type. These settings control the amount of additional CPU capacity the system should be prepared to consume beyond what the system projects it will need. For additional details about this setting, see [“SET SRM” on page 1704](#).

For additional information on CPUPAD and HiperDispatch, see the [SRM Statement](#) and [z/VM HiperDispatch](#) in *z/VM: CP Planning and Administration*.

#### DSPBuf

displays the current DSPBUF (dispatch buffer) values used by the scheduler to limit the number of users allowed in the dispatch list for each transaction class. For a description of the values, see [“SET SRM” on page 1704](#).

#### DSPSlice

displays the current setting of the dispatching timeslice in milliseconds.

**DSPWDMethod**

displays the current DSPWDMethod setting. This indicates which work distribution algorithm the dispatcher is using.

For additional information on DSPWDMETHOD and HiperDispatch, see the [SRM Statement](#) and [z/VM HiperDispatch](#) in *z/VM: CP Planning and Administration*.

**EXCESSuse**

displays the current EXCESSUSE (unentitled CPU use) setting for each CPU type. These settings control how aggressively the system should attempt to use CPU capacity beyond its entitlement. For additional details about this setting, see [“SET SRM” on page 1704](#).

For additional information on EXCESSUSE and HiperDispatch, see the [SRM Statement](#) and [z/VM HiperDispatch](#) in *z/VM: CP Planning and Administration*.

**IABias**

specifies that the current settings for the interactive bias *intensity* and *duration* should be displayed. For a description of the interactive bias facility, see [“SET SRM” on page 1704](#).

**LDUBuf**

displays the current LDUBUF (loading user buffer) percentages used by the scheduler to partition access to the paging configuration based on transaction classes. For a description of the percentage values, see [“SET SRM” on page 1704](#).

**LIMITHard**

displays the method the scheduler uses to enforce hard limiting of scheduled system resources. This setting only affects users with absolute maximum shares defined with the SET SHARE command or the SHARE directory statement. The LIMITHARD *method* can be either CONSUMPTION or DEADLINE. For a description of these methods, see [“SET SRM” on page 1704](#).

**MAXWSS**

displays the current maximum working set size (MAXWSS) percentage of pageable real storage and the corresponding number of page frames.

**POLARization**

displays the partition's polarization mode and whether the partition has access to global performance data.

For additional information on POLARIZATION and HiperDispatch, see the [SRM Statement](#) and [z/VM HiperDispatch](#) in *z/VM: CP Planning and Administration*.

The display includes:

1. Polarization mode:
  - VERTICAL. The partition is running in vertical polarization mode. This mode allows logical CPUs in a partition to receive differing entitlements.
  - HORIZONTAL. The partition is running in horizontal polarization mode. Each online (configured) logical CPU of a particular CPU type gets an equal portion of the partition's weight for that CPU type.

For additional details about these settings, see [“SET SRM” on page 1704](#).
2. Global performance data indicator. Global performance data (GPD) is a setting turned on in the partition's activation profile on the HMC (Hardware Management Console) or SE (Support Element). This setting allows PR/SM to tell a partition about usage on other partitions within the CPC.

**STORBuf**

displays the current STORBUF (storage buffer) percentages used by the scheduler to partition storage based on transaction classes. For a description of the percentage values and the transaction classes represented, see [“SET SRM” on page 1704](#).

**UNPARKing**

displays the setting of the unparking heuristic.

**WARNingtrack**

displays the current warning-track setting, along with facility availability.

## Usage Notes

1. For explanations of all settings displayed by the QUERY SRM command, see “SET SRM” on page 1704.
2. For information about the allocation of storage resources to users, see [Checking the Allocation of Real Storage in z/VM: System Operation](#).

## Responses

Response 1:

```
LIMITHARD METHOD: method
IABIAS : INTENSITY=mmm%; DURATION=nnn
LDUBUF : Q1=ddd% Q2=eee% Q3=fff%
STORBUF: Q1=aaa% Q2=bbb% Q3=ccc%
DSPBUF : Q1=iiii Q2=jjjj Q3=kkkk
DISPATCHING MINOR TIMESLICE = xxx MS
MAXWSS : LIMIT=nnnn%
..... : PAGES=mmmmmmmmmm
XSTORE : ---
POLARIZATION: type

EXCESSUSE: CP-excess IFL-excess ICF-excess ZIIP-excess
CPUPAD: CP-qqqq% IFL-qqqq% ICF-qqqq% ZIIP-qqqq%
DSPWMETHOD: RESHUFFLE|REBALANCE
UNPARKING: LARGE|MEDIUM|SMALL
WARNING TRACK: AVAILABLE|UNAVAILABLE ON|OFF
```

is the response to QUERY SRM ALL, where *excess* = {HIGH|MEDIUM|LOW|NONE}.

Response 2:

```
LIMITHARD METHOD: method
```

is the response to QUERY SRM LIMITHARD.

Response 3:

```
IABIAS : INTENSITY=mmm%; DURATION=nnn
```

is the response to QUERY SRM IABIAS.

Response 4:

```
LDUBUF : Q1=ddd% Q2=eee% Q3=fff%
```

is the response to QUERY SRM LDUBUF.

Response 5:

```
STORBUF: Q1=aaa% Q2=bbb% Q3=ccc%
```

is the response to QUERY SRM STORBUF.

Response 6:

```
DSPBUF : Q1=iiii Q2=jjjj Q3=kkkk
```

is the response to QUERY SRM DSPBUF.

Response 7:

```
DISPATCHING MINOR TIMESLICE = xxx MS
```

is the response to QUERY SRM DSPSLICE.

Response 8:

## QUERY SRM

```
MAXWSS : LIMIT=nnnn%  
... .. : PAGES=mmmmmmmmmm
```

is the response to QUERY SRM MAXWSS.

Response 9:

```
POLARIZATION: type  
GLOBAL PERFORMANCE DATA: ON|OFF|NA
```

is the response to QUERY SRM POLARIZATION.

Response 10:

```
EXCESSUSE: CP-excess IFL-excess ICF-excess ZIIP-excess
```

is the response to QUERY SRM EXCESSUSE, where *excess* = { HIGH | MEDIUM | LOW | NONE }.

Response 11:

```
CPUPAD: CP-qqqqq% IFL-qqqqq% ICF-qqqqq% ZIIP-qqqqq%
```

is the response to QUERY SRM CPUPAD.

Response 12:

```
DSPWDMETHOD: RESHUFFLE|REBALANCE
```

is the response to QUERY SRM DSPWDMETHOD.

Response 13:

```
UNPARKING: { LARGE | MEDIUM | SMALL }
```

is the response to QUERY SRM UNPARKING.

Response 14:

```
WARNING TRACK: AVAILABLE|UNAVAILABLE ON|OFF
```

is the response to QUERY SRM WARNINGTRACK.

### Messages

- HCP026E Operand missing or invalid
- HCP1401I Expanded storage not supported.

## QUERY SSI

### Authorization

Privilege Class: B, E

### Purpose

Use QUERY SSI to display the single system image (SSI) name, member status, and connectivity status.

### Operands

#### STATUS

displays the state and heartbeat information for each of the SSI members.

#### CONNECTivity

displays the status of connections to the SSI members.

#### SSI\_CONTRols

#### CONTRols

displays the SPOOL\_MEMBERS setting of the SSI\_CONTROLS statement in the system configuration file for each of the joined SSI members. This setting determines among how many members of the SSI cluster the spool file ID numbers are allocated for use when new spool files are created. For more information about the SSI\_CONTROLS statement, see *z/VM: CP Planning and Administration*.

#### SHOrtdate

specifies that dates in the response to this command are displayed in *mm/dd/yy* format, where *mm* is the month, *dd* is the day of the month, and *yy* is the 2-digit year.

#### FULldate

specifies that dates in the response to this command are displayed in *mm/dd/yyyy* format, where *mm* is the month, *dd* is the day of the month, and *yyyy* is the 4-digit year.

#### ISOdate

specifies that dates in the response to this command are displayed in *yyyy-mm-dd* format, where *yyyy* is the 4-digit year, *mm* is the month, and *dd* is the day of the month.

### Usage Notes

1. You can use the SET SSI command to add systems to available slots in the SSI member list or to remove members from the SSI member list.

2. The default date format for certain CP and CMS commands can be set on a system-wide basis and also for the individual user. The system-wide default date format is set with the SYSTEM\_DATEFORMAT system configuration statement. The user's default date format is set with the DATEFORMAT directory statement. The system-wide default and the user's default can also be set with the CP SET DATEFORMAT command. The user's default date format defaults to the system-wide default. The system-wide and user settings can be queried with the CP QUERY DATEFORMAT command. The hierarchy of possible date format settings for the QUERY SSI command, from highest priority to lowest, is:
  - QUERY SSI operand
  - User default
  - System-wide default.
3. When the response indicates that a slot is AVAILABLE, it means there is no member defined in that slot, but the slot is supported at this level of z/VM. It might be possible to use the SET SSI SLOT command to define a member in that slot, but this is not always the case. Whether those slots are usable or not depends on the settings of the SPOOL\_MEMBERS operand of the SSI\_CONTROLS statement in the system configuration file for all joined members of the cluster. For example, a member can only be defined in slots 5-8 if all joined members are running with a SPOOL\_MEMBERS setting of 8 rather than 4.

## Responses

1. If you enter any form of the QUERY SSI command on a system that is not a member of an SSI cluster, you might see a response similar to this:

```
query ssi status
This system is not a member of an SSI cluster
```

2. If you enter the QUERY SSI STATUS command on a system that is a member of an SSI cluster, you might see a response similar to this:

```
query ssi
SSI Name:  ALEAST
SSI Mode:  Stable
Cross-System Timeouts: Enabled
SSI Persistent Data Record (PDR) device: SSIVOL on 3333
SLOT SYSTEMID STATE      PDR HEARTBEAT      RECEIVED HEARTBEAT
  1 YANKEES  Joined    01/30/2010 12:03:33 01/30/2010 12:03:35
  2 REDSOX   Joined    01/30/2010 12:03:47 01/30/2010 12:03:49
  3 ORIOLES  Down (shut down successfully)
  4 ----- Available
  5 ----- Available
  6 ----- Available
  7 ----- Available
  8 ----- Available
```

where:

**SSI Name: ALEAST**

ALEAST is the name of the SSI cluster.

**SSI Mode: Stable**

**SSI Mode: Influx**

**SSI Mode: Safe**

indicates this member's view of the SSI mode. Valid SSI modes are:

**Stable**

All IPLed systems in the SSI cluster are joined and participating in all SSI services.

**Influx**

A member is in a transition state.

**Safe**

A member is in an unknown state.

**Cross-System Timeouts: Enabled | Disabled**

indicates the status of cross-system timeouts. For more information, refer to the CROSS\_SYSTEM\_TIMEOUTS operand on the FEATURES configuration statement. See [FEATURES Statement](#) in *z/VM: CP Planning and Administration*.

**SSI Persistent Data Record Device (PDR): SSIVOL on 3333**

SSIVOL is the volume label and 3333 is the real device address of the device that contains the SSI persistent data record.

**SLOT**

indicates the slot number in the SSI member list.

**SYSTEMID**

is the system name of the member occupying that slot.

**STATE**

is the issuing member's view of the state of the associated member. Valid states are:

**Down**

A member is in the Down state when any of the following are true, as indicated by the parenthetical text that follows:

- (shut down successfully) it has left the SSI cluster due to a system shutdown.
- (not shut down successfully) it has left the SSI cluster due to a system abend.
- (declared down) it has been declared down by use of the SET SSI command.
- (not IPLed) it has not been IPLed as a member of the SSI cluster.
- (initializing, not yet joining) it has been IPLed, but it hasn't joined the SSI cluster.
- (reason undetermined)
- (reason not valid)

**Joining**

A member is in the Joining state when it is in the process of joining an SSI cluster that already has one or more joined members. Only one member can be in the Joining state at a time.

**Joined**

A member is in the Joined state when it has successfully joined the SSI cluster and is participating in SSI-wide operations.

**Leaving**

A member is in the Leaving state when it was joined to an SSI cluster and is shutting down.

**Isolated**

A member is in the Isolated state when it cannot join the SSI cluster due to a failure in the enablement of SSI-wide operations or due to a failure occurring while attempting to join the SSI cluster.

**Suspended**

A member is in the Suspended state when it does not have connectivity to another member in the SSI cluster that is in a state other than Down or Isolated.

**Unknown**

A remote member is in the Unknown state when the connectivity from the local member is lost.

**PDR HEARTBEAT**

is the timestamp in the local member's time zone of the heartbeat in the SSI persistent data record for the specified member. Besides containing a timestamp, the PDR heartbeat field can contain one of the following values:

- Error reading PDR
- System not found
- Hyperswap occurring

**RECEIVED HEARTBEAT**

is the timestamp in the local member's time zone of the last received heartbeat from the specified member.

3. If you enter the QUERY SSI command on a system that has been IPLed with the REPAIR IPL parameter, you might see a response similar to the following:

```
query ssi status
This system was IPLed with the REPAIR IPL parameter and is
currently operating as if not in an SSI cluster.
```

4. If you enter the QUERY SSI CONNECTIVITY command on system YANKEES, you might see a response similar to this:

```
q ssi connect
SSI Name: ALEAST
SSI Mode: Stable
Cross-System Timeouts: Disabled
SLOT SYSTEMID STATE CONNECT TYPE HOPS
 1 YANKEES Joined Local -
 2 REDSOX Joined Direct 0
 3 ORIOLES Joined Direct 0
 4 ----- Available
 5 ----- Available
 6 ----- Available
 7 ----- Available
 8 ----- Available
```

where:

**SSI Name: ALEAST**

ALEAST is the name of the SSI cluster.

**SSI Mode: Stable**

**SSI Mode: Influx**

**SSI Mode: Safe**

indicates this member's view of the SSI mode. Valid SSI modes are:

**Stable**

All IPLed systems in the SSI cluster are joined and participating in all SSI services.

**Influx**

A member is in a transition state.

**Safe**

A member is in an unknown state.

**Cross-System Timeouts: Enabled | Disabled**

indicates the status of cross-system timeouts. For more information, refer to the CROSS\_SYSTEM\_TIMEOUTS operand on the FEATURES configuration statement. See the [FEATURES Statement in z/VM: CP Planning and Administration](#).

**SLOT**

indicates the slot number in the SSI member list.

**SYSTEMID**

is the system name of the member occupying that slot.

**STATE**

is the issuing member's view of the state of the associated member. Valid states are:

**Down**

A member is in the Down state when any of the following are true, as indicated by the parenthetical text that follows:

- (shut down successfully) it has left the SSI cluster due to a system shutdown.
- (not shut down successfully) it has left the SSI cluster due to a system abend.
- (declared down) it has been declared down by use of the SET SSI command.

- (not IPLed) it has not been IPLed as a member of the SSI cluster.
- (initializing, not yet joining) it has been IPLed, but it hasn't joined the SSI cluster.
- (reason undetermined)
- (reason not valid)

**Joining**

A member is in Joining state when it is in the process of joining an SSI cluster that already has one or more joined members. Only one member can be in the Joining state at a time.

**Joined**

A member is in the Joined state when it has successfully joined the SSI cluster and is participating in SSI-wide operations.

**Leaving**

A member is in the Leaving state when it was joined to an SSI cluster and is shutting down.

**Isolated**

A member is in the Isolated state when it cannot join the SSI cluster due to a failure in the enablement of SSI-wide operations or due to a failure occurring while attempting to join the SSI cluster.

**Suspended**

A member is in the Suspended state when it does not have connectivity to another member in the SSI cluster that is in a state other than Down or Isolated.

**Unknown**

A remote member is in the Unknown state when the connectivity from the local member is lost.

**CONNECT TYPE**

is the type of connection the issuing member has to the associated system. Values for CONNECT TYPE include:

**Not connected**

There is no ISFC connection to this system.

**Direct**

There is a direct ISFC connection to this system.

**Local**

This is the system on which the command was issued.

**Incomplete**

The process to determine connectivity is not complete. Reissue the command to see the connection status.

**HOPS**

Specifies the number of hops to the node. This field has a value of 0 or –.

5. If you enter the QUERY SSI SSI\_CONTROLS command, you might see a response similar to this:

```
q ssi ssi_controls
SSI Name: ALEAST
SSI Mode: Stable
Cross-System Timeouts: Disabled
SLOT SYSTEMID STATE      SPLMEMS
  1 YANKEES  Joined      8
  2 REDSOX   Down        -
  3 ORIOLES  Joined      4
  4 ----- Available
  5 ----- Available
  6 ----- Available
  7 ----- Available
  8 ----- Available
```

where:

All of the response fields are defined in response “2” on page 1178, except the following field, which is unique to the SSI\_CONTROLS response:

## QUERY SSI

### SPLMEMS

shows the spool members setting of each joined member of the SSI cluster. This indicates the spool ID assignment algorithm in use by the member as set on the SSI\_CONTROLS statement in the system configuration file. A hyphen appears for any member that is currently not joined.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *operand*

## QUERY STGEXEMPT

### Notes:

- <sup>1</sup> Operands are not valid for class G users.
- <sup>2</sup> If QUERY STGEXEMPT is executed with the AT command, the *userid* or ALL operand is required.

### Authorization

Privilege Class: A, B, C, E, G

### Purpose

Use QUERY STGEXEMPT to determine the state of free storage limit detection for a virtual machine. A class G user can display the state of free storage limit detection for the user's own virtual machine. A class A, B, C, or E user can display the state of free storage limit detection for any user or all users.

### Operands

**\***

displays the state of free storage limit detection for the user who issues the command.

**userid**

specifies the user ID for which the state of free storage limit detection is to be displayed.

**ALL**

specifies that the state of free storage limit detection for all logged on users is to be displayed.

### Usage Notes

1. The QUERY STGEXEMPT command displays the state of free storage limit detection for the user ID. If a user ID is exempt from free storage limit detection, usage of CP storage in support of the user ID is unbounded. If a user ID is subject to free storage limit detection, CP will detect if too much CP storage is consumed in support of the user ID and if so, the user ID will be stopped and possibly forced off the system.

### Responses

Response 1:

```
Userid USERID is {exempt from} free storage limit detection.
                  {subject to }
```

is the response for QUERY STGEXEMPT, QUERY STGEXEMPT USERID, or QUERY STGEXEMPT \*.

There may be additional response saying that free storage limit detection is off for the system.

Response 2:

```
The following users are exempt from
free storage limit detection:
```

## QUERY STGEXEMPT

```
USERID1 USERID2 USERID3 USERID4 USERID5  
USERID6 USERID7 USERID8 USERID9 ...
```

is the response for QUERY STGEXEMPT ALL.

Response 3:

```
There are no users that are exempt  
from free storage limit detection
```

is the response for QUERY STGEXEMPT ALL when no users are exempt.

### Messages

# QUERY STGLIMIT

---

► Query — STGLimit ◄

## Authorization

Privilege Class: A, B, C, E

## Purpose

Use QUERY STGLIMIT to determine the state of free storage limit detection for the system.

## Usage Notes

1. If free storage limit detection for the system is off, usage of CP storage in support of the user ID is unbounded.
2. If free storage limit detection for the system is on, CP will detect if too much CP storage is consumed in support of userids and if so, those userids consuming excessive free storage will be stopped and possibly forced off the system.

## Responses

Response 1:

```
FREE STORAGE LIMIT DETECTION IS {ON }  
                                {OFF}
```

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

## QUERY STORAGE/STORE

### Authorization

Privilege Class: A, B, E

### Purpose

Use QUERY STORAGE or QUERY STORE to display z/VM's real storage configuration. The command also displays the status of a storage reconfiguration in progress, and the values used to initialize the storage configuration the last time the system was started.

### Operands

#### RECONFiguration

displays the status of a storage reconfiguration in progress. If a reconfiguration is not in progress, the current storage configuration is displayed.

#### IPL

displays the current amount of permanent and reconfigurable storage, along with the storage specification that z/VM used the last time the system was started.

### Usage Notes

1. When you define a logical partition, two storage allocations, *Initial* and *Reserved*, are specified in the image profile for the partition. The maximum amount of storage that can be used by an operating system running in the partition is the sum of these two storage allocations. The machine uses the *Initial* and *Reserved* amounts in determining the storage-increment size. The storage-increment size is the unit in which storage can be added to or removed from the configuration.

For a fresh IPL (one that is not an automatic restart), the following considerations apply:

- CP uses the PERMANENT and RECONFIGURABLE specifications on the STORAGE statements in the system configuration file to determine how to initialize storage. There must be at least 4 GB of permanent storage online before any reconfigurable storage can be configured.
- Alternatively, you can use the IPL parameter STORE=*n* to override the storage configuration information in the system configuration file. In this case, all of the storage specified via STORE=*n* is initialized as permanent.
- If neither the STORAGE statement nor the IPL parameter STORE= was specified, all of the storage that z/VM finds configured in the partition is initialized as permanent storage. If this is the first IPL after the logical partition was activated, the amount of configured storage equals the *Initial* storage allocation. If this is a subsequent IPL, the amount of storage configured at IPL depends on the configuration left by the operating system previously running in the partition.

The storage values on the STORAGE statement and the IPL parameter STORE=*n* are rounded up to a multiple of the storage-increment size, if necessary.

For an IPL that is the result of an automatic restart, the AFTER\_RESTART and AFTER\_SHUTDOWN\_REIPL operands on the STORAGE statement in the system configuration file determine z/VM's behavior in establishing the storage configuration. The AFTER\_RESTART operand applies to an automatic reIPL resulting from a CP abend or a PSW restart. The

AFTER\_SHUTDOWN\_REIPL operand applies to an automatic reIPL resulting from the SHUTDOWN command with the REIPL operand. Parameters on these operands provide the ability for you to either initialize the storage configuration as though it were a fresh IPL, or to keep the storage configuration as it was at system termination prior to the reIPL. See the [STORAGE Statement](#) in *z/VM: CP Planning and Administration* for more information.

2. Usable storage is not necessarily contiguous. There can be unaddressable address ranges resulting from a SET STORAGE command to remove reconfigurable storage.
3. The STORAGE= and CONFIGURED= values in the QUERY STORAGE command response might include frames taken offline due to an error. The OFFLINE= value displayed in the QUERY FRAMES command response is the count of frames taken offline due to an error.
4. The sum of CONFIGURED=, STANDBY=, and RESERVED equals the sum of the Initial and Reserved storage allocations in the image profile for the logical partition, or the z/VM-supported maximum, whichever is less.
5. The STORAGE=, CONFIGURED=, and Reconfigurable= values might continue to change after a storage reconfiguration completes. When storage is removed from the reconfiguration, it is done in two parts: vacating the storage and transitioning the storage to the standby state. After the storage is completely vacated, it might take extra time to complete the storage transitions. The SET STORAGE command will have already returned, but the values on the QUERY STORAGE command might continue to update until the transitions are complete.
6. A VIRTUAL version of this command, QUERY VIRTUAL STORAGE/STORE, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL STORAGE/STORE”](#) on page 1333.

## Responses

Response 1:

When a QUERY STORAGE command is issued and a storage reconfiguration is in progress to add storage to the z/VM configuration, you will receive the following command response:

```
STORAGE = nu CONFIGURED = nu INC = nu STANDBY = nu RESERVED = nu
Permanent = nu Reconfigurable = nu Maximum STORAGE = nu
```

where:

### **STORAGE = nu**

specifies the size of real storage (permanent plus reconfigurable) in use by z/VM).

### **CONFIGURED = nu**

specifies the amount of real storage configured for the logical partition in which z/VM is running.

### **INC = nu**

specifies the size of the real storage increment. Storage must be added or removed in multiples of the increment size.

### **STANDBY = nu**

specifies the amount of real storage in standby state that is available to be brought online with the SET STORAGE command. Standby storage is a calculated value based on the amount of installed storage that is not currently claimed by active logical partitions and the reserved storage specified for the logical partition in which z/VM is running, subject to the z/VM-supported maximum.

### **RESERVED = nu**

specifies the amount of real storage in reserved state that can become available via manual storage actions (if another logical partition is deactivated, for example).

### **Permanent = nu**

specifies the amount of online real storage that cannot be removed.

**Reconfigurable = nu**

specifies the amount of online real storage that can be removed using the SET STORAGE command. If your z/VM system is running on a machine that does not support reconfigurable storage, the reconfigurable storage value is displayed as Reconfigurable = --.

**Maximum STORAGE = nu**

specifies the largest amount of storage that can be brought online to z/VM in this partition. The value is the sum of the Initial + Reserved settings for the logical partition in the image profile, or is the maximum amount of real storage this z/VM system supports, whichever is less.

**u**

is the storage unit suffix:

**M**

megabytes

**G**

gigabytes

**T**

terabytes

**P**

petabytes

**E**

exabytes

Response 2:

When a QUERY STORAGE RECONFIGURATION command is issued and a storage reconfiguration is in progress to add storage to the z/VM configuration, you will receive the following response:

```
STORAGE = nu CONFIGURED = nu INC = nu STANDBY = nu RESERVED = nu
Permanent = nu Reconfigurable = nu Maximum STORAGE = nu
Storage increase in progress. Elapsed time = ddd hh:mm:ss
Target:          {Permanent = nu} {Reconfigurable = nu}
Total to add:   {Permanent = nu} {Reconfigurable = nu}
Remainder to add: {Permanent = nu} {Reconfigurable = nu}
Storage reconfiguration is active.
```

The first two lines of output are described under Response 1. The values on the additional lines are as follows:

**Elapsed time = ddd hh:mm:ss**

specifies the amount of time in days, hours, minutes, and seconds that the add operation has been in progress.

**Target: {Permanent = nu} {Reconfigurable = nu}**

specifies the amount of permanent storage, reconfigurable storage, or both that will be in use by z/VM after the add operation completes.

**Total to add: {Permanent = nu} {Reconfigurable = nu}**

specifies the amount of permanent storage, reconfigurable storage, or both to be added as requested on the SET STORAGE command that initiated the reconfiguration.

**Remainder to add: {Permanent = nu} {Reconfigurable = nu}**

specifies the amount of permanent storage, reconfigurable storage, or both that still needs to be added for the storage reconfiguration in progress.

**Storage reconfiguration is active.**

indicates that a reconfiguration is in progress. This will appear as the last line of output if a user issued a SET STORAGE command, or if the system is initializing and needs to initialize or remove storage to match the requested configuration. SET STORAGE commands cannot be issued while another storage reconfiguration is in progress.

Response 3:

When a QUERY STORAGE RECONFIGURATION command is issued and a storage reconfiguration is in progress to remove storage from the z/VM configuration, you will receive the following response:

```
STORAGE = nu CONFIGURED = nu INC = nu STANDBY = nu RESERVED = nu
Permanent = nu Reconfigurable = nu Maximum STORAGE = nu
Storage decrease in progress. Elapsed time = ddd hh:mm:ss
Target Reconfigurable = nu
Total to remove = nu
Remainder to remove = nu
MAXPAGEFULL = nnn% | Forced to no limit
Storage reconfiguration is active.
```

The first two lines of output are described under Response 1. The values on the additional lines are as follows:

**Elapsed time = ddd hh:mm:ss**

specifies the amount of time in days, hours, minutes, and seconds that the removal operation has been in progress.

**Target reconfigurable = nu**

specifies the amount of reconfigurable storage that will be in use by z/VM after the removal operation completes.

**Total to remove = nu**

specifies the amount of reconfigurable storage to be removed as requested on the SET STORAGE command initiating the reconfiguration.

**Remainder to remove = nu**

specifies the amount of reconfigurable storage that still needs to be removed for the storage reconfiguration in progress.

**MAXPAGEFULL = nnn%**

is the maximum percent of paging slots in use that you will tolerate for this reclamation. This is the value of the MAXPAGEFULL operand specified on the SET STORAGE command, or if MAXPAGEFULL was not specified on the command, it is the PAGING WARNING value specified via the PAGING system configuration statement or a previous SET PAGING command. If the amount of paging space in use reaches this percentage, the storage removal operation terminates with message HCP2650E. Any storage already removed is not brought back online.

When `Forced to no limit` is displayed, the `FORCE` operand was specified on the SET STORAGE remove command, causing all viability checks to be bypassed.

Response 4:

When a QUERY STORAGE IPL command is issued and a storage reconfiguration is in progress to add storage to the z/VM configuration, you will receive the following response:

```
STORAGE = nu CONFIGURED = nu INC = nu STANDBY = nu RESERVED = nu
Permanent = nu Reconfigurable = nu Maximum STORAGE = nu
IPL actual: Permanent = nu Reconfigurable = nu
IPL requested: Permanent = nu Reconfigurable = nu
IPL requested data source: specification
Last start was a type
```

The first two lines of output are described under Response 1. The values on the additional lines are as follows:

**IPL actual: Permanent = nu Reconfigurable = nu**

identifies the amount of permanent and reconfigurable storage brought online at the last start of the system. These values could differ from the requested amounts because CP rounded the values to a multiple of the storage-increment size, there is insufficient standby storage in the partition, or an error was encountered. Refer to the console log during IPL to determine if any storage configuration messages were issued. If your z/VM system is running on a machine that does not support reconfigurable storage, the reconfigurable storage value is displayed as `Reconfigurable = --`.

**IPL requested: Permanent = *nu* Reconfigurable = *nu***

identifies the amount of permanent and reconfigurable storage requested at the last start of the system.

**IPL requested data source: *specification***

identifies where the requested storage configuration specification was obtained the last time the system started. Possible values for *specification* are:

**IPL parameter STORE=*n***

storage configuration information for the last start was obtained from the IPL parameter STORE=*n*.

**IPL parameter STORE=INITIAL**

storage configuration information for the last start was obtained from the Initial storage allocation value in the image profile for the logical partition.

**STORAGE system configuration statement(s)**

storage configuration information for the last start was obtained from the PERMANENT specification, the RECONFIGURABLE specification, or both on the STORAGE statements in the system configuration file.

**None**

no explicit storage configuration data was provided on the IPL parameter STORE= or the STORAGE statement in the system configuration file. In this case, CP brings online only the amount of storage already configured to the partition and all of this storage is permanent.

**Kept from previous IPL**

the last start was an automatic restart. The STORAGE AFTER\_RESTART or AFTER\_SHUTDOWN\_REIPL statement in the system configuration file indicated that the storage configuration at system termination should be reestablished during the restart.

**Last start type was a *type***

identifies how the system was started. Possible values for *type* are:

**system IPL**

indicates that CP was started by the operator at the system console.

**system restart from SHUTDOWN REIPL**

indicates that the operator restarted CP using the CP SHUTDOWN command with the REIPL operand.

**system restart after system failure *XXXnnn***

indicates that CP restarted itself after an abend. *XXXnnn* is the abend code.

## Messages

## QUERY STP

---

```
▶▶ Query — STP ▶▶
```

### Authorization

Privilege Class: B

### Purpose

Use QUERY STP to display Server Time Protocol status.

### Responses

Response 1:

If you issue the QUERY STP command and the Server Time Protocol facility has not been installed on your machine, you will receive the following response:

```
Server Time Protocol facility not installed
```

Response 2:

If you issue the QUERY STP command and the Server Time Protocol facility is installed but not enabled for use, you will receive the following response:

```
Server Time Protocol facility not enabled
```

Response 3:

If the STP facility is installed and enabled, but STP has not been enabled from the system configuration file, you will receive the following response:

```
Server Time Protocol available but not enabled for CP use
```

Response 4:

If STP is enabled but CP has been unable to synchronize with the STP server and XRC\_OPTIONAL has not been specified in the system configuration file, you will receive the following response:

```
Server Time Protocol activation has not completed.  
I/O to XRC-capable DASD will be delayed until activation completes.
```

Response 5:

If STP is enabled but CP has been unable to synchronize with the STP server but XRC\_OPTIONAL was specified in the system configuration file, you will receive the following response:

```
Server Time Protocol activation has not completed.  
I/O to XRC-capable DASD will be issued without timestamps until  
activation completes.
```

Response 6:

If STP\_Timestamping is enabled and CP has successfully synchronized with STP, you will receive the following response:

```
Server Time Protocol synchronization activated for timestamping
```

## QUERY STP

### Response 7:

If QUERY STP is issued while VM is responding to an STP synchronization check, and XRC\_OPTional was not specified in the system configuration, you will receive the following response:

```
Server Time Protocol synchronization suspended.  
I/O to XRC-capable DASD will be delayed until synchronization completes.
```

### Response 8:

If QUERY STP is issued while VM is responding to an STP synchronization check, but XRC\_OPTional was specified in the system configuration, you will receive the following response:

```
Server Time Protocol synchronization suspended.  
I/O to XRC-capable DASD will be issued without timestamps until  
synchronization completes.
```

### Response 9:

If XRC\_TEST has been specified, you will receive the following response:

```
Server Time Protocol disabled: Timestamping enabled without  
a synchronized clock source for testing purposes.
```

### Response 10:

If STP has been enabled without timestamping support (for example, with the STP\_TZ statement) and CP has successfully synchronized with STP, you will receive the following response:

```
Server Time Protocol synchronization activated.
```

### Response 11:

If STP has been enabled without timestamping support (for example, with the STP\_TZ statement) and CP is currently responding to an STP synchronization check, you will receive the following response:

```
Server Time Protocol synchronization suspended.
```

# QUERY SUBSTITUTE

## Authorization

Privilege Class: B

## Purpose

Use QUERY SUBSTITUTE to display the current virtual machine substitute definitions.

## Operands

### *alias*

is the alias definition to be displayed.

### ALL

causes all alias definitions to be displayed. If no operand is specified, ALL is assumed.

## Responses

Response 1:

Substitute	Userid	Defined By	Status
xxxxxxx	yyyyyyy	zzzzzzz	logged on
aaaaaaa	bbbbbbb	ccccccc	not logged on

Response 2:

*alias* is not a substitute

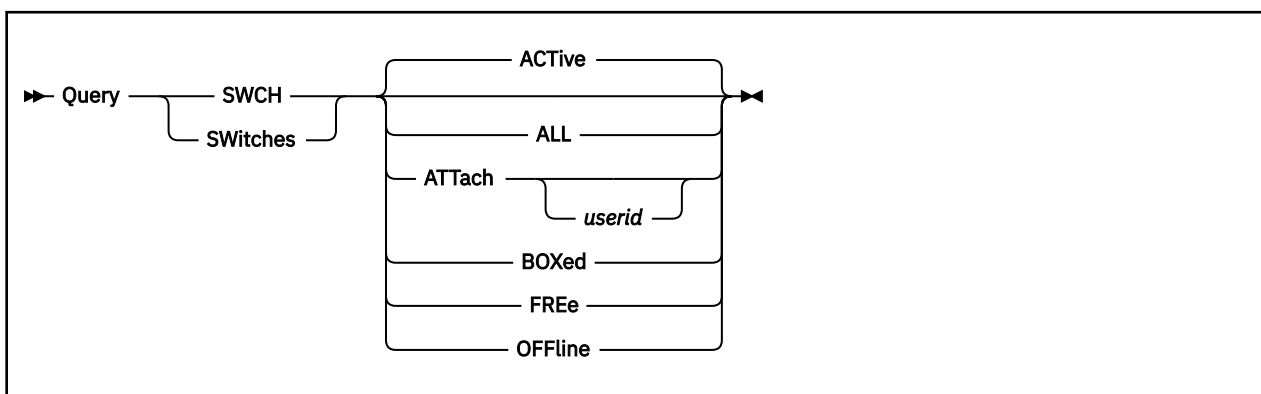

Response 3:

No substitutes defined or active

## Messages

- HCP007E Invalid userid - *userid*

## QUERY SWITCHES

### Authorization

Privilege Class: B

### Purpose

Use QUERY SWITCHES to display the status of real dynamic switching devices.

### Operands

#### ACTive

indicates active dynamic switching devices. An active device is in use by a user or the system and is specified as neither FREE nor OFFLINE.

#### ALL

indicates all dynamic switching devices attached to the system. The status is displayed in ACTIVE, FREE, and OFFLINE order and is equivalent to the response you would receive if you entered all of the following commands:

```
query swch active
query swch free
query swch offline
```

#### ATTach *userid*

indicates the dynamic switching devices that are dedicated to a user on the system. If you specify *userid*, only switching devices attached to that user's virtual machine are indicated. If you do not specify *userid*, you receive the status of all switching devices dedicated to any user on the system. Attached devices are always active.

#### BOXed

indicates the dynamic switching devices that are unavailable, usually because of a hardware condition. A boxed device may also be active, free, or offline.

#### FREe

indicates all free dynamic switching devices. A free device is one not currently in use by a user or the system, and specified as neither ACTIVE nor OFFLINE.

#### OFFline

indicates all offline dynamic switching devices. An offline device is one specified as neither ACTIVE nor FREE.

## Usage Notes

1. A VIRTUAL version of this command, QUERY VIRTUAL SWITCHES, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL SWITCHES”](#) on page 1336.

## Responses

Response 1:

If you enter a QUERY SWCH, QUERY SWCH ACTIVE, or QUERY SWCH ATTACH command, and there is a dynamic switching device dedicated to a user, you see something like this:

```
q switches
SWCH 0CD5 ATTACHED TO EMILY 0012
Ready;
```

This means that the switching device at the real device number 0CD5 is attached to EMILY's virtual machine as the virtual device number 0012. ATTACHED may be replaced by BOX/ATTC, which indicates that the dedicated switching device is not available, usually because of a hardware condition.

Response 2:

If you enter a QUERY SWCH FREE command, and there is a free switching device attached to the system, you see something like this:

```
q swch free
SWCH 0387 FREE      , SWCH 03A1 FREE      , SWCH 03A2 FREE      , SWCH 03A3 FREE
SWCH 03A4 FREE      , SWCH 03A5 FREE      , SWCH 03A9 FREE      , SWCH 03AA FREE
Ready;
```

This response shows the real device number for each free switching device.

If you enter a QUERY SWCH OFFLINE or QUERY SWCH BOXED command, the response is in the same format as the response for QUERY SWCH FREE.

Response 3:

If you enter a QUERY SWCH ALL command, CP displays what it would display if you had entered QUERY SWCH ACTIVE, QUERY SWCH FREE, and QUERY SWCH OFFLINE commands.

Response 4:

If CP cannot find a switching device of the type you specified, you see a message in this format:

```
q switches boxed
A BOXED SWCH was not found.
Ready;
```

In this response, BOXED may be replaced with active, attached, free, or offline, depending on what you specified on the command.

## Messages

- HCP003E Invalid option - *option*
- HCP020E Userid missing or invalid
- HCP263E Too many operands were supplied for this command.

## QUERY SXSPAGES

► Query — SXSPages ◄

### Authorization

Privilege Class: A, B, E

### Purpose

Use QUERY SXSPAGES to display the status of pages in the system execution space below 2 GB (the system execution area). All system execution space pages below 2 GB are:

- Backed or unbacked – Backed pages have an associated frame in real storage; unbacked pages do not.
- Available or in-use – Available pages are candidates for usage by CP; in-use pages are used for aliases or free storage requests. An alias is a system execution space page associated with a pageable frame table entry.

Page usage for the system execution space above 2 GB (the frame table and the system execution space page management table) is not included in the response from this command.

If no real storage is available above 2 GB, those fields are still included in the response, but the status is displayed as zeros.

To display the host logical storage address ranges that are in use or usable by the system for the system execution space, use the QUERY SXSSTORAGE command.

### Usage Notes

1. The numbers displayed under Locked SXS pages identify only locked pages containing guest data.
2. Due to serialization, the number of free storage pages displayed under SXS pages in use might be different from the number of pages in the Free Storage section.
3. Trace pages associated with trace frames are in system execution space (SXS) and backed by a below-2-GB frame. This means that there is a limit on the number of trace frames due to the storage limit on SXS. An "insufficient storage" condition might occur when requesting more trace frames for each logical processor and will become more likely as the number of running logical processors in a configuration increases.

### Responses

All SXS pages:

Total=*n...n* Backed<2G=*n...n* Backed>2G=*n...n* Unbacked=*n...n*

Available SXS pages:

Total=*n...n* Backed<2G=*n...n* Backed>2G=*n...n* Unbacked=*n...n*

SXS pages in use:

Total=*n...n* Alias=*n...n* Nucleus/Prefix=*n...n* FreeStorage=*n...n* Other=*n...n*

Free Storage:

Backed<2G=*n...n* Backed>2G=*n...n* ReservedPages=*n...n*

Locked SXS pages:

Total=*n...n* ByCommand=*n...n*

Deferred SXS page requests waiting for:

Available page:

Alias=*n...n* Backed<2G=*n...n* BackedAny=*n...n*

Available frame:

```
Frame<2G=n...n  FrameAny=n...n
Total=n...n
```

All SXS pages:

**Total**

identifies the total number of pages in the system execution space:

```
Total = Backed<2G + Backed>2G + Unbacked
```

**Backed<2G**

identifies the number of pages in the system execution space that are backed with real storage frames below 2 GB.

**Backed>2G**

identifies the number of pages in the system execution space that are backed with real storage frames above 2 GB.

**Unbacked**

identifies the number of pages in the system execution space that are not backed.

Available SXS pages:

**Total**

identifies the total number of available pages in the system execution space:

```
Total = Backed<2G + Backed>2G + Unbacked
```

**Backed<2G**

identifies the number of available pages in the system execution space that are backed with real storage frames below 2 GB.

**Backed>2G**

identifies the number of available pages in the system execution space that are backed with real storage frames above 2 GB.

**Unbacked**

identifies the number of available pages in the system execution space that are not backed.

SXS pages in use:

**Total**

identifies the total number of pages in the system execution space that are currently in use:

```
Total = Alias + FreeStorage + Nucleus/Prefix + Other
```

**Alias**

identifies the number of pages in the system execution space that have an alias.

**FreeStorage**

identifies the number of pages in the system execution space that are being used for free storage requests.

**Nucleus/Prefix**

identifies the number of pages in the system execution space that are being used for the CP nucleus and the prefix pages.

**Other**

identifies the number of pages in the system execution space that are being used for purposes other than those listed elsewhere in the response.

Free Storage:

**Backed<2G**

identifies the number of pages being used for free storage requests that are backed with real storage frames below 2 GB.

## QUERY SXSPAGES

### **Backed>2G**

identifies the number of pages being used for free storage requests that are backed with real storage frames above 2 GB.

### **ReservedPages**

identifies the number of free storage reserved pages that are available for use.

Locked SXS pages:

### **Total**

identifies the total number of pages in the system execution space that are locked.

### **ByCommand**

identifies the number of pages in the system execution space that are locked by a command.

Deferred SXS page requests:

### **Alias**

identifies the number of requests that are waiting for a page for an alias.

### **Backed<2G**

identifies the number of requests that are waiting for a page backed with a real storage frame below 2 GB.

### **BackedAny**

identifies the number of requests that are waiting for a page backed with a real storage frame either above or below 2 GB.

### **Frame<2G**

identifies the number of requests that have a page but are waiting for a backing frame in real storage below 2 GB.

### **FrameAny**

identifies the number of requests that have a page but are waiting for a backing frame in real storage either above or below 2 GB.

### **Total**

identifies the total number of system execution space page requests that are waiting to be satisfied:

```
Total = Alias + Backed<2G + BackedAny + Frame<2G + FrameAny
```

## **Messages**

- HCP263E Too many operands were supplied for this command.

# QUERY SXSSTORAGE

## Authorization

Privilege Class: A, B, E

## Purpose

Use QUERY SXSSTORAGE to display the host logical storage address ranges that are in use or usable by the system for the system execution space (SXS). The command response provides the following information:

- System execution area: this area contains the CP nucleus, the prefix pages, dynamically allocated CP-use pages (including free storage pages), aliases (references to guest pages), and routines loaded with the CPXLOAD system configuration statement or the CP CPXLOAD command.

The system execution area resides below 2 GB in the SXS.

- Frame table: there is one entry in this table for every real frame in the logical partition, up to the maximum amount of real storage supported by z/VM. Each frame table entry identifies the state of the frame. For example, the frame is online and therefore addressable by z/VM, or the frame is offline and not in use. The SET STORAGE command can be used to bring frames online or to take frames offline.

The frame table resides above 2 GB in the SXS.

- System execution space page management table: there is one entry in this table for every page within the system execution area to identify its usage, including whether it is backed by a real frame, and if that frame is below 2 GB or above 2 GB.

The system execution space page management table resides above 2 GB in the SXS.

- Frame table active range: this section of the frame table bounds the online portion of real storage. The lower value corresponds to absolute frame zero, and the upper value identifies the highest addressable frame. Some of the frames within this range might be offline.

To display the status of pages in the system execution area, use the QUERY SXSPAGES command.

## Responses

Response 1:

```
System Execution Area      nnnnnnnnnnnnnnnnn - nnnnnnnnnnnnnnnnn
Frame Table                nnnnnnnnnnnnnnnnn - nnnnnnnnnnnnnnnnn
SXS Page Management Table  nnnnnnnnnnnnnnnnn - nnnnnnnnnnnnnnnnn
Frame Table Active Range   nnnnnnnnnnnnnnnnn - nnnnnnnnnnnnnnnnn
```

**Note:** If SET UNDERSCORE ON is in effect, an underscore character ( \_ ) is used to divide each 16-digit address into two 8-digit entities.

## Messages

- HCP263E Too many operands were supplied for this command.

## QUERY SYSASCII

---

► Query — SYSAscii ◄

### Authorization

Privilege Class: B

### Purpose

Use QUERY SYSASCII to determine the status of the ASCII console.

### Usage Notes

1. A VIRTUAL version of this command, QUERY VIRTUAL SYSASCII, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL SYSASCII” on page 1337](#).

### Responses

Response 1:

```
SYSASCII free status
```

is the response to QUERY SYSASCII when the ASCII console is available and not attached to a guest.

#### **status**

is either *active* or *inactive*, corresponding to whether the ASCII console session on the Hardware Management console (HMC) is open or not open.

Response 2:

```
SYSASCII attached to userid status
```

is the response to QUERY SYSASCII when the ASCII console is available and attached to a guest.

#### **userid**

is the user ID of the specified guest that has the ASCII console attached.

#### **status**

is either *active* or *inactive*, corresponding to whether the ASCII console session on the Hardware Management Console (HMC) is open or not open.

### Messages

- HCP046E SYSASCII offline
- HCP263E Too many operands were supplied for this command.

## QUERY SYSCONTROL

---

► Query — SYSCONTROL ◄

### Authorization

Privilege Class: A, E

### Purpose

Use QUERY SYSCONTROL command to determine the current values of the algorithm settings controlled by the SET SYSCONTROL command. These values should be changed only when advised by IBM support personnel.

## QUERY SYSOPER

---

► Query — SYSOPER ◄

### Authorization

Privilege Class: G

### Purpose

Use QUERY SYSOPER to display the user ID of the current primary system operator.

### Usage Notes

1. Use the SET SYSOPER command to specify the user ID for the current primary system operator. For more information, see [“SET SYSOPER” on page 1731](#).
2. When you send messages to the user ID defined as the system operator, you can use the minimum abbreviation for OPERATOR, which is OP.

### Responses

Response 1:

When you enter a QUERY SYSOPER command, you receive the response:

```
Operator ID is userid.
```

Response 2:

If no operator ID is currently defined, the response is:

```
No operator ID is currently active.
```

### Messages

# QUERY SYSTEM

## Authorization

Privilege Class: B

## Purpose

Use QUERY SYSTEM to display current user access to a system DASD volume.

## Operands

### *rdev*

is the real device number of a system DASD volume. Specify *rdev* when you want information about a single system device.

### ALL

requests a display of information about all system volumes. This is the default.

### TDisk

### TDsk

requests a display of information only about temporary disk (TDISK) usage on the volume or volumes.

## Usage Notes

1. You can use QUERY SYSTEM to display usage information about all user minidisks or only temporary disks on system DASD volumes. If you do not specify a choice, CP displays information about all user minidisks, including all temporary disks, on the volumes.
2. In an SSI cluster where there is sharing of real DASD among multiple z/VM images, QUERY SYSTEM will display only the user IDs of users on the system from which the query is made. It will not display user IDs of users linked on other systems in the SSI cluster.

## Responses

Response 1:

```

DASD rdev ATTACHED {SYSTEM} nnnn {volid}
                   {CPVOL }   {HYPERPAV ALIAS}
  
```

### *rdev*

identifies the real device number of the DASD volume.

### SYSTEM

indicates that the volume is attached to the system.

### CPVOL

indicates that the volume is owned by CP.

### *nnnn*

identifies the number of active minidisks on the volume or the number of users sharing the HyperPAV alias.

**valid**

identifies the volume label.

**HYPERPAV ALIAS**

indicates that the device is a system attached HyperPAV alias.

Response 2:

```
userid vdev xxxx[,... ] (up to three responses per line)
```

**userid**

identifies the users who have links to minidisks on the real device or users who share access to the real HyperPAV alias device.

**vdev**

identifies the virtual address by which the user refers to the minidisk or HyperPAV alias.

**xxxx**

identifies the type of access the user has, either R/O or R/W, for a minidisk, R/W for a HyperPAV alias, or the number of cylinders (CKD/ECKD) or blocks (FBA) of temporary disk space allocated. For some volumes such as CP-owned, the type of access is suppressed.

Response 3:

```
DASD MDISKS NOT FOUND
```

indicates that no active minidisks have been defined on this DASD volume.

Response 4:

```
DASD TDSKS NOT FOUND
```

indicates that no temporary disk space was defined on the indicated volume.

Response 5:

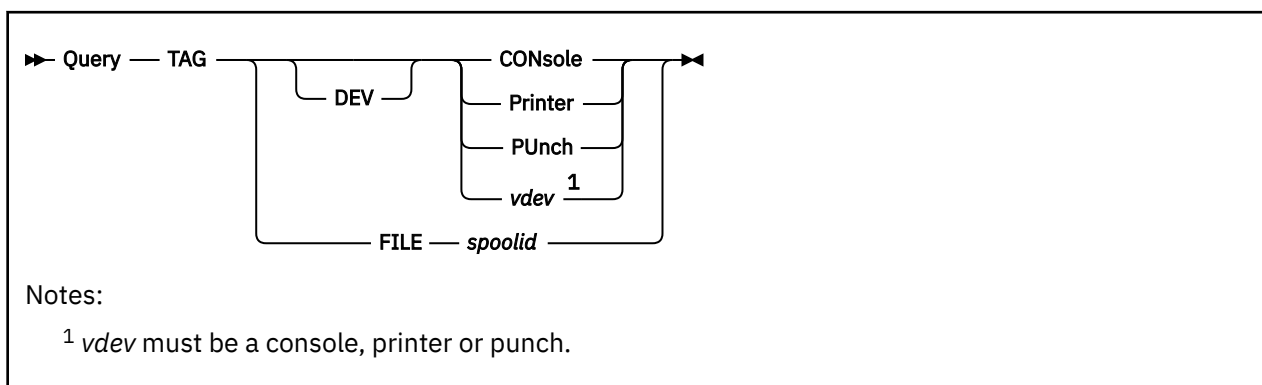

```
NO VIRTUAL HYPERPAV ALIASES DEFINED
```

indicates that no guests have defined HyperPAV aliases to share access to the real system attached HyperPAV alias device.

### Messages

- HCP002E Invalid operand - *operand*
- HCP021E A real device number was not supplied or it is invalid.
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP1008E Device *rdev* is not a DASD
- HCP1009E Device *rdev* is not attached to the system

## QUERY TAG

### Authorization

Privilege Class: G

### Purpose

Use QUERY TAG to display the tag information associated with a specific virtual spool device or file.

### Operands

#### DEV

is an optional keyword which VM/ESA accepts for compatibility reasons.

#### CONsole

#### Printer

#### PUnch

#### *vdev*

specifies the virtual spooling device whose tag information you want to display. You can specify the virtual device number *vdev* of a device if you want to query the tag information associated with a virtual spooling device at a particular device location.

#### FILE *spoolid*

specifies that you want to display the tag information associated with a previously closed spool file owned by your virtual machine. The operand *spoolid* is the system-assigned spool file identifier that belongs to the file.

### Usage Notes

1. You can control the format and content of the tag field using the TAG command.
2. If an external security manager is installed on your system, you may not be authorized to enter this command. For additional information, contact your security administrator.

### Responses

Response 1:

```
type vdev TAG:
tagtext
```

displays the tag information associated with a virtual spooling device.

#### *type*

identifies the type as PRT, PUN, or CONS.

## QUERY TAG

### ***vdev***

identifies the virtual device number.

### ***tagtext***

identifies the tag information associated with the device. This tag information may be up to 136 characters long.

Response 2:

```
tagtext
```

- or -

```
(TAG BLANK)
```

displays the tag information associated with a specified spool file.

### ***tagtext***

identifies the tag information associated with the file. This tag information may be up to 136 characters long.

### **(TAG BLANK)**

is displayed when the tag is all blanks.

Response 3:

```
type {vdev } TAG NOT SET
```

is the response if:

- You have not specified tag information for a device
- You have explicitly set the tag field to blanks.

### ***type***

identifies the type as PRT, PUN, or CONS.

### ***vdev***

identifies the virtual device number.

## **Messages**

- HCP002E Invalid operand - *operand*
- HCP016E TAG invalid for specified file type
- HCP022E A virtual device number was not supplied or it was invalid.
- HCP026E Operand missing or invalid
- HCP035E Device type missing or invalid
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP413E Command processing cannot complete due to a spool paging error.

## QUERY TAPES

### Authorization

Privilege Class: B

### Purpose

Use QUERY TAPES to display the status of real magnetic tape drives.

### Operands

#### ACTive

indicates active magnetic tape drives. An active device is one that is in use by a user or the system and is specified as neither FREE nor OFFLINE. This is the default.

#### ALL

indicates all magnetic tape drives attached to the system. The status is displayed in the order of ACTIVE, FREE, and OFFLINE. You receive the same response as you would receive if you entered all of the following commands:

```
query tapes active
query tapes free
query tapes offline
```

#### ATTach *userid*

indicates the magnetic tape drives that are attached to a user on the system. If you specify *userid*, only tape drives attached to that user's virtual machine are indicated. If you do not specify *userid*, you receive the status of all tape drives attached to any user on the system. Attached drives are always active.

#### BOXed

indicates the magnetic tape drives that are unavailable (usually because of a hardware condition). A boxed drive may also be active, free, or offline.

#### DETailS

displays detailed information about real tapes.

## QUERY TAPES

### **rdev**

#### **rdev1-rdev2**

is the real device number (*rdev*), a range of real device numbers (*rdev1-rdev2*), or some combination of those items.

For tapes attached to a library, the information provided is:

- Library Identifier (sequence number)
- Logical Device Group Identifier (libport)

For tapes not attached to a library, the information is not relevant and is returned as a string of dashes ("-").

For tapes that are capable of hardware encryption, this information will also be presented, along with any encryption settings that were established via the ATTACH or SET RDEV commands.

### **FREE**

indicates all free magnetic tape drives. A free drive is one that is not currently in use by a user or the system and is specified as neither ACTIVE nor OFFLINE.

### **OFFline**

indicates all offline magnetic tape drives. An offline drive is one that is specified as neither ACTIVE nor FREE. This offline response will also show offline drives that are quiesced.

### **QUIesced**

indicates all quiesced magnetic tape drives. An quiesced drive is an OFFLINE drive that cannot be varied online until a resume request is received for the drive.

### **SYStem**

indicates the drives in use by the system. A system device is always active.

## Usage Notes

1. A VIRTUAL version of this command, QUERY VIRTUAL TAPES, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL TAPES”](#) on page 1338.

## Responses

If the system is using a magnetic tape drive that is in an intervention-required state and you enter QUERY TAPES, you receive a response like this:

```
Tape 0104 has intervention required.
```

0104 is the real device number of the tape drive that needs the operator's intervention.

**Note:** This response will be preceded by one of the following.

Response 1:

If you enter a QUERY TAPES, QUERY TAPES ACTIVE, or QUERY TAPES ATTACH command and there is a tape drive dedicated to a user, you see something like this:

```
q tapes attach
TAPE 0102 ATTACHED TO RALPH 0236 R/W
Ready;
```

This means the magnetic tape drive at the address 0102 is attached to RALPH's virtual machine as the virtual device number 0236. R/W means the user RALPH has read-write access to the tape drive. R/W might also read R/O, which means the user has read-only access.

Response 2:

If the tape drive is currently being used by the TRSAVE command, you see something like this:

```
q tapes
TAPE 0242 ASSIGNED SYSTEM TRSAVE
Ready;
```

## Response 3:

If a tape that is not dedicated to a user is not available (boxed) or you enter a QUERY TAPES BOXED command, you see something like this:

```
q tapes boxed
TAPE 0244 BOXED
Ready;
```

## Response 4:

If you enter a QUERY TAPES ALL command, CP displays the same response as it would display if you entered QUERY TAPES ACTIVE, QUERY TAPES FREE, and QUERY TAPES OFFLINE commands.

## Response 5:

If CP cannot find a tape drive of the type you specified, you see a response like this:

```
q tapes offline
An offline tape was not found.
Ready;
```

In this response, *offline* may be replaced with *active*, *attached*, *BOXED*, *free*, depending on what you specified on the command.

## Response 6:

If you enter a QUERY TAPES, QUERY TAPES ACTIVE, QUERY TAPES ALL, or QUERY TAPES ATTACH command, and the tape drive was previously attached with the MULTIUSER option of the CP ATTACH command or the MULTIUSER operand of the DEDICATE directory statement, you see a response like this:

```
q tapes attach
TAPE 2100 ATTACHED TO USER1    0181 R/W  NOASSIGN MULTIUSER
TAPE 2100 ATTACHED TO USER2    0181 R/W  NOASSIGN MULTIUSER
Ready;
```

This means that the magnetic tape drive at real address 2100 is attached to USER1 and USER2 at virtual device address 0181. MULTIUSER indicates that the tape drive is shared by both users, and NOASSIGN states that the users must manage the assignment of the tape drive by using *assign* and *unassign* I/O.

## Response 7:

If you enter a QUERY TAPES DETAILS *rdev(s)* command, and the tape drive is not a part of the library, you will see a response like this:

```
q tapes details 4499
16:06:22 TAPE 4499 SEQUENCE NUMBER ----- LIBPORT -
Ready; T=0.01/0.01 16:06:22
```

For a device that is part of a library, you will see a response like this:

```
q tapes details 4300
20:04:04 TAPE 4300 SEQUENCE NUMBER 00103 LIBPORT 1
Ready; T=0.01/0.01 20:04:04
```

**Note:** For the 3592 Model E07 and higher, an additional line showing the current tape block position and relative position will be shown. See the next response below for an example.

## Response 8:

If you enter a query TAPES DETAILS command, and the tape drive is capable of hardware encryption, you will see a response like this:

```
q tapes details BB00
TAPE BB00 SEQUENCE NUMBER E0010 LIBPORT 1 ENCRYPTION CAPABLE
```

## QUERY TAPES

```
ACTIVE KEY LABEL(S):  
  (L) existing key label one  
  (H) a different key label used with a hash mechanism  
ATTACHED KEY LABEL(S):  
  (L) the first mighty key label  
  (H) the second mighty key label  
INACTIVE KEY LABEL(S): DEFAULT  
Position: 1350147 BLK Relative position: 005%  
Ready; T=0.01/0.01 00:11:09
```

### Note:

1. The ATTACHED KEY LABEL(S) are only displayed if they differ from what is currently being used on the tape cartridge, such as when data is being appended to an existing tape.
2. An encoding mechanism of "label" means the key label is used directly, while a "hash" encoding mechanism creates a hash out of the key label and provides more flexibility in sharing encrypted data.
3. The "inactive" keys are specified on a SET RDEV command, while the "active" keys are either specified on an ATTACH command, or are promoted from the "inactive" setting when an ATTACH does not include encryption keys.
4. The last line, showing the current tape block position and relative position, is shown only for the 3592 Model E07 and higher.

### Messages

## QUERY TDISK

### Authorization

Privilege Class: B

### Purpose

Use QUERY TDISK to display all defined and assigned temporary disk (TDISK) space.

### Responses

Response 1:

```
DASD rdev ATTACHED CPVOL nnnn valid
```

#### ***rdev***

identifies the real device number of the DASD volume.

#### **CPVOL**

indicates that the volume is a CP volume.

#### ***nnnn***

identifies the number of temporary disk links on this volume.

#### ***valid***

identifies the volume label.

Response 2:

```
userid vdev nnnn [,...] (up to 3 responses per line)
```

#### ***userid***

identifies the users who have temporary disk links on *rdev*.

#### ***vdev***

identifies the virtual address by which the user refers to the tdisk.

#### ***nnnn***

identifies the number of cylinders (CKD/ECKD) or blocks (FBA) of temporary disk space allocated.

Response 3:

```
DASD TDSKS NOT FOUND
```

indicates that no active temporary DASD have been defined.

### Messages

- HCP002E Invalid operand - *operand*

## QUERY TDISKCLR

---

► Query — TDISKCLR ◄

### Authorization

Privilege Class: B

### Purpose

Use QUERY TDISKCLR to display the status of the TDISK clearing function. This status depends on the setting in the FEATURES system configuration statement.

### Responses

Response 1:

```
Temporary Disk Security is active.
```

is displayed if all TDISK space is currently being cleared whenever a DASD volume is attached to the system or whenever a TDISK minidisk is being detached from a user.

Response 2:

```
Temporary Disk Security is inactive.
```

is displayed if no TDISK clearing is being performed.

### Messages

# QUERY TERMINAL

► Query — TERminal ◄

## Authorization

Privilege Class: G

## Purpose

Use QUERY TERMINAL to display the options active for your virtual console.

## Usage Notes

1. The SCRNSAVE function of the TERMINAL command is not supported by z/VM. It is included with its default setting only for compatibility with VM/SP HPO.
2. CP displays the TYPE, PROMPT, SCROLL, CNTL, and ASCIITBL messages only when you enter the command from a TTY device.

## Responses

Response 1:

```

LINEND {char}, LINEDEL {char}, CHARDEL {char}, ESCAPE {char}, TABCHAR {char}
      {OFF} {OFF} {OFF} {OFF} {OFF}

LINESIZE {nnn}, ATTN {ON}, APL {ON}, TEXT {ON}, MODE {CP}, HIGHLIGHT {ON}
      {OFF} {OFF} {OFF} {OFF} {VM} {OFF}

CONMODE {3215}, BREAKIN {IMMED}, BRKKEY {PA1}, SCRNSAVE {OFF}
      {3270} {GUESTCTL} {PA2}
      {NONE} {PFnn}
      {CLEAR}
      {NONE}

TYPE {3101}, PROMPT {VM}, SCROLL {nnn}, CNTL {SYS}, ASCIITBL {VM1}
      {TTY} {TTY} {CONT} {USR} {VM2}

AUTOOCR {ON}, MORE nnn mmm, HOLD {ON}, TIMESTAMP {CP}, SYS3270 {ON}
      {OFF} {OFF} {ON} {OFF} {OFF}
      {OFF}

PRECEDENCE {SECUSER}
      {STARMSG}

```

### LINEND char

#### LINEND OFF

displays the logical line end symbol in effect for your virtual machine (*char*), or indicates that no logical line end symbol is allowed (OFF).

### LINEDEL char

#### LINEDEL OFF

displays the logical line delete symbol in effect for your virtual machine (*char*), or indicates that no logical line delete symbol is allowed (OFF).

### CHARDEL char

#### CHARDEL OFF

displays the logical character delete symbol in effect for your virtual machine (*char*), or indicates that no logical character delete symbol is allowed (OFF).

**ESCAPE char****ESCAPE OFF**

displays the logical escape character in effect for your virtual machine (*char*), or indicates that no logical escape character is allowed (OFF).

**TABCHAR char****TABCHAR OFF**

displays the tab character symbol in effect for your virtual machine (*char*), or indicates that no logical tab character is defined (OFF).

**LINESIZE nnn****LINESIZE OFF**

specifies the maximum allowable line length for terminal output that is in effect for your virtual machine. OFF specifies that the terminal output line length is not adjusted by CP.

**ATTN ON****ATTN OFF**

indicates whether the attention signal is to be reflected on keyboard or printer terminals. If ON, the printer reflects it as an exclamation point (!) followed by a carriage return.

**APL ON****APL OFF**

indicates whether CP is to use the APL terminal translation tables or the normal translation tables. If APL is ON, CP uses the APL translation tables.

**TEXT ON****TEXT OFF**

indicates whether CP is to use the TEXT terminal translation tables or the normal terminal translation tables. If TEXT is ON, CP uses the TEXT translation tables.

**MODE CP****MODE OFF**

indicates whether one or more attentions force your virtual machine into the CP environment, or whether one or more attentions are reflected to your virtual machine. If MODE is CP, one attention forces your virtual machine into the CP environment.

**HILIGHT ON****HILIGHT OFF**

ON means CP highlights the command redisplay line. OFF means CP displays the command redisplay line at normal intensity.

**CONMODE 3215****CONMODE 3270****CONMODE NONE**

indicates the console mode of your virtual console. 3215 indicates that CP provides 3215 CCW processing, and 3270 indicates that it provides 3270 CCW processing. NONE indicates that your virtual machine does not currently have a console defined.

**BREAKIN IMMED****BREAKIN GUESTCTL**

lets you control break-in by CP for full-screen guests. The GUESTCTL option specifies that, while in full-screen mode, messages from CP are displayed only when you press the BRKKEY key. If you specify GUESTCTL, CP break-in still occurs if you request a CP function or if a priority message is pending for your virtual machine. GUESTCTL is specified using TERMINAL BREAKIN. If you specify IMMED, which is the default, break-in by CP takes place on any full-screen READ and full-screen WRITE that has an inactive keyboard. Break-in also takes place when you press the BRKKEY.

**BRKKEY PA1****BRKKEY PA2****BRKKEY PFnn****BRKKEY CLEAR****BRKKEY NONE**

displays the key that controls break-in by CP for full-screen guests (to allow you to return to CP mode). NONE indicates that there is no BRKKEY defined or it is disabled.

**SCRNSAVE OFF**

is included with its default setting for reasons of compatibility.

**TYPE 3101****TYPE TTY**

3101 identifies the terminal as a display device, and 3101 functions are enabled. TTY identifies the terminal as a typewriter terminal, and 3101 functions are not in effect.

**PROMPT VM****PROMPT TTY**

VM indicates that VM enables the line feed prompting sequence. TTY indicates that VM enables the normal TTY prompting sequence of a period in column 1 and the cursor in column 2.

**SCROLL nnn****SCROLL CONT**

The operand *nnn* specifies the number of lines displayed before the status **\*\*\* MORE \*\*\*** is displayed. CONT specifies continuous scrolling without interruption.

**CNTL SYS****CNTL USR**

SYS specifies that CP inserts TTY line control characters for output directed to a TTY terminal. USR specifies that the application program inserts TTY line control characters for output directed to a TTY terminal.

**ASCIITBL VM1****ASCIITBL VM2**

VM1 specifies the use of the translation table based on the TTY ANSI X3.4 1977 standard. VM2 specifies the use of the translation table based on the TTY ANSI X3.26 1980 standard.

**AUTO CR ON****AUTO CR OFF**

ON specifies that a carriage return is performed following the execution of the 3215 CCW X'01' (write without carriage return to a graphic display operating in line mode). OFF specifies that a carriage return not be performed.

**MORE nnn mmm**

specifies the number of seconds that will elapse between system actions. *nnn* is the number of seconds between when the time when a MORE . . . is displayed and the terminal alarm sounds. *mmm* is the number of seconds between the time when the alarm sounds and the screen is cleared.

**HOLD ON****HOLD OFF**

ON means CP displays a status of HOLDING when the screen fills up and at least one highlighted message appears on the screen. OFF means CP does not display a status of HOLDING. You can still cause CP to display a HOLDING status by pressing the Enter key when CP has displayed a MORE . . . status.

**TIMESTAMP CP****TIMESTAMP ON****TIMESTAMP OFF**

CP means control program messages and command responses on the console are prefixed with the local time of day. OFF means messages are displayed with no prefix. ON causes all virtual machine and CP messages to be identified with time stamps.

**SYS3270 ON****SYS3270 OFF**

ON means the virtual console emulates an integrated 3270 device. OFF means the virtual console does not emulate an integrated 3270 device.

**PRECEDENCE SECUSER****PRECEDENCE STARMMSG**

The PRECEDENCE setting determines the order of preference for delivering virtual console output that is eligible for routing both to a secondary user and through the primary user's connection to the \*MSG or \*MSGALL IUCV system service. SECUSER means that such output should be sent to a secondary

## QUERY TERMINAL

user. STARMMSG means that such output should be sent through IUCV. See [“TERMINAL PRECEDENCE”](#) on page 1938 for details.

### Messages

- HCP263E Too many operands were supplied for this command.

## QUERY THROTTLE

### Authorization

Privilege Class: B, E

### Purpose

Use QUERY THROTTLE to display the devices being throttled and their I/O rates.

### Operands

#### ALL

tells CP to display all the real devices that are being throttled, their I/O rates and any delays that have occurred for the given devices. ALL is the default.

#### *rdev*

#### *rdev1-rdev2*

is the real device number or range of real device numbers for which you want I/O throttling information.

### Usage Notes

1. To change I/O throttling on your system, use the SET THROTTLE command (see [“SET THROTTLE”](#) on page 1734).

### Responses

Response 1:

To display all of the real devices in the I/O throttling list and their current I/O rates, enter the following QUERY THROTTLE command:

```
query throttle all
I/O throttling is currently active. 2 device(s) are in the list
Device 0701 has 6 delays. Rate is 1 I/Os per second
Device 0702 has 0 delays. Rate is 2 I/Os per second
Ready;
```

Response 2:

To query throttling of a specified device enter the following QUERY THROTTLE command:

```
query throttle 702
Device 0702 has 0 delays. Rate is 2 I/Os per second
Ready;
```

Response 3:

To query throttling for a range of devices enter the following QUERY THROTTLE command:

## QUERY THROTTLE

```
query throttle 701-704
Device 0701 has 6 delays. Rate is 1 I/Os per second
Device 0702 has 0 delays. Rate is 2 I/Os per second
Device 0703 has 0 delays. Rate is 4 I/Os per second
Device 0704 is not in the I/O throttling list
Ready;
```

Response 4:

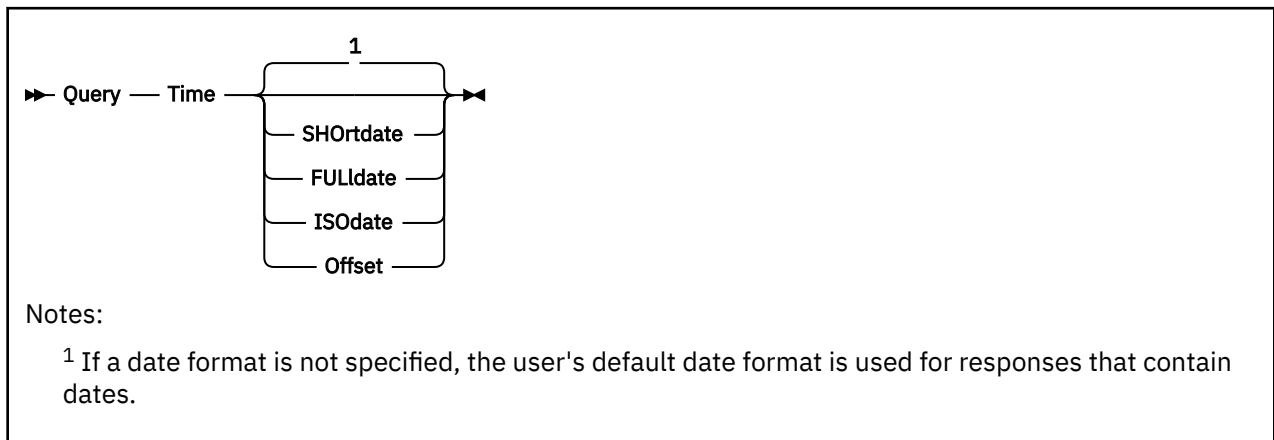

If no throttling is active:

```
query throttle
I/O throttling is not currently active
Ready;
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP009E An invalid address range was specified.
- HCP040E Device *rdev* does not exist
- HCP1150E DASD *rdev* is not a valid base exposure.

## QUERY TIME

### Authorization

Privilege Class: G

### Purpose

Use QUERY TIME to display the following:

- Current time
- Time zone
- Day of the week
- Date
- Connect time for the current session
- Processor time for the current session

### Operands

#### SHOrtdate

specifies that dates in the response to this command will be displayed in *mm/dd/yy* format, where *mm* is the month, *dd* is the day of the month, and *yy* is the 2-digit year.

#### FULldate

specifies that dates in the response to this command will be displayed in *mm/dd/yyyy* format, where *mm* is the month, *dd* is the day of the month, and *yyyy* is the 4-digit year.

#### ISOdate

specifies that dates in the response to this command will be displayed in *yyyy-mm-dd* format, where *yyyy* is the 4-digit year, *mm* is the month, and *dd* is the day of the month.

#### Offset

indicates that you want to see the difference between the system's current time zone and Coordinated Universal Time (UTC).

### Usage Notes

1. If the wait-state interpretation capability is available on the real processor, it is used for dedicated virtual CPUs. When the wait-state interpretation capability is used, the guest virtual machine remains dispatched even when it enters a PSW enabled-wait state. Time consumed dispatched in the wait state is included in the virtual and total CPU time reported for the guest.

## QUERY TIME

2. The default date format for certain CP and CMS commands can be set on a system-wide basis and also for the individual user. The system-wide default date format is set with the `SYSTEM_DATEFORMAT` system configuration statement. The user's default date format is set with the `DATEFORMAT` directory statement. The system-wide default and the user's default can also be set with the `CP SET DATEFORMAT` command. The user's default date format defaults to the system-wide default. The system-wide and user settings can be queried with the `CP QUERY DATEFORMAT` command. The hierarchy of possible date format settings for the `QUERY TIME` command, from highest priority to lowest, is:

- `QUERY TIME` command operand
- User default
- System-wide default

### Responses

Response 1:

If you enter `QUERY TIME SHORTDATE`, you get the following response:

```
TIME IS hh:mm:mm zone weekday mm/dd/yy  
CONNECT= hh:mm:ss VIRTCPU= mmm:ss.hs TOTCPU= mmm:ss.hs
```

This shows the current real clock time (in hours, minutes, and seconds), the time zone (for example, EST), the day of the week, and the calendar date.

Response 2:

If you enter `QUERY TIME FULLDATE`, you get the following response:

```
TIME IS hh:mm:mm zone weekday mm/dd/yyyy
```

```
CONNECT= hh:mm:ss VIRTCPU= mmm:ss.hs TOTCPU= mmm:ss.hs
```

Response 3:

If you enter `QUERY TIME ISODATE`, you get the following response:

```
TIME IS hh:mm:mm zone weekday yyyy-mm-dd
```

```
CONNECT= hh:mm:ss VIRTCPU= mmm:ss.hs TOTCPU= mmm:ss.hs
```

*Explanation of Response 1, 2, and 3 Contents:*

#### **CONNECT= hh:mm:ss**

identifies the actual clock time consumed in the current session in hours, minutes, and seconds. The maximum value for this field is 99:59.59. A time value larger than the maximum will be indicated by this value.

#### **VIRTCPU= mmm:ss.hs**

identifies the virtual processor time consumed in the current session in minutes, seconds, and hundredths of seconds. The maximum value for this field is 999:59.99. A time value larger than the maximum will be indicated by this value. If multithreading is enabled, this is reported as MT-1 equivalent time.

#### **TOTCPU= mmm:ss.hs**

identifies the total processor time (virtual and overhead) consumed in the current session in minutes, seconds, and hundredths of seconds. The maximum value for this field is 999:59.99. A time value larger than the maximum will be indicated by this value. If multithreading is enabled, this is reported as MT-1 equivalent time.

Response 4:

If you enter `QUERY TIME OFFSET`, you get the following response:

```
Time zone zone is hh.mm.ss direction of UTC.
```

shows the current time zone's offset from UTC, Coordinated Universal Time.

***zone***

is the identifier (for example, EST) that indicates the current time zone.

***hh.mm.ss***

is the number of hours, minutes, and seconds that the current time is offset from UTC.

***direction***

is the geographical direction of this time zone from longitude 0. *direction* may be EAST or WEST.

You could also receive this response:

```
Time zone zone is equivalent to UTC.
```

This means the value for the adjustment from UTC (the *hh.mm.ss* value) is zero.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

# QUERY TIMEZONES

## Authorization

Privilege Class: G

## Purpose

Use QUERY TIMEZONES to display the list of active and inactive time zone definitions on your system.

## Operands

### *zoneid*

specifies the time zone ID definition that you wish to display. When *zoneid* is omitted, CP displays information about all defined time zones and identifies the active time zone.

## Usage Notes

1. To define new time zones or to change existing time zone characteristics, use the DEFINE TIMEZONE command. For more information, see [“DEFINE TIMEZONE” on page 225](#).
2. To select a new active time zone, use the SET TIMEZONE command. For more information, see [“SET TIMEZONE” on page 1738](#).
3. You can also define time zones and set the active time zone in the system configuration file by using the [TIMEZONE\\_DEFINITION Statement](#) and [TIMEZONE\\_BOUNDARY Statement](#). For more information, see *z/VM: CP Planning and Administration*.

## Responses

Response 1:

The QUERY TIMEZONES command provides this type of response:

Zone	Direction	Offset	Status
GMT	----	00.00.00	Inactive
UTC	----	00.00.00	Inactive
EDT	West	04.00.00	Active
EST	West	05.00.00	Inactive
PDT	West	07.00.00	Inactive
PST	West	08.00.00	Inactive
CET	East	01.00.00	Inactive
CDT	West	05.00.00	Inactive

The first column shows the time zone ID (*zoneid*). This identifier can be used in a SET TIMEZONE command. CP automatically defines the Greenwich Mean Time (GMT) and Coordinated Universal Time (UTC) time zones.

The second column shows the geographical direction of this time zone from longitude 0. If you define a time zone with an offset of 00.00.00, CP does not display a direction.

The third column shows the offset (expressed in hours, minutes, and seconds) between the time zone and the UTC time zone.

The fourth column tells whether the time zone is currently active. Only one time zone can be active at one time.

Response 2:

When in an STP environment that derives time zone information from the STP server, the QUERY TIMEZONES command lists only the time zones provided by STP as well as the default GMT/UTC. The format of the boundary output is dependent on the issuing user's dateformat setting. The response looks like the following:

Zone	Direction	Offset	Status	Boundary
GMT	----	00.00.00	Inactive	
UTC	----	00.00.00	Inactive	
EDT	West	04.00.00	Active-(STP)	
EST	West	05.00.00	Inactive-(STP)	10/31/09 02:00:00

If the Adjust Time Zone panel on the HMC is configured to MANUAL, and no boundary has been configured then the boundary output defaults to 'Not Scheduled' as shown in the following:

Zone	Direction	Offset	Status	Boundary
GMT	----	00.00.00	Inactive	
UTC	----	00.00.00	Inactive	
EDT	West	04.00.00	Active-(STP)	
EST	West	05.00.00	Inactive-(STP)	Not Scheduled

### Messages

## QUERY TOKEN

### Authorization

Privilege Class: B

### Purpose

Use QUERY TOKEN to display the current or target configuration token for your machine. CP uses this token and the channel subsystem when making dynamic I/O changes.

### Operands

#### CURrent

tells CP to display the current configuration token.

#### TARget

tells CP to display the target configuration token.

### Usage Notes

1. The *current* configuration token is a string value associated with the present I/O configuration.
2. The *target* configuration token is a string value associated with the I/O configuration after a dynamic I/O configuration change has completed successfully.
3. For more information on configuration tokens see the [SAY Statement](#) in *z/VM: CP Planning and Administration*.

### Responses

Response 1:

To display the current token, enter the following:

```
query token current
The current VM configuration token is:
VM-TOKEN05/03/9507:02:51    ...05/03/9506:42:27
Ready;
```

If your system is not allowed to make dynamic I/O changes you will see the following:

```
query token current
HCPCC06816E Dynamic I/O changes are not allowed on this system
The current channel subsystem configuration token is:
PKSTYAC1 99-12-10 07:24:43 WRY    IODF
Ready(06816);
```

Response 2:

To display the target token, enter the following:

```
query token target
The target VM configuration token is:
VM-TOKEN05/03/9507:02:51    ...05/03/9506:42:27
Ready;
```

If your system is not allowed to make dynamic I/O changes you will see the following:

```
query token target
HCPCC06816E Dynamic I/O changes are not allowed on this system
The target channel subsystem configuration token is:
PKSTYAC1 99-12-10 07:24:43 WRY      IODF
Ready(06816);
```

## QUERY TRACE

### Authorization

Privilege Class: G

### Purpose

Use QUERY TRACE to display the TRACE settings.

### Operands

#### ACTive

identifies the default option and displays attributes of all traps within the active trace set. This is the default.

#### ALL

displays attributes of all traps within all trace sets.

#### *name*

displays attributes of all traps within the trace set specified by the 1- to 8-character name.

#### RETurns

displays TRACE CALL return path. No trap attributes are displayed.

#### SETS

displays all trace set names. No trap attributes are displayed.

### Usage Notes

1. QUERY PER is accepted as a synonym for QUERY TRACE.

### Responses

Response 1:

```
TRACE COUNT IS nnnnnnnn
```

precedes the display of trace traps if TRACE COUNT is active.

Response 2:

The following response is to QUERY TRACE SETS.

```
SETS: name1, name2, ...
```

#### *name1...*

identifies trace set names.

Response 3:

The following response is to QUERY TRACE RETURNS.

```
RETURNS: name1, name2,...
```

**name1...**

identifies trace sets in the trace return path.

Response 4:

```
No trace sets defined
```

is the response for any form of the QUERY TRACE command if no trace sets have been defined.

Response 5:

```
No trace calls active
```

is the response for QUERY TRACE RETURNS if no trace calls are active; therefore, there are no return paths.

Response 6:

The following responses are to QUERY TRACE ALL, QUERY TRACE ACTIVE, and QUERY TRACE *name*.

The current status of all defined trace sets, of trace traps within the active trace set, or of a specifically identified trace set, is displayed by QUERY TRACE. Each trace trap has a specific format as shown below where *ident* is the trace trap identifier for each trap within the trace set. A common header exists for these responses.

```
NAME setname (ACTIVE+[NO]TXSUSPEND)
              (ACTIVE+SUSPEND+[NO]TXSUSPEND)
              ([NO]TXSUSPEND)
```

**Notes:**

1. The parenthesized word ACTIVE appears in the "NAME *setname* ..." header line for the set that is currently active.
2. TXSUSPEND indicates that traps in this trace set will be suspended while the virtual CPU is in transactional-execution mode. See "[TRACE TXSUSPEND/NOTXSUSPEND](#)" on page 2003 for details.

Trace entries can be displayed as `STO raddr; ASN xxx` or as `ASCE raddr;`; the STO or ASCE information may be on a line by itself, depending on the length of the FROM and INTO information.

Query Trace Examples:

```
1  BRANCH FROM 0000000000000000-1111111111111111
    INTO 0000222222222222-0000555555555555
    TERM  NOPRINT NORUN SIM
    SKIP 00000 PASS 00000 STOP 00000 STEP 00000
    CMD  NONE

2  BRANCH FROM 0000000000000000-1111111111111111
    STO 00000000 ASN 0000
    INTO 0000222222222222-0000555555555555
    STO 00000000 ASN 0000
    TERM  NOPRINT NORUN SIM
    SKIP 00000 PASS 00000 STOP 00000 STEP 00000
    CMD  NONE

3  BRANCH FROM 00000000-00000011          STO 00000000 ASN 0000
    INTO 00002222-00005555          STO 00000000 ASN 0000
    TERM  NOPRINT NORUN SIM
    SKIP 00000 PASS 00000 STOP 00000 STEP 00000
    CMD  NONE

4  STORE FROM 00000000-00000011          STO 00000000 ASN 0000
    INTO 00000000000000222-0000055555555555
    STO 00000000 ASN 0000
    TERM  NOPRINT NORUN SIM
    SKIP 00000 PASS 00000 STOP 00000 STEP 00000
    CMD  NONE
```

Access Register Alteration Trap Format

```

## QUERY TRACEFRAMES

---

► Query — TRACEFRAMES ◄

### Authorization

Privilege Class: A, B, C, E

### Purpose

Use QUERY TRACEFRAMES to display the number of frames that are set aside for an internal trace table for the master processor and the alternate processors in the configuration.

### Usage Notes

1. CP maintains separate internal trace tables for each processor in the configuration. The QUERY TRACEFRAMES command displays the number of trace frames in the internal trace table of the master processor and the size of the internal trace tables of the alternate processors. The size of the internal trace table of an alternate processor is expressed as a percentage of the master processor's trace table.
2. Use the SET TRACEFRAMES command to change the size of the internal trace tables. For more information, see [“SET TRACEFRAMES” on page 1742](#).
3. See [“QUERY FRAMES” on page 925](#) for information on the current usage of real storage, including trace frames.

### Responses

Response 1:

If the response to a QUERY TRACEFRAMES command were:

```
Master processor trace frames = 100  
Alternate processor trace frames = 90 percent of master
```

and you had a 4-processor CPU, the master processor would have a 100-frame internal trace table, and each of the three alternate processors would have a 90-frame internal trace table.

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *operand*

# QUERY TRFILES

## Authorization

Privilege Class: A, C, D, E, G

## Purpose

Use QUERY TRFILES to display detailed information about the following:

- One or more system trace files
- The count of system trace files belonging to one or all users

**Note:** System trace files are system data files created by the TRSAVE and TRSOURCE commands.

## Operands

### ALL

queries all system trace files.

### SYSTEM

specifies that the files should be queried regardless of who owns or originated them.

### U

### USERID

indicates that the next operand is a user ID.

### \*

### *userid*

specifies the owner or originator of the files to be queried. The file owner is specified by TO *userid* on the TRSAVE command. When TO is not specified, the owner is the command issuer. For trace IDs specified by the TRSOURCE ID xxx TYPE GT FOR *userid* command, the file originator is specified by FOR *userid*. Otherwise, it is SYSTEM.

If you are a class G user, you may query only the files that you own or originate. If you, as a class G user, use the *userid* operand to specify a user ID other than your own, you receive information on all spool files that you originated and are owned by the specified user ID. If you use asterisk (\*), or you default to it, you receive information on the files you currently own.

### NAME *fn*

specifies the file name of the files to be queried. This is the file name specified on the command TRSAVE...ON DASD NAME *fn*... when the trace was started. More than one file can exist with the same file name for a given owner.

### *spoolid*

identifies the spool file to be queried.

### SHOrtdate

specifies that dates in the response to this command will be displayed in *mm/dd* format, where *mm* is the month and *dd* is the day of the month.

### FULldate

specifies that dates in the response to this command will be displayed in *mm/dd/yyyy* format, where *mm* is the month, *dd* is the day of the month, and *yyyy* is the 4-digit year.

### ISOdate

specifies that dates in the response to this command will be displayed in *yyyy-mm-dd* format, where *yyyy* is the 4-digit year, *mm* is the month, and *dd* is the day of the month.

### COUNT

displays only the number of system trace files that match the criteria specified on the command.

## Usage Notes

1. The default date format for certain CP and CMS commands can be set on a system-wide basis and also for the individual user. The system-wide default date format is set with the SYSTEM\_DATEFORMAT system configuration statement. The user's default date format is set with the DATEFORMAT directory statement. The system-wide default and the user's default can also be set with the CP SET DATEFORMAT command. The user's default date format defaults to the system-wide default. The system-wide and user settings can be queried with the CP QUERY DATEFORMAT command. The hierarchy of possible date format settings for the QUERY TRFILES command, from highest priority to lowest, is:
  - QUERY TRFILES command operand
  - User default
  - System-wide default

## Responses

Response 1:

The following is an example of a response to QUERY TRFILES SYSTEM SHORTDATE:

```
OWNERID FILE TYPE CL RECS DATE TIME FILENAME FILETYPE ORIGINID
ownerid file type c recs mm/dd hh:mm:ss filename filetype
orig
```

Response 2:

The following is an example of a response to QUERY TRFILES SYSTEM FULLDATE:

```
OWNERID FILE TYPE CL RECS DATE TIME FILENAME FILETYPE ORIGINID
ownerid file type c recs mm/dd/yyyy hh:mm:ss filename filetype
orig
```

Response 3:

The following is an example of a response to QUERY TRFILES SYSTEM ISODATE:

```
OWNERID FILE TYPE CL RECS DATE TIME FILENAME FILETYPE ORIGINID
ownerid file type c recs yyyy-mm-dd hh:mm:ss filename filetype
orig
```

### OWNERID

identifies the file owner. The file owner is specified by TO *userid* when the TRSAVE command is issued; if TO is not specified, the owner is the TRSAVE command issuer.

### FILE

identifies the spool file.

### TYPE

indicates the type of system data file. This is TRF for system trace files.

### CL

identifies the class file, either A or W. If the file class is A, the file can be processed. If the file class is W, the file is in the set of files to which an active trace is writing.

### RECS

identifies the number of 4 KB pages in the file.

### DATE

identifies the date the file was closed. If the file is open for reading or writing, or if the file is being processed by the TRACERED utility, OPEN-TRSAVE is displayed instead of a date and time. The format of the date is determined by the SHORTDATE, FULLDATE, or ISODATE operand. If no date format operand is specified, the user's default date format setting is used.

### TIME

identifies the time the file was closed.

### FILENAME

identifies the file name assigned by the issuer of the TRSAVE command.

### FILETYPE

identifies the file type assigned to the file. System trace files are typed as follows:

#### Type

#### Meaning

#### CP

CP system trace tables

#### VM

Trace data for a user ID

#### VMG

Trace data for a virtual machine group

## QUERY TRFILES

### IO

Trace data from IO trace

### DATA

Trace data from DATA trace

### PCI

Trace data from PCI function trace

### ORIGINID

identifies the originator of the trace file. For traces defined by TRSOURCE...TYPE GT FOR USER... commands, *originid* is the user ID specified by FOR USER. For VM GROUPS, *originid* is the user ID that originated the trace file. For traces defined by the TRSOURCE...TYPE IO... command or by the TRSOURCE...TYPE DATA...command, *originid* is SYSTEM.

Response 4:

If no files as specified by the command line exist, the following response is given:

```
FILES:    NO TRF
```

Response 5:

If the COUNT option is specified on the QUERY TRFILES command, only the number of system trace files that match the criteria specified is displayed. The following is the response:

```
FILES: {nnnn} TRF
       { } NO{ }
```

### *nnnn*

identifies the number of system trace files. If no files are found that match the selection criteria, then NO replaces *nnnn*.

Response 6:

If an external security manager (ESM) is installed and security label checking is enabled, the ESM is called to verify the user's access to each file. If the user is denied access to a specific file, some of the information about that file must be hidden from the user. The only fields of the response that will contain information are OWNERID, FILE, TYPE, CLASS, DATE, TIME, and ORIGINID. All other fields contain asterisks.

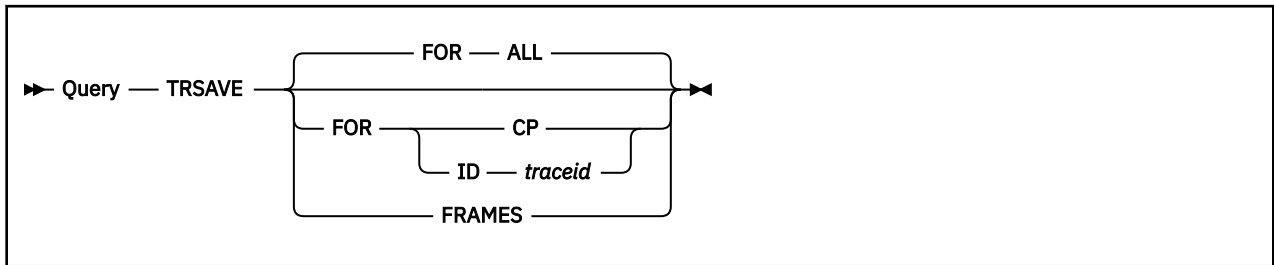

The system response when you are denied access to the file is similar to the following:

```
OWNERID  FILE TYPE CL RECS DATE  TIME      FILENAME FILETYPE ORIGINID
*****  file type c  **** date  hh:mm:ss ***** *****
orig
```

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP413E Command processing cannot complete due to a spool paging error.
- HCP422E The same option was specified twice.
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP848E SYSTEM parameter is invalid with the spoolid option
- HCP849E A userid must be specified with the spoolid
- HCP1558E Command processing cannot complete.

# QUERY TRSAVE

## Authorization

Privilege Class: A, C, E, G

## Purpose

Use QUERY TRSAVE to display the destination of traces defined by TRSOURCE, or to display the status of traces controlled by SET CPTRACE.

## Operands

### ALL

displays the status of all active TRSAVE functions, or indicates that there are no active functions.

### CP

displays the status of TRSAVE activity for CP system tracing. This option is allowed only for class A, C, and E users.

### FRAMES

displays the number of frames allocated from the system dynamic paging area for active DEFERIO traces and for DEFERIO CP system tracing and displays the number of pageable pages in the system dynamic paging area that are still eligible for DEFERIO traces.

### ID *traceid*

displays the status of TRSAVE activity for the specified trace ID.

## Usage Notes

1. For class G users, QUERY TRSAVE displays the destination of data derived from the trace or traces for that user's virtual machine.
2. For class A, C, or E users, QUERY TRSAVE displays the status of any TRSAVE activity.

## Responses

Response 1:

If tracing is done to DASD:

SOURCE	FILENAME	RECEIVER	KEEP	SIZE	FRAMES	FILLED	
CPTRACE	<i>filename</i>	<i>userid</i>	<i>n</i>	<i>mmm</i>	[ <i>mmmm</i>	<i>nnnn</i>	DEFERIO]
<i>traceid</i>	<i>filename</i>	<i>userid</i>	<i>n</i>	<i>mmm</i>	[ <i>mmmm</i>	<i>nnnn</i>	DEFERIO]

### SOURCE

identifies the source of the trace. CPTRACE identifies tracing activity resulting from the TRSAVE FOR CP ON command. The operand *traceid* identifies tracing activity resulting from a TRSOURCE ID *traceid* command.

## QUERY TRSAVE

### FILENAME

identifies the file names specified, or defaulted to, on the TRSAVE command.

### RECEIVER

identifies the users specified, or defaulted to, as the TO *userid* on the TRSAVE commands. Each *userid* listed in the column is the only user authorized to read this system trace file.

### KEEP

identifies the maximum number of files that CP keeps each time this trace is active.

### SIZE

identifies the maximum size, in 4 KB pages, for each of the files created when this trace is active.

### FRAMES

identifies the number of real storage frames that are set aside for an in-storage-wrap of the DEFERIO trace. The frames are allocated from the system dynamic paging area when the *traceid* is enabled or, for trace table data, when TRSAVE CP ON is issued. Blanks are displayed if the trace is not a DEFERIO trace.

### FILLED

identifies the number of those real storage frames that are filled with trace data. Blanks are displayed if the trace is not a DEFERIO trace. The *nnnnn* value will not exceed *mmmmm-1*, because one frame is set aside as the current frame being filled. When *nnnnn* reaches *mmmmm-1*, the displayed value of *nnnnn* remains at that level until the *traceid* is disabled.

### DEFERIO

indicates that no trace data is recorded on DASD until the *traceid* is disabled or, for trace table data, until TRSAVE CP OFF is issued. Blanks are displayed if the trace is not a DEFERIO trace.

When ALL is specified, the above information is displayed for all existing *traceids* and for CPTRACE when it is active.

Response 2:

The following message is displayed when a class A, C, or E user issues QUERY TRSAVE ID *traceid* for a trace ID that is not defined.

```
Traceid traceid is not defined.
```

Response 3:

The following message is displayed when a class G user issues QUERY TRSAVE ID *traceid* for a trace ID that is not defined or when the user is not authorized to view information for that particular *traceid*.

```
Traceid traceid is not tracing for your virtual machine.
```

Response 4:

The following message is displayed when the user issues QUERY TRSAVE ALL but no trace IDs have been defined.

```
No traceids defined.
```

Response 5:

The following message is displayed when a class G user issues QUERY TRSAVE ALL but no trace IDs have been defined for which the user is authorized to view information.

```
No traceids defined for your virtual machine.
```

Response 6:

If CP system trace data is being written to tape, the following message is displayed:

```
TRSAVE for CP on drive rdev1 [rdev2] MODE nnnn
```

```
{rewind} [DEFERIO FRAMES mmmmm FILLED nnnnn]  
{run }
```

**rdev1 [rdev2]**

identifies the real device number or numbers of the tape drives being used for the TRSAVE function. If only one tape drive is being used, *rdev2* is not shown.

**MODE *nnnn***

identifies the tape's format density.

**REWIND****RUN**

indicates that the tape is to be rewound (REWIND) or rewound and unloaded (RUN) when the tape fills.

**DEFERIO**

indicates that no trace data is recorded on tape until TRSAVE CP OFF is issued.

**FRAMES *mmmmm***

identifies the number of real storage frames that are set aside for an in-storage-wrap of the DEFERIO trace. The frames have been allocated from the system dynamic paging area.

**FILLED *nnnnn***

identifies the number of those real storage frames that have been filled with trace data. The *nnnnn* value will not exceed *mmmmm*-1, because one frame is set aside as the current frame being filled. When *nnnnn* reaches *mmmmm*-1, the displayed value remains at that level until TRSAVE CP OFF is issued.

Response 7:

The following message is displayed if TRSAVE FOR CP is not active:

```
TRSAVE inactive for CP
```

Response 8:

The following message indicates that TRSAVE FOR CP is neither active nor inactive, but is in a transition state between the two:

```
TRSAVE pending active for CP
```

Response 9:

The following messages are displayed when a class A, C, or E user issues QUERY TRSAVE FRAMES.

```
nnnnnn frames are allocated for active DEFERIO traces.  
mmmmmm pages are still eligible to be allocated for DEFERIO traces.
```

The frames are allocated from the system dynamic paging area. Keep in mind that number of pageable pages in the system dynamic paging area is affected by the locking and unlocking of frames for various reasons. For more information see the TRSAVE command's usage notes regarding DEFERIO.

Response 10:

The following message indicates that TRSAVE FOR CP is terminating:

```
TRSAVE terminating for CP
```

**Messages**

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP410E CP ENTERED; PAGING ERROR
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP1001E An operand is missing for *option*.
- HCP1013E An invalid operand was supplied for *option* - *operand*.

## QUERY TRSAVE

- HCP6525E Authorization request failed.

# QUERY TRSOURCE

## Authorization

Privilege Class: A, C, E, G

## Purpose

Use QUERY TRSOURCE to display the current status of those traces defined using TRSOURCE.

## Operands

### ALL

requests the status of all defined traces. ALL is the default.

### ID *traceid*

requests the status of the specified trace ID.

### SET *traceset*

requests the status of all defined traces of the specified set.

### TYPE DATA

### TYPE GT

### TYPE IO

### TYPE LAN

### TYPE PCI

### TYPE NONE

requests the status of all traces of the following types:

#### Type

#### Meaning

#### IO

IO

#### GT

GT

#### LAN

LAN

#### PCI

PCI

## QUERY TRSOURCE

### DATA

DATA

### NONE

Unspecified.

### USER *userid*

#### USER \*

requests the status of all traces of type GT that are defined for the specified user's virtual machine. You can use asterisk (\*) to specify your own virtual machine.

## Usage Notes

1. A trace of type NONE occurs when a trace has been defined by the TRSOURCE or TRSAVE command, but the TYPE xxx parameter of the TRSOURCE command is not specified.
2. The class G user may not specify any parameters. The response to the class G user is that of the QUERY TRSOURCE USER \* command.
3. An IO trace may be defined for a nonexistent device—that is, a device that has no RDEVICE definition. If a trace with *only* such devices is enabled, message HCP477E is issued:

```
Traceid (TRACE ID) not enabled; incomplete definition
```

Note, however, that a trace with a nonexistent device and a real device (whether the latter be online or offline) *can* be enabled, and the response to QUERY TRSOURCE indicates that a trace for the nonexistent device is activated.

## Responses for Undefined Traces

Response 1:

```
No traces are defined
```

is the response for QUERY TRSOURCE ALL if no traces are defined.

Response 2:

```
Traceid traceid is not defined
```

is the response for QUERY TRSOURCE ID trace ID if the specified trace ID is not defined.

Response 3:

```
Traceset traceset is not defined
```

is the response for QUERY TRSOURCE SET *traceset* if no traces are defined for the specified trace set.

Response 4:

```
No GT traces are defined for user userid
```

is the response for QUERY TRSOURCE USER *userid* if no GT traces are defined for the specified user's virtual machine.

Response 5:

```
No trace was defined for type type
```

is the response for QUERY TRSOURCE TYPE *type* if no traces are defined for the specified trace type.

## Responses for Defined Traces

The format of the responses depends upon the trace types. The grouping of the responses for QUERY TRSOURCE ALL is by trace set.

Response 1:

```
SET setid
```

is the response that heads each group of traces included in a set, *setid* being the set name of the set. When no set name has been defined, the set name is NULL.

Response 2:

```
ID      TYPE  SET      STATUS      DEVICES      USER      IODATA
traceid IO  setname  {ENABLED }  rdev(s)      userid    nnnn
          {DISABLED }
```

or

```
ID      TYPE  SET      STATUS      LDEVS      USER      IODATA
traceid IO  setname  {ENABLED }  ldev(s)     userid    nnnn
          {DISABLED }
```

is displayed for traces of type IO.

**ID**

identifies the name of the trace, as specified on the ID xxx parameter of the TRSOURCE...TYPE IO... command.

**TYPE**

identifies the type of trace.

**SET**

is the name used to group traces into a logically related set as specified on SET xxx parameter of the TRSOURCE ID *traceid* command or NULL.

**STATUS ENABLED**

**STATUS DISABLED**

ENABLED indicates that the defined trace is active. DISABLED indicates that the trace is inactive.

**DEVICES**

*rdev(s)* indicates the device number (*rdev1*) or ranges (*rdev1-rdev2*) of device numbers whose I/O activity should be traced. It is the value specified on the DEVICE xxx parameter of the TRSOURCE ID *traceid* command.

**LDEVS**

*ldev(s)* indicates the logical device number (*ldev1*) or ranges (*ldev1-ldev2*) of logical device numbers whose I/O activity should be traced. It is the value specified on the LDEV xxx parameter of the TRSOURCE ID *traceid* command.

**USER**

indicates which user's I/O should be traced. It is specified on the USER xxx parameter of the TRSOURCE ID *traceid* command. ALL indicates that all I/O to the specified devices are traced for all users.

**IODATA**

indicates how many bytes of the transferred data are being traced for the defined I/O trace.

Response 3:

```
ID      TYPE  SET      STATUS      ORIGINID      INCLUDED
traceid GT-x  setname  {ENABLED }  {sysname}     {userid}
          {DISABLED }  {userid}     {useridb}
```

```
ID      TYPE  SET      STATUS      ORIGINID      EXCLUDED
traceid GT-x  setname  {ENABLED }  {sysname}     {userid}
          {DISABLED }  {userid}     {useridy}
```

```
ID      TYPE  SET      STATUS      ORIGINID
traceid GT-x  setname  {ENABLED }  userid
          {DISABLED }
```

## QUERY TRSOURCE

is displayed for traces of type GT.

### ID

identifies the name of the trace, as specified on the ID *xxx* parameter of the TRSOURCE...TYPE GT... command.

### TYPE GT-x

indicates the type of the trace; *x* stands for E or B.

E indicates that the guests being traced are sending trace data to CP in EVENT mode—that is, the virtual machine sends one trace entry at a time.

B indicates that the guests being traced are sending trace data to CP in BLOCK mode—that is, the guest virtual machine is collecting the trace entries into buffers and then requesting CP to receive the entire block of trace data at a time.

### SET

is the name used to group traces into a logically related set as specified on the SET *xxx* parameter of the TRSOURCE ID *traceid* command or NULL.

### STATUS ENABLED

### STATUS DISABLED

ENABLED indicates that the defined trace is active. DISABLED indicates that the trace is inactive.

### ORIGINID

identifies a virtual machine group if TRSOURCE...FOR VMGROUP *sysname* was entered to define the GT *traceid*. When tracing is active for a virtual machine group, the user IDs of the group members for which tracing is active are displayed as shown. When TYPE GT tracing is being done for a single virtual machine (the command TRSOURCE...FOR USER *userid* was entered), *originid* is the name of the virtual machine.

### INCLUDED

displays a list of the virtual machines that are included in the virtual machine group trace. These virtual machines may or may not be logged on.

ALL indicates that every virtual machine that connects to the virtual machine group is included in the group trace.

NONE indicates that no virtual machines are included in the group trace.

### EXCLUDED

displays a list of the virtual machines that are excluded from the virtual machine group trace. These virtual machines may or may not be logged on.

**Note:** Either an included list or an excluded list is displayed for a virtual machine group.

Response 4:

```
  ID      TYPE  SET      STATUS      LOC      INSTRUCTION
  traceid DATA setname {ENABLED } { nnnnnn } string...
                   {DISABLED} {modname+disp}

DATALINKS
DATALINK 001 ...
DATALINK 002 ...
                   IF ... THEN
                   IF ... THEN
DATALINK 004 ...
                   ELSE
DATALINK 005 ...
DATALINK 006 ...
                   ENDIF
                   ENDIF
:
DATALINK XXX ...
```

- or -

```
DATALINKS
NO DATALINKS DEFINED
```

is displayed for traces of type DATA.

**ID**

identifies the trace, as specified on the ID xxx parameter of the TRSOURCE...TYPE DATA... command.

**TYPE**

indicates the type of trace.

**SET**

is the name used to group traces into a logically related set as specified on SET xxx parameter of the TRSOURCE ID *traceid* command or NULL.

**STATUS ENABLED**

**STATUS DISABLED**

ENABLED indicates that the defined trace is active. DISABLED indicates that the trace is inactive.

**LOC nnnnnn**

**LOC modname+disp**

indicates the host address of the instruction that, when executed, triggers tracing information.

The operand *modname+disp* indicates the module name and displacement of the instruction that, when executed, triggers tracing information.

**INSTRUCTION**

identifies the instruction string located at the indicated location.

**DATALINKS**

defines the information collected when the trace springs. If no data links were specified for this trace ID, NO DATALINKS DEFINED is displayed under the DATALINKS header line.

**IF**

determines whether a subsequent THEN statement or ELSE statement is executed.

**THEN**

indicates that subsequent datalinks and IF statements are executed only if the preceding IF statement is true.

**ELSE**

indicates that subsequent datalinks and IF statements are executed only if the preceding IF statement is false.

**ENDIF**

closes the last unclosed IF statement.

Response 5:

ID	TYPE	SET	STATUS
<i>traceid</i>	NONE	<i>setname</i>	DISABLED

is displayed for traces of unspecified type, or type NONE.

**ID**

identifies the name of the trace, as specified on the ID xxx parameter of the TRSOURCE command.

**TYPE**

indicates that the TYPE xxx parameter was not specified on the TRSOURCE ID *traceid* command.

**SET**

is the name used to group traces into a logically related set as specified on SET xxx parameter of the TRSOURCE ID *traceid* command.

**STATUS DISABLED**

indicates the trace is inactive.

Response 6:

ID	TYPE	SET	STATUS	OWNER	NAME	LENGTH	OPTIONS
<i>traceid</i>	LAN	<i>setname</i>	{ENABLED} {DISABLED}	<i>owner</i>	<i>lanname</i>	<i>bytes</i>	{TRUNK {DROPPED {NIC <i>owner vdev</i> {NONE

## QUERY TRSOURCE

```
VLANID
-  {vlanid(4)}
   {ALL }
```

is displayed for traces of type LAN.

### ID

identifies the trace, as specified on the ID *xxx* parameter of the TRSOURCE...TYPE LAN... command.

### TYPE

indicates the type of trace.

### SET

is the name used to group traces into a logically related set as specified on SET *xxx* parameter of the TRSOURCE ID *traceid* command or NULL.

### STATUS ENABLED

### STATUS DISABLED

ENABLED indicates that the defined trace is active. DISABLED indicates that the trace is inactive.

### OWNER *owner*

the userid that owns the specified guest LAN or virtual switch.

### NAME *lanname*

the name of the specified guest LAN or virtual switch.

### LENGTH *bytes*

the number of *bytes* of traffic to be collected.

### OPTIONS

#### TRUNK

only traffic flowing over the virtual switch OSA connection will be captured. If TRUNK is specified on a guest LAN, no traffic is collected.

#### DROPPED

only traffic that has been DROPPED due to an error or an unknown destination will be collected.

#### NIC *owner vdev*

only traffic for the specified guest machine (identified by owner and vdev) will be collected.

#### NONE

no options were specified; therefore, all traffic on the specified guest LAN or virtual switch will be captured.

### VLANID

#### *vlanid*

only traffic destined for one of the vlan ids specified will be captured. Up to four vlan ids can be specified.

#### ALL

all traffic regardless of vlan id will be collected.

Response 7:

ID	TYPE	SET	STATUS	PCIF	USER
<i>traceid</i>	PCI	<i>setname</i>	{ENABLED} {DISABLED}	<i>pcif(s)</i>	<i>userid</i>

is displayed for traces of type PCI.

### ID

identifies the name of the trace, as specified on the ID *xxx* parameter of the TRSOURCE...TYPE PCI... command.

### TYPE

indicates the type of trace.

**SET**

is the name used to group traces into a logically related set as specified on SET xxx parameter of the TRSOURCE ID *traceid* command or NULL.

**STATUS ENABLED****STATUS DISABLED**

ENABLED indicates that the defined trace is active. DISABLED indicates that the trace is inactive.

**PCIF**

*pcif(s)* indicates the PCI function (*pcif*) or ranges (*pcif1-pcif2*) of PCI functions whose activity should be traced. It is the value specified on the PCIFUNCTION xxx parameter of the TRSOURCE ID *traceid*.

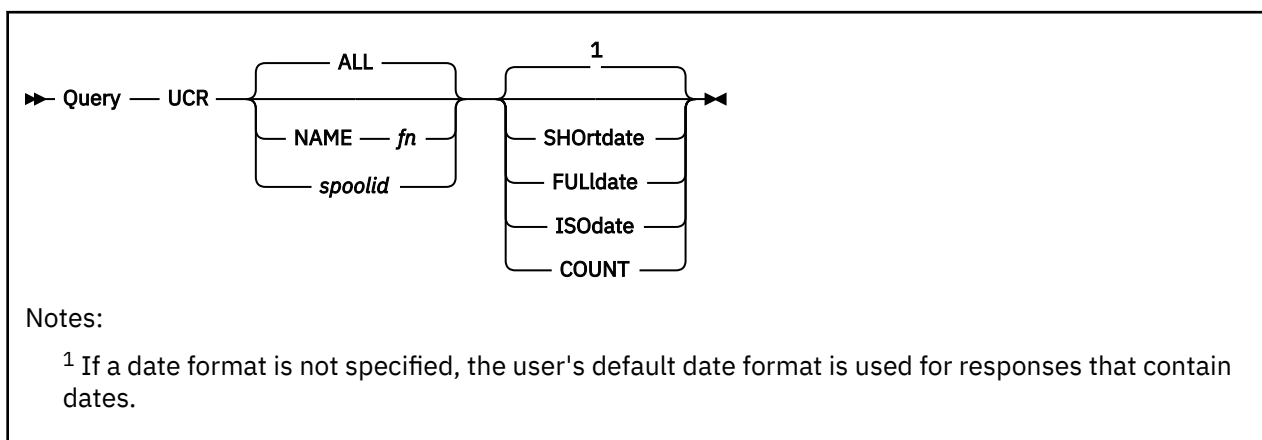

**USER**

indicates which user's PCI function should be traced. It is specified on the USER xxx parameter of the TRSOURCE ID *traceid* command. ALL indicates that activity to the specified PCI functions are traced for all users.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP6163E Internal error during command processing: *module + offset*
- HCP6525E Authorization request failed.

## QUERY UCR

### Authorization

Privilege Class: A, B, C

### Purpose

Use QUERY UCR to display detailed information about one or more user class restructure (UCR) files.

**Note:** This command is equivalent to the QUERY RDR/PRT/PUN command for spool files.

### Operands

#### ALL

lets you query all UCR files. This is the default.

#### NAME *fn*

specifies the name of the file to be queried. This is the file name specified when the file was created. More than one file can exist with the same file name.

#### *spoolid*

identifies the spool file to be queried.

#### SHOrtdate

specifies that dates in the response to this command will be displayed in *mm/dd* format, where *mm* is the month and *dd* is the day of the month.

#### FULLdate

specifies that dates in the response to this command will be displayed in *mm/dd/yyyy* format, where *mm* is the month, *dd* is the day of the month, and *yyyy* is the 4-digit year.

#### ISOdate

specifies that dates in the response to this command will be displayed in *yyyy-mm-dd* format, where *yyyy* is the 4-digit year, *mm* is the month, and *dd* is the day of the month.

#### COUNT

displays only the number of UCR files that match the criteria specified on the command. No other information is provided.

### Usage Notes

1. The default date format for certain CP and CMS commands can be set on a system-wide basis and also for the individual user. The system-wide default date format is set with the SYSTEM\_DATEFORMAT system configuration statement. The user's default date format is set with the DATEFORMAT directory

statement. The system-wide default and the user's default can also be set with the SET DATEFORMAT command. The user's default date format defaults to the system-wide default. The system-wide and user settings can be queried with the QUERY DATEFORMAT command. The hierarchy of possible date format settings for the QUERY UCR command, from highest priority to lowest, is:

- QUERY UCR command operand
  - User default
  - System-wide default
2. UCR spool files and the OVERRIDE command are no longer supported. Use the MODIFY command or statement to change command privilege classes. For information about MODIFY, see [Modifying a Command and Diagnose Code in z/VM: CP Exit Customization](#). Use the CVTOVRID utility to convert a class override file (formerly processed by the CP OVERRIDE utility) into a series of MODIFY statements to imbed into a system configuration file. Use the QUERY UCR command to display information about the UCR files on your system. Use the PURGE UCR command to purge all UCR files once your conversion to MODIFY statements is complete.

## Responses

Response 1:

The following response is issued when you specify QUERY UCR SHORTDATE:

```
OWNERID  FILE TYPE CL RECS DATE   TIME
ownerid  nnnn type c  nnnn mm/dd hh:mm:ss

FILENAME FILETYPE ORIGINID
fn       ft       originid
```

Response 2:

The following response is issued when you specify QUERY UCR FULLDATE:

```
OWNERID  FILE TYPE CL RECS DATE       TIME
ownerid  nnnn type c  nnnn mm/dd/yyyy hh:mm:ss

FILENAME FILETYPE ORIGINID
fn       ft       originid
```

Response 3:

The following response is issued when you specify QUERY UCR ISODATE:

```
OWNERID  FILE TYPE CL RECS DATE       TIME
ownerid  nnnn type c  nnnn yyyy-mm-dd hh:mm:ss

FILENAME FILETYPE ORIGINID
fn       ft       originid
```

### OWNERID

indicates that the file is a UCR file owned by the system. \*UCR is not a *userid*; it indicates the queue on which the file resides.

### FILE

identifies the spool file.

### TYPE

indicates that the file is a UCR file.

### CL

identifies the class, either D or I. Class D indicates that the file was created with the DEFER option of the OVERRIDE command. Class I indicates that the file was created with the IMMEDIATE option of the OVERRIDE command.

### RECS

identifies the number of 4 KB pages in the file.

## QUERY UCR

### DATE

identifies the date that the file was closed. If the file is being created, “OPEN—UCR” is displayed instead of a date and time. The format of the date is determined by the SHORTDATE, FULLDATE, or ISODATE operand. If no date format operand is specified, the user's default date format setting is used.

### TIME

identifies the time the file was closed in hours, minutes, and seconds.

### FILENAME

identifies the file name.

### FILETYPE

identifies the file type.

### ORIGINID

identifies the file originator.

Response 4:

```
FILES:  NO UCR
```

is returned when no specified file exists.

Response 5:

If the COUNT option is specified on the QUERY UCR command, only the number of user class restructure files that match the criteria specified is displayed:

```
FILES:  {nnnn} UCR  
        { } NO }
```

### *nnnn*

identifies the number of UCR files. If no files match the selection criteria, then NO replaces *nnnn*.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP042E User *userid* spoolid *nnnn* does not exist
- HCP413E Command processing cannot complete due to a spool paging error.
- HCP422E The same option was specified twice.
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP848E SYSTEM parameter is invalid with the spoolid option
- HCP849E A userid must be specified with the spoolid
- HCP1558E Command processing cannot complete.

# QUERY UNDERSCORE

---

► Query — UNDERscore ◄

## Authorization

Privilege Class: G

## Purpose

Use QUERY UNDERSCORE to determine if an underscore character is used to separate 16-digit output values in CP command responses for your user ID.

## Usage Notes

1. To change the UNDERSCORE setting, use SET UNDERSCORE.
2. For a list of CP commands affected by the UNDERSCORE setting, see [“SET UNDERSCORE” on page 1744](#).
3. An underscore character is always allowed on input, regardless of the setting of the UNDERSCORE option. When specifying an underscore on input, there must be exactly eight characters following the underscore.

## Responses

Response 1:

```
UNDERSCORE {ON }  
           {OFF}
```

### ON

indicates that an underscore character will be used to separate 16-digit output values into two 8-digit entities.

### OFF

indicates that an underscore character will not be used to separate 16-digit output values.

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*

## QUERY UNRESOLVED

► Query — UNRESolved ◄

### Authorization

Privilege Class: A, C, E

### Purpose

Use QUERY UNRESOLVED to display whether there are any references to unresolved (unknown) entry points or external symbols for customer-written CP routines that were loaded using the CPXLOAD command or configuration file statement.

### Usage Notes

1. To load customer-written CP routines into CP's virtual storage, use the CPXLOAD command (see [“CPXLOAD” on page 111](#)) or the CPXLOAD configuration file statement. For more information about the [CPXLOAD Statement](#), see *z/VM: CP Planning and Administration*.
2. The customer-written CP routines that you loaded must be on a disk that CP can access, both during and after initialization. If you have any unresolved entry points or external symbols that you thought you loaded, check to see where you loaded them. They may be on a disk that is not CP-accessed. If this turns out to be the problem, give CP access to the disk using the CPACCESS command (see [“CPACCESS” on page 89](#)).
3. To revoke one or more entry point or external symbol assignments, use the DISASSOCIATE command (see [“DISASSOCIATE” on page 324](#)).
4. To unload the customer-written CP routines, use the CPXUNLOAD command (see [“CPXUNLOAD” on page 117](#)).
5. For more information about unresolved entry points or external symbols for customer-written CP routines, see *z/VM: CP Exit Customization*.

### Responses

Response 1 (Unresolved References Exist):

To display all references that remain unresolved after all CPXLOAD requests, enter the following:

```
query unresolved
CSECT      Offset  Refers to
HCPNEW    000FBC  HCPSOON
HCPNEW    000FC0  HCPNOYET
HCPNEW    000FC4  HCPIHOPE
Ready;
```

In this example:

#### CSECT

is the control section (CSECT) of the program that was loaded using CPXLOAD. The CSECT contains address constants that refer to other entry points that CP cannot locate. Either the entry points have not yet been loaded, or they are on a disk to which CP does not have access.

#### Offset

is the location in the CSECT where the the address constant is.

**Refers to**

is the name of the entry point that the CSECT's address constant is referencing.

Response 2 (No Unresolved References):

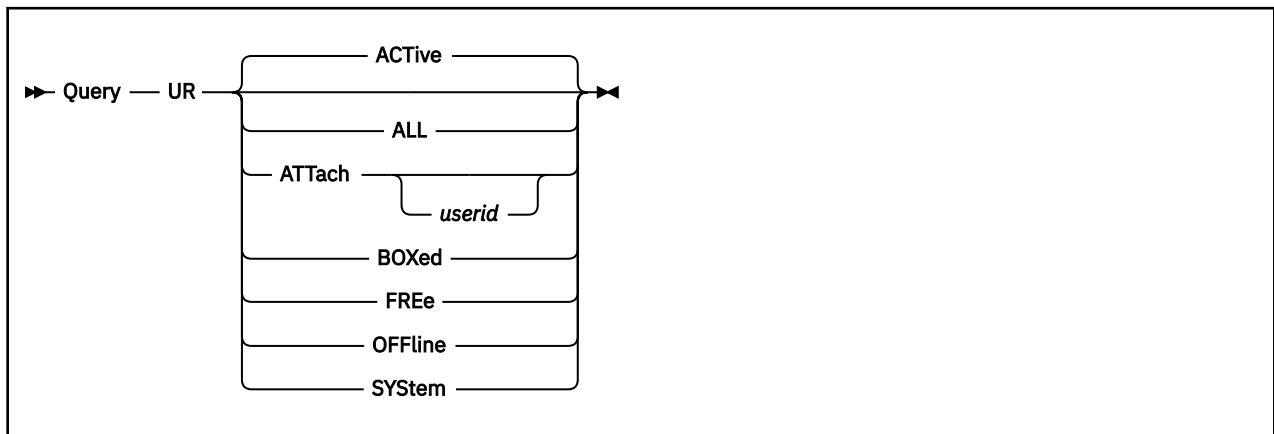

If you issue QUERY UNRESOLVED and there are no unknown entry points or external symbols, you will see:

```
query unresolved
There are no unresolved external references caused by CPXLOAD operations
Ready;
```

**Messages**

- HCP003E Invalid option - command contains extra option(s) starting with *option*

## QUERY UR

### Authorization

Privilege Class: B

### Purpose

Use QUERY UR to display the status of unit record devices.

### Operands

#### ACTive

indicates the active unit record devices. An active device is one in use by a user or the system, and specified as neither FREE nor OFFLINE. ACTIVE is the default.

#### ALL

indicates all devices of the type specified. The status is displayed in ACTIVE, FREE, and OFFLINE order, and is equivalent to the response you would receive if you entered all of the following commands:

```
query ur active
query ur free
query ur offline
```

#### ATTach *userid*

indicates the devices that are dedicated to a user on the system. If you specify *userid*, only devices attached to that user's virtual machine are indicated. If you do not specify *userid*, you receive the status of all unit record devices dedicated to any user on the system. Attached devices are always active.

#### BOXed

indicates the unit record devices that are unavailable, usually because of a hardware condition. A boxed device may also be ACTIVE, FREE, or OFFLINE.

#### FREe

indicates the free unit record devices. A free device is one not currently in use by a user or the system, and specified as neither ACTIVE nor OFFLINE.

#### OFFline

indicates the offline unit record devices. An offline device is one specified as neither ACTIVE nor FREE.

#### SYStem

indicates the unit record devices in use by the system. A system device is always active.

## Usage Notes

1. When you enter a QUERY UR command, you must make sure that the command's options are valid for each virtual machine associated with one or more *prtids*.
2. A VIRTUAL version of this command, QUERY VIRTUAL UR, also exists to facilitate a per-userid version of this data request. In some cases the VIRTUAL keyword is optional, so the output of this command may supersede QUERY VIRTUAL output. For more information, please see [“QUERY VIRTUAL UR” on page 1340](#).

## Responses

If the system is using a unit record device that is in an intervention-required state when you enter QUERY UR, you receive a response that looks like this:

```
RDR 000C has intervention required.
```

000C is the real device number of the reader that needs the operator's intervention. RDR may be replaced by PRT or PUN, depending on the type of the device.

**Note:** This response will be preceded by one of the following.

Response for Dedicated Devices:

If you enter QUERY UR and a unit record device is dedicated to a user, you see something like this:

```
q ur
RDR 000C ATTACHED TO JAMES 02F0
Ready;
```

This response means that the real card reader at the device number 000C is dedicated to JAMES's virtual machine at the virtual device number 02F0. RDR might be replaced by PRT or PUN, depending on the kind of unit record device. ATTACHED might be replaced by BOX/ATTC, which indicates that the device is attached to the virtual machine but is unavailable, usually because of a hardware problem.

Responses from Active Readers:

If a reader is assigned to the system for spooling activity and it is currently active with a spool file, you see a message like this:

```
q ur
RDR 000C STARTED SYSTEM
RDR 000C READING PERCY FILE 0021
Ready;
```

000C is the real device number of the card reader. STARTED indicates the device is available for spooling activity. SYSTEM means the device is available for input with user identification cards. STARTED might be replaced by any of the following:

- DRAINING, which would mean that the device would be unavailable for spooling activity as soon as it finished processing the current file.
- DRAINED, which would mean that the device was unavailable for spooling activity; you could enter the CP START command to restart it.
- INT REQ, which would mean that the device was not ready and required manual intervention before spool file processing could resume.

**Note:** If STARTED were replaced by any of the above options except DRAINING, the second line of the response would not appear.

SYSTEM might be replaced by a user ID, which would mean that the device was available for input without user identification cards. All input decks would be assigned to the user ID specified.

The second line of the response means that the card reader is currently active with a spool file. In this example, the reader at the real device number 000C is reading a card deck and creating a file that will be the user PERCY's spool file 0021.

Responses from Active Printers:

If there is an impact printer in use as a system spooling device, you see a response like this:

```
PRT 0E0E STARTED SYSTEM CLASS 1 SECLABEL
PRT 0E0E FORM STANDARD MANUAL SEP N03800 DEFFCB LIMIT NONE
PRT 0E0E FOLD IMAGE IMAG4248 CHARS FCB FCB8 LPP 068
PRT 0E0E DEST OFF DEST - NONE - DEST - NONE - DEST - NONE -
PRT 0E0E NOAFP
```

This response tells you the following about the impact printer at the real device number 0E0E. The first line tells you that the printer will:

- Be available for spooling activity
- Process files for any user ID
- Select only class 1 spool files for processing.

The second line tells you that it will:

- Select files requesting the STANDARD form
- Wait for the operator to schedule forms output
- Generate a separator page for output files
- Not accept spool files that contain 3800 load CCWs
- Use the default forms control buffer that was loaded into it
- Process spool files regardless of their length.

The third line tells you that it will:

- Translate (fold) lower case characters into upper case
- Use the system image library file IMAG4248
- Not use a character set
- Use the forms control buffer FCB8.
- Print separator pages with 68 lines per page.

The fourth line tells you that the printer will not use destination values as a criterion for selecting files.

The fifth line tells you that the printer will not process files with advanced function printer (AFP) characteristics, that is, files that contain X'5A' CCWs or an extended attributes buffer (XAB). For more information about each line of the response, see the tables below.

You see a response like the following if there is a 3800 printer in use as a system spooling device, and that printer is currently active with a spool file:

```
PRT 0F10 STARTED SYSTEM CLASS * SECLABEL
PRT 0F10 FORM STANDARD AUTO SEP ANY3800 LIMIT NONE
PRT 0F10 FLASH 0987 IMAGE IMAG3800 CHARS GF10 FCB 6 HOLD LPP 060
PRT 0F10 DEST OFF DEST - NONE - DEST - NONE - DEST - NONE -
PRT 0F10 AFP MARK
PRT 0F10 PRINTING DAVID FILE 0002 RECS 130K COPY 005 SEQ 001
```

This response tells you the following about the printer at the real device number 0F10. The first line means that the printer will:

- Be available for spooling activity
- Process files for any user ID
- Select spool files regardless of class.

The second line tells you that the printer will:

- Select files requesting the STANDARD form
- Automatically schedule forms output
- Generate a separator page for output files
- Accept spool files that contain 3800 load CCWs
- Process spool files regardless of their length.

The third line tells you that the printer will:

- Use the forms overlay negative called 0987
- Use the system image library file IMAG3800
- Use the character set GF10
- Print six lines per inch
- Put spool files causing 3800 load checks into system HOLD status.
- Print separator pages with 60 lines per page.

The fourth line tells you that the printer will not use destination values as a criterion for selecting files.

The fifth line tells you that the printer will:

- Process files with advanced function printer (AFP) characteristics, that is, files that contain X'5A' CCWs or an extended attributes buffer (XAB).
- Mark separator trailer pages with separator bars.

The last line tells you the following:

- The printer is active with the spool file 0002, owned by the user DAVID.
- The number of records remaining for output in the file is 130K, where K is the number of records in thousands rounded to the nearest 1000. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines in millions rounded to the nearest million.
- There are five copies remaining for output.
- The sequence for the file on the printer is 001.

The parts of the first line of the response for impact printers and 3800 printers might also be as follows:

Category	Possible Values	Meaning
Status	STARTED	Device is available for spooling activity.
	DRAINING	Device is processing a file, but will be drained after the file is finished.
	DRAINED	Device is not available for spooling activity. Issue the CP START command to activate the device.
	INT REQ	Device is not available, and needs manual intervention before it can continue to process spool files.
	SETUP REQ	Printer is ready to print an alignment page so that the operator can align the forms properly on an impact printer. The operator must press the STOP and START buttons to print another alignment page, or enter the START command to begin printing the entire file.
	MOUNT REQ	Printer is waiting for the operator to mount a new form.
User ID	SYSTEM	Device processes files for any user ID.
	<i>userid</i>	Device processes files only for the specified user ID.

Category	Possible Values	Meaning
Spool file class	CLASS <i>cl</i>	Device services spool files of the specified classes, in the specified order. An output device can service as many as 8 output classes.

The parts of the second line of the response can be:

Category	Possible Values	Meaning
Form	FORM <i>form</i>	Device services the specified 1- to 8-character operator form number.
Scheduling	MANUAL	Operator schedules forms output. Only spool files with the form currently active on the device are processed. When the last spool file with the current form is printed, the printer stops.
	AUTO	Operator wants CP to schedule forms output. The form that is currently active is processed first. When all files with the current form have been printed, CP selects a new form for the device.
	SETUP	Operator wants CP to print a page for forms alignment verification. (Only valid for impact printers.) The operator receives a message to set up the form. After setting up the form, the operator must press the STOP button, then the START button. An alignment page prints with letters replaced by X's and numbers replaced by 9's on the first page of the file.  Each time the operator presses STOP and START after a full alignment page is printed, another alignment page prints. After aligning the forms, the operator enters the START command for the device. The printer then returns to its previous mode (AUTO or MANUAL), and the file prints in its entirety.  <b>Note:</b> If neither MANUAL, AUTO, nor SETUP is specified and the printer is currently in SETUP mode, it returns to the previous mode, AUTO or MANUAL. The default forms output is MANUAL.
File separator	SEP	File separator prints between output files.
	NOSEP	File separator does not print between output files.
3800 load CCWs	NO3800	Printer does not print any spool files containing 3800 load CCWs. This option ensures a fast output queue, because load CCWs issued to 3800 printers can take a lot of time.
	BEG3800	Only spool files without 3800 load CCWs, or spool files with 3800 load CCWs only at the beginning of the file, print on this device. This allows the user an initial setup with which the entire file can be printed.
	ANY3800	Output device will process spool files regardless of whether they contain 3800 load CCWs. This option may cause a slower output queue, based on the number of 3800 load CCWs issued by the spool files.

Category	Possible Values	Meaning
Default FCB	DEFFCB	Printer uses the default FCB with which it was loaded. CP does not send imbedded LOAD FCB CCWs to the printer. The LOADBUF command specifies the default FCB.
	FILEFCB	CP sends FCBs to the real printer. File FCBs are LOAD FCB CCWs imbedded in the spool file. This is the default when you start the printer after a cold start. <b>Note:</b> DEFFCB and FILEFCB only appear for non-1403 impact printers.
Length limit	LIMIT NONE	CP selects files for printing regardless of the number of records.
	LIMIT <i>nnnnnnnnn</i>	CP only selects spool files for printing that are less than or equal to the specified number of records. The spool file record number is the number of copies multiplied by the size of the file.

The parts of the third line of the response can be:

Category	Possible Values	Meaning
Folding into upper case	FOLD	CP translates (folds) lower case characters into upper case.
	NOFOLD	CP does not translate lower case characters into upper case. <b>Note:</b> FOLD and NOFOLD only appear for impact printers.
Forms overlay negative	FLASH <i>name</i>	Printer uses the specified forms overlay negative, which is from 1 to 4 characters long. <b>Note:</b> FLASH only appears for 3800 printers.
Image library	IMAGE <i>imagelib</i>	Printer uses the specified system image library file, which contains the load images (character sets, FCBs, graphic character modifications, or copy modifications) used for printing files and separator pages.
Character set	CHARS <i>chars</i>	Printer uses the specified character set, which is from 1 to 4 characters long, when printing the separator page.
FCB	FCB <i>name</i>	For impact printers: printer uses the specified FCB when printing the file or the separator page. For 3800 printers: the FCB is the number of lines per inch. <b>Note:</b> FCB does not appear for 1403-type printers.
3800 load checks	HOLD	Printer puts spool files causing 3800 load checks in system HOLD status.
	PURGE	Printer deletes spool files causing 3800 load checks. <b>Note:</b> HOLD and PURGE only appear for 3800 printers.
Lines per page	LPP	Defines the number of lines for file separator pages on the printer.

The parts of the fourth line of this response can be:

Category	Possible Values	Meaning
Destination	DEST	Printer services the specified destination values. The printer can service up to 4 destination values. The first value for the device is always OFF if it was not specifically set by either a START command, or at initialization with the RDEVICE statement in the system configuration file. If it was set, the specified destination is shown. If the remaining destination values were not specified, the values are null and are shown as – NONE –. If they were specified, the specified value is shown.
AFP characteristics	AFP	Printer processes files with advanced function printer (AFP) characteristics, that is, files that contain X'5A' CCWs or an extended attributes buffer (XAB).
	NOAFP	Printer does not process files with AFP characteristics.
Mark separator trailer pages	MARK	Printer marks 3800 trailer pages with separator bars.
	NOMARK	Printer does not mark 3800 trailer pages with separator bars.

**Note:** MARK and NOMARK only appear for 3800 printers.

Responses from Active Card Punches:

If a punch is attached to a user and is currently active with a spool file, you see a message like:

```
PUN 1F30 STARTED   SYSTEM CLASS 1
PUN 1F30 FORM STANDARD AUTO   NOSEP LIMIT NONE
PUN 1F30 DEST OFF   DEST - NONE - DEST - NONE - DEST - NONE -
PUN 1F30 PUNCHING JAMES   FILE 0042 RECS 012K COPY 002 SEQ 001
```

This response tells you the following about the card punch at the real device number 1F30. The first line means that the punch will:

- Be available for spooling activity
- Process files for any user ID
- Select only class 1 spool files

The second line tells you that the punch will:

- Select files requesting the STANDARD form
- Automatically schedule forms output
- Not generate a separator page for output files

The third line tells you that the punch will not use destination values as a criterion for selecting files.

The parts of the first line of the response can also be:

Category	Possible Values	Meaning
Status	STARTED	Device is available for spooling activity.
	DRAINING	Device is processing a file, but will be drained when the file is finished.
	DRAINED	Device is not available for spooling activity. Issue the CP START command to activate the device.
	INT REQ	Device is not available; it needs manual intervention before it can continue to process spool files.
	SETUP REQ	Punch is ready to generate an alignment page to let the operator align the forms properly on an impact printer. The operator must press the STOP and START buttons to print another alignment page, or enter the START command to begin printing the entire file.
	MOUNT REQ	Punch is waiting for the operator to mount a new form.
User ID	SYSTEM	Device processes files for any user ID.
	<i>userid</i>	Device processes files only for the specified user ID.
Spool file class	CLASS <i>cl</i>	Device services spool files of the specified classes, in the specified order. An output device can service as many as 8 output classes.

The options for the second line of the response can be:

Category	Possible Values	Meaning
Form	FORM <i>form</i>	Device services the specified 1- to 8-character operator form number.
Scheduling	MANUAL	Operator schedules forms output. Only spool files with the form currently active on the device are processed. When the last spool file with the current form is punched, the punch stops.
	AUTO	Operator wants CP to schedule forms output. The form that is currently active is processed first. After punching all files with the current form, CP selects a new form for the device.
File separator	SEP	File separator prints between output files.
	NOSEP	File separator does not print between output files.
Length limit	LIMIT NONE	CP selects files for punching regardless of the number of records.
	LIMIT <i>nnnnnnnnnn</i>	CP only selects spool files for punching that are less than or equal to the specified number of records. The spool file record number is the number of copies multiplied by the size of the file.

The options for the third line of the response can be:

Category	Possible Values	Meaning
Destination value	DEST	Punch services the specified destination values. The punch can service up to 4 destination values. The first value for the device is always OFF if it was not specifically set by either a START command, or at initialization with the RDEVICE statement in the system configuration file. If it was set, the specified destination is shown. If the remaining destination values were not specified, the values are null and are shown as – NONE –. If they were specified, the specified value is shown.

The last line of this response only appears if there is a file active on the card punch. The line in the example above tells you that the punch at the real device number 1F30 is punching the spool file 0042, owned by the user JAMES. The number of records remaining for output in the file is 12K, where K is the number of records in thousands rounded to the nearest 1000. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines in millions rounded to the nearest million. There are two copies remaining for output. The sequence for the file on the punch is 001.

Response from Boxed Unit Record Devices:

If a unit record that is not dedicated to a user is unavailable, you see a message like the following:

```
q ur
RDR 000F BOXED
Ready;
```

000F is the real device number of the card reader that is unavailable. RDR might be replaced by PRT or PUN.

Response from CP if there is no match:

If CP cannot find any unit record devices of the type you specified, you see a message like this:

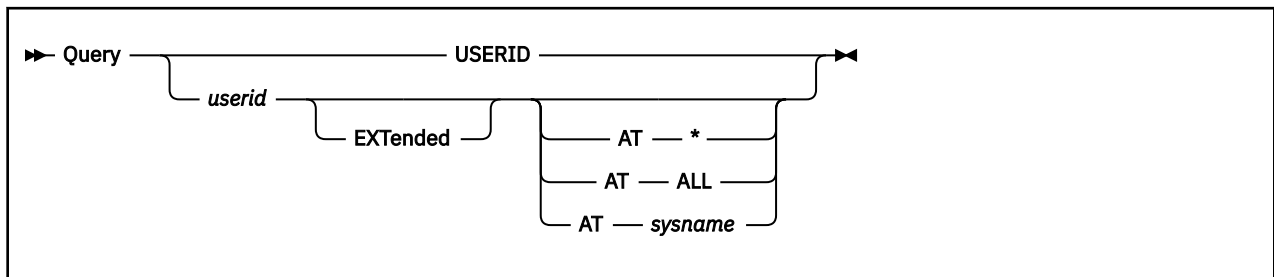

```
q ur boxed
A BOXED unit record device was not found.
Ready;
```

BOXED may be replaced with *active*, *attached*, *free*, *offline*, or *system*, depending on what you specified on the command.

## Messages

- HCP003E Invalid option - *option*
- HCP007E Invalid userid - *userid*
- HCP263E Too many operands were supplied for this command.

## QUERY USERID

### Authorization

Privilege Class: G

### Purpose

Use QUERY USERID to identify the user ID and the system name or device address of a logged-on user.

### Operands

#### USERID

displays the user ID and local system name for the user issuing the command.

#### *userid*

displays the user ID and device address of the specified user.

#### EXTENDED

specifies that logical unit network qualifiers or logical device host names and associated IP addresses are displayed, if they exist. In an SSI cluster, the member where the specified user is logged on is displayed. See [Response 3](#) for details on how the EXTENDED operand changes the responses.

#### AT \*

displays the user ID and device address of the specified user only if that user is logged on to the local system.

#### AT ALL

displays the user ID and device address of the specified user on all members of the SSI cluster. The command issues a response for each member where the user is logged on. The responses are displayed in the order they are received, and each response is prefixed with the source member name.

#### AT *sysname*

displays the user ID and device address of the specified user on system *sysname*, which must be the local system or another member of the same SSI cluster.

### Usage Notes

1. In an SSI cluster, a remote single-configuration virtual machine or any local user might be returned in response to a QUERY *userid* command. If the user is remote, "SSI" is displayed instead of a device address. To get the device address and member name for a remote single-configuration virtual machine, issue QUERY *userid* EXTENDED. To get information about all the logon instances of a multiconfiguration virtual machine, issue QUERY *userid* AT ALL.

### Responses

Response 1:

When you issue QUERY USERID, you will receive the following response:

## QUERY USERID

```
userid [AT sysname]
```

### **sysname**

is the 1- to 8-character name of the system where the command is issued. If no name has been assigned to the system being used, this field is omitted.

Response 2:

When you issue `QUERY userid`, you will receive the following response:

```
userid - {rdev }
         {DSC }
         {SSI }
         {ldev }
         {luname}
         {SYSC}
         {SYSG }
```

### **userid**

identifies the user specified.

### **rdev**

identifies the real device number of the display where the user is logged on.

### **DSC**

identifies a user disconnected from the system.

### **SSI**

identifies a user logged on to another member of the SSI cluster.

### **ldev**

identifies the logical device number through which CP accesses the display where the user is logged on.

### **luname**

identifies the SNA logical unit name of the terminal through which the user is logged on.

### **SYSC**

identifies the system console.

### **SYSG**

identifies the integrated 3270 console.

Response 3:

When you issue `QUERY userid EXTENDED`, you will receive the following response:

```
userid - {rdev [AT member] }
         {DSC [AT member] }
         {ldev HOST hostname [FROM ipaddr [AT member]] }
         {[netname.]luname [AT member] }
         {SYSC [AT member] }
         {SYSG [AT member] }
```

### **AT member**

identifies the member of the SSI cluster that the user is logged on to.

### **HOST hostname**

identifies the virtual machine that created and manages the logical device where the user is logged in.

### **FROM ipaddr**

provides the IP address of the TCP/IP Telnet client associated with the logical device.

An IPv4 address is displayed in dotted-decimal format, for example:

```
9.130.44.144
```

An IPv6 address is displayed in compressed format ("::" designates multiple 16-bit groups of zeros). For example, this IPv6 address:

```
F802:0000:0000:0000:0000:0000:0A00:0001
```

is displayed in compressed format as:

```
F802::A00:1
```

### ***netname.luname***

identifies the fully qualified SNA logical unit name of the terminal through which the user is logged on.

Response 4:

When you issue QUERY *userid* AT ALL in an SSI cluster, you will receive the following response:

```
member : userid - {rdev }
                  {DSC }
                  {ldev }
                  {luname}
                  {SYSC }
                  {SYSG }
:
```

### **Messages**

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP045E *userid* not logged on
- HCP361E [XAUTOLOG failed for *userid*:] LOGOFF/FORCE pending for user *userid*
- HCP2970E The SSI cluster member name is missing or invalid.
- HCP2971I Specified SSI cluster member is not joined.

## QUERY USERS

### Authorization

Privilege Class: Any

### Purpose

Use QUERY USERS to display:

- The number of logged-on users
- The number of users dialed to other virtual machines
- The device number of a specified user

### Operands

#### *userid*

displays the user ID and device address of the specified user.

**\***

displays the user ID and device address of the user who issues the command.

#### **EXTended**

specifies that logical unit network qualifiers or logical device host names and IP addresses are displayed, if they exist. In an SSI cluster, the member where the specified user is logged on is displayed. See [Response 3](#) for details on how the EXTENDED operand changes the responses.

#### **AT \***

displays the number of users logged on to the system you are logged on to. When specified with *userid*, it displays the user ID and device address of that user on the system you are logged on to.

#### **AT ALL**

displays the number of users logged on to all members of the SSI cluster. When specified with *userid*, it displays the user ID and device address of that user on all members of the SSI cluster.

If *userid* is not specified, the command issues a response for each active member. If *userid* is specified, the command issues a response for each member where that user is logged on. The responses are displayed in the order they are received, and each response is prefixed with the source member name.

#### **AT sysname**

displays the number of users logged on to system *sysname*. When specified with *userid*, it displays the user ID and device address of that user on system *sysname*. The specified system must be the local system or another member of the same SSI cluster.

### Usage Notes

1. A dialed display device is not available to CP because it is logically attached to a logged-on user and is a part of that user's virtual machine configuration. For more information, see [“DIAL” on page 308](#).
2. In an SSI cluster, if QUERY USERS is issued with no additional operands, the response displays values that are sums for the entire cluster. If counts from only the local system are desired, issue QUERY

USERS AT \*. If counts for each member are desired, issue QUERY USERS AT ALL. User counts for other cluster members are cached and updated each time a virtual machine logs on or off.

3. In an SSI cluster, a remote single-configuration virtual machine or any local user might be returned in response to a QUERY USERS *userid* command. If the user is remote, "SSI" is displayed instead of a device address. To get the device address and member name for a remote single-configuration virtual machine, issue QUERY USERS *userid* EXTENDED. To get information about all the logon instances of a multiconfiguration virtual machine, issue QUERY USERS *userid* AT ALL.
4. QUERY NAMES and QUERY USERS can return different responses for the number of users logged on. The number of users in the process of logging on and logging off accounts for this difference. Also, in an SSI cluster, QUERY NAMES does not include multiconfiguration virtual machine logon instances on all members of the cluster (that is, the user ID is displayed once), but they are included in the totals displayed by QUERY USERS.

## Responses

Response 1:

When you issue QUERY USERS, you will receive the following response:

```
nnnnnn USERS, mmmmmm DIALED, xxxxxx NET
```

### **nnnnnn**

is the total number of logged-on users.

### **mmmmmm**

is the total number of users logically attached to virtual machines using the DIAL command.

### **xxxxxx**

is the total number of SNA/CCS terminals currently in use. This number includes SNA/CCS terminals that are at the logon prompt or are in use by either a LOGON or DIAL connection.

Response 2:

When you issue QUERY USERS *userid*, you will receive the following response:

```
userid - {rdev }
         {DSC }
         {SSI }
         {ldev }
         {luname}
         {SYSC }
         {SYSG }
```

### **userid**

identifies the user specified.

### **rdev**

identifies the real device number of the display where the user is logged on.

### **DSC**

identifies a user disconnected from the system.

### **SSI**

identifies a user logged on to another member of the SSI cluster.

### **ldev**

identifies the logical device number through which CP accesses the display where the user is logged on.

### **luname**

identifies the SNA logical unit name of the terminal through which the user is logged on.

### **SYSC**

identifies the system console.

## QUERY USERS

### SYSG

identifies the integrated 3270 console.

Response 3:

When you issue `QUERY USERS userid EXTENDED`, you will receive the following response:

```
userid - {rdev [AT member]
         {DSC [AT member]
         {ldev HOST hostname [FROM ipaddr [AT member]]
         {[netname.]luname [AT member]
         {SYSC [AT member]
         {SYSG [AT member]
```

### AT member

identifies the member of the SSI cluster that the user is logged on to.

### HOST hostname

identifies the virtual machine that created and manages the logical device where the user is logged in.

### FROM ipaddr

provides the IP address of the TCP/IP Telnet client associated with the logical device.

An IPv4 address is displayed in dotted-decimal format, for example:

```
9.130.44.144
```

An IPv6 address is displayed in compressed format (":" designates multiple 16-bit groups of zeros). For example, this IPv6 address:

```
F802:0000:0000:0000:0000:0A00:0001
```

is displayed in compressed format as:

```
F802::A00:1
```

### netname.luname

identifies the fully qualified SNA logical unit name of the terminal through which the user is logged on.

Response 4:

When you issue `QUERY USERS userid AT ALL` in an SSI cluster, you will receive the following response:

```
member : userid - {rdev }
          {DSC }
          {ldev }
          {luname}
          {SYSC }
          {SYSG }
:
```

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

- HCP2971I Specified SSI cluster member is not joined.

## QUERY VARIABLE

### Authorization

Privilege Class: G

### Purpose

Use QUERY VARIABLE to obtain a list of system environment variables or the value of a single variable.

### Operands

#### SYSTEM

indicates that system environment variables are to be displayed.

#### ALL

displays all of the environment variables in alphabetical order.

#### NAME

displays the value of the variable with the specified name.

#### *name*

specifies the name of the environment variable, which must satisfy the following rules:

- It is 1 - 63 characters in length with no blanks.
- Valid characters are 0-9, A-Z, \_ (underscore), and . (period).
- It cannot begin or end with a period
- It cannot begin with a numeric digit.

### Usage Notes

1. The **QUERY VARIABLE** responses are expected to be read by programs and are designed to be easily parsed by programs and read by users, as follows:
  - a. No extra blanks or headers are included.
  - b. When a single variable is queried, one output line is provided that displays only the variable's value. The variable name is not included in the response.
  - c. The query of an undefined variable does not generate an error; it displays a null line, or null string. A *null string* is a string that contains no characters. Null strings have a length of zero.
  - d. When **QUERY VARIABLE SYSTEM ALL** is issued, one output line is provided for each defined variable. Each line begins with SYSTEM, and is followed by the variable name and value, with a single blank (x'40') between SYSTEM, name, and value.
  - e. Output lines are wrapped on the display screen according to the TERMINAL LINESIZE, but are not split in the Diagnose x'08' response buffer. When returning the response in a buffer, Diagnose x'08' processing adds an x'15' line-end character at the end of each response line.
2. To avoid potential ambiguity and ensure upward compatibility, especially when using this command in a program, code the ALL or NAME keyword explicitly.

## QUERY VARIABLE

3. Be careful when using **QUERY VARIABLE NAME** *name* with the cp built-in program of CMS Pipelines, as in this REXX statement:

```
'PIPE CP QUERY VARIABLE NAME RUNMODE | VAR rmode'
```

The cp program discards null lines in the CP command response. Therefore, if RUNMODE is an undefined CP environment variable, the stage emits zero records, rather than emitting a single record of length zero. Consequently, the REXX variable *rmode* will be undefined following execution of this statement, rather than having the null string as its value. The REXX function Symbol(*rmode*) or the Signal On NoValue statement can be used to detect this condition, or a technique like the following could be used to set *rmode* to the default value 'NORMAL' when RUNMODE is undefined:

```
'PIPE CP QUERY VARIABLE NAME RUNMODE|APPEND LITERAL NORMAL|VAR rmode'
```

4. Any variable with the prefix "CP." is interpreted by CP as an attribute of the system, configuration, or environment. For example, CP.IPLPARMS.IPLVAR is set according to an option in the IPL parameters, and variables of the form CP.FUNCTION.xxx indicate the level of functionality within the CP nucleus. A full list of valid variable names and values as well as descriptions of those variables can be found at the following location: <https://www.vm.ibm.com/newfunction/varlist.html>
5. You can use a CMS pipeline to filter the **QUERY VARIABLE** output for specific groups of variables. For example, to select CP new function variables, use the following REXX statement:

```
'pipe CP QUERY VARIABLE | strfind /SYSTEM CP.FUNCTION./ | console'
```

## Responses

Response 1:

When the following command is issued to set an environment variable:

```
SET VARIABLE SYSTEM RUNMODE NORMAL
```

the response to **QUERY VARIABLE ALL** is:

```
SYSTEM RUNMODE NORMAL
```

Response 2:

When the following command is issued to set an environment variable:

```
SET VARIABLE SYSTEM RUNMODE NORMAL
```

the response to **QUERY VARIABLE RUNMODE** is:

```
NORMAL
```

Response 3:

When the following commands are issued to set environment variables:

```
SET VARIABLE SYSTEM RUNMODE NORMAL
SET VARIABLE SYSTEM TESTLEVEL XR_TRIAL1
SET VARIABLE SYSTEM K.GROUP 1TSR
```

the response to **QUERY VARIABLE ALL** is:

```
SYSTEM K.GROUP 1TSR
SYSTEM RUNMODE NORMAL
SYSTEM TESTLEVEL XR_TRIAL1
```

Response 4:

When the following commands are issued to set environment variables:

```
SET VARIABLE SYSTEM RUNMODE NORMAL
SET VARIABLE SYSTEM TESTLEVEL XR_TRIAL1
SET VARIABLE SYSTEM K.GROUP 1TSR
```

the response to **QUERY VARIABLE NAME TESTLEVEL** is:

```
XR_TRIAL1
```

Response 5:

When the following command is issued to delete an environment variable:

```
SET VARIABLE SYSTEM TEMP_LIMIT
```

the response to **QUERY VARIABLE NAME TEMP\_LIMIT** is a null line.

Response 6:

This example shows how embedded blanks can be used in the environment variable value. A sample REXX EXEC, which sets a long environment variable value, follows.

When the following is issued to set environment variables:

```
(a sample REXX exec)
/* This comment format indicates the REXX interpreter is to be used */
address command
"CP SET VARIABLE SYSTEM RUNMODE NORMAL"
"CP SET VAR SYSTEM ERROR_LOG7      First I Logged on,      then",
"I brought up my system and issued the command START TEST3 then ",
"I got the MESSAGE 'XYZ ABEND43    TRY AGAIN LATER  '"
```

The response to **QUERY VARIABLE ALL** is shown below as it is displayed on a terminal screen when **TERMINAL LINESIZE 60** is set:

```
SYSTEM ERROR_LOG7 First I Logged on,      then I brought up m
y system and issued the command START TEST3 then I got th
e MESSAGE 'XYZ ABEND43    TRY AGAIN LATER  '
SYSTEM RUNMODE NORMAL
```

## Messages

## QUERY VCONFIG

---

► Query — VCONFIG ◄

### Authorization

Privilege Class: G

### Purpose

Use QUERY VCONFIG to display the virtual configuration mode for a virtual machine.

### Usage Notes

1. The SET VCONFIG command can be issued to change the virtual configuration mode for the virtual machine.

### Responses

Response 1:

```
MODE = m
```

where:

***m***

identifies the configuration mode and is set to one of the following:

*ESA390*  
*GENERAL*  
*LINUX*  
*VM*

VCONFIG modes ESA390 and GENERAL are functionally equivalent, which means that the same virtual CPU types can be defined in an ESA390 mode virtual machine and in a GENERAL mode virtual machine. For the SET VCONFIG command, ESA390 and GENERAL are synonyms and cause a configuration of the same capabilities to be defined when specified. The QUERY VCONFIG command will display ESA390 when MACHINE is set to XA, ESA, or XC, and will display GENERAL when MACHINE is set to Z.

### Messages

- HCP263E Too many operands were supplied for this command.

## QUERY VDISK

### Authorization

Privilege Class: B

### Purpose

Use QUERY VDISK to display a list of all existing virtual disks in storage, or to display information about the system or user limits on the storage available for virtual disks in storage.

### Operands

#### Syslim

displays the maximum amount of system storage that may be allocated for virtual disks in storage on the system.

#### Userlim

displays the maximum amount of system storage that may be allocated for virtual disks in storage defined by a single user using the DEFINE command.

#### Default

displays the default limit. If an installation default is defined in the system configuration file, that value is displayed. If an installation default is not defined in the system configuration file, or if the file is not found, the built-in default is displayed.

### Responses

Response 1:

If QUERY VDISK or QUERY VDSK is entered with no additional operands:

```
VDISK userid vdev nnnnnnnn BLK [nnnn LINKS]
```

is displayed for each virtual disk in storage that currently exists.

#### *userid*

is the owner of the virtual disk in storage.

#### *vdev*

is the virtual device number of the virtual disk in storage in the owner's virtual machine.

#### *nnnnnnnn* BLK

is the size of the virtual disk in storage in 512-byte blocks.

#### *nnnn* LINKS

is the number of links to this virtual disk in storage. This value is displayed only for a virtual disk in storage defined in the directory.

Response 2:

```
userid vdev {R/O}, ...  
          {R/W}
```

## QUERY VDISK

is displayed following Response 1 for each current link to the virtual disk in storage. Up to three responses are displayed on each line.

### ***userid***

is the user ID of the linking user.

### ***vdev***

is the virtual device number of the virtual disk in storage in the linking user's virtual machine.

### **R/O**

### **R/W**

identifies the type of access the linking user has to the virtual disk in storage.

Response 3:

```
VDISKS NOT FOUND
```

is displayed for a QUERY VDISK or QUERY VDSK command with no additional operands if no virtual disks in storage are in use.

Response 4:

```
VDISK SYSTEM LIMIT IS {nnnnnnnnnn BLK,} nnnnnnnnnn  
                      {INFINITE,  }  
BLK IN USE
```

is displayed if the command is entered with the SYSLIM operand.

Response 5:

```
VDISK USER LIMIT IS {nnnnnnnnnn BLK}  
                   {INFINITE  }
```

is displayed if the command is entered with the USERLIM operand.

## **Messages**

- HCP002E Invalid operand - *operand*

## QUERY VIRTUAL ALL

Notes:

<sup>1</sup> This operand is required for privilege class G users who also have privilege class B.

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL ALL to display the size of your storage and the status of your devices and processors.

### Operands

#### ALL

displays the status of all devices in your virtual machine system, the size of your virtual storage, and the status of your virtual processors. This is the default.

### Usage Notes

1. The response order for this command is as follows:

- Storage
- Expanded Storage
- CPUs
- Consoles
- Readers
- Punches
- Printers
- DASDs
- FCPs
- ASCII console
- Tapes
- Displays
- Lines
- CTCAs
- OSAs
- CTLR
- Switches

- Unsupported devices.

## QUERY VIRTUAL ALL

- Virtual cryptographic facilities

### Responses

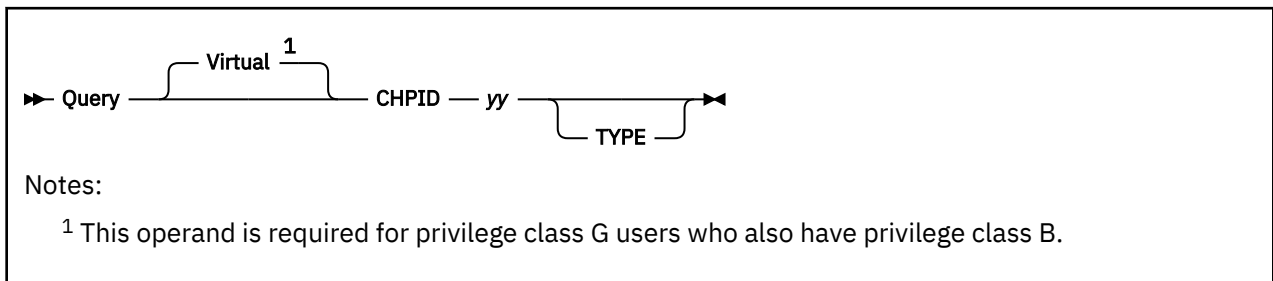

You receive responses for all devices that are defined in your virtual machine system. These responses are explained in the QUERY VIRTUAL command corresponding to each device.

**Note:** Expanded storage is not supported. The response XSTORE=- - - is displayed only for compatibility.

### Messages

- HCP022E A virtual device number was not supplied or it was invalid.
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP263E Too many operands were supplied for this command.
- HCP1003E {*CP module name/rdev/ldev*} {*is|was*} not found.

## QUERY VIRTUAL CHPID

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL CHPID to display the devices associated with a virtual CHPID number or the virtual CHPID type.

### Operands

#### CHPID

*yy* is the logical channel path of the virtual CHPID whose device allocation information is requested. The variable *yy* must be a 1- to 2-digit hexadecimal number between X'00' and X'FF'.

#### TYPE

Display the CHPID type.

### Responses

Response for Path Status:

```
PATH yy {ONLINE } TO DEVICES xxxx(1)
... xxxx(n)

PATH yy {OFFLINE} TO DEVICES zzzz(1)
... zzzz(n)
```

indicates that path *yy* to device *xxxx*(1) through device *xxxx*(*n*) is logically available (online), and path *yy* to device *zzzz*(1) through device *zzzz*(*n*) is logically unavailable (offline).

#### *yy*

is the logical channel path.

#### *xxxx*

#### *zzzz*

are the real device numbers.

Response for No Devices on Path:

```
NO DEVICES ON PATH yy
```

indicates there are no devices on the specified channel path.

#### *yy*

is the logical channel path.

Response for Nonexistent CHPID:

```
INVALID CHPID yy
```

indicates that a nonexistent channel path ID was specified.

**yy**

is the nonexistent logical channel path.

Responses for Optional TYPE Operand

```
Path yy is a parallel block-multiplexer channel
Path yy is a parallel byte-multiplexer channel
Path yy is an ESCON unswitched channel
Path yy is an ESCON switched channel
Path yy is an ESCON channel
      (switched or unswitched has not been determined)
Path yy is an ESCON channel to a parallel block-multiplexer converter
Path yy is a native-interface channel
Path yy is an ESCON CTC unswitched channel
Path yy is an ESCON CTC switched channel
Path yy is an ESCON CTC channel
      (switched or unswitched has not been determined)
Path yy is a coupling-facility-sender (CFS) channel
Path yy is a coupling-facility-receiver (CFR) channel
Path yy is an ESCON channel to a parallel byte-multiplexer converter
Path yy is an Open Systems Adapter (OSA) channel
Path yy is an Open Systems Adapter-Express (OSE) channel
Path yy is an Open Systems Adapter Direct Express (OSD) channel
Path yy is an Open Systems Adapter 3270-Console (OSC) channel
Path yy is an Open Systems Adapter NCP (OSN) channel
Path yy is an internal-system-device (ISD) channel
Path yy is a cluster-bus-sender (CBS) channel
Path yy is a cluster-bus-receiver (CBR) channel
Path yy is an internal-coupling-sender (ICS) channel
Path yy is an internal-coupling-receiver (ICR) channel
Path yy is a FICON unswitched channel
Path yy is a FICON switched channel
Path yy is a FICON channel to an ESCON Director FICON Bridge card
Path yy is a FICON channel
      (switched or unswitched has not been determined)
Path yy is a direct-system-device (DSD) channel
Path yy is an emulated-I/O (EIO) channel
Path yy is a cluster-bus-peer (CBP) channel
Path yy is a coupling-facility-peer (CFP) channel
Path yy is an internal-coupling-peer (ICP) channel
Path yy is an internal-queued-direct-communications (IQDC) channel
Path yy is an open-fibre-channel-protocol (FCP) channel
Path yy is a coupling over InfiniBand (CIB) channel
Path yy is an Open Systems Adapter Direct Express IEDN (OSX) channel
Path yy is an Open Systems Adapter Direct Express INMN (OSM) channel
Path yy is an unknown or unrecognized channel type - xx
```

**yy**

is the logical channel path.

**xx**

is the CHPID descriptor value found.

## Usage Notes

The following commands are used to find the virtual CHPID number for a virtual device. In this example, the device number is 191, the subchannel ID is 5, and the CHPID numbers are 60-67.

```
QUERY VIRTUAL 191
DASD 0191 3390 USP756 R/W          25 CYL ON DASD 5AA0 SUBCHANNEL = 0005
DISPLAY SCHIB 5
SCHIB DEV INT-PARM ISC FLG LP PNO LPU PI MBI PO PA CHPID0-3 CHPID4-7
0005 0191 00000000 0 83 FF 00 00 FF ---- FF FF 60616263 64656667
```

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid

- HCP846E Invalid channel path identifier.

## QUERY VIRTUAL CONSOLE

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL CONSOLE to display status of the console device accessible to your virtual machine.

### Responses

Response 1:

```

CONS vdev {ON [netname.]luname} {TERM } {STOP } [VSM userid]
           {ON GRAF rdev}      {NOTERM} {START} [HOST userid [FROM ipadr]]
           {ON LDEV ldev}
           {ON LINE rdev}
           {ON SYSC
           }
           {DISCONNECTED}

vdev CL c {CONT } {HOLD } {CPY *nnn} {READY }
          {NOCONT} {NOHOLD} {COPY nnn} {NOTREADY} FORM userform

vdev TO userid {RDR} DIST distcode FLASHC ccc DEST dest
              {PRT}
              {PUN}

vdev FLASH name CHAR char [char[char[char]]] MDFY cmod n FCB fcb LPP nnn

vdev {3215} {EOF } {OPEN spoolid} {KEEP } {MSG }
      {3270} {NOEOF} {CLOSED } {NOKEEP} {NOMSG}

{NAME fname ftype }
{NONAME }

[vdev SUBCHANNEL = vsub ]
    
```

#### **vdev**

is the virtual machine console.

#### **[netname.]luname**

is an SNA/CCS terminal (controlled by a VTAM service machine) that is the virtual console of this virtual machine. It is the name from the VTAM definition of the terminal as an SNA logical unit. The *netname.* is a network qualifier followed by a period delimiter, and is only present when the the EXTended option is specified and the VSM supports network qualified names.

#### **rdev**

is the real or logical device number associated with the virtual console if the console is not disconnected.

#### **ON GRAF rdev**

#### **ON LINE rdev**

#### **ON LDEV ldev**

is the real or logical device number of the virtual console if the console is not disconnected.

#### **ON SYSC**

identifies the system console as being associated with the virtual console.

**DISCONNECTED**

indicates that the console is disconnected.

**TERM****NOTERM**

indicates whether terminal output is or is not produced when console spooling is in effect.

**START****STOP**

indicates whether console spooling has been started or stopped for the device.

**VSM *userid***

provides the user ID of the VTAM service machine managing the device.

**HOST *userid***

provides the user identifier of the virtual machine managing the logical device.

**FROM *ipadr***

provides the IP address of the TCP/IP Telnet client associated with the logical device.

An IPv4 address is displayed in dotted-decimal format.

**Example:** 9 . 130 . 44 . 144

An IPv6 address is displayed in compressed format (":" designates multiple 16-bit groups of zeros).

**Example:** The following is an IPv6 address:

```
F802:0000:0000:0000:0000:0A00:0001
```

This address is displayed in compressed format as:

```
F802::A00:1
```

**CL *c***

identifies the class of spool file created on this device.

**CONT****NOCONT**

controls the continuous spooling option. For output files, CONT causes all CLOSE requests to be ignored unless specified with the EOF override option.

**HOLD****NOHOLD**

controls the HOLD status. For output devices, HOLD prevents files from being punched or printed on a real device by putting a USER HOLD status on the file. If you specify NOHOLD, you override the spool device HOLD option and prevent the file from being placed in HOLD status.

**CPY *\*nnn*****COPY *nnn***

specifies the number of file copies you want printed or punched when the file is produced. When the optional asterisk (\*) is specified, the 3800 printer copies each page from the spooled output files *nnn* times before going on to the next page. If a file is not spooled to the 3800 printer, the function performed by specifying the asterisk (\*) is ignored, and duplication occurs normally.

**READY****NOTREADY**

indicates whether the device is in a ready or not-ready status. The status can be changed by the READY and NOTREADY commands.

**FORM *userform***

identifies the form associated with the device and assigned to the spool files as they are created.

**TO *userid***

identifies the virtual machine that receives spool files created on the device.

**RDR****PRT****PUN**

identifies the spool file queue onto which spool files created on this device are placed. Unless changed by the SPOOL or CLOSE command, output normally goes to the PRT queue for a console spool file.

**DIST *distcode***

identifies the distribution code for spool files created on this device.

**FLASHC *ccc***

identifies the flash count for the file.

**DEST *dest***

identifies the destination value to be assigned to each spool file created on the device. If the destination value has not been changed by a SPOOL command, the default is OFF.

**FLASH *name***

identifies the forms overlay frame superimposed on the output pages if the file is printed on the 3800 printer.

**CHAR *char***

identifies the name of the character set or sets used to generate output if the file is printed on the 3800 printer.

**MDFY *cmod***

identifies the copy modification module used to alter output text if the file is printed on the 3800 printer.

***n***

identifies the copy modification character set number.

**FCB *fc***

identifies the forms control buffer used in the vertical formatting of a page if the file is printed on the 3800 printer.

**LPP *nnn***

identifies the lines per page setting for the virtual printer where the console output will be generated. The value can be a decimal number in the range 30 to 255, or 'OFF', which indicates that internal defaults will be used.

**3215****3270**

identifies the virtual console device type. A 3270 device type is only supported if the user is logged on at a real 3270.

**EOF****NOEOF**

EOF closes, or NOEOF leaves open, the spool file on the specified device, regardless of the CONT setting for the device.

**OPEN *spoolid*****CLOSED**

indicates that a spool file (*spoolid*) has been created on the console and that the file is still open (OPEN), or indicates that no spool file is open on the device (CLOSED).

**KEEP****NOKEEP**

controls the KEEP status, which indicates whether the current spool file is to be placed in user HOLD after processing. For output files, the KEEP status is placed on the spool file. After it is transcribed at the real printer or punch, the file is assigned user HOLD status, and is not purged. The file's KEEP status is retained. Specify NOKEEP to override the current KEEP setting for the device so that KEEP is not set on the spool file.

**MSG****NOMSG**

indicates whether you want to be informed about file printing and punching. If you specify MSG, you are informed of file printing and punching. The message is sent to you when the file begins printing or punching on a real device. This message is not sent if you enter SET IMSG OFF. Specify NOMSG to reset the MSG option.

**NAME *fname ftype*****NONAME**

identifies the file name and file type, if any, to be assigned to spool files created on the device.

***vsub***

identifies the virtual subchannel number.

**Messages**

- HCP003E Invalid option - *option*
- HCP263E Too many operands were supplied for this command.
- HCP1003E {*CP module name/rdev/ldev*} {is|was} not found.

## QUERY VIRTUAL CPUS

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL CPUS to display a list of CPUs currently defined for your virtual machine.

### Responses

Response 1:

```
CPU nn ID FFssssssmmmm0000 [(BASE)|(ADJUNCT)] status type affinity
```

is displayed for each processor defined in the virtual machine configuration.

#### **nn**

identifies the processor address in hexadecimal, as established by DEFINE CPU.

#### **FFssssssmmmm0000**

identifies the processor associated with the virtual machine.

#### **FF**

identifies the version code. These two digits are forced to X'FF' to indicate that the virtual machine is running under z/VM.

#### **ssssss**

identifies the serial number of the processor as established by SET CPUID or by a CPU directory entry.

#### **mmmm**

identifies the model number of the processor.

#### **0000**

identifies the machine check extended logout length. This field is forced to X'0000'. For a virtual processor using the SET command, these values are the same as for the real processor.

#### **BASE**

indicates that this is the base processor in a virtual MP configuration.

#### **ADJUNCT**

indicates that this is the virtual processor of an adjunct configuration.

#### **status**

indicates the status of the virtual processor. Status can be as follows:

##### **STOPPED**

indicates the virtual processor is in the hard-stopped state.

##### **CHECK-STOPPED**

indicates an error occurred on the virtual processor.

If no status is shown, the processor is running or in the soft-stopped state.

#### **type**

indicates the type of the virtual processor. Type can be as follows:

**CP**

indicates the virtual processor is a central processor.

**IFL**

indicates the virtual processor is an IBM Integrated Facility for Linux. The virtual CPU can run on a real IFL or it can be simulated.

**ZIIP**

indicates the virtual processor is an IBM z Integrated Information Processor. The virtual CPU can run on a real zIIP or it can be simulated.

**ICF**

indicates the Internal Coupling Facility. The virtual CPU can run on a real ICF or it can be simulated.

***affinity***

indicates the affinity of the virtual processor. Affinity can be as follows:

**CPUAFFIN ON**

indicates CPU affinity has been set on for this user with the SET CPUAFFINITY command and this virtual CPU is dispatched on a real CPU of the same type.

**CPUAFFIN SUPP**

indicates CPU affinity is suppressed. Although CPU affinity has been set on for this user with the SET CPUAFFINITY command, there is currently no matching real processor on which to run.

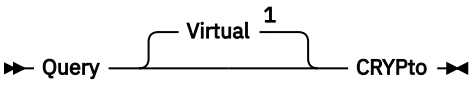

**CPUAFFIN OFF**

indicates CPU affinity has not been set on for this user. When OFF is in effect the virtual CPU is dispatched on only real CPUs of primary type.

**Messages**

- HCP263E Too many operands were supplied for this command.

## QUERY VIRTUAL CRYPTO

Notes:

<sup>1</sup> This operand is required for privilege class G users who also have privilege class A, B, C, or E.

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL CRYPTO to display the status of the virtual crypto resources.

### Responses

Response 1:

The following response is displayed when one or more crypto resources are attached to this virtual machine.

```
AP apnum CEXtm Domain domnum {shared|dedicated} config_state
```

#### **apnum**

is a three-digit virtual crypto adapter number (in decimal). If the resource is shared, then 001 is assigned to the virtual adapter number. If the resource is dedicated, then the actual hardware adapter number of the resource is assigned.

#### **CEXtm**

is the virtual crypto adapter, where *t* indicates the adapter type and *m* indicates the adapter mode. For dedicated resources, the value indicates the physical resource. For shared resources, the value indicates the lowest type of crypto express adapter that is available in the shared pools of all systems in the user's relocation domain. Shared crypto modes are accelerator mode or CCA coprocessor mode.

For more information, see [Crypto Planning and Management in z/VM: CP Planning and Administration](#).

The CEXtm value can be one of the following:

#### **CEX3C**

Crypto Express3 configured in CCA coprocessor mode

#### **CEX3A**

Crypto Express3 configured in accelerator mode

#### **CEX4C**

Crypto Express4 configured in CCA coprocessor mode

#### **CEX4A**

Crypto Express4 configured in accelerator mode

#### **CEX4P**

Crypto Express4 configured in EP11 coprocessor mode

#### **CEX5C**

Crypto Express5 configured in CCA coprocessor mode

**CEX5A**

Crypto Express5 configured in accelerator mode

**CEX5P**

Crypto Express5 configured in EP11 coprocessor mode

**CEX6C**

Crypto Express6 configured in CCA coprocessor mode

**CEX6A**

Crypto Express6 configured in accelerator mode

**CEX6P**

Crypto Express6 configured in EP11 coprocessor mode

**CEX7C**

Crypto Express7 configured in CCA coprocessor mode

**CEX7A**

Crypto Express7 configured in accelerator mode

**CEX7P**

Crypto Express7 configured in EP11 coprocessor mode

**CEX8C**

Crypto Express8 configured in CCA coprocessor mode

**CEX8A**

Crypto Express8 configured in accelerator mode

**CEX8P**

Crypto Express8 configured in EP11 coprocessor mode

**NONE**

There are no crypto resources attached to the shared pool.

**UNKN**

z/VM is unable to determine the type of crypto adapter.

***domnum***

is a three-digit virtual domain number (in decimal). If the resource is shared, then 001 is assigned to the virtual domain number. If the resource is dedicated, then the actual hardware adapter number of the resource is assigned.

***config\_state***

is CP's logical view of the resource state, as controlled by VARY CRYPTO.

For an APVIRT virtual machine, the configuration state is reported for the pool of shared resources. The shared pool could have one of the following configuration states:

- online - At least one shared crypto resource is online and operational.
- offline - All shared crypto resources are offline.
- unavailable - No crypto resources are attached to SYSTEM.
- error - All online shared resources are in error recovery.

For an APDED virtual machine, the configuration state is reported for each crypto resource dedicated to the virtual machine. A dedicated crypto resource could have one of the following configuration states:

- online - Dedicated crypto resource is online.
- offline - Dedicated crypto resource is offline and not available for use.

**Note:**

1. An adapter must be configured in CCA coprocessor mode or accelerator mode in order to be attached to the system for shared use.
2. An adapter that is configured in CCA coprocessor mode, accelerator mode or EP11 coprocessor can be attached to a virtual machine for dedicated use.

## QUERY VIRTUAL CRYPTO

3. For information on planning and managing crypto resources on a z/VM system, see [Crypto Planning and Management](#) in *z/VM: CP Planning and Administration*.

Response 2:

The following response is displayed when no crypto resources are available to the guest virtual machine.

```
No AP crypto domains are available
```

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid

## QUERY VIRTUAL CTCA

Notes:

<sup>1</sup> This operand is required for privilege class G users who also have privilege class B.

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL CTCA to display status of the channel-to-channel adapters accessible to your virtual machine.

### Responses

Response 1:

```
CTCA  vdev1 subclass {NOT READY [FOR userid2] } [SUBCHANNEL = vsub]
                   {COUPLED TO  userid vdev2 }
```

is displayed for each virtual channel-to-channel adapter in your virtual machine system.

Response 2:

```
CTCA  vdev1  ON DEV rdev [SUBCHANNEL = vsub]
```

is returned when your CTCA is a real device dedicated to your virtual machine.

#### **vdev1**

identifies the virtual device number of the CTCA.

#### **subclass**

identifies the subclass of the virtual CTCA (3088, SCTC, BCTC, CNC, or FCTC).

#### **userid**

identifies the virtual machine to which your CTCA is connected.

#### **userid2**

identifies the user authorized to couple to this device. This is configured on the SPECIAL directory statement in the user directory.

#### **vdev2**

identifies the virtual device number of the CTCA connected by the virtual machine identified as *userid*.

#### **rdev**

identifies the real device number of your CTCA.

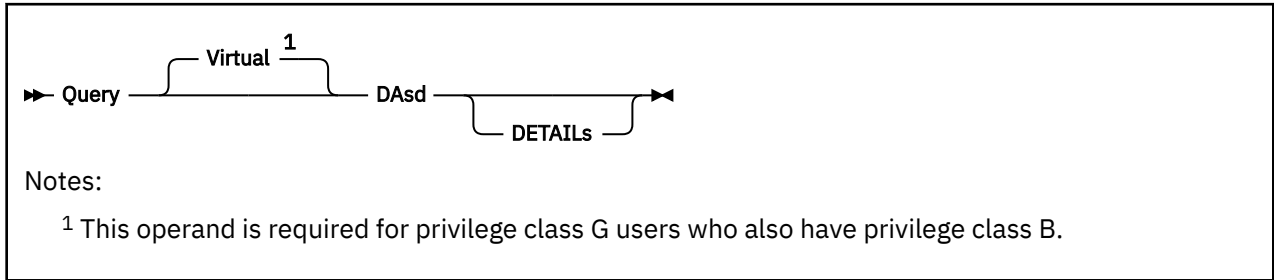

#### **vsub**

identifies the virtual subchannel number.

### Messages

- HCP040E Device {rdev/vdev/ldev} does not exist
- HCP263E Too many operands were supplied for this command.

## QUERY VIRTUAL DASD

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL DASD to display the status of all DASDs accessible to your virtual machine, including temporary disks (T-disks) and virtual disks in storage.

### Operands

#### DETAILS

displays additional information for DASD as well as the usual response, if applicable.

### Usage Notes

1. The DETAILS operand is meaningful only for dedicated DASDs or minidisk DASDs on a cache subsystem. The response for other virtual DASD remains the same.

### Responses

Response 1:

```
DASD vdev type {valid} {R/W} {nnnnnnn CYL} ON DASD rdev [SUBCHANNEL=vsub]
                {(TEMP)} {R/O} {nnnnnnn BLK}
```

displays for each minidisk or temporary disk in your virtual machine.

#### *vdev*

is the virtual device number.

#### *type*

is an IBM direct access device type.

#### *valid*

#### (TEMP)

#### (VDSK)

identifies the volume label of the real device on which your virtual disk resides. (TEMP) indicates that your virtual DASD has been defined from system temporary disk space (a T-disk). (VDSK) indicates that your virtual DASD has been simulated in system storage (a virtual disk in storage).

#### R/W

#### R/O

identifies the type of access you have to the disk. R/O is read-only access; R/W is read and write access.

#### *nnnnnnn* CYL

identifies the number of cylinders on the virtual CKD or ECKD DASD device.

**nnnnnnn BLK**

identifies the number of blocks on the virtual FBA DASD device.

**rdev**

**VDSK**

identifies the real device number of the volume containing the virtual device. VDSK is displayed for a virtual disk in storage because it is not mapped to a real device.

**vsub**

identifies the virtual subchannel number.

Response 2:

```
DASD vdev type (VDSK) {R/W} nnnnnnn BLK ON DASD VDSK [SUBCHANNEL=vsub]
                    {R/O}
```

is displayed for each virtual disk in storage attached to your virtual machine. For an explanation of the response contents, see **Response 1**.

Response 3:

```
DASD vdev ON DASD rdev {R/W} valid [SUBCHANNEL = vsub]
                       {R/O}
```

is displayed for each real device dedicated to your virtual machine. For an explanation of the response contents, see **Response 1**.

Response 4:

The following line is displayed in addition to **Response 1** or **Response 3** when the DETAILS operand is specified in the command:

```
[SYSCTL | DEVCTL | NOCTL | CACHE | NOCACHE | STABLE | EXCLUSIVE]
[PRIMARY DUPLEX | SECONDARY DUPLEX][REAL-MPLF | SIMULATED-MPLF]
[PAVBASE (nn) | PAVALIAS (vdev/rdev) | HYPERPAVBASE (poolnum) |
HYPERPAVALIAS (rdev,poolnum)]
[ALIASES: vdev/rdev vdev/rdev vdev/rdev vdev/rdev][SEF]
```

**SYSCTL**

specifies that CCWs are accepted which have a direct effect on global subsystem resources and functions, and not just those related to the device.

**DEVCTL**

specifies that CCWs are accepted that have an effect on resources and functions directly related to the device.

**NOCTL**

No CCWs are accepted that can exercise control of subsystem resources and functions, regardless of whether they are directly related to the device.

**CACHE**

means that the minidisk has access to control unit cache storage.

**NOCACHE**

means that CP forces I/O to the minidisk to bypass storage control cache.

**STABLE**

means that the disk was acquired with either an SR, SW, or SM access mode, preventing all other users from getting write access to this disk.

**EXCLUSIVE**

means that the disk was acquired with either an ER or EW link mode, preventing all other users from getting any access to this disk.

**PRIMARY DUPLEX**

means that the disk is on the primary volume of a duplex pair.

**SECONDARY DUPLEX**

means that the disk is on the secondary volume of a duplex pair.

## QUERY VIRTUAL DASD

### REAL-MPLF

means that the device is enabled to use the multi-path lock facility on the real control unit.

### SIMULATED-MPLF

means that the device is enabled to use VM's simulation of the multi-path lock facility.

### PAVBASE (*nn*)

indicates that the device is a base Parallel Access Volume. *nn* indicates the number of alias Parallel Access Volumes that are associated with this base.

### PAVALIAS (*vdev/rdev*)

indicates that the device is an alias Parallel Access Volume. *vdev* indicates the device number of the associated virtual base Parallel Access Volume and *rdev* indicates the device number of the assigned real alias Parallel Access Volume.

### HYPERPAVBASE (*poolnum*)

indicates that the device is a base HyperParallel Access Volume (HyperPAV). *poolnum* indicates the associated pool for this HyperPAV base device.

### HYPERPAVALIAS (*rdev,poolnum*)

indicates that the device is an alias HyperParallel Access Volume (HyperPAV). *rdev* indicates the device number of the assigned real HyperPAV alias device. *poolnum* indicates the associated pool for this HyperPAV alias device.

### ALIASES: *vdev/rdev vdev/rdev vdev/rdev vdev/rdev*

indicates the list of alias Parallel Access Volumes that are associated with the base Parallel Access Volume (PAVBASE (*nn*)). *vdev* indicates the device number of the virtual alias Parallel Access Volume and *rdev* indicates the device number of the assigned real alias Parallel Access Volume. The number of *vdev/rdev* pairs that are displayed equals the (*nn*) number after the PAVBASE parameter. A maximum of four *vdev/rdev* pairs will be listed per response line.

### SEF

specifies that the underlying real device is a space-efficient volume.

```
q v dasd details
DASD 019E 3390 PACK03 R/O      355 CYL ON DASD  5C81 SUBCHANNEL = 0011
CACHE
DASD 0200 3390 PACK01 R/W      100 CYL ON DASD  5100 SUBCHANNEL = 0002
CACHE SEF
```

## Messages

- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP263E Too many operands were supplied for this command.

## QUERY (Virtual Device)

### Authorization

Privilege Class: G

### Purpose

Use QUERY (virtual device) to display the status of devices accessible to your virtual machine. These devices may be located at a specific virtual device number or located in a range of virtual device numbers.

### Operands

**vdev**

**vdev1-vdev2**

identifies the device or range of virtual device numbers for devices whose status is to be displayed.

**DETAILS**

displays additional information for the specified virtual device or range of devices.

### Usage Notes

1. The DETAILS option is meaningful only for dedicated DASDs, or minidisk DASDs, on a cache subsystem, or for tapes. The responses for devices other than DASD, if specified, remain the same.

### Responses

For devices not listed below, see the QUERY (individual device type) command description for their response formats.

Response 1:

Responses you receive depend on the type of device located at the device number you specify. These responses are included in the QUERY VIRTUAL commands for those devices.

You receive this response if the device is one of the following:

- 3745 Communications Controller
- A Mass Storage Controller
- A virtual 270x line
- A message device
- A tape device
- A miscellaneous device (one not explicitly described in the QUERY VIRTUAL family of commands).

```
type vdev {ON DEV rdev          } [SUBCHANNEL = vsub] [encap]
          {ON NIC vdev AS UNIT unit}
```

**type**

identifies the virtual device type; it can be any of the following:

## QUERY (Virtual Device)

<u>Type</u>	<u>Meaning</u>
CTLR	3745 Communications Controller
MSC	Mass Storage Controller
LINE	Virtual 270x line
MSGD	Message Device
OSA	Open Systems Adapter
FCP	SCSI Device Adapter
TAPE	Tape Device
DEV	Any miscellaneous device

### **vdev**

identifies the virtual device number.

### **ON DEV rdev**

identifies the real device number.

### **ON NIC vdev AS UNIT unit**

identifies the base device (for a virtual network adapter) and the relative device (starting with 0).

### **vsub**

identifies the virtual subchannel number.

### **enccap**

If the device is capable of hardware encryption, the string "ENCRYPTION CAPABLE" will be included. Otherwise, this field will be blank.

Response 2:

```
[SYSCTL | DEVCTL | NOCTL | CACHE | NOCACHE | STABLE | EXCLUSIVE]
[PRIMARY DUPLEX | SECONDARY DUPLEX]
[REAL-MPLF | SIMULATED-MPLF]
[PAVBASE (nn) | PAVALIAS (vdev/rdev) | HYPERPAVBASE (poolnum) |
HYPERPAVALIAS (rdev,poolnum)]
[ALIASES: vdev/rdev vdev/rdev vdev/rdev vdev/rdev]
[ACTIVE KEY LABEL(S): keys]
[ATTACHED KEY LABEL(S): keys]
[INACTIVE KEY LABEL(S): keys]
[Position: pos BLK Relative position: relpos%]
```

is the response displayed, in addition to the normal QUERY VIRTUAL DEVICE response, if the DETAILS option is specified.

### **SYSCTL**

specifies that CCWs are accepted that have a direct effect on global subsystem resources and functions and not just those related to the device.

### **DEVCTL**

specifies that CCWs are accepted that have an effect on resources and functions directly related to the device.

### **NOCTL**

No CCWs are accepted that can exercise control of subsystem resources and functions, regardless of whether they are directly related to the device.

### **CACHE**

indicates that the minidisk has access to storage control cache.

### **NOCACHE**

indicates that CP forces I/O to the minidisk to bypass storage control cache.

### **STABLE**

indicates that the disk was acquired with either an SR, SW, or SM access mode, preventing all other users from getting write access to this disk.

**EXCLUSIVE**

indicates that the disk was acquired with either an ER or EW link mode, preventing all other users from getting any access to this disk.

**PRIMARY DUPLEX**

means that the disk is on the primary volume of a duplex pair.

**SECONDARY DUPLEX**

means that the disk is on the secondary volume of a duplex pair.

**REAL-MPLF**

means that the device is enabled to use the multi-path lock facility on the real control unit.

**SIMULATED-MPLF**

means that the device is enabled to use VM's simulation of the multi-path lock facility.

**PAVBASE (nn)**

indicates that the device is a base Parallel Access Volume. *nn* indicates the number of alias Parallel Access Volumes that are associated with this base.

**PAVALIAS (vdev/rdev)**

indicates that the device is an alias Parallel Access Volume. *vdev* indicates the device number of the associated virtual base Parallel Access Volume and *rdev* indicates the device number of the assigned real alias Parallel Access Volume.

**HYPERPAVBASE (poolnum)**

indicates that the device is a base HyperParallel Access Volume (HyperPAV). *poolnum* indicates the associated pool for this HyperPAV base device.

**HYPERPAVALIAS (rdev,poolnum)**

indicates that the device is an alias HyperParallel Access Volume (HyperPAV). *rdev* indicates the device number of the assigned real HyperPAV alias device. *poolnum* indicates the associated pool for this HyperPAV alias device.

**ALIASES: vdev/rdev vdev/rdev vdev/rdev vdev/rdev**

indicates the list of alias Parallel Access Volumes that are associated with the base Parallel Access Volume (PAVBASE (*nn*)). *vdev* indicates the device number of the virtual alias Parallel Access Volume and *rdev* indicates the device number of the assigned real alias Parallel Access Volume. The number of *vdev/rdev* pairs that are displayed equals the (*nn*) number after the PAVBASE parameter. A maximum of four *vdev/rdev* pairs will be listed per response line.

**ACTIVE KEY LABEL(S): keys**

indicates the active key labels that are currently associated with the attached device. This is usually through either an ATTACH command with the KEY option, or by an unmodified ATTACH that follows a SET RDEV command with the FEATURE KEY option, but this could also be the case when a tape is mounted that was previously encrypted with different key labels or had been rekeyed. If "keys" indicates "DEFAULT", the external key manager's default keys will be used. Otherwise, will indicate the encoding mechanism ("L" for Label, "H" for Hash of Label) and the associated key label that was specified.

**ATTACHED KEY LABEL(S): keys**

indicates the key labels that were specified through the ATTACH command. This is only displayed if it differs from what is currently in use on the tape cartridge and displayed under the "active" heading.

**INACTIVE KEY LABEL(S): keys**

indicates the key labels that are associated with the device as a result of a SET RDEV command with the FEATURE KEY option. If "keys" indicates "DEFAULT", the external key manager's default keys will be used. Otherwise, will indicate the encoding mechanism ("L" for Label, "H" for Hash of Label) and the associated key label that was specified.

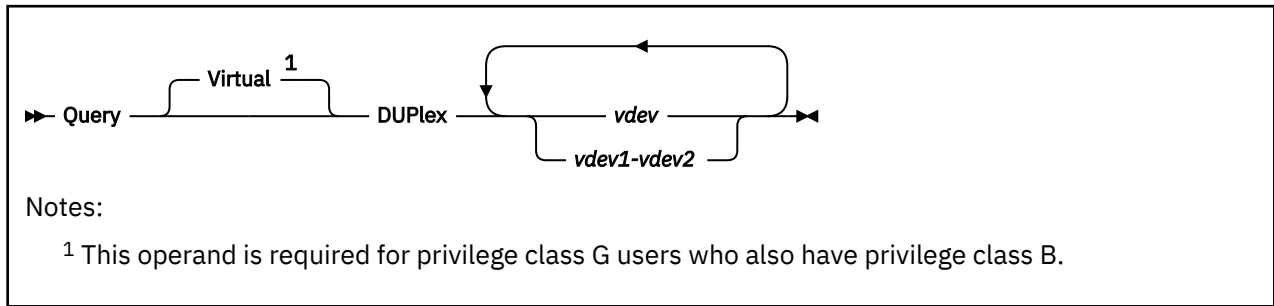

**Position: pos BLK Relative position: relpos%**

indicates the current tape block position and relative position. Note that this line is shown only for the 3592 Model E07 and higher.

## QUERY VIRTUAL DUPLEX

### Authorization

Privilege Class: G

### Purpose

Use the QUERY VIRTUAL DUPLEX command to display the status of virtual duplex pairs attached to 3990-3 and 3990-6 storage subsystems.

### Operands

**vdev**

**vdev1-vdev2**

is the virtual device number, a list of virtual device numbers, or a range of virtual device numbers of the primary or secondary volumes in the established duplex pairs.

### Usage Notes

1. The device number of either the primary or secondary volume in a duplex pair may be specified on this command.
2. If both the primary and secondary of a duplex pair are included in the device list or device range, two identical responses will be displayed.

### Responses

Response 1:

```
Duplex pair (pvdev,svdev) - active
```

is displayed for each duplex pair that is not in the *suspended duplex* state and for which synchronization is not in progress. If either the primary or secondary device is not a virtual device for the user, hyphens (----) will appear in the corresponding *pvdev* or *svdev* position.

**pvdev**

is the virtual device number of the primary volume in the duplex pair.

**svdev**

is the virtual device number of the secondary volume in the duplex pair.

Response 2:

```
Duplex pair (pvdev,svdev) - copy operation is in progress.
```

is displayed for each duplex pair that is in the process of being synchronized. If either the primary or secondary device is not a virtual device for the user, hyphens (----) will appear in the corresponding *pvdev* or *svdev* position.

***pvdev***

is the virtual device number of the primary volume in the duplex pair.

***svdev***

is the virtual device number of the secondary volume in the duplex pair.

Response 3:

```
Duplex pair (pvdev,svdev) - suspended
```

is displayed for each duplex pair that is in the *suspended duplex* state. Either the primary or the secondary volume has been suspended. If either the primary or secondary device is not a virtual device for the user, hyphens (----) will appear in the corresponding *pvdev* or *svdev* position.

***pvdev***

is the virtual device number of the primary volume in the duplex pair.

***svdev***

is the virtual device number of the secondary volume in the duplex pair.

Response 4:

```
vdev The associated {primary|secondary}  
volume in the duplex pair is not online to VM.
```

is displayed when the virtual device number of the primary or secondary volume is specified on the command and the associated real device number is not in the CP I/O configuration.

***vdev***

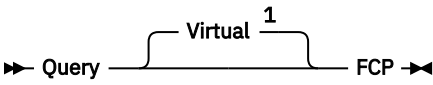

is the virtual device number of the primary or secondary volume in the duplex pair.

### Messages

- HCP006E Invalid device type - {*rdev/vdev/ldev*}
- HCP009E Invalid range - *range*
- HCP022E A virtual device number was not supplied or it is invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP319E Error processing subsystem command - *cmd* for DASD *vdev*
- HCP332E Invalid control unit type - *vdev*
- HCP1110E Device *rdev/vdev* is not in a duplex pair.

## QUERY VIRTUAL FCP

Notes:

<sup>1</sup> This operand is required for privilege class G users who also have privilege class B.

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL FCP to display status of the Fibre Channel Protocol (FCP) adapter devices accessible to your virtual machine.

### Responses

For each FCP device dedicated to your virtual machine configuration, the following is displayed:

```
FCP vdev ON DEV rdev UNIT unit CHPID chp SUBCHANNEL = vsub [TOKEN = token]
      vdev DEVTYP devtyp CHPID chp chptyp
      vdev [QDIO-ELIGIBLE|QDIO PENDING ACTIVE|QDIO ACTIVE|QIOASSIST status] [(QEBSM)]
      vdev [DATA ROUTER ELIGIBLE|DATA ROUTER ACTIVE]
```

If the subchannel for the FCP device is in either QDIO PENDING ACTIVE or QDIO ACTIVE state, the following is displayed for each input and output data queue that was established by a program running in a V=V virtual machine only:

```
vdev type sync priority IOCNT = nnnnnnnn ADP = nnn PROG = nnn UNAVAIL = nnn
vdev BYTES = nnnnnnnnnnnnnnnnnn
```

The terms shown in the above Results have the following meanings:

***vdev***

identifies the virtual device number of the FCP device.

***rdev***

identifies the real device number of the FCP device.

**CHPID *chp***

identifies the real CHPID number of the FCP device.

**SUBCHANNEL = *vsub***

identifies the virtual subchannel number associated with the attached FCP device.

**TOKEN = *token***

identifies the subchannel token assigned to the QDIO connection when it is managed by QDIO enhanced buffer state management (QEBSM).

**DEVTYP *devtyp***

identifies the real device type of the FCP device.

**CHPID *chp chptyp***

identifies the real CHPID number and CHPID type of the FCP device.

**QDIO-ELIGIBLE**

indicates that the device is eligible to use the QDIO Hardware Facility for direct data transfer.

### **QDIO PENDING ACTIVE**

indicates that a program running in the virtual machine has established the QDIO data queues for transferring data between the program and the specified FCP device. Although the data queues are created, they must be activated by the program running in the virtual machine before data transfer can commence.

### **QDIO ACTIVE**

indicates that a program running in the virtual machine has activated the QDIO data queues. Direct data transfer between the specified FCP device and the program may now occur.

### **QIOASSIST status**

The status is one of the following:

- **QIOASSIST NOT AVAILABLE** – indicates that the processor does not support the queue-I/O assist (QDIO performance assist for V=V guests), or z/VM is running in an environment where the queue-I/O assist is not available. See the SET QIOAssist command for a list of requirements to use the queue-I/O assist.
- **QIOASSIST- ELIGIBLE** – indicates the device is eligible to use the queue-I/O assist (QDIO performance assist for V=V guests), when the virtual machine begins using the device with no traces in effect.
- **QIOASSIST DISABLED** – indicates the device is not permitted to use the queue-I/O assist (QDIO performance assist for V=V guests). The device must have been attached to the virtual machine with the NOQIOAssist option either on the CP ATTACH command or the system-directory DEDICATE statement.
- **QIOASSIST ACTIVE** – indicates the queue-I/O assist (QDIO performance assist for V=V guests) is active and in-use.

### **QEBSM**

indicates that the device connection is managed using enhanced QDIO buffer state management protocol. When QEBSM manages a QDIO connection, a QDIO I/O request can be initiated without z/VM involvement.

### **DATA ROUTER ELIGIBLE**

indicates that the device is eligible to use the Data Router facility to directly transfer data from guest memory to the FCP device.

### **DATA ROUTER ACTIVE**

indicates that a program running on the virtual machine requested that the Data Router facility be used when transferring data between guest memory and the FCP device.

### **type**

indicates the type of QDIO data queue:

#### **INP**

Input

#### **OUT**

Output

### **sync**

indicates whether the program and CP versions of the QDIO data queue are currently synchronized:

+

Input

-

Output

### **priority**

indicates the priority of the QDIO data queue. All input and output queues are listed according to their queue priority, with the lowest number queues having the highest priority.

**IOCNT = *nnnnnnnn***

specifies the number of data transfers that have completed since the QDIO data queue was last activated by the program, in decimal. CP increments the IOCNT each time a QDIO data buffer changes from an adapter-owned state to a program-owned state.

**BYTES = *nnnnnnnnnnnnnnnn***

specifies the number of bytes transferred on that queue since device activation, in hexadecimal.

**ADP = *nnn***

specifies the number of QDIO data buffers currently pending or available for a direct data transfer. This is the number of QDIO data buffers currently owned by the adapter.

**PROG = *nnn***

specifies the number of QDIO data buffers currently owned by the program running in the virtual machine that have storage blocks allocated.

**UNAVAIL = *nnn***

specifies the number of QDIO data buffers currently owned by the program running in the virtual machine that have no storage blocks allocated.

**Examples**

This example displays three virtual FCP devices within the virtual machines' I/O configuration:

```
cp query virtual fcp
FCP 0500 ON FCP 0500 CHPID 80 SUBCHANNEL = 000D
    0500 DEVTYPE FCP          CHPID 80 FCP
    0500 QDIO-ELIGIBLE
FCP 0501 ON FCP 0500 CHPID 80 SUBCHANNEL = 000E
    0501 DEVTYPE FCP          CHPID 80 FCP
    0501 QDIO-ELIGIBLE
FCP 0502 ON DEV 0500 CHPID 80 SUBCHANNEL = 000F
    0502 DEVTYPE FCP          CHPID 80 FCP
    0502 QDIO-ELIGIBLE
```

**Messages**

- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP263E Too many operands were supplied for this command

## QUERY VIRTUAL FLASHCOPY

### Authorization

Privilege Class: G

### Purpose

This command allows interrogation of persistent FlashCopy relationships in the Persistent FlashCopy Relationship Table. Each FlashCopy relationship is identified with a unique sequence number that is derived from the TOD clock when the relationship is established.

The Persistent FlashCopy Relationship Table is maintained to preserve additional information regarding relationships. Note that this table is NOT maintained over system IPLs and is intended to be used as supplemental information regarding FlashCopy relationships.

### Operands

#### **vdev**

defines a virtual device in your current virtual configuration that is to be interrogated.

#### **ALL**

specifies that all virtual devices are to be interrogated.

#### **CREATED \***

#### **CREATED *userid***

displays additional information regarding persistent FlashCopy relationships that were established by the current user during the current system IPL session. When specifying a *userid*, it must be the user issuing this command.

#### **OWNer \***

#### **OWNer *userid***

displays additional information regarding persistent FlashCopy relationships that were established on minidisks owned by the current user during the current system IPL session. When specifying a *userid*, it must be the user issuing this command.

## Usage Notes

1. The contents of the Persistent FlashCopy Relationship Table are lost when the system is IPLed.
2. Entries might exist in the list for relationships that have been partially withdrawn by this or another LPAR.
3. Entries will not exist for relationships that have been completely withdrawn.

## Responses

The responses you receive will depend on the device extents, full-pack or minidisk, for the device numbers being returned. The number of active FLASHCOPY relationships is defined within the extent of the virtual device, while the maximum number of FLASHCOPY relationships is a limit for the entire volume on which the virtual device is defined. When the active number of FLASHCOPY relationships approaches the maximum number, defining new FLASHCOPY relationships might be limited due to unavailable resources within the Enterprise Storage Server or by extent conflicts for either the source or target relationships.

```
q v flashcopy F48 F66
VDEVN SSID LSS UA CU SERIAL ACTIVE MAX PPRC
0F48 A760 00 28 2105 0000000FCA76 263 951 Secondary
0F66 B660 01 30 2105 0000000FCB66 0 0
```

where:

Field	Meaning
VDEVN	Virtual device number
SSID	Subsystem identifier
LSS	Logical subsystem number
UA	Unit address
CU	Control unit type
SERIAL	Storage facility serial number
ACTIVE	Number of active FLASHCOPY relationships
MAX	Maximum number of FLASHCOPY relationships allowed
PPRC	Peer-to-Peer Remote Copy status
	Primary - device is a Peer-to-Peer Primary volume
	Secondary - device is a Peer-to-Peer Secondary volume
	Cascading - device is a Peer-to-Peer Cascading volume
	Blank - device is not active for Peer-to-Peer copy

```

# QUERY VIRTUAL GRAF

## Authorization

Privilege Class: G

## Purpose

Use QUERY VIRTUAL GRAF to show the status of all display devices attached to your virtual machine.

## Operands

### EXTended

specifies that logical unit network qualifiers, or logical device host names and IP addresses, are displayed, if they exist.

An IPv4 address is displayed in dotted-decimal format.

**Example:** 9 . 130 . 44 . 144

An IPv6 address is displayed in compressed format (":" designates multiple 16-bit groups of zeros).

**Example:** The following is an IPv6 address:

```
F802:0000:0000:0000:0000:0A00:0001
```

This address is displayed in compressed format as:

```
F802::A00:1
```

## Responses

Response 1:

You receive the following response for each of your locally attached display devices:

```
GRAF vdev {ON GRAF rdev          } [SUBCHANNEL = vsub]
           {ON LDEV ldev         }
           {ON [netname.]luname VSM userid}
           {NOT DIALED          }
```

### vdev

identifies the virtual display device.

### ON GRAF rdev

### ON LDEV ldev

shows the real (*rdev*) or logical (*ldev*) device that is dialed into, or attached to, this virtual machine.

### ON [netname.]luname

identifies an SNA/CCS terminal (controlled by the VTAM service machine) that is dialed into this virtual machine. It is the name from the VTAM definition of the terminal as an SNA logical unit. The *netname*.

## QUERY VIRTUAL GRAF

is a network qualifier followed by a period delimiter, and is only present when the EXTended option is specified and the VSM supports network qualified names.

### **VSM *userid***

identifies the user ID of the VTAM service machine managing the device.

### **NOT DIALED**

shows the status of a virtual display device that has not been attached using the DIAL command.

### ***vsub***

identifies the virtual subchannel number.

Response 2:

```
CONS vdev {ON GRAF rdev } [SUBCHANNEL = vsub]  
          {ON LDEV ldev }  
          {ON luname VSM userid }  
          {ON [netname.]luname VSM userid}  
          {DISCONNECTED }
```

is returned if your virtual console is conmode 3270.

### ***vdev***

identifies the virtual display device.

### **ON GRAF *rdev***

### **ON LDEV *ldev***

shows the real (*rdev*) or logical (*ldev*) device that is logged onto this virtual machine.

### **ON [*netname.*]*luname***

identifies an SNA/CCS terminal (controlled by the VTAM service machine) that is logged onto this virtual machine. It is the name from the VTAM definition of the terminal as an SNA logical unit. The *netname.* is a network qualifier followed by a period delimiter, and is only present when the EXTended option is specified and the VSM supports network qualified names.

### **VSM *userid***

identifies the user ID of the VTAM service machine managing the device.

### **DISCONNECTED**

indicates that the console is disconnected.

### ***vsub***

identifies the virtual subchannel number.

Response 3:

```
PRT vdev { ON DEV rdev } [SUBCHANNEL = vsub]  
          { ON DEV ldev }
```

is returned for each of your locally attached display 328x printers.

### ***vdev***

identifies the virtual display 328x printer.

### **ON DEV *rdev***

### **ON DEV *ldev***

shows the real (*rdev*) or logical (*ldev*) device number of the display 328x printer attached to this virtual machine.

### ***vsub***

identifies the virtual subchannel number.

## Messages

# QUERY VIRTUAL LINES

Notes:

<sup>1</sup> This operand is required for privilege class G users who also have privilege class B.

## Authorization

Privilege Class: G

## Purpose

Use QUERY VIRTUAL LINES to display the status of all of your virtual communications lines.

## Usage Notes

1. The QUERY LINES, QUERY LINKS, and QUERY VIRTUAL LINES commands share the two possible abbreviations "LI" and "LIN". If you are authorized to issue these commands, we recommend that you specify at least 4 character abbreviations of the LINES or LINKS operand to ensure that you invoke the intended command. For example, instead of "Q LI" specify "Q LINE".

## Responses

Response 1:

```
LINE vdev {ON LINE rdev} [SUBCHANNEL = vsub]
          {ENABLED      }
          {DISABLED     }
```

is returned for each of your communications lines.

### **vdev**

identifies the virtual device number of the communication line.

### **ON LINE rdev**

shows the real (*rdev*) device dialed into, or attached to, this virtual machine.

### **ENABLED**

shows the status of a virtual communication line that is enabled.

### **DISABLED**

shows the status of a virtual communication line that is disabled.

### **vsub**

identifies the virtual subchannel number.

Response 2:

```
CONS vdev {ON LINE rdev          } [SUBCHANNEL = vsub]
          {ON GRAF rdev          }
          {ON LDEV ldev          }
          {ON [netname.]luname VSM userid}
          {ON SYSC                }
          {DISCONNECTED          }
```

is returned for your virtual console if your virtual console is conmode 3215.

## QUERY VIRTUAL LINES

### ***vdev***

identifies the virtual device number of the communication line.

### **ON LINE *rdev***

### **ON GRAF *rdev***

### **ON LDEV *ldev***

shows the real (*rdev*) or logical (*ldev*) device that is logged onto this virtual machine.

### **ON [*netname.*]*luname***

identifies an SNA/CCS terminal (controlled by the VTAM service machine) that is logged onto this virtual machine. It is the name taken from the VTAM definition of the terminal as an SNA logical unit. The *netname.* is a network qualifier followed by a period delimiter, and is only present when the the EXTended option is specified and the VSM supports network qualified names.

### **VSM *userid***

identifies the user ID of the VTAM service machine managing the device.

### **ON SYSC**

identifies the system console as the real device that is logged onto this virtual machine.

### **DISCONNECTED**

indicates that the real device is disconnected.

### ***vsub***

identifies the virtual subchannel number. This value is displayed only if the real device that is logged onto this virtual machine is other than the system console.

## **Messages**

- HCP003E Invalid option - *option*
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP263E Too many operands were supplied for this command.

## QUERY VIRTUAL MSGDEVICES

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL MSGDEVICES to display a list of all message devices within your I/O configuration.

### Usage Notes

1. To define a virtual message processor and associated virtual message devices, use the DEFINE MSGPROC command.
2. To display information about virtual message processors in your I/O configuration, use the QUERY VIRTUAL MSGPROC command.
3. To restart a virtual message processor that is in your I/O configuration, use the RESTART MSGPROC command.
4. To remove all message facility capability from your virtual machine, use the SET MSGFACIL OFF command.
5. To detach a virtual message processor and associated virtual message devices, use the DETACH MSGPROC command.

### Responses

Response 1:

To display a list of all message devices within your I/O configuration, enter the following:

```
query msgd
MSGD 0500 MESSAGE PROCESSOR = CFCC2   SUBCHANNEL = 0010
MSGD 0501 MESSAGE PROCESSOR = CFCC2   SUBCHANNEL = 0011
MSGD 0502 MESSAGE PROCESSOR = CFCC2   SUBCHANNEL = 0012
MSGD 0503 MESSAGE PROCESSOR = CFCC2   SUBCHANNEL = 0013
```

#### MSGD

indicates that the following four digit hex number is a message device number.

#### MESSAGE PROCESSOR

specifies the user ID of the message processor that is associated with the message device.

#### SUBCHANNEL

is the subchannel number for the message device.

### Messages

- HCP003E Invalid option – command contains extra option starting with *option*
- HCP040E Device MSGD does not exist

## QUERY VIRTUAL MSGPROC

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL MSGPROC to display information about virtual message processors within your I/O configuration.

### Operands

#### ALL

specifies that information about all CF Service Machines within your I/O configuration are to be displayed.

#### NAME *msgprocid*

specifies the user ID of a specific CF Service Machine within your I/O configuration to display.

### Usage Notes

1. To define a virtual message processor and associated virtual message devices, use the DEFINE MSGPROC command.
2. To display information about the virtual message devices within your I/O configuration, use the QUERY VIRTUAL MSGDEVICES command.
3. To restart a virtual message processor that is in your I/O configuration, use the RESTART MSGPROC command.
4. To remove all message facility capability from your virtual machine, use the SET MSGFACIL OFF command.
5. To detach a virtual message processor and associated virtual message devices, use the DETACH MSGPROC command.

### Responses

Response 1:

To display information for all message processors within your I/O configuration, enter the following:

```
query msgp
MESSAGE PROCESSOR=01      USERID=CFCC20K  USERS=01
TYPE=SIMDEV  MODEL=001  MFG=IBM  PLANT=EN  SEQ=00000CFCC20K
DEVICES=0103 0102 0101 0100
CGS=C0 80 (PA=C0) CFR=80 C0 (PA=C0)
CG=CFCCMNT

MESSAGE PROCESSOR=02      USERID=CFCC2      USERS=04
TYPE=SIMDEV  MODEL=001  MFG=IBM  PLANT=EN  SEQ=0000000CFCC2
DEVICES=0500 0501 0502 0503
CGS=C1 81 (PA=C0) CFR=81 C1
CG=SHARE1  SHARE2  SHARE4  SHARE3
Ready;
```

**MESSAGE PROCESSOR**

specifies the processor number assigned to the CF Service Machine. The first message processor defined by a user will be assigned as processor 1. Subsequent processors defined will be assigned the next lowest available number from two to eight.

**USERID**

is the user ID of the CF Service Machine that is running as a message processor.

**USERS**

is the total number of guests coupled to the message processor.

**TYPE**

is the six character device type in the worldwide unique ID of the message processors Node Descriptor

**MODEL**

is the three character model number in the worldwide unique ID of the message processors Node Descriptor.

**MFG**

is the three character code that identifies the manufacturer in the worldwide unique ID of the message processors Node Descriptor.

**PLANT**

is the two character code that identifies the plant of manufacture in the worldwide unique ID of the message processors Node Descriptor.

**SEQ**

is the twelve character code that contains the serial number in the worldwide unique ID of the message processors Node Descriptor. This field will make the Node Descriptor of the CF Service Machine unique in z/VM. The sequence field will contain the CF Service Machine user ID right justified. All leading or illegal characters will be padded with EBCDIC zeros.

**DEVICES**

is a list of message device numbers in the user's I/O configuration that represent the message processor.

**CGS**

(Coupled Guest Sender) is a list of message facility sender CHPIDS in the coupled guest's virtual I/O configuration, which are used by the devices specified in the DEVICES= list to communicate to the displayed message processor.

**CFR**

(Coupling Facility Receiver) is a list of message facility receiver CHPIDS in the message processor's virtual I/O configuration, which are used by the message processor to communicate to the devices specified in the DEVICES= list.

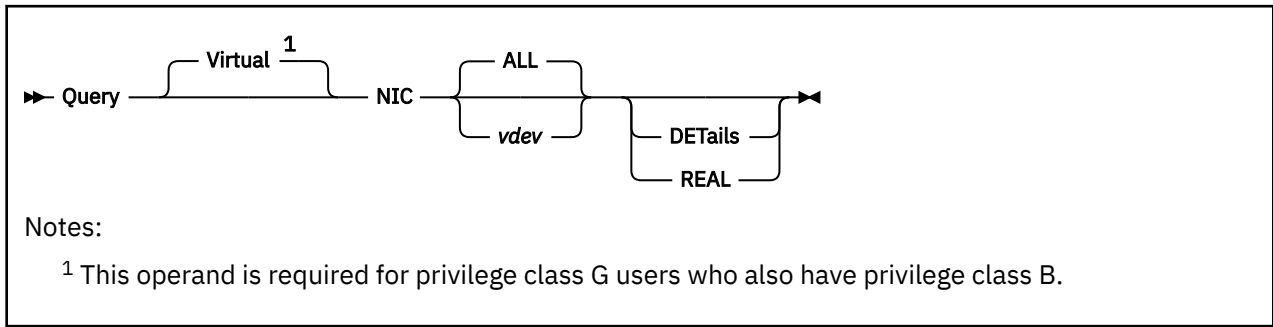

**CG**

is a list of all the coupled guests (CFUSER virtual machines) that are currently coupled to the message processor.

**Messages**

- HCP002E Invalid operand — *operand*
- HCP003E Invalid option — *option*
- HCP003E Invalid option — command contains extra option(s) starting with *option*
- HCP020E Userid missing or invalid
- HCP2805E Message processor *msgprocid* does not exist in your I/O configuration.

## QUERY VIRTUAL NIC

### Authorization

Privilege Class: G

### Purpose

Use QUERY NIC to display information about a network device in your virtual machine configuration. The response for each network adapter includes:

- Adapter configuration (base device address, number of devices)
- Adapter type for example, HIPER for HiperSockets
- Assigned MAC address and associated attributes.
- Status of each associated virtual device for example, DETAILS option

### Operands

#### ALL

indicates a request for "all" simulated network interface cards (NIC) in the invoker's virtual machine configuration

#### vdev

specifies the virtual device number (hex) of the adapter to be examined. You may specify the virtual device number of any virtual device that is attached to the adapter. However, CP responses will refer to each virtual adapter by its *base* device address; this is the first device in the range.

#### DETAils

indicates a request for full details about the selected adapters. The response includes the following information for each adapter:

- the role (CTL-READ, CTL-WRITE, or DATA) assigned to this device
- the IP Addresses registered to this device
- the priority for all packets sent from this virtual NIC's network connection to an external network if the virtual NIC is connected to a virtual switch. The priority value (PQUPLINKTX) will be used when priority queuing is enabled on the virtual switch (PRIQueueing ON).

#### REAL

indicates a request for a display of real network devices attached to the invoker's virtual machine.

### Examples

#### 1. QUERY NIC:

Display a list of simulated network interface cards belonging to this virtual machine:

```
cp query v nic
Adapter 0500.P00 Type: QDIO      Name: UNASSIGNED  Devices: 3
```

```

MAC: 02-00-0F-00-01-4B      LAN: FARRELLS TEST
Adapter 05D0.P00 Type: HIPERS  Name: UNASSIGNED  Devices: 8
MAC: 02-00-0F-00-01-4E      LAN: * Internal      MFS: 163

```

This response describes a QDIO adapter at 0500 which is connected to a guest LAN, and a HiperSockets adapter at 05D0 which is using its internal LAN (indicated by LAN "\* Internal"). "UNASSIGNED" means your software has not yet assigned a name to this interface.

## 2. QUERY NIC DETAILS:

- Display detailed information about a simulated network interface card:

```

cp q v nic 2000 det
Adapter 2000.P00 Type: QDIO      Name: TCPIP20      Devices: 3
MAC: 02-00-00-00-00-13 LAN: SYSTEM SUBNTA
PQUplinkTX: Normal
RX Packets: 33521      Discarded: 0      Errors: 0
TX Packets: 24955      Discarded: 0      Errors: 0
RX Bytes: 34225670      TX Bytes: 33713275
Connection Name: z/VM0000 State: Session Established
Device: 2000 Unit: 000 Role: CTL-READ
Device: 2001 Unit: 001 Role: CTL-WRITE
Device: 2002 Unit: 002 Role: DATA      Port: 0065
VLAN: 0002 Assigned by user
Router: Primary IPv4 VLAN 0002
Options: Broadcast Multicast IPv4 VLAN
Unicast IP Addresses:
  9.60.59.32      MAC: 02-00-00-00-00-13
Multicast IP Addresses:
  224.0.0.1      MAC: 01-00-5E-00-00-01
  224.0.0.9      MAC: 01-00-5E-00-00-09

```

This response describes a QDIO adapter at 2000 which is connected to a guest LAN, and provides detailed information about each active connection group.

- Display detailed information about a device managed by DIAGNOSE Code X'2A8':

```

cp q v nic 0AAA det
Adapter 0AAA.P00 Type: QDIO      Name: UNASSIGNED  Devices: 3
MAC: 02-34-56-00-01-00      VSWITCH: SYSTEM TEST
PQUplinkTX: Normal
RX Packets: 2      Discarded: 0      Errors: 0
TX Packets: 4      Discarded: 0      Errors: 0
RX Bytes: 64      TX Bytes: 128
Connection Name: *DIAG2A8 State: Session Established
Device: 0AAA Unit: 000 Role: DATA-DIAG Port: 65
VLAN: 0001
Options: Ethernet Broadcast
Unicast MAC Addresses:
  02-34-56-00-01-00 IP: 10.1.6.3
  02-34-56-00-01-00 IP: 50C0:C216::10:1:6:3
Multicast MAC Addresses:
  01-00-00-00-00-01
  01-00-00-00-00-02
  01-00-00-00-00-03
  01-00-00-00-00-04
  01-00-00-00-00-05
Unassigned Devices:
Device: 0AAB Unit: 001 Role: Unassigned
Device: 0AAC Unit: 002 Role: Unassigned

```

For more information on [DIAGNOSE Code X'2A8'](#), see *z/VM: CP Programming Services*.

## 3. QUERY NIC REAL

Display a list of real network devices attached to the virtual machine:

```

cp q v nic real
Adapter 0400 Type: QDIO      Name: UNASSIGNED  Devices: 1
MAC: 02-15-24-00-00-09      LAN: * External
Adapter 0401 Type: QDIO      Name: UNASSIGNED  Devices: 1
Adapter 0402 Type: QDIO      Name: UNASSIGNED  Devices: 1

```

## 4. QUERY NIC 7000 DET

If you enter QUERY NIC 7000 DET, you will see something like this:

## QUERY VIRTUAL NIC

```
Adapter 7000.P00 Type: QDIO      Name: NIC_7000    Devices: 3
MAC: 02-22-96-00-00-04        VSWITCH: SYSTEM ETH1
MAC: 02-22-96-00-00-05        Device: 7000 Current Protected
PQUplinkTX: Normal
Data Counters Cleared: 9/24/15 02:35:40
Discarded Counters Cleared: 9/24/15 02:35:40
Error Counters Cleared: 9/24/15 02:35:40
RX Packets: 25                Discarded: 0      Errors: 0
TX Packets: 9                 Discarded: 2      Errors: 0
RX Bytes: 1086                TX Bytes: 378
Connection Name: HALLOLE      State: Session Established
Device: 7000 Unit: 000 Role: CTL-READ
Device: 7001 Unit: 001 Role: CTL-WRITE
Device: 7002 Unit: 002 Role: DATA Port: 0066
VLAN: 0001
Options: Ethernet Broadcast
Unicast MAC Addresses:
02-22-96-00-00-04
Multicast MAC Addresses:
01-00-5E-00-00-01 IP: 224.0.0.1
33-33-00-00-00-01 IP: FF02::1
33-33-FF-00-00-04 IP: FF02::FF00:4
```

## Responses

The **QUERY NIC** response includes optional lines. The general format is:

```
Adapter vdev.Pnn Type: type      Name: portname   Devices: devs
MAC: macaddr LAN: ownerid lanname MFS: mfsize
MAC: macaddr Device: dev macstatus
PQUplinkTX: priority
Data Counters Cleared: mm/dd/yy hh:mm:ss
Discarded Counters Cleared: mm/dd/yy hh:mm:ss
Error Counters Cleared: mm/dd/yy hh:mm:ss
RX packets: rpackets            Discarded: nnn      Errors: nnn
TX packets: tpackets            Discarded: nnn      Errors: nnn
RX bytes: rbytes                TX bytes: tbytes
Connection Name: groupid       State: description
Device: vdev Unit: nnn Role: role Port: portnum
VLAN: nnnn status
Router: type ipversion vlan
Options: options
Unicast IP Addresses:
ipaddr MAC: macaddr <flags>
ipaddr MAC: macaddr <flags>
Multicast IP Addresses:
mpaddr MAC: macaddr <flags>
mpaddr MAC: macaddr <flags>
Device: (repeated for each device in the group)
...
Connection Name: ...
Unassigned Devices:
Device: vdev Unit: nnn Role: Unassigned
Device: (repeated for each unassigned device)
```

### Adapter

*vdev.Pnn* is the base virtual device address and port number of the simulated NIC.

### Type

*type* is the adapter type (QDIO or HIPERS).

### Name

*portname* is the adapter (or port) name assigned by your communications software. The value "UNASSIGNED" is displayed if your software does not assign a value.

### Devices

*devs* is the number of devices that form this adapter.

### LAN

*ownerid lanname* uniquely identifies the coupled guest LAN (or displays "\*" internal" for an uncoupled adapter).

### MFS

*mfssize* indicates the Maximum Frame Size. It is displayed only for HiperSockets adapters.

This line may contain a value of "SYSTEM" for the MAC address. That indicates that a SYSTEM MAC was requested, but has not yet been allocated.

**Current**

indicates a MAC address that is currently assigned to the device address.

**Pending**

indicates a MAC address that is pending. When the device is re-initialized, the pending MAC address will become current.

**PQUplinkTX**

indicates the priority for all packets sent from a virtual NIC's network connection to an external network. The PQUplinkTX value will be used when the virtual NIC is connected to a virtual switch, and priority queuing is enabled on the virtual switch (PRIQueuing ON).

**LOW**

specifies that outbound traffic to the external network will be sent at a low priority. This traffic will use the low priority queue which is serviced less frequently than the normal or high priority queues.

**NORMAL**

specifies that outbound traffic to the external network will be sent at a normal priority. This traffic will use the normal priority queue which is serviced less frequently than the high priority queue but more frequently than the low priority queue.

**HIGH**

specifies that outbound traffic to the external network will be sent at a high priority. This traffic will use the high priority queue which is serviced more frequently than the normal or low priority queues.

**RX packets**

*rxpackets* is the number of packets received.

**TX packets**

*txpackets* is the number of packets transmitted.

**Discarded**

*nnn* indicates the number of packets discarded.

**Errors**

*nnn* indicates the number of error packets discarded.

**RX bytes**

*rxbytes* is the number of bytes received.

**TX bytes**

*txbytes* is the number of bytes transmitted.

**Connection Name**

*groupid* is the name assigned by your communications software to this connection.

**State**

*description* represents the current state of this connection (usually "Session Established").

**MAC: mm-mm-mm-mm-mm-mm Device: vdev macstatus port**

Device MAC address and attributes line

This line will be displayed for each network device defined on the NIC adapter that has a MAC address assigned by the system administrator. If no MAC address assignments are made, then a network connection established on any device associated with this NIC will use the adapter MAC address. The adapter MAC address is the first MAC address displayed following the "Adapter" line (line 2).

**MAC: mm-mm-mm-mm-mm-mm**

Mac address assigned.

**Device vdev**

is the virtual device number assigned to the MAC address.

### ***macstatus***

is the current status of the specified MAC address.

#### **Current**

indicates the MAC address is currently assigned.

#### **Pending**

indicates the MAC address is waiting to be assigned the next time a network connection is reestablished.

### **Data Counters Cleared**

Indicates that the transmitted and received counters were reset to zero via the SET VSWITCH COUNTERS CLEAR DATA command at the time stated in the message.

### **Discarded Counters Cleared**

Indicates that the discarded counters were reset to zero via the SET VSWITCH COUNTERS CLEAR DISCARDED command at the time stated in the message.

### **Error Counters Cleared**

Indicates that the errors counters were reset to zero via the SET VSWITCH COUNTERS CLEAR ERRORS command at the time stated in the message.

### ***port***

is the current status of the specified MAC address.

#### **Protected**

when displayed indicates the MAC address is protected and cannot be overridden by the guest when establishing a network connection. If not displayed, then it is an unrestricted MAC address and may be overridden by a guest.

### **Unit**

*nnn* indicates the relative device number on this adapter (the base device is unit 000).

### **Role**

*role* is the role assigned to this device (CTL-READ, CTL-WRITE, or DATA).

### **Port**

*portnum* is the port number associated with the guest connection or the virtual switch network connection.

### **VLAN**

*nnnn(n)* indicates the effective VLAN ID or IDs for the device. Multiple VLAN ID lines may be shown if the virtual switch is protected by an ESM.

*status* is "Assigned by system" or "Assigned by user". If the specified VLAN ID conflicts with the authorizations for this user, "Conflicting VLAN ID" is displayed.

### **Router**

*type ipversion* indicates the adapter has configured itself as a router with type Primary, Secondary or Multicast in IP version IPv4 or IPv6. *vlan* is either VLAN followed by the VLAN ID, if it is a VLAN-specific router, or Global, if it is a global router. If it is a global router, lines will follow to describe which VLAN IDs the adapter is routing for.

The router line is displayed only when a router is configured.

### **Options**

*options* indicates the currently enabled features for this interface, such as Broadcast, Multicast, IPv4 or IPv6.

### ***ipaddr***

represents one Unicast IP address that has been registered to this device and optional information relating to the IP address.

An IPv4 address is displayed in dotted-decimal format, for example 9 . 130 . 44 . 144.

An IPv6 address is displayed in compressed format ("::" designates multiple 16-bit groups of zeros). For example, the IPv6 address

```
F802:0000:0000:0000:0000:0000:0A00:0001
```

is displayed in compressed format as `F802::A00:1`.

### ***mpaddr***

represents one Multicast IP Address.

For IPv4, the address is displayed in dotted-decimal format with the associated MAC address.

For IPv6, the address is displayed in compressed format ("::" designates multiple 16-bit groups of zeros).

### **MAC**

*macaddr* represents a MAC address.

### ***flags***

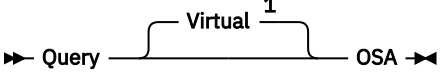

additional information that may be displayed with the IP address. These include:

- If the simulated NIC is coupled to a virtual switch, local indicates that this address was registered in a virtual switch LAN, but is NOT currently registered in the external network. This may indicate the external interface is disconnected. It may also indicate that this address is only supported within the immediate network (as it is in the case of an IPv6 address within an IP Layer VSWITCH).
- Conflict indicates that this address was registered locally but cannot be used at all because of a conflict with the network external to the virtual switch LAN.
- Remote indicates that this address was registered automatically to represent a source address found in a datagram. This entry is automatically removed after the IP Timeout (IPTIMEOUT) has expired.
- Manual indicates that this address was registered manually by an ARP cache control command from the driver. This entry will be automatically removed after the IP Timeout (IPTIMEOUT) has expired, or it may be removed earlier by the driver.

### **Messages**

- HCP006E Invalid device type *vdev*
- HCP040E Device {*vdev*|NIC} does not exist

## QUERY VIRTUAL OSA

Notes:

<sup>1</sup> This operand is required for privilege class G users who also have privilege class B.

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL OSA to display status of the Open Systems Adapter (OSA) devices accessible to your virtual machine.

### Responses

For each OSA device dedicated to your virtual machine configuration, the following is displayed:

```
OSA vdev {ON DEV rdev } [SUBCHANNEL = vsub] [(OSA AGENT)] [TOKEN = token]
      {ON NIC vdev AS UNIT unit}
      vdev DEVTYP devtyp CHPID chp chptyp
```

For each OSA device that uses the Queued Direct I/O (QDIO) hardware, the following is displayed:

```
vdev {QDIO-ELIGIBLE } [(QEBSM)]
     {QDIO PENDING ACTIVE}
     {QDIO ACTIVE }
     {QIOASSIST status }
```

If the subchannel for the OSA device is in either QDIO PENDING ACTIVE or QDIO ACTIVE state, the following line is displayed for each input and output data queue that was established by a program running in a V=V virtual machine only:

```
vdev type sync priority IOCNT = nnnnnnnn ADP = nnn PROG = nnn UNAVAIL = nnn
vdev BYTES = nnnnnnnnnnnnnnnnn
```

*nnn*

If a virtual MAC address is assigned, the following is displayed:

```
vdev MAC macaddr status
```

The terms shown in the above Results have the following meanings:

**vdev**

is the virtual device number of the OSA device.

**rdev**

is the real device number of the OSA device.

**SUBCHANNEL = vsub**

identifies the virtual subchannel number.

**OSA AGENT**

indicates that the device is an OSA Agent.

**DEVTYPE *devtyp***

identifies the device type of the OSA device.

**CHPID *chp chptyp***

identifies the CHPID number and CHPID type of the OSA device.

**TOKEN = *token***

identifies the subchannel token assigned to the QDIO connection when it is managed by QDIO enhanced buffer state management (QEBSM).

**QDIO-ELIGIBLE**

indicates that the device is eligible to use the QDIO Hardware Facility for direct data transfer.

**QDIO PENDING ACTIVE**

indicates that a program running in the virtual machine has established QDIO data queues for transferring data between the program and the specified OSA device. Although the data queues are created, they must be activated by the program running in the virtual machine before data transfer can commence.

**QDIO ACTIVE**

indicates that a program running in the virtual machine has activated the QDIO data queues. Direct data transfer between the specified OSA device and the program may now occur.

**QIOASSIST *status***

The status is one of the following:

- **QIOASSIST NOT AVAILABLE** – indicates that the processor does not support the queue-I/O assist (QDIO performance assist for V=V guests), or z/VM is running in an environment where the queue-I/O assist is not available. See the SET QIOASSIST command for a list of requirements to use queue-I/O assist.
- **QIOASSIST- ELIGIBLE** – indicates the device is eligible to use the queue-I/O assist (QDIO performance assist for V=V guests) when the virtual machine begins using the device with no traces in effect.
- **QIOASSIST DISABLED** – indicates the device is not permitted to use the queue-I/O assist (QDIO performance assist for V=V guests). The device must have been attached to the virtual machine with the NOQIOAssist option either on the CP ATTACH command or the system-directory DEDICATE statement.
- **QIOASSIST ACTIVE** – indicates the queue-I/O assist (QDIO performance assist for V=V guests) is active and in-use.

**QEBSM**

indicates that the device connection is managed using enhanced QDIO buffer state management protocol. When QEBSM manages a QDIO connection, a QDIO I/O request can be initiated without z/VM involvement.

***type***

indicates the type of QDIO data queue:

**INP**

Input queue, used to transfer data from the OSA device to the program

**OUT**

Output queue, used to transfer data from the program to the OSA device

***sync***

indicates whether the program and CP versions of the QDIO data queue are currently synchronized:

+

Synchronized

-

Not synchronized

For V=V virtual machines, CP translates the guest's virtual environment to the real hardware. On behalf of the guest, CP makes a replica, or shadow, of the QDIO data queues created by a program

## QUERY VIRTUAL OSA

running in the virtual machine. CP gives the shadow queues to the hardware to use. CP is then responsible for keeping the data queues synchronized between the program and the hardware.

### **priority**

indicates the priority of the QDIO data queue. All input and output queues are listed according to their queue priority, with the lowest number queues having the highest priority.

### **IOCNT = nnnnnnnn**

specifies the number of data transfers that have completed since the QDIO data queue was last activated by the program, in decimal. CP increments the IOCNT each time a QDIO data buffer changes from an adapter-owned state to a program-owned state.

### **BYTES = nnnnnnnnnnnnnnnn**

specifies the number of bytes transferred on that queue since device activation, in hexadecimal.

### **ADP = nnn**

specifies the number of QDIO data buffers currently pending or available for a direct data transfer. This is the number of QDIO data buffers currently owned by the adapter.

### **PROG = nnn**

specifies the number of QDIO data buffers currently owned by the program running in the virtual machine that have storage blocks allocated.

### **UNAVAIL = nnn**

specifies the number of QDIOw data buffers currently owned by the program running in the virtual machine that have no storage blocks allocated.

### **MAC macaddr**

specifies the MAC address assigned.

*Status* contains one of the following:

#### **Current**

indicates a MAC address that is currently assigned to the device address.

#### **Pending**

indicates a MAC address that is pending. When the device is re-initialized, the pending MAC address will become current.

This example displays three virtual OSA devices that are part of a single virtual network adapter:

## Examples

Example 1:

If you enter QUERY VIRTUAL OSA, you might see something like this:

```
cp query virtual osa
OSA 0500 ON NIC 0500 UNIT 000 SUBCHANNEL = 000D
      0500 DEVTYPE OSA          CHPID 80 OSD
0500 MAC 02-00-00-00-00-05 CURRENT
      0500 QDIO-ELIGIBLE
OSA 0501 ON NIC 0500 UNIT 001 SUBCHANNEL = 000E
      0501 DEVTYPE OSA          CHPID 80 OSD
      0501 QDIO-ELIGIBLE
OSA 0502 ON NIC 0500 UNIT 002 SUBCHANNEL = 000F
      0502 DEVTYPE OSA          CHPID 80 OSD
      0502 QDIO-ELIGIBLE
```

## Messages

- HCP040E Device {rdev/vdev/ldev} does not exist
- HCP263E Too many operands were supplied for this command

## QUERY VIRTUAL PAV

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL PAV to display information about the Parallel Access Volume (PAV) devices and the HyperParallel Access Volume (HyperPAV) devices accessible to your virtual machine.

### Operands

#### ALL

tells CP to display a list of all PAV and HyperPAV devices accessible to your virtual machine.

#### *vdev*

#### *vdev1-vdev2*

is the virtual device address of the device for which you want PAV or HyperPAV information. You can specify a single device address, a range of device addresses, or any combination.

### Usage Notes

1. Use the QUERY VIRTUAL *vdev* DETAILS command or the QUERY VIRTUAL DASD DETAILS command to display all the virtual alias Parallel Access Volumes associated with a particular virtual base Parallel Access Volume.

### Responses

Response 1:

If you enter QUERY V PAV 300, and virtual device 300 is a dedicated PAV base device, you see a response like this:

```
q v pav 300
PAV BASE 0300 ON E100 RWS001
Ready;
```

This response tells you that virtual PAV base 300 is defined on dedicated real PAV base E100 with label RWS001.

Response 2:

If you enter QUERY V PAV 4300, and virtual device 4300 is a dedicated HyperPAV base device, you see a response like this:

## QUERY VIRTUAL PAV

```
q v pav 4300
HYPERPAV BASE 4300 on F900 YAC001 POOL 2
Ready;
```

This response tells you that virtual HyperPAV base 4300 is defined on dedicated real HyperPAV base F900 with label YAC001 which resides in HyperPAV pool number 2.

Response 3:

If you enter QUERY V PAV 301, and virtual device 301 is a dedicated PAV alias device, you see a response like this:

```
q v pav 301
PAV ALIAS 0301 on E149 RWS001 FOR BASE 0300
Ready;
```

This response tells you that virtual PAV alias 301 is defined on dedicated real PAV alias E149 with label RWS001. It also tells you that alias 301 is associated with PAV base 300.

Response 4:

If you enter QUERY V PAV 4301, and virtual device 4301 is a dedicated HyperPAV alias device, you see a response like this:

```
q v pav 4301
HYPERPAV ALIAS 4301 ON F981 POOL 2
Ready;
```

This response tells you that virtual HyperPAV alias 4301 is defined on dedicated real HyperPAV alias F981 which resides in HyperPAV pool number 2.

Response 5:

If you enter QUERY V PAV 680, and virtual device 680 is a PAV base device defined as a minidisk or temporary disk, you see a response like this:

```
q v pav 680
PAV BASE 0680 ON E101 RWS002 ASSIGNED E101
Ready;
```

This response tells you that virtual PAV base 680 is defined on, and assigned to, real base E101 with label RWS002.

Response 6:

If you enter QUERY V PAV 4680, and virtual device 4680 is a HyperPAV base device defined as a minidisk or temporary disk, you see a response like this:

```
q v pav 4680
HYPERPAV BASE 4680 ON F901 YAC002 ASSIGNED F901 POOL 4
Ready;
```

This response tells you that virtual HyperPAV base 4680 is defined on and assigned to real HyperPAV base F901 with label YAC002 which resides in HyperPAV pool number 4.

Response 7:

If you enter QUERY V PAV 681, and virtual device 681 is a PAV alias device defined as a minidisk or temporary disk, you see a response like this:

```
q v pav 681
PAV ALIAS 0681 ON E101 RWS002 ASSIGNED E14F FOR BASE 0680
Ready;
```

This response tells you that virtual PAV alias 681 is defined on real PAV base E101 with label RWS002. It also tells you that it is assigned to real PAV alias E14F and is associated with virtual PAV base 680.

Response 8:

If you enter QUERY V PAV 4681, and virtual device 4681 is a HyperPAV alias device defined as a minidisk or temporary disk, you see a response like this:

```
q v pav 4681
HYPERPAV ALIAS 4681 ASSIGNED F991 POOL 4
Ready;
```

This response tells you that virtual HyperPAV alias 4681 is assigned to real HyperPAV alias F991 which resides in HyperPAV pool number 4.

Response 9:

If you enter a QUERY V PAV command specifying specific devices and/or device ranges and none of those devices are PAV or HyperPAV devices, you see a response like this:

```
q v pav 999 A00-A10
NO VIRTUAL PAV DEVICES
Ready;
```

Response 10:

If you enter QUERY V PAV ALL, you see a response like this:

```
q v pav all
PAV BASE 0300 ON E100 RWS001
PAV ALIAS 0301 ON E149 RWS001 FOR BASE 0300
PAV ALIAS 0302 ON E14A RWS001 FOR BASE 0300
PAV ALIAS 0303 ON E14B RWS001 FOR BASE 0300
PAV ALIAS 0304 ON E14C RWS001 FOR BASE 0300
PAV BASE 0680 ON E101 RWS002 ASSIGNED E101
PAV ALIAS 0681 ON E101 RWS002 ASSIGNED E14F FOR BASE 0680
PAV ALIAS 0682 ON E101 RWS002 ASSIGNED E150 FOR BASE 0680
PAV ALIAS 0683 ON E101 RWS002 ASSIGNED E14D FOR BASE 0680
PAV ALIAS 0684 ON E101 RWS002 ASSIGNED E14E FOR BASE 0680
HYPERPAV BASE 4300 ON F900 YAC001 POOL 2
HYPERPAV ALIAS 4301 ON F981 POOL 2
HYPERPAV ALIAS 4302 ON F982 POOL 2
HYPERPAV ALIAS 4303 ON F983 POOL 2
HYPERPAV ALIAS 4304 ON F984 POOL 2
HYPERPAV BASE 4680 ON F901 YAC002 POOL 4
HYPERPAV ALIAS 4681 ASSIGNED F991 POOL 4
HYPERPAV ALIAS 4682 ASSIGNED F992 POOL 4
HYPERPAV ALIAS 4683 ASSIGNED F993 POOL 4
HYPERPAV ALIAS 4684 ASSIGNED F994 POOL 4
Ready;
```

Response 11:

If you enter a QUERY V PAV ALL command and there are no PAV or HyperPAV devices in your configuration, you see a response like this:

```
q v pav all
NO VIRTUAL PAV DEVICES
Ready;
```

## QUERY VIRTUAL PCIFUNCTION

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL PCIFUNCTION to display the status of PCI functions accessible to your virtual machine.

### Operands

#### ALL

specifies all virtual PCI functions accessible to your virtual machine

#### *vpfid*

#### *vpfid1-vpfid2*

specifies a virtual PCI function ID or a range of virtual PCI function IDs whose status is to be queried. Specify a PCI function ID as 8 hexadecimal digits. You may omit leading zeros. The total number of virtual PCI functions specified cannot exceed 256.

### Responses

Response 1:

If you enter QUERY VIRTUAL PCIFUNCTION, you will see something like:

```
PCIF 00000003 ON 00000021 ENABLED 10GbE RoCE
PCIF 00000004 ON 00000046 DISABLED 10GbE RoCE
PCIF 00000005 ON 00000058 ENABLED 10GbE RoCE
PCIF 00000006 ON 00000024 ERROR 10GbE RoCE
```

The first number is the virtual PCI function ID. The next number is the real PCI function ID followed by the state of the PCI function and the type of PCI function.

The state of the function is one of the following:

#### **BLOCKED**

PCI function blocked

#### **DISABLED**

PCI function available for use by the configuration but not enabled

#### **ENABLED**

PCI function available for use by the configuration and enabled

**ERROR**

Error detected by z/PCI facility

**PERMERR**

Error recovery for PCI function unsuccessful

**Messages**

- HCP002E Invalid operand - *operand*
- HCP009E Invalid range - *range*
- HCP022E A virtual PCI function ID was not supplied or it was invalid.
- HCP040E PCI function *vpfid* does not exist
- HCP1003E *vpfid* not found.
- HCP5780E Adjunct does not support the *command subcommand* command
- HCP6000E The range of PCI function ids cannot exceed 256.

## QUERY VIRTUAL PRINTER

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL PRINTER to display the status of all print devices accessible to your virtual machine.

### Usage Notes

1. VAFP spool files are intended for use by AFP printers and real printers managed by RSCS. VAFP printers are not intended for normal use as a virtual printer.

### Responses

Response 1:

For **each virtual printer** defined in your virtual machine configuration, the first three lines of the response are:

```
PRT  vdev CL c { CONT} { HOLD} {COPY nnn} { READY} FORM userform
          {NOCONT} {NOHOLD} {CPY *nnn} {NOTREADY}

vdev TO userid {RDR} DIST distcode FLASHC ccc DEST dest
          {PRT}
          {PUN}

vdev FLASH name CHAR char [char[char[char]]] MDFY cmod n FCB fcb LPP nnn
```

For **3800 printers only**, an additional line follows:

```
vdev SIZE width length {2WCGM} {BTS} {DATCK }
          {4WCGM} {CFS} {NODATCK}
```

The remaining lines of the response for **all printers** are:

```
vdev type { EOF} {OPEN spoolid} { KEEP} { MSG} { NAME fname ftype}
          {NOEOF} {CLOSED } {NOKEEP} {NOMSG} {NONAME }

[vdev SUBCHANNEL = vsub]
```

#### **vdev**

identifies the virtual printer.

#### **CL c**

identifies the spool file class given to spool files created on this device.

#### **CONT**

#### **NOCONT**

controls the continuous spooling option. CONT causes all CLOSE requests to be ignored unless specified with the EOF override option.

**HOLD****NOHOLD**

controls the HOLD status. HOLD prevents files from being printed on a real device by putting a user hold status on the file.

**COPY *nnn*****CPY *\*nnn***

identifies the number of copies requested for the spool file. This is shown as a 3-digit number (*nnn*). The asterisk (\*) indicates that the 3800 printer prints each page from the spooled output files *nnn* times before going on to the next page. If the asterisk (\*) is not present, the entire file is printed sequentially.

**READY****NOTREADY**

indicates whether the device is in ready or not-ready status. The status can be changed by the READY and NOTREADY commands.

**FORM *userform***

displays the form associated with the device and assigned to the spool files as they are created.

**TO *userid***

identifies the virtual machine that receives output from your virtual printer.

**RDR****PRT****PUN**

identifies the spool file queue to receive your printer output.

**DIST *distcode***

identifies the distribution code assigned to each spool file produced from the device.

**FLASHC *ccc***

identifies the number of copies printed while the forms overlay frame is superimposed on the output pages. The default is *ccc*=000.

**DEST *dest***

identifies the destination value to be assigned to each spool file created on the device. If the destination value has not been changed by a SPOOL command, the default is OFF.

**FLASH *name***

identifies the name of the forms overlay frame superimposed on the output pages if the file is printed on the 3800 printer.

**CHAR *char***

identifies the name of the character set or sets used to generate output if the file is printed on the 3800 printer.

**MDFY *cmod***

identifies the copy modification module used to alter output text if the file is printed on the 3800 printer.

***n***

identifies the copy modification character set number. If no copy modification character is set, *n* is 0.

**FCB *fc***

identifies the forms control buffer used in the vertical formatting of a page if the file is printed on the 3800 printer.

**LPP *nnn***

identifies the lines per page setting for the virtual printer. The value can be a decimal number in the range 30 to 255, or 'OFF', which indicates that internal defaults will be used.

***width***

indicates the form width code (in hexadecimal) for a virtual 3800 printer and is a 2-character field.

***length***

identifies, in decimal notation, the length of the paper in half-inches loaded into a 3800 printer.

**2WCGM**

**4WCGM**

specifies the number of writable character generation modules (WCGM) for the virtual 3800 printer. A WCGM is a 64-position portion of the 3800's character generation storage that holds the scan elements of one character set.

**BTS**

**CFS**

designates the stacker assumed for the virtual 3800 printer. BTS is a burster-trimmer-stacker, and CFS is a continuous forms stacker.

**DATCK**

**NODATCK**

specifies the handling of certain virtual 3800 data checks. If DATCK is specified, all 3800 data checks are reflected to the virtual machine (provided the BLOCK DATA CHECK CCW has not been issued). If NODATCK is specified, only data checks that occur because of invalid translate table specifications or unmatched FCB codes are reflected to the virtual machine.

**type**

identifies an IBM printer type or VAFP printer.

**EOF**

**NOEOF**

EOF closes, or NOEOF leaves open, the spool file on the specified device regardless of the CONT setting for the device.

**OPEN spoolid**

**CLOSED**

indicates that a spool file has been created on the console and that the file is still open (OPEN), or indicates that no spool file is open on the device (CLOSED).

**KEEP**

**NOKEEP**

controls the keep status, which indicates whether the current spool file is to be placed in user hold after processing.

The keep status is placed on the spool file. After it is transcribed at the real printer, the file is assigned user hold status and is not purged. The file's keep status is retained.

**MSG**

**NOMSG**

indicates whether you want to be informed about file printing and punching. If you specify MSG, you are informed. The message is sent to you when the file begins either printing or punching on a real device. This message is not sent if you have issued SET IMSG OFF. Specify NOMSG to reset the MSG option.

**NAME *fname ftype***

**NONAME**

identifies the file name and file type, if any, to be assigned to spool files created on the device.

***vsub***

identifies the virtual subchannel number.

Response 2:

```
PRT vdev ON PRT rdev [SUBCHANNEL = vsub]
```

is returned when the printer is a real device dedicated to your virtual machine.

***vdev***

identifies the virtual device number.

***rdev***

identifies the real device number.

***vsub***

identifies the virtual subchannel number.

**Messages**

- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP263E Too many operands were supplied for this command

## QUERY VIRTUAL PUNCH

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL PUNCH to display the status of all punch devices accessible to your virtual machine.

### Responses

Response 1:

```
PUN  vdev CL a { CONT} { HOLD} {COPY nnn} { READY} FORM userform
      {NOCONT} {NOHOLD} {CPY *nnn} {NOTREADY}

vdev TO userid {RDR} DIST distcode DEST dest
              {PRT}
              {PUN}

vdev FLASH name ccc CHAR char [char[char[char]]] MDY cmod n FCB fcb

vdev type { EOF} {OPEN spid} { KEEP} { MSG} { NAME fname ftype}
          {NOEOF} {CLOSED } {NOKEEP} {NOMSG} {NONAME }

[vdev SUBCHANNEL = vsub]
```

is returned for each of your virtual punches.

Response 2:

```
PUN vdev ON PUN rdev [SUBCHANNEL = vsub]
```

is returned when the punch is a real device dedicated to your virtual machine.

#### **vdev**

identifies the virtual device number.

#### **CL a**

identifies the spool file class assigned to spool files created on this punch.

#### **CONT**

#### **NOCONT**

controls the continuous spooling option. CONT causes all CLOSE requests to be ignored unless specified with the EOF override option.

#### **HOLD**

#### **NOHOLD**

controls the hold status. HOLD prevents files from being punched on a real device by putting a user hold status on the file. If you specify NOHOLD, you override the spool device HOLD option and prevent the file from being placed in hold status.

#### **COPY nnn**

#### **CPY \*nnn**

identifies the number of copies requested for the spool file. This is shown as a 3-digit number (*nnn*). An asterisk (\*) indicates that the 3800 printer prints each page from the spooled output files *nnn*.

times before going on to the next page. If the asterisk (\*) is not present, the entire file is printed sequentially.

**READY****NOTREADY**

indicates whether the device is in a ready or not-ready status. You can change the status with the READY and NOTREADY commands.

**FORM *userform***

displays the form associated with the device and assigned to the spool files as they are created.

**TO *userid***

identifies the virtual machine that receives output from your virtual punch.

**RDR****PRT****PUN**

identifies the spool file queue to receive your punch output.

**DIST *distcode***

identifies the spool file distribution code.

**DEST *dest***

identifies the destination value to be assigned to each spool file created on the device. If the destination value has not been changed by a SPOOL command, the default is OFF.

**FLASH *name ccc***

*name* is the name of the forms overlay frame superimposed on the output pages if the file is printed on a 3800 printer. *ccc* is the number of copies printed while the forms overlay frame is superimposed on the output pages. The default for *ccc* is 000.

**CHAR *char ...***

identifies the character sets used to generate output if the file is printed on a 3800 printer.

**MDFY *cmod***

identifies the copy modification module used to alter output text if the file is printed on a 3800 printer.

***n***

identifies the copy modification character set number. If no copy modification character is set, *n* is 0.

**FCB *fc***

identifies the forms control buffer used in the vertical formatting of a page if the file is printed on a 3800 printer.

***type***

identifies an IBM punch type.

**EOF****NOEOF**

closes (EOF), or leaves open (NOEOF), the spool file on the specified device regardless of the CONT setting for the device.

**OPEN *spid*****CLOSED**

indicates that a spool file (*spid*) has been created on the console and that the file is still open (OPEN), or indicates that no spool file is open on the device (CLOSED).

**KEEP****NOKEEP**

controls the keep status, which indicates whether the current spool file is to be placed in user hold after processing.

The keep status is placed on the spool file. After it is transcribed at the real punch, the file is assigned user hold status and is not purged. The file's keep status is retained. Specify NOKEEP to override the current KEEP setting for the device so that KEEP is not set on the spool file.

**MSG****NOMSG**

indicates whether you want to be informed about file printing and punching. If you specify MSG, you are informed of file printing and punching. The message is sent to you when the file begins either printing or punching on a real device. This message is not sent if you have issued SET IMSG OFF. Specify NOMSG to reset the MSG option.

***rdev***

identifies the real device number.

**NAME *fname ftype*****NONAME**

indicates whether a file name and file type are to be assigned to the spool file. If a name is to be assigned, it is also displayed.

***vsub***

identifies the virtual subchannel number.

### Messages

- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP263E Too many operands were supplied for this command

## QUERY VIRTUAL READER

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL READER to display the status of all readers accessible to your virtual machine.

### Responses

Response 1:

```

RDR  vdev CL a   { CONT } { HOLD } { EOF } { READY }
           { NOCONT } { NOHOLD } { NOEOF } { NOTREADY }

           vdev type      { OPEN spid }
                           { CLOSED }

{ KEEP } { RESCAN } [SUBCHANNEL = vsub]
{ NOKEEP } { NORESCAN }
  
```

is returned for each of your virtual readers.

Response 2:

```
RDR vdev ON RDR rdev [SUBCHANNEL = vsub]
```

is returned when the reader is a real device dedicated to your virtual machine.

#### **vdev**

is the virtual device number.

#### **CL a**

is the spool file class that your reader services; your reader can only read files of a matching class. A class of asterisk (\*) indicates that your reader can read files of any class.

#### **type**

is an IBM reader device type.

#### **CONT**

#### **NOCONT**

controls the continuous spooling option. CONT specifies that reading continues without end-of-file indications at the end of each virtual spool file until the virtual device is empty. NOCONT specifies that the end-of-file is signaled after each spool file is read, and then the reader is reset at the next logical file.

#### **HOLD**

#### **NOHOLD**

controls the HOLD status. The HOLD/NOHOLD options override the setting for the virtual device or the spool file. The file is not put in HOLD status unless the KEEP option is also specified. If you specify HOLD, the file is not purged after processing and remains eligible for the device. If you specify NOHOLD, the file is purged unless the KEEP option is also specified.

**EOF****NOEOF**

EOF closes, and NOEOF does not close, the spool file on the specified device, regardless of the CONT setting for the device.

**READY****NOTREADY**

indicates whether the device is in a ready or not-ready status. To change the status, use the READY and NOTREADY commands.

**OPEN spid****CLOSED**

indicates the status of the spool file. If the status is open, the system spool file ID is also displayed.

**KEEP****NOKEEP**

controls the keep status, which indicates whether the current spool file is to be placed in user hold after processing. KEEP overrides the keep setting on either the virtual reader or the spool file. After processing, the file is placed in hold status, and the KEEP option on the file remains unchanged. Specify NOKEEP to override either file or device keep characteristics. The disposition of a file closed with NOKEEP (whether it is purged or retained) is controlled by the hold status of the virtual reader. If it were closed KEEP, it would never be purged.

**RESCAN****NORESCAN**

When a reader is spooled CONT, RESCAN causes the first logical file in the virtual reader queue to always be the next file read. This allows files which have been ordered or changed during continuous processing to become eligible for processing. NORESCAN causes scanning to resume at the next logical file in the virtual reader queue.

A reader cannot be spooled CONT, RESCAN, HOLD, and NOKEEP, as this would cause the same file to be processed repeatedly. If a SPOOL command is issued which would result in the reader being spooled with this combination, the reader will be spooled KEEP to remove the conflict.

***vsub***

is the virtual subchannel number.

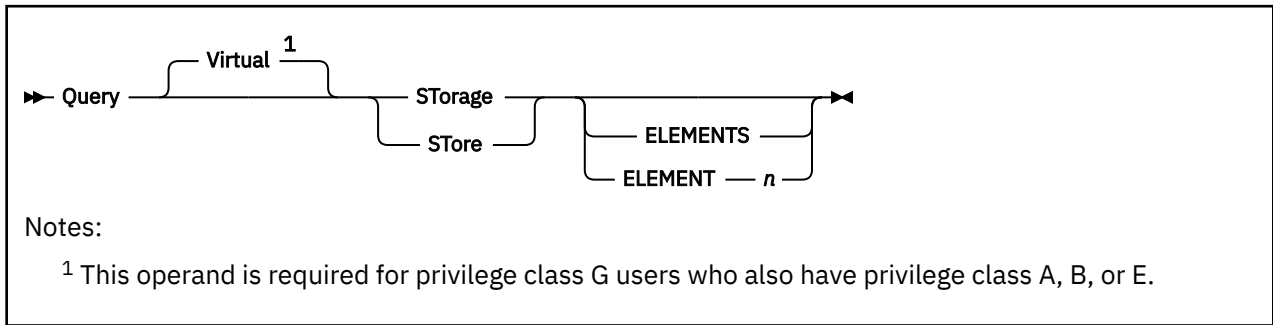

***rdev***

is the real device number of the reader.

**Messages**

- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP263E Too many operands were supplied for this command

## QUERY VIRTUAL STORAGE/STORE

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL STORAGE or QUERY VIRTUAL STORE to display information about the storage accessible to your virtual machine.

If the virtual storage configuration was defined with reserved or standby storage, then dynamic storage reconfiguration (DSR) is supported. Otherwise, DSR is not supported. If DSR is supported, then virtual storage is comprised of storage element 0 and storage element 1.

### Operands

#### ELEMENTS

displays information about storage elements 0 and 1.

#### ELEMENT *n*

displays information about a specific storage element, where *n* is either 0 or 1.

### Responses

Response 1:

This response is issued if no reserved or standby storage has been defined since the last system reset:

```
STORAGE = nu
```

where:

***n***

is a 1- to 7-digit decimal number.

***u***

is the storage unit suffix:

**M**

megabytes

**G**

gigabytes

**T**

terabytes

**P**

petabytes

**E**

exabytes

Response 2:

This response is issued if reserved or standby storage has been defined since the last system reset. The first line is a summary. If you specified the ELEMENT *n* or ELEMENTS operand, one or two additional lines are displayed to provide details about the storage elements.

```
STORAGE = nu MAX = nu INC = nu STANDBY = nu RESERVED = nu
[ELEMENT 0 ATTACHED ASSIGNED = nu STANDBY = nu RESERVED = nu]
[ELEMENT 1 {ATTACHED} ASSIGNED = nu STANDBY = nu RESERVED = nu]
           {STANDBY }
           {RESERVED}
```

where:

**STORAGE = nu**

specifies the size of online (assigned) virtual machine storage.

**MAX = nu**

specifies the maximum size of virtual machine storage as defined in the user directory entry for the virtual machine.

**INC = nu**

specifies the size of the virtual machine storage increment.

**STANDBY = nu**

specifies the amount of virtual machine storage in standby state that is available to be configured online.

**RESERVED = nu**

specifies the amount of virtual machine storage in reserved state that can be defined online or as standby.

**ELEMENT 0 ATTACHED**

**ELEMENT 1 ATTACHED**

**ELEMENT 1 STANDBY**

**ELEMENT 1 RESERVED**

specifies the state of the storage element:

**ATTACHED**

The specified storage is available to the guest. Storage element 0 is always attached.

**STANDBY**

Storage element 1 is in detached-standby state and not available to the guest. The guest can issue an instruction to attach the element.

**RESERVED**

Storage element 1 is in detached-reserved state and not available to the guest. To make the storage available, the virtual machine console operator must issue the DEFINE STORAGE STANDBY command to increase the size of the virtual machine's standby storage and change the state of storage element 1 to detached-standby. The guest can then issue an instruction to attach the element.

**ASSIGNED = nu**

specifies the amount of storage in the storage element that is online (assigned to the virtual machine).

Response 3:

This response is issued if CONFIGURATION was specified on DEFINE STORAGE:

```
STORAGE = nu
Storage Configuration:
configspec

Extent Specification          Address Range
-----
0.sssssssssssssu 00000000_00000000 - endadres_endadres
```

```
boundaryaddressu.ssssssssssssu begadres_begadres - endadres_endadres
boundaryadru-nnnnu.ssssssssssssu begadres_begadres - endadres_endadres
```

where:

**STORAGE = nu**

specifies the size of online (assigned) virtual machine storage, including the configuration extents.

**configspeg**

is the storage configuration specification input used on the DEFINE STORAGE CONFIGURATION command that defines the current storage configuration.

**Extent Specification**

specifies the information supplied by the DEFINE STORAGE command. Each configuration extent is listed on a separate line:

**boundaryaddressu**

**boundaryadru**

is the boundary address as specified in the DEFINE STORAGE command, where *u* is the 1-character storage unit suffix.

**sssssssssssssu**

is the extent size, 1 - 14 decimal digits followed by the 1-character storage unit suffix.

**nnnnu**

is the decrement specified in DEFINE STORAGE used to modify the extent start boundary address, expressed as 1 - 4 decimal digits followed by the 1-character storage unit suffix (which must be a smaller storage unit than that used for the start boundary it modifies). The decrement is subtracted from the base start boundary specification to determine the effective extent start boundary address.

**Address Range**

specifies the extent information converted to beginning and ending addresses:

**begadres\_begadres**

is the 16-digit extent start address expressed in hexadecimal (always ends in X'00000', a megabyte boundary). Underscores are used for readability if SET UNDERSCORE ON has been issued.

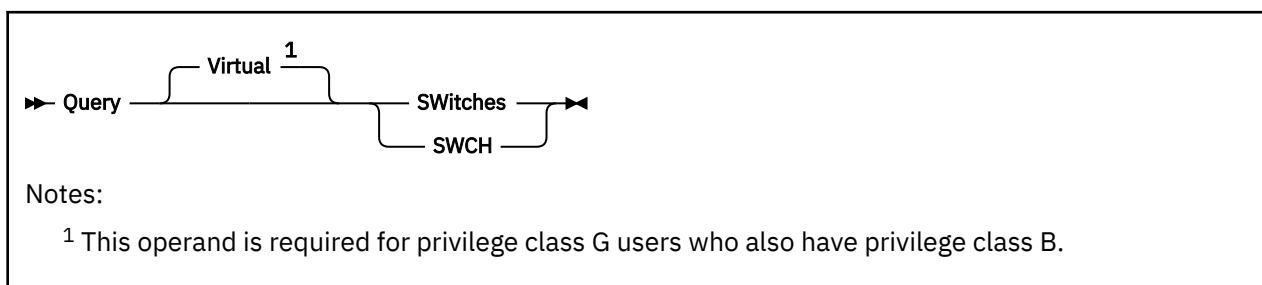

**endadres\_endadres**

is the 16-digit extent end address expressed in hexadecimal (always ends in X'FFFFFF', one less than a megabyte boundary). Underscores are used for readability if SET UNDERSCORE ON has been issued.

**Messages**

## QUERY VIRTUAL SWITCHES

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL SWITCHES to display the status of all your virtual switch devices.

### Operands

#### SWitches

#### SWCH

displays the status of your virtual switch devices.

### Responses

Response 1:

```
SWCH vdev ON SWCH rdev {SUBCHANNEL = vsub}
```

is displayed for each switch device attached to your virtual machine system

#### **vdev**

is the virtual device number.

#### **rdev**

is the real device number

#### **vsub**

is the virtual subchannel number.

### Messages

- HCP040E Device {rdev/vdev/ldev} does not exist
- HCP263E Too many operands were supplied for this command.

## QUERY VIRTUAL SYSASCII

►► Query — Virtual 1 — SYSAscii ►►

### Notes:

<sup>1</sup> This operand is required for privilege class G users who also have privilege class B.

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL SYSASCII to display the status of the ASCII console in your virtual machine configuration.

### Responses

SYSASCII *status*

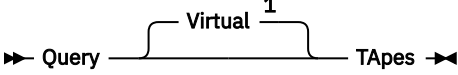

#### ***status***

is either *active* or *inactive*, corresponding to whether the ASCII console session on the Hardware Management Console (HMC) is open or not open.

### Messages

- HCP121E SYSASCII not attached to you
- HCP263E Too many operands were supplied for this command.

## QUERY VIRTUAL TAPES

Notes:

<sup>1</sup> This operand is required for privilege class G users who also have privilege class B.

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL TAPES to display the status of all tape devices accessible to your virtual machine.

### Responses

Response 1:

```
TAPE vdev ON DEV rdev type [GIVEN BY userid] {R/O }
[GIVEN TO userid] {R/W*}

[SUBCHANNEL = vsub] [NOASSIGN]

[SPXTAPE operation status]

[ENCRYPTION CAPABLE]
```

is displayed for each tape device attached to your virtual machine.

Note that (\*) this is the mode that the giver currently has the tape drive in and is *not* the mode in which it was given.

#### **vdev**

identifies the virtual device number.

#### **rdev**

identifies the real device number.

#### **type**

identifies the device type of the attached tape device.

#### **GIVEN BY *userid***

#### **GIVEN TO *userid***

indicates that the real device was given to another user ID or was received from another user ID through the GIVE command. These parameters only appear for tape drives that have been given with the return option specified.

#### **R/O**

#### **R/W**

identifies the type of access you have to the device. R/O indicates that you have read only access; R/W indicates that you have both read and write access.

#### **SUBCHANNEL = *vsub***

identifies the virtual subchannel number.

#### **NOASSIGN**

indicates the tape drive was attached with the NOASSIGN option.

**SPXTAPE**

indicates an SPXTAPE operation is running on the virtual tape drive.

**operation**

is the SPXTAPE operation: DUMP, LOAD, or SCAN.

**status**

is the status of the SPXTAPE operation:

**ACTIVE**

Read (LOAD or SCAN) or write (DUMP) operations are currently being done to the tape drive.

**MOUNT**

The tape drive is not active because SPXTAPE is waiting for a tape to be mounted.

**APPEND**

The SPXTAPE command that started the operation was entered with the APPEND option, and the append sequence is not complete. Enter another SPXTAPE command (addressing the same tape devices) with the APPEND option to select more files, or enter the command without the APPEND option to complete the append. If the operation is LOAD or SCAN, actual loading or scanning of files cannot begin until the append sequence is complete.

**ENCRYPTION CAPABLE**

indicates the tape device supports hardware encryption.

**Messages**

- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP263E Too many operands were supplied for this command.

## QUERY VIRTUAL UR

Notes:

- <sup>1</sup> This operand is required for privilege class G who also have privilege class B.

### Authorization

Privilege Class: G

### Purpose

Use QUERY VIRTUAL UR to display the status of all unit record devices (printers, punches, and readers) accessible to your virtual machine.

### Responses

See responses under [“QUERY VIRTUAL PRINTER”](#) on page 1324, [“QUERY VIRTUAL PUNCH”](#) on page 1328, and [“QUERY VIRTUAL READER”](#) on page 1331.

### Messages

- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP263E Too many operands were supplied for this command

## QUERY VMDUMP

### Authorization

Privilege Class: G

### Purpose

Use QUERY VMDUMP to identify the output mode of VMDUMP and any open VMDUMP spool file.

### Operands

#### MAP

indicates that a map of the address ranges of guest storage in the open VMDUMP file should be displayed, in addition to the other command responses.

### Usage Notes

1. If a continuous mode dump file was open when noncontinuous mode is set, that file remains open until completion of the next VMDUMP or DIAGNOSE X'94' request that writes to the file. For this reason, it is possible to receive the response VMDUMP NOCONT as well as responses describing an open, continuous-mode VMDUMP file.
2. The file type of the open VMDUMP file may not match that displayed from QUERY READER. This may occur if the FORMAT option was used after the spool file was initially open. The file type is not changed until the spool file is completed and closed. The file type shown in response to QUERY VMDUMP is the type given the dump file when it is closed.
3. Use SET UNDERSCORE to control whether an underscore character is used to separate 16-digit addresses for the VMDUMP command.

### Examples

```
q vmd map
VMDUMP CONT
File 0018 VMDUMP RSCSV2 is open for output
*no output on SNA printer
The VMDUMP address ranges are:
00000000-0000BFFF 0001A000-000FFFFF 00200000-003CDFFF 00EF0000-00EF4FFF
00F00000-01088FFF 02000000-02FFFFFF

For ASIT 1B543C7563DF6923
SPACEID JOE:SPACE1
Format: RSCSV2
Dump identifier: *no output on SNA printer
The VMDUMP address ranges are:
00001000-00002FFF 00004000-00004FFF 0001C000-0001FFFF 00021000-0003AFFF
00051000-00060FFF 000BB000-000CDFFF

For ASIT 1A23B5678C912D45
SPACEID JOE:SPACE2
Format: FILE
Dump identifier: none
The VMDUMP address ranges are:
00001000-00001FFF 0000B000-0000FFFF
```

## Responses

Response 1:

```
VMDUMP NOCONT
```

is returned when the virtual machine is not in continuous output mode for VMDUMP.

Response 2:

```
VMDUMP CONT
```

is returned when the virtual machine is in continuous output mode for VMDUMP.

Response 3:

The following additional lines are returned for a QUERY VMDUMP or QUERY VMDUMP MAP command when an open output file exists (from one or more prior VMDUMP requests while in continuous output mode). The following second line is returned only if the dump has a *dumpid*:

```
File spid VMDUMP filetype is open for output
*dumpid
```

### ***spid***

identifies the spool file.

### ***filetype***

identifies the virtual machine type (*filetype*) supplied by the FORMAT operand of the VMDUMP command.

### **\**dumpid***

identifies the dump. It is preceded by an asterisk (\*).

For each address space in the dump, these lines are displayed:

```
For ASIT asit
  SPACEID owner:space_name
Format:      format
Dump identifier: *dumpid
```

### ***asit***

is the ASIT of the address space.

### ***owner:***

is the user ID that owns the address space.

### ***space\_name***

is the name of the address space. The space name is a string of alphanumeric and national characters, 1 to 24 characters long.

A header line and additional response lines are returned for a QUERY VMDUMP MAP command when an open output file exists.

For virtual machines in ESA/390 mode, each line maps from one to four address ranges:

```
The VMDUMP address ranges are:
xxxxxxxx-yyyyyyyy xxxxxxxx-yyyyyyyy . . .
:
```

### ***xxxxxxxx-yyyyyyyy***

identifies a hexadecimal address range of guest real storage contained in the VMDUMP spool file.

For virtual machines in z/Architecture mode, each line maps from one to two address ranges:

```
The VMDUMP address ranges are:
xxxxxxxx_xxxxxxxx-yyyyyyyy_yyyyyyyy xxxxxxxx_xxxxxxxx-yyyyyyyy_yyyyyyyy
:
```

**xxxxxxxx\_xxxxxxxxx-yyyyyyyy-yyyyyyyy**

identifies a hexadecimal address range of guest real storage contained in the VMDUMP spool file.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP260E {Command|*command* command} processing cannot complete due to errors.
- HCP410E CP ENTERED; PAGING ERROR

## QUERY VMLAN

► Query — VMLAN ◄

### Authorization

Privilege Class: G

### Purpose

Use QUERY VMLAN to determine the current status of guest LAN activity on the CP system. The response indicates the current value of the system-wide guest LAN attributes, and the number of guest LANs and virtual switches currently defined in the system.

Use the QUERY LAN command to obtain information about specific guest LANs. Use the QUERY VSWITCH command to obtain information about specific virtual switches.

### Usage Notes

System-wide attributes for guest LAN or virtual switch support can be set using the [VMLAN Statement](#) in the SYSTEM CONFIG file. For more information, see in *z/VM: CP Planning and Administration*. These attributes can be changed during normal system operation by using the SET VMLAN command. See [“SET VMLAN” on page 1752](#).

### Examples

Display a typical guest LAN response:

```
query vmlan
  VMLAN maintenance level:
    Latest Service: VM65918
  VMLAN MAC address assignment:
    System MAC Protection: OFF
    MACADDR Prefix: 023456 USER Prefix: 023456
    MACIDRANGE SYSTEM: 800000-801000
                      USER: 800000-800100

  VMLAN default accounting status:
    SYSTEM Accounting: OFF   USER Accounting:OFF
  VMLAN general activity:
    PERSISTENT Limit: 20     Current: 15
    TRANSIENT Limit: 10     Current: 0
  Trace Pages: 8

  VMLAN Directory Network Authorization: ENABLED
  IVL Domain: A   MAC address: 03-FF-FF-FF-FF-01   VLAN: NONE
  IVL Domain Heartbeat Timeout: 30
  IVL Domain Capability: 8000000000000000
  Member: CASEY   MAC address: 02-34-56-00-00-05
    State: Active
    Port Group Status: Synchronized
    Global VSWITCH Status: Synchronized
    Heartbeat Count: <local>
    Member Capability: C000000000000000 Maintenance level: V642

  Member: JONES   MAC address: 02-34-77-00-00-08
    State: Active
    Port Group Status: Synchronized
    Global VSWITCH Status: Synchronized
    Heartbeat Count: 20
    Member Capability: 8000000000000000 Maintenance level: V632
```

## Responses

The normal response is:

```
VMLAN maintenance level:
Latest Service: update
VMLAN MAC address assignment
System MAC Protection: setting
MACADDR Prefix: prefix  USER Prefix: prefix
MACIDRANGE SYSTEM: range
                USER: range

VMLAN default accounting status:
SYSTEM Accounting: onoff  USER Accounting: onoff
VMLAN general activity
PERSISTENT Limit: max           Current: count
TRANSIENT Limit: max           Current: count
Trace Pages: nn

VMLAN Directory Network Authorization: DISABLED | ENABLED
IVL Domain: x  MAC address: macid  VLAN: [ NONE | vlanid]
IVL Domain Heartbeat Timeout: timeout
IVL Domain Capability: capabilitystring
Member: membername  MAC address: macid
State: state
Port Group Status: pgstatus
Global VSWITCH Status: gvstatus
Heartbeat Count: hbcount
Member Capability: capabilitystring  Maintenance level: mntid
```

### **update**

is the most recent update that affects guest LAN and virtual switch simulation.

### **System MAC Protection**

*setting* indicates the level of MAC address protection level to be used for virtual and real networks whose MAC address protection settings are not specified (set to UNSPECIFIED).

### **prefix**

is the prefix used for MAC addresses that are automatically assigned by CP to a network device. This value (MACPREFIX) is set by a VMLAN statement in the SYSTEM CONFIG file.

### **USER prefix**

is the prefix used for MAC addresses explicitly assigned by a user from CP's system directory. This value is set by a VMLAN (USERPREFIX) statement in the SYSTEM CONFIG file.

### **range(s)**

are the ranges defined to be used for the MACID portion of MAC address generation. These values (MACIDRANGE SYSTEM and MACIDRANGE USER) are set by a VMLAN statement in the SYSTEM CONFIG file.

The MACIDRANGE SYSTEM and USER range specified in the VMLAN statement are valid only when MACADDR and USER prefix values are identical. When a different USER prefix value is specified, the entire MACIDRANGE is used for both automatic and user defined locally administered MAC addresses on the system. As a result the MACIDRANGE specified on the VMLAN statement is ignored. The SYSTEM range is set to 000001-FFFFFF and the USER range is set to 000000-000000.

### **onoff**

indicates whether this feature is **ON** (enabled) or **OFF** (disabled).

### **max**

represents the preset limit for this category.

### **count**

represents the actual number of guest LANs and virtual switches in this system.

### **Trace Pages**

indicates the number of pages allocated for an internal trace table to keep track of general networking events.

### **VMLAN Directory Network Authorization: *DISABLED | ENABLED***

indicates whether Directory Network Authorization is enabled (default setting) or disabled. See [“SET VMLAN”](#) on page 1752.

**IVL Domain: x**

identifies the domain to which the virtual switch belongs, where x is a letter, A-H. Global networking objects such as a global virtual switch can span system running z/VMs that are members of the same IVL domain.

When no IVL Virtual Switch has been defined, the system is not a member of an IVL domain. The IVL domain line displayed is the following, and no additional lines are shown.

```
IVL Domain: None
```

When the IVL Virtual Switch has been defined, but there is a system configuration which prevents the z/VM image from becoming an active IVL member, the following line is displayed. For more information on the reason, see [z/VM: CP Messages and Codes](#).

```
IVL Domain: Isolated          Reason: HCPIVLxxxxE
```

**macid**

identifies a MAC address used to communicate with IVL domain members. The IVL domain MAC address is a multicast address used to communicate with all members. The Member MAC address is a unicast MAC address to communicate with a specific member.

**VLAN [NONE | *vlanid*]**

identifies the VLAN, if any, to which the IVL domain belongs.

**IVL Domain Heartbeat Timeout: *timeout***

identifies the length of time that is allowed to expire before the local system declares a communication problem with another IVL domain member if heartbeat signals are missing. Every 5 seconds, each IVL member broad casts a signal to confirm communications with all IVL domain members.

**IVL Domain Capability: *capabilitystring***

identifies the minimum capability of all members.

**Member *membername***

identifies the 8 byte EBCDIC z/VM system identifier of the domain member.

**State *state***

is the local system's view of the other member's state.

**Inactive**

The state indicates the member was previously known to the local system, but has not responded to the most recent communication attempts.

**Pending Leave**

This transitional state indicates the member is leaving the domain.

**Error**

An error was encountered when the member attempted to join the domain.

**Pending Join**

This transitional state indicates the member is joining the domain.

**Active**

The member is active in the IVL domain.

**Port Group Status *pgstatus***

describes whether or not the overall shared port group definitions are compatible. The Port Group Status line is displayed only when a shared port group has been defined.

**Synchronized**

The local system has exchanged messages with the domain member and determined that the domain member's configuration of all shared port groups matches the shared port groups defined on the local system.

**Pending Synchronization**

The local system is checking to make sure that configuration of the shared port group matches on the remote system.

**Not Synchronized**

The local system's shared port group configuration does not match the other members configuration for one or more shared port groups. Use the QUERY PORT GROUP command with the DETAILS option to display details about configuration mismatches.

**Global VSWITCH Status *gvstatus***

describes whether or not the global virtual switch definitions are compatible. The Global VSWITCH Status line is displayed only when a global virtual switch has been defined.

**Synchronized**

The local system has exchanged messages with the domain member and determined that the domain member's configuration of all global virtual switches matches the global virtual switches defined on the local system.

**Pending Synchronization**

The local system is checking to make sure that configuration of the global virtual switch matches on the remote system.

**Not Synchronized**

The local system's global virtual switch configuration does not match the other members configuration for one or more global virtual switches. Use the QUERY VSWITCH command with the DETAILS option to display details about configuration mismatches.

**Heartbeat Count *hbcount***

represents the number of times a heartbeat message has been received from the domain member.

**Member Capability: *capabilitystring* Maintenance Level: *mntid***

identifies the capability of individual members, and maintenance level id of the system. As z/VM enhancements are made IVL domain members may be using different maintenance levels or releases of z/VM. The *capabilitystring* for each system indicates which enhancements are available on that IVL domain member.

```
8000000000000000 - Base capability
C000000000000000 - Collaborative Load Balance Support
```

## QUERY VMRELOCATE

### Authorization

Privilege Class: A, B, C, E

### Purpose

Use the QUERY VMRELOCATE command to display the relocation capability of the specified user. This command can be used to determine to which relocation domain a particular user belongs, and therefore, to which SSI members it may be relocated.

### Operands

#### USER *userid*

specifies the user ID whose relocation capability is being queried. The user ID must be logged on. If "\*" is specified, the target user is the command issuer.

### Usage Notes

1. Use the QUERY RELODOMAIN command to determine which member systems are included in the user's relocation domain.
2. If the QUERY VMRELOCATE command is issued for a user ID defined by a multiconfiguration virtual machine definition, which cannot be relocated, the response will indicate the single-member domain of the system where the command is issued, with relocation disabled. The relocation capability of such a user cannot be changed with the SET VMRELOCATE command.
3. For information about [Using Relocation Domains](#), see *z/VM: CP Planning and Administration*.

### Responses

Response 1:

```
Running on member sysname
Relocation enabled|disabled in Domain domain
```

Response 2:

```
This system is not a member of an SSI cluster
```

### Messages

- HCP0002E Invalid operand - *operand*
- HCP0003E Invalid option - *option*
- HCP0013E Conflicting option - *option*
- HCP0026E Operand missing or invalid
- HCP0045E *userid* not logged on
- HCP1818I Excluded members: *system\_names*
- HCP1831E The command could not be completed because of a temporary condition. Try again later.
- HCP6706E Invalid string - *string*

## QUERY VMSG/PVMSG

### Authorization

Privilege Class: G

### Purpose

Use QUERY VMSG/PVMSG to recall the last 16 messages that your virtual machine operating system sent to the system console.

The z/VM control program, as part of its service processor simulation, intercepts these messages and displays them on the virtual machine operator console.

For operating system messages requiring an operator response, use the VINPUT command to direct the z/VM control program to send data to the operating system running in your virtual machine as though the data had been entered from the system console.

### Operands

#### VMSG

requests a list of the last 16 nonpriority messages that the operating system running in your virtual machine sent to the system console.

#### PVMSG

requests a list of the last 16 priority messages which the operating system running in your virtual machine sent to the system console.

### Responses

Response 1:

```
1 [H] [Prompt text:] message text1
2 [H] [Prompt text:] message text2
...
nnn [H] [Prompt text:] message text nnn
```

where messages 1 through *nnn* are the last 16 messages (of the type requested) that the operating system running in your virtual machine sent to the system console. They are displayed in the order of their receipt. Note that the list does not include messages deleted by the virtual machine console operator or by the operating system running in your virtual machine.

The H is displayed on an operating system message designated by the operating system to be “held” until it has been deleted by the virtual machine console operator or by the operating system running in your virtual machine. These messages are displayed even though they may not be within the last 16 messages intercepted.

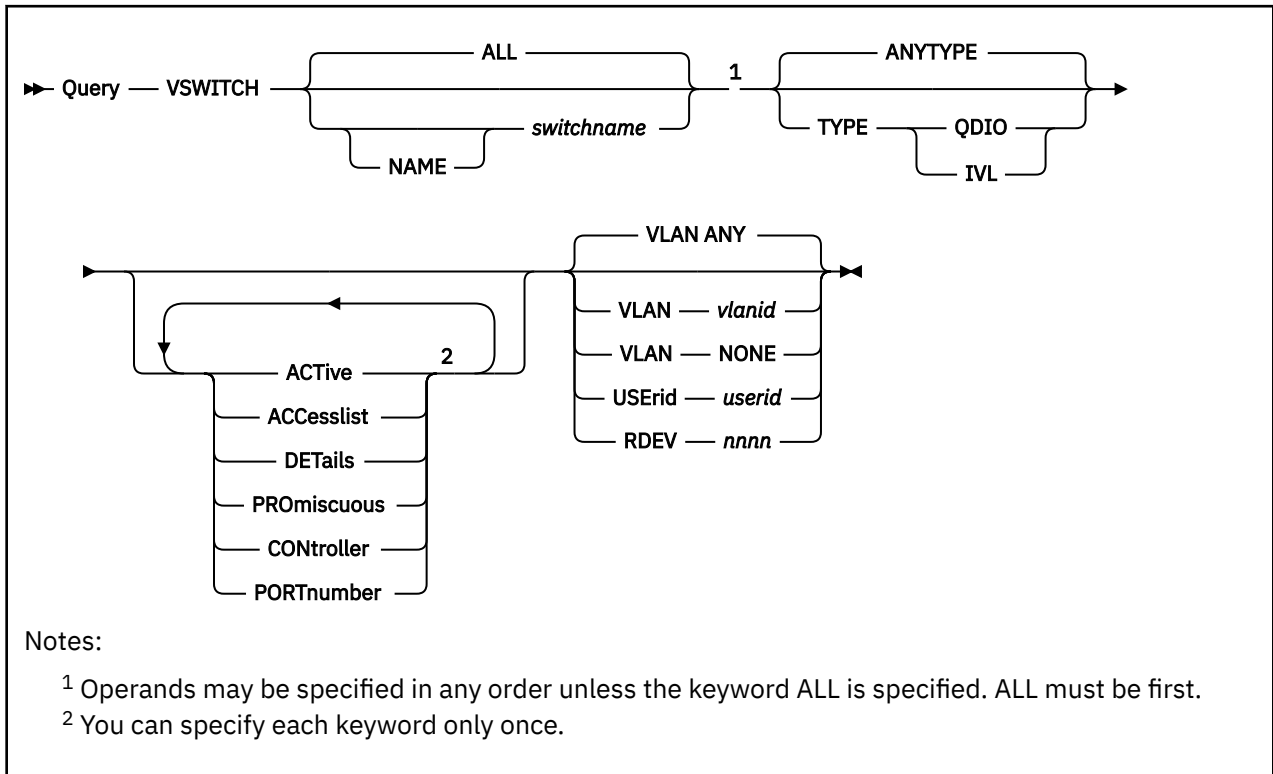

“Prompt text” identifies message text the operating system has designated as a prompt, associated with a related message.

**Note:** The number preceding each message may be used with VDELETE to identify the messages to be deleted from the list of messages sent to the system console.

### Messages

- HCP002E Invalid operand - *operand*
- HCP6530I There are no {priority|non-priority} messages currently outstanding.

# QUERY VSWITCH

## Authorization

Privilege Class: B, G

## Purpose

Use **QUERY VSWITCH** to display information about the designated virtual switch, or all virtual switches.

A class G user can view information about a virtual switch if the user is in the CP access list for the virtual switch, or if the user currently has an adapter connected to it.

A class B user can view information about any virtual switch in the system.

## Operands

### ALL

displays information for all possible virtual switches. This is the default value when an explicit *NAME switchname* is omitted.

### ANYTYPE

indicates a request for any virtual switch regardless of LAN TYPE. This is the default when the TYPE operand is omitted.

### TYPE QDIO

### TYPE IVL

restricts the responses to virtual switches of the specified type.

### NAME *switchname*

restricts the response to the virtual switch with the specified *switchname*. Use of the NAME keyword is required to restrict the response if the virtual switch name matches any of the QUERY VSWITCH keywords.

## QUERY VSWITCH

### ACTive

displays information about each active connection and each HiperSockets Bridge Capable Port. Each active connection represents a simulated network interface card (NIC) that has been connected to the virtual switch. The information displayed includes:

- Identity of the virtual switch.
- The list of users connected to each virtual switch, including the VLAN IDs each is authorized to use.
- IP addresses registered to the adapter.

Each HiperSockets Bridge Capable Port represents a guest on the HiperSocket channel that is bridge capable and is being bridged by the virtual switch.

### ACCesslist|PORTnumber

displays a list of ports that are authorized to connect to each virtual switch with a simulated network adapter.

This is the list pre-authorized through the use of the SET VSWITCH command with GRANT or PORTNUMBER operands, or currently connected as authorized by the NICDEF directory statement or an External Security Manager (ESM).

**Note:** When a NICDEF directory statement is used to authorize access to the VSWITCH, the list only includes the active connections. The user directory must be examined to get a complete access list. When the virtual switch is protected by an External Security Manager (ESM) the ESM interfaces must be used to determine the true authorization list.

### DETAils

displays all available information for each virtual switch. This is similar to specifying ACTIVE, except the display includes users that are coupled, but not active.

For global virtual switches, the display includes information about how each member of the global virtual switch is configured on each IVL domain member.

### PRomiscuous

displays a list of ports that are authorized for promiscuous mode on the virtual switch.

This is the list pre-authorized through the use of the SET VSWITCH command with GRANT or PORTNUMBER operands, or currently connected as authorized by the NICDEF directory statement or an External Security Manager (ESM).

### CONtroller

displays the list of user IDs that can control the OSA-Express devices associated with the virtual switch.

### USERid *userid*

displays the information as requested by other specified options, along with the subset of QUERY VSWITCH DETAILS that applies to either the named guest or HiperSockets Bridge Capable Port. An error is displayed if the guest *userid* is not coupled.

### RDEV *nnnn*

displays the information as requested by other specified options. Only the subset of QUERY VSWITCH DETAILS that applies to the matching Uplink or Bridge device is displayed. An error is displayed if device *nnnn* does not exist.

### VLAN *vlanid*

displays information restricted to connections (guest connections and HiperSockets Bridge Capable Ports) that have the specified *vlanid* active. **VLAN ANY** displays all connections regardless of any VLAN settings. **VLAN NONE** displays connections that have not enabled VLAN support.

## Usage Notes

**QUERY VSWITCH** can display the following state values for either an UPLINK or Bridge Port connection:

### Defined

The virtual switch is created, but no real device address has been specified.

**Defined-NOUPLINK**

The virtual switch is created, but the NOUPLINK option has been specified.

**Controller not available**

A z/VM TCP/IP virtual switch controller is not available to manage the device. The connection to the network is not operational.

**Disconnected**

The virtual switch is created, but the connection to the network is not operational. An operator stopped operation of the device using the TCP/IP STOP command, or there was an error during device initialization, such as a portname conflict or primary router setting. This case is also shown when the connection to the OSA-Express is lost.

**Disconnected – operator**

The virtual switch is created, but the connection to the network is not operational and requires operator intervention. The virtual switch was defined with the DISCONNECT option, or an operator stopped operation of the device using the SET VSWITCH DISCONNECT command.

**Devices attached**

The devices are attached to a virtual switch controller, but the connection to the network is not operational.

**Initialization in progress**

Initialization of the devices has begun. The connection to the real hardware LAN is not operational.

**Device not ready**

Initialization has completed, but the virtual switch controller received a response from the device indicating that the device is not ready. The connection to the network is not operational.

The virtual switch will wait a short period of time for the device to become ready. If that is not successful, the virtual switch will attempt to establish the network connection on a different device if one exists that reported a recoverable error condition.

**Ready**

The connection to the network is operational.

**Device disconnect in progress**

The connection to the network is not operational.

**Detach VSWITCH pending**

The virtual switch is being removed from the system.

**In Error Recovery**

Because of a failure, the virtual switch has started the process to move to a backup device and controller. Data transfer has been suspended for the connection, but will resume when recovery is complete.

**Restarting**

Because a failure occurred and no operational backup device was available, the virtual switch is attempting automatic restart of the failing device. Data transfer has been suspended for the connection, but will resume when the auto restart completes successfully.

The virtual switch will wait a short period of time for the device to recover. If that is not successful, the virtual switch will attempt to establish the network connection on a different device if one exists that reported a recoverable error condition.

**NOUPLINK**

There is no UPLINK port on this virtual switch.

**Examples****1. QUERY VSWITCH:**

```
cp query vswitch uvsw
VSWITCH SYSTEM UVSW Type: QDIO Connected: 0 Maxconn: INFINITE
PERSISTENT RESTRICTED NONROUTER Accounting: OFF
USERBASED LOCAL
VLAN Unaware
```

## QUERY VSWITCH

```
MAC address: 02-6F-5C-60-00-0B   MAC protection: UNSPECIFIED
IPTimeout: 5                     QueueStorage: 8

### 3. QUERY VSWITCH PROMiscuous:

This example shows the users who are authorized to use promiscuous mode on the simulated network adapter.

```

cp q vswitch wadp pro
VSWITCH SYSTEM WADP      Type: VSWITCH Connected: 0      Maxconn: INFINITE
PERSISTENT RESTRICTED  NONROUTER      Accounting: OFF
USERBASED LOCAL
VLAN Aware Default VLAN: 0001      Default Porttype: Trunk      GVRP: Disabled
Native VLAN: 0001      VLAN Counters: Off
MAC address: 02-6F-5C-00-00-1E      MAC protection: ON
IPTimeout: 5      QueueStorage: 8
Isolation Status: OFF      VEPA Status: OFF
Unicast IP address count: 0
Promiscuous ports:
2176 Userid: TCPIPX
2177 Userid: TCPIP1
Uplink port:
State: Defined      PriQueueing: OFF
PMTUD setting: EXTERNAL      PMTUD value: 65535      Trace Pages: 8
RDEV: 1000.P00      Controller: NONE      Error: No RDEV

```

### 4. QUERY VSWITCH PORTNUMBER:

This example shows the ports that are authorized to connect to the virtual switch with a simulated network adapter.

```

cp q vswitch vswpb3 portnumber
VSWITCH SYSTEM VSWPB3  Type: QDIO      Connected: 0      Maxconn: INFINITE
PERSISTENT RESTRICTED  IP      Accounting: OFF
PORTBASED LOCAL
VLAN Aware Default VLAN: 0008      Default Porttype: Access      GVRP: Disabled
Native VLAN: 0001      VLAN Counters: OFF
MAC address: 02-00-22-00-00-09      MAC Protection: Unspecified
State: Defined
IPTimeout: 5      QueueStorage: 8
Isolation Status: OFF      VEPA Status: OFF
Unicast IP address count: 0
Ports:
0010 Porttype: Access Userid: SUSAN H      VLAN: 0008
0011 Porttype: Access Userid: JOE N      VLAN: 0008
0012 Porttype: Access Userid: MARY N      VLAN: 0008
0100 Porttype: Trunk Userid: SAM N      VLAN: 0002 0003 0008
VLAN: 0009-0015 0047 0049
0101 Porttype: Trunk Userid: JULIA L      VLAN: 0010-0012

```

## QUERY VSWITCH

```

The fields in this response are described as follows:

**VSWITCH**

[SYSTEM *switchname* | *systemname.switchname*] uniquely identifies the virtual switch. For GLOBAL virtual switches, *systemname.switchname* is shown in place of SYSTEM *switchname* where *systemname* is the 8 byte EBCDIC z/VM system identifier.

**Type**

*type* is the VSWITCH TYPE or the adapter type (QDIO or IVL).

**Connected**

- *count1* indicates the sum of the number of coupled adapters and the number of guest ports.
- *count2* indicates the number of coupled adapters.
- *count3* indicates the number of HyperSockets Bridge Capable guest ports.

**Domain x**

where *x* is the IVL VSWITCH domain and *x* can be A to H.

**Maxconn**

*max* indicates the maximum number of connections. The value is always INFINITE for a virtual switch.

***persistence***

indicates whether the virtual switch is PERSISTENT or TRANSIENT. The value is always PERSISTENT for a virtual switch.

### ***restriction***

indicates whether the virtual switch is RESTRICTED or UNRESTRICTED. All z/VM virtual switches are RESTRICTED.

### ***routermode***

for a VSWITCH of type IP (with an OSA-Express device as the UPLINK port) indicates whether NONROUTER or PRIROUTER was set for the VSWITCH. Otherwise, *routermode* indicates the VSWITCH is of type IP or ETHERNET.

### ***Accounting setting***

indicates whether accounting records will or will not be generated for this virtual switch.

### **USERBASED**

### **PORTBASED**

indicates whether the virtual switch is defined as user based or port based. The type determines what rules are applied when relocating a guest in an SSI.

### **GLOBAL**

### **LOCAL**

indicates whether the virtual switch is a local virtual switch or a global virtual switch, which can span systems running z/VM.

### ***VLAN awareness***

indicates whether the virtual switch is VLAN-aware or VLAN-unaware.

### ***Default VLAN nnnn***

indicates the default VLAN ID setting for the virtual switch.

*nnnn* indicates the default VLAN ID to be associated with a port when no VLAN IDs are specified. This is displayed only for VLAN-aware virtual switches. NONE indicates no default VLAN ID is associated with guest ports coupled to the virtual switch.

### ***Native VLAN nnnn***

indicates the native VLAN ID setting for the virtual switch.

*nnnn* indicates the VLAN ID to be associated with untagged frames that are received and transmitted by the virtual switch. NONE indicates no native VLAN has been assigned.

### ***VLAN Counters setting***

indicates the level of detail that is maintained for the virtual switch network activity.

*Off* indicates that the detailed VLAN counters are not needed. That is, transmission counters are kept at the port level. Packet counters are kept for each port to show the number of frames received, transmitted or discarded.

*On* indicates that transmission counters are kept at the VLAN level. That is, for each port, packet counters are maintained to show the number of frames received, transmitted or discarded for each VLAN.

### ***Default Porttype type***

indicates the default porttype attribute for guests authorized for the virtual switch. This is only displayed for VLAN-aware virtual switches.

### ***GVRP status***

indicates whether or not GVRP is enabled for a VLAN AWARE virtual switch with the GVRP attribute.

### ***IP Address***

*ipaddr* is the identity of the virtual switch. This is known as the management interface. *Ipaddr* is used by clients involved in switch management. For example, a Network Management Systems (NMS) requests Bridge MIB (Management Information Base) information using *ipaddr*.

### ***Management ID***

*stacknm* identifies the user ID of the TCP/IP stack providing switch management services.

### ***MAC address***

is the MAC address associated with the virtual switch.

**MAC protection**

*setting* indicates the MAC address protection level of protection to be used for network devices coupled to the virtual switch whose MAC address protection settings are not specified (set to UNSPECIFIED) by the CP SET NIC command.

**IPTimeout**

indicates the length of time in minutes that a transient IP address table entry remains in the IP address table for the virtual network. A transient entry is an entry added to the virtual network by one guest on behalf of another. This value has no meaning for ETHERNET networks.

**QueueStorage**

*nnn* is the maximum amount of fixed storage that CP will allocate for QDIO queues used for data transfer.

**Isolation Status**

*nnn* indicates the isolation status of the VSWITCH and its UPLINK port data connection.

**VEPA Status**

*nnn* indicates the VEPA status of the VSWITCH and its UPLINK port data connection.

**Unicast IP address count**

*nnn* indicates the number of Unicast IP addresses associated with this VSwitch.

***user(1)***

represents one user ID in a list of users authorized to COUPLE to this virtual switch.

***vlan(1)***

indicates the list of VLAN IDs this user ID is authorized to access. *vlan(n)* may be ANY, indicating all VLAN IDs are authorized.

**State**

indicates the current state of the virtual switch. For more information about the states, see [“Usage Notes” on page 1352](#).

**PriQueuing**

indicates the current priority queuing setting for the virtual switch uplink port. The values for *setting* are: ON, OFF, and FORCED OFF.

**ON**

The virtual switch will exploit priority queuing. If the customer configured the OSA-Express features used by a virtual switch uplink port for priority queuing via IOCP (PQ\_ON), then z/VM will establish one input queue and four output queues when activating its network connection. This will allow z/VM to transmit data to the external network at four different priorities. CP will use the highest priority queue for control and management traffic. The other three queues (low, normal and high) can be used for virtual NIC's network connections.

**OFF**

The virtual switch will not exploit priority queuing. All outbound data to the external network is transmitted with equal priority.

**FORCED OFF**

The IVL virtual switch is configured to exploit priority queuing but priority queuing is forced off by z/VM because the OSA-Express features used by an IVL virtual switch uplink port are configured without priority queuing (PQ\_OFF).

The default for TYPE IVL virtual switches is PRIQUEUING ON, given priority queuing of both management and encapsulated production data is required to maintain a viable IVL Network. Only an OSA-Express feature configured for priority queuing should be used on an IVL virtual switch's uplink port.

**PMTUD setting *setting***

indicates the current Path MTU Discovery setting for the Uplink RDEV port device, configured either by the SET VSWITCH UPLINK PATHMTUDISCOVERY command or assigned as the default. The values for *setting* are: EXTERNAL (the default), Value, or Off.

**Note:** If the virtual switch is defined with either the NOUPLINK or UPLINK NIC options, the PMTUD setting and value fields are not displayed.

**PMTUD value *value***

indicates the Path MTU Discovery value, *value*, currently in effect for the virtual switch Uplink Port.

**Note:** This field is not displayed if the Path MTU Discovery setting is Off.

**Group *groupname***

is the port group assigned to this virtual switch, if any.

**LACP Mode *mode***

indicates whether LACP is Active or Inactive for the port group.

**RDEV**

*nnnn.Pnn* indicates the base real device number and the OSA-Express port number of the QDIO device attached to the virtual switch or specified as an alternate real device address. If the value "Error" is displayed on the same line, the device is not functional, and the problem must be corrected. Where possible, the error condition is included. Examine the operator console and the console of the z/VM TCP/IP stack controller for more information about the error.

Error conditions for both the Uplink and Bridge Port devices include:

- Operational
- Portname conflict
- No Layer 2
- No RDEV
- RDEV attached
- Invalid port number
- Incompatible for VSWITCH type
- Initialization
- Stalled OSA-E
- Stalled controller
- Path severed
- Routing conflict
- Offline
- Detached
- Type mismatch
- TCP/IP conflict
- Invalid device state
- Not ready
- TCP/IP resources
- No Link Aggregate support
- Hardware attributes
- Exclusive use error
- Unexpected internal error
- Attempting restart
- No OSA QDIO Connection Isolation
- Incompatible controller
- EQID mismatch
- No HiperSockets Bridge support
- HiperSockets Bridge error
- No VEPA support
- No Reflective Relay

- Reflective Relay error
- SET VSWITCH SWITCHOVER issued
- No priority queuing

**VDEV**

*nnnn* indicates the base virtual number used by the virtual switch controller for this RDEV.

**Controller**

is the user ID of the TCP/IP virtual machine acting as a controller for this RDEV.

**NIC**

*userID vdev* indicates the virtual device address of the NIC attached to the VSWITCH as the UPLINK port. If the value "Error" is displayed next to the NIC address, the device cannot be attached, and the problem must be corrected. Where possible, an explanation for the error is included. Error explanations include:

- No user
- Not authorized
- No VDEV
- VDEV attached
- Incompatible for VSWITCH type
- VLAN conflict
- Type mismatch
- No MAC address
- Port Error
- Unexpected error

**EQID *eqid***

indicates the EQID for the device, if any.

**Adapter ID *adapterid***

describes the OSA-Express port in use on system *systemname*. The format is:

cccccccccccc.pchid

**cccccccccccc**

represents the 12 bytes of text character and hexadecimal information that uniquely identifies the processor.

**pchid**

identifies the Physical Channel ID representing the OSA-Express adapter.

**ACTIVE**

indicates the port is currently available and in use.

**BACKUP**

indicates whether the alternate real device address has been initialized as a backup device to the base real device.

**Data Counters Cleared**

Indicates that the transmitted and received counters were reset to zero via the SET VSWITCH COUNTERS CLEAR DATA command at the time stated in the message.

**Discarded Counters Clearer**

Indicates that the discarded counters were reset to zero via the SET VSWITCH COUNTERS CLEAR DISCARDED command at the time stated in the message.

**Error Counters Cleared**

Indicates that the errors counters were reset to zero via the SET VSWITCH COUNTERS CLEAR ERRORS command at the time stated in the message.

### **MAC address *macaddr***

is the real or virtual MAC address associated with the UPLINK port device. For an IP VSWITCH, this is the adapter MAC address. For an ETHERNET VSWITCH, this is a virtual MAC address.

### **RX packets**

*rxpackets* is the number of packets received. If "Data Counters Cleared:" is displayed above this value, the value was cleared at the time indicated by the SET VSWITCH COUNTERS CLEAR DATA command.

### **TX packets**

*txpackets* is the number of packets transmitted. If "Data Counters Cleared:" is displayed above this value, the value was cleared at the time indicated by the SET VSWITCH COUNTERS CLEAR DATA command.

### **Discarded**

*nnn* indicates the number of packets discarded. A packet can be discarded because it is not formatted correctly, for example, or contains an unauthorized VLAN ID. Packets can also be discarded if the virtual switch's internal buffer limit has been reached. The internal buffer limit is reached when the virtual switch is unable to send packets over the OSA port or deliver packets to a guest VM port. Examples of this include: (1) An OSA port (RDEV) output buffer is not being serviced quickly enough by the adapter. A fully utilized OSA adapter will cause this condition. (2) A guest VM port input buffer is not being serviced quickly enough by the guest operating system. This can happen when a highly utilized guest operating system needs additional resources (memory or processor) to handle the workload. If "Discarded Counters Cleared:" is displayed above this value, the value was cleared at the time indicated by the SET VSWITCH COUNTERS CLEAR DISCARDED command.

### **Errors**

*nnn* indicates the number of error packets discarded. If "Error Counters Cleared:" is displayed above this value, the value was cleared at the time indicated by the SET VSWITCH COUNTERS CLEAR ERRORS command.

### **RX bytes**

*rxbytes* is the number of bytes received. If "Data Counters Cleared:" is displayed above this value, the value was cleared at the time indicated by the SET VSWITCH COUNTERS CLEAR DATA command.

### **TX bytes**

*txbytes* is the number of bytes transmitted. If "Data Counters Cleared:" is displayed above this value, the value was cleared at the time indicated by the SET VSWITCH COUNTERS CLEAR DATA command.

### **Bridge Port Role**

indicates the Bridge Port is configured for either the Primary or Secondary role.

### **Status *status***

indicates the status of the Bridge Port. It can be either Active, Inactive, Standby, or Unknown.

#### **Active**

currently provides the bridge connection to the HiperSockets CHPID.

#### **Inactive**

indicates the configured Bridge Port is disconnected and unable to assume the active Bridge Port connection.

#### **Standby**

indicates the Secondary Bridge Port connection is waiting to or available to become the active Bridge Port connection.

#### **Unknown**

indicates the Bridge Port connection is in transition. This status is temporary.

### **Active LPAR *lparname***

is acting as the Active Bridge Port connection, if known. Otherwise, Unknown is displayed.

### **State**

indicates the current state of the virtual switch's Bridge Port. See ["Usage Notes" on page 1352](#) for the list of possible state values and their descriptions.

**RDEV**

*nnnn* indicates the base real device number of the HiperSockets device used for the Bridge Port. If the value "Error" is displayed next to the RDEV address, the device cannot be attached and the problem must be corrected. Where possible, an explanation for the error is included. Examine the operator console and the console of the z/VM TCP/IP stack controller for more information about the error. See the error conditions listed under RDEV for a list of possible Bridge Port errors.

**VDEV**

*nnnn* indicates the base virtual number used by the virtual switch controller for this Bridge Port RDEV.

**Controller**

is the user ID of the TCP/IP virtual machine acting as a controller for this Bridge Port RDEV.

**Data Counters Cleared**

Indicates that the transmitted and received counters were reset to zero via the SET VSWITCH COUNTERS CLEAR DATA command at the time stated in the message.

**Discarded Counters Cleared**

Indicates that the discarded counters were reset to zero via the SET VSWITCH COUNTERS CLEAR DISCARDED command at the time stated in the message.

**Error Counters Cleared**

Indicates that the errors counters were reset to zero via the SET VSWITCH COUNTERS CLEAR ERRORS command at the time stated in the message.

**MFS**

*nnK* is the Maximum Frame Size configured for the HiperSockets CHPID based on the IOCP channel parameters. If the MFS cannot be determined (for example, if the device is not found), the MFS value will be displayed as "---".

**Buffer Limit**

indicates the buffer limit (BUFFERS) configured for the Bridge Port on the SET VSWITCH command or MODIFY VSWITCH statement.

**InUse**

indicates how many buffers configured are currently in use.

**Trace Pages**

indicates the number of pages allocated for use by the Bridge Port or UPLINK Port internal trace table. This size is set by the SET VSWITCH BRIDGEPORT TRACESIZE or SET VSWITCH UPLINK TRACESIZE command.

**NIC Distribution**

indicates the status of NIC distribution for the Bridge Port. The value can be either OFF (default) or ON. For more information, see the NICDISTRIBUTION operand of the ["SET VSWITCH"](#) on page 1757 command.

**RX packets**

*rxpackets* is the number of packets received on the Bridge Port. If "Data Counters Cleared:" is displayed above this value, the value was cleared at the time indicated by the SET VSWITCH COUNTERS CLEAR DATA command.

**TX packets**

*txpackets* is the number of packets transmitted on the Bridge Port. If "Data Counters Cleared:" is displayed above this value, the value was cleared at the time indicated by the SET VSWITCH COUNTERS CLEAR DATA command.

**Discarded**

*nnn* indicates the number of packets discarded on the Bridge Port. If "Discarded Counters Cleared:" is displayed above this value, the value was cleared at the time indicated by the SET VSWITCH COUNTERS CLEAR DISCARDED command.

**Errors**

*nnn* indicates the number of error packets discarded on the Bridge Port. If "Error Counters Cleared:" is displayed above this value, the value was cleared at the time indicated by the SET VSWITCH COUNTERS CLEAR ERRORS command.

**RX bytes**

*rxbytes* is the number of bytes received on the Bridge Port. If "Data Counters Cleared:" is displayed above this value, the value was cleared at the time indicated by the SET VSWITCH COUNTERS CLEAR DATA command.

**TX bytes**

*txbytes* is the number of bytes transmitted on the Bridge Port. If "Data Counters Cleared:" is displayed above this value, the value was cleared at the time indicated by the SET VSWITCH COUNTERS CLEAR DATA command.

**Asynchronous Requests**

indicates the total number of completed asynchronous data transfers.

**Unavailable Buffers**

indicates the number of times the virtual switch or HiperSockets firmware could not perform an asynchronous request due to unavailable buffers on the target port.

**Device**

*vdev* indicates one of the devices assigned to this connection.

**Unit**

*nnn* indicates the relative device number of this adapter. The base device is unit 000.

**Role**

*role* indicates the role assigned to this device (CTL-READ, CTL-WRITE, or DATA).

**HiperSockets Bridge Capable Ports**

section describes the guests on the HiperSockets channel that are bridge capable.

**ID *logicalGuestPortID***

represents a specific bridge capable HiperSockets device. It will be displayed in one of the following formats:

- The HiperSockets device is attached to a z/VM guest on the same LPAR as the Bridge Port. The *logicalGuestPortID* will be displayed as a z/VM user ID followed by the device number. For example: LINUX001.1F00.
- The HiperSockets device is in use on a different LPAR and the LPAR name can be determined. The format will be an LPAR name followed by the device number. For example: SYSTEM1.304.
- The HiperSockets device is in use on a different LPAR and the LPAR name cannot be determined. z/VM generated a unique value that will be displayed followed by the device number. For example: LPAR010F.308.

**VLAN *vlan(1) vlan(2) ... vlan(n)***

indicates the list of VLAN IDs that are associated with the *logicalGuestPortID*.

**Options**

*options* indicates the currently enabled features for this *logicalGuestPortID*, such as Broadcast.

***macaddr***

indicates a unicast or multicast MAC address associated with the *logicalGuestPortID*.

***status Error***

indicates that this MAC address in the virtual switch LAN could not be registered. This could indicate a conflict for this particular MAC address.

**Member: *systemname.switchname***

describes the members of the global virtual switch where *systemname* identifies the 8 byte EBCDIC z/VM system identifier of the system where a member of the global virtual switch exists.

**State *state***

indicates the state of the global member.

**Synchronized**

the local system's view of the global virtual switch matches the configuration on other IVL domain members.

**Pending Synchronization**

the local system is checking to make sure that configuration of the global virtual switch matches the existing configuration on all systems in the IVL domain.

**Error [Reason:msgno]**

the local system has identified a configuration mismatch with the way the global virtual switch is configured on another system in the IVL domain.

A message number will also be displayed to identify a specific synchronization problem. For more information on the reason, see [z/VM: CP Messages and Codes](#).

**Not Synchronized**

the local system's view of the global virtual switch does not match the configuration on other IVL domain members.

**IVL Port**

section describes the IVL NIC port.

When a IVL virtual switch has been defined, and the system is a member of an IVL domain, the display includes information describing the IVL port.

When the IVL virtual switch has been defined, but there is a system configuration which prevents the z/VM image from becoming an active IVL member, the following line is displayed. For more information on the reason, see [z/VM: CP Messages and Codes](#).

```
IVL Domain: Isolated          Reason: HCPIVLxxxxE
```

**Adapter Owner**

*userid* indicates the userid of the virtual machine owning the simulated NIC.

**NIC**

*dev.Pnn* indicates the base virtual device address and port number of the simulated NIC.

**Name**

*portname* indicates the portname assigned to the virtual adapter. The value "UNASSIGNED" is displayed if your software does not assign a value.

**PQUplinkTx**

*priority* indicates the priority with which outbound traffic will be sent to the external network (Low, Normal, High) if the virtual NIC is connected to a virtual switch. The PQUPLINKTX value will be displayed for all non-IVL virtual switches regardless of the priority queuing setting (ON and OFF). The PQUPLINKTX value will be used when priority queuing is enabled on the virtual switch (PRIQueuing ON).

**Porttype**

*porttype* indicates the port type of the simulated NIC.

**Port**

*portnum* is the port number associated with the guest connection or the virtual switch network connection.

**Device**

*vdev* indicates one of the devices assigned to this connection.

**Unit**

*nnn* indicates the relative device number of this adapter. The base device is unit 000.

**Role**

*role* indicates the role assigned to this device (CTL-READ, CTL-WRITE, or DATA).

**VLAN**

*ipversion* can be IPv4 or IPv6 when a single VLAN is set per IP Protocol.

*nnnn(n)* indicates the effective VLAN ID or IDs for the device. Multiple VLAN ID lines may be shown. If no VLANs are configured for a VLAN aware virtual switch, NONE will be displayed.

*status* is "Assigned by system" or "Assigned by user". If the specified VLAN ID conflicts with the authorizations for this user, "Conflicting VLAN ID" is displayed. "Inactive" is displayed when no active

VLANs are configured - that means that all ingress and egress frames will be discarded until a VLAN is configured.

### Router

*type ipversion* indicates the adapter has configured itself as a router with type Primary, Secondary or Multicast in IP version IPv4 or IPv6. *vlan* is either VLAN followed by the VLAN ID, if it is a VLAN-specific router, or Global, if it is a global router. If it is a global router, lines will follow to describe which VLAN IDs the adapter is routing for.

The router line is displayed only when a router is configured.

### Options

*options* indicates the currently enabled features for this interface, such as Broadcast, Multicast, IPv4 or IPv6. A value of VLAN\_ARP means the controller can register IP addresses on the OSA-Express with the proper VLAN groups.

### Partner Switch Capabilities

*options* indicates the capabilities of the partner switch. If CP is unable to retrieve the capabilities (for example, because of lack of support in the OSA-Express device), "Unavailable" is displayed. Otherwise the response is "Reflective\_Relay" if the partner switch has that capability (required for VEPA) or "No Reflective\_Relay."

### Take-over Status Member: *systemname* MAC address: *mac*

an additional line(s) shows take over status when the shared port group is involved in MAC address takeover to maintain connectivity following a failure.

A different global VSwitch member had an UPLINK port failure, and its MAC addresses are now assigned to one of the local OSAs on this global VSwitch member. The member name may be omitted if it cannot be obtained (for example if the member left the IVL domain). This is followed by a list of MAC Addresses.

### *ipaddr*

represents one Unicast IP address that has been registered to this device and optional information relating to the IP address.

An IPv4 address is displayed in dotted-decimal format, for example 9 . 130 . 44 . 144.

An IPv6 address is displayed in compressed format (":" designates multiple 16-bit groups of zeros). For example, the IPv6 address

```
F802:0000:0000:0000:0000:0A00:0001
```

is displayed in compressed format as F802 : :A00:1.

### *mpaddr*

represents one Multicast IP Address.

For IPv4, the address is displayed in dotted-decimal format with the associated MAC address.

For IPv6, the address is displayed in compressed format (":" designates multiple 16-bit groups of zeros).

### MAC

*macaddr* represents a MAC address.

### *flags*

additional information that may be displayed with the IP address. These include:

- Local indicates that this address was registered in a virtual switch LAN, but is NOT currently registered in the external network. This may indicate the external interface is disconnected. It may also indicate that this address is only supported within the immediate network (as it is in the case of an IPv6 address within an IP Layer VSWITCH).
- Conflict indicates that this address was registered locally but cannot be used at all because of a conflict with the network external to the virtual switch LAN.

- Remote indicates that this address was registered automatically to represent a source address found in a datagram. This entry is automatically removed after the IP Timeout (IPTimeout) has expired.
- Manual indicates that this address was registered manually by an ARP cache control command from the driver. This entry will be automatically removed after the IP Timeout (IPTimeout) has expired, or it may be removed earlier by the driver.
- NotOwner means that the IP address was registered by the guest using an ARP Add Unconditional setting, but another guest on the virtual switch had already registered the IP address. If the owner of the IP address removes its registration, this guest can become the owner and receive incoming traffic for the IP address.

## Messages

- HCP2783E VSWITCH *switchname* does not exist
- HCP2783E VSWITCH SYSTEM *switchnm* of type *type* does not exist
- HCP2836E VLAN was not found
- HCP3185I The displayed response may be incomplete. The system is not joined with the IVL Domain.

## QUERY VTOD

Notes:

<sup>1</sup> You can specify the operands in any order.

<sup>2</sup> A class G only user must be coupled to *userid* to use this operand.

### Authorization

Privilege Class: A, B, G

### Purpose

QUERY VTOD allows the virtual machine operator to interrogate the difference between their virtual machine's TOD clock and the system (hardware) TOD clock. This command also allows virtual machine operators to determine the set of logged-on virtual machines with TOD clock settings synchronized with their own.

A privileged user (class A or class B) can see such information for any logged-on user ID, not just the user's own virtual machine. Similarly, a class G user can see such information for any user ID to which the user is coupled.

### Operands

#### FOR *userid*

allows a privilege class user A or B to display the virtual TOD clock setting for any logged-on user ID. A class G user can display the same information for any user ID to which the user is coupled.

#### SYNC

allows the issuer to display the set of logged-on virtual machines with TOD clock settings that are in synchronism with their own. However, if the system TOD clock is in sync with their own, then only "System TOD" is displayed.

### Usage Notes

1. If the QUERY VTOD command is executed without any options, the virtual time-of-day of the user ID entering the command is displayed.
2. Instead of displaying user IDs virtual TOD clock settings, the SYNC option can be used to just display the system TOD.

### Responses

Response 1:

Three lines of numeric information are displayed followed by a list of user IDs if the SYNC option was used and the system TOD clock is not in sync with their own. This sample illustrates both portions:

```
System TOD: yyyy-mm-dd hh:mm:ss (xxxxxxxxxxxxxxxxxxxx)
User TOD:   yyyy-mm-dd hh:mm:ss (xxxxxxxxxxxxxxxxxxxx)
Delta:      xxxxxxxxxxxxxxxxxxxx
Synchronized with:
USERABCD USEREFGH USER1234 USER2345 USER4321 USER5647 USER2213 USERFRED
USERSAM USERJAKE USERRICK
```

In this sample, xxxxxxxxxxxxxxxx is a 16-digit hexadecimal number, and the other outputs are date and time stamps.

### Examples

To display your own offset, enter: `query vtod`.

If you are a class G only user and are coupled to CFVM1, you can display CFVM1's offset by entering: `query vtod for cfvm1`.

To display your own offset in addition to everyone with whom you are synchronized, enter: `query vtod sync`.

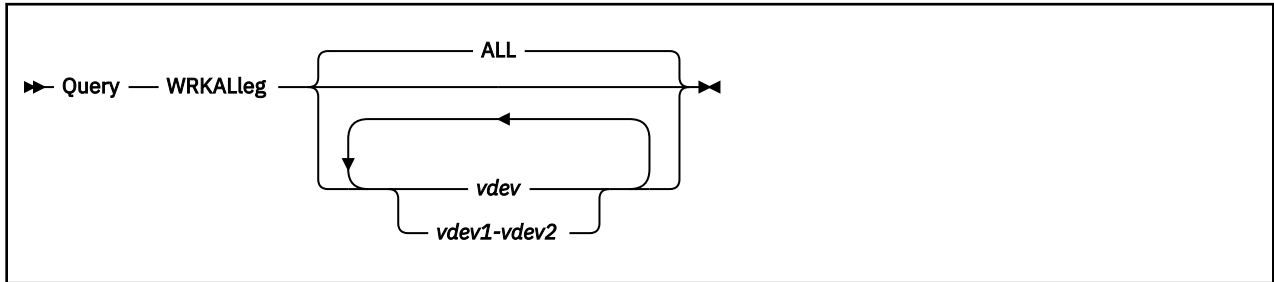

If you are a class G only user and are coupled to CFVM1, you can display CFVM1's offset and the names of everyone synchronized with CFVM1 by entering: `query vtod for cfvm1 sync`

If you are a class A or B user, you can display any VTOD offset in the system. For example, to display MAINT's VTOD setting and the set of users synchronized with MAINT, enter: `query vtod for maint sync`.

### Messages

- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on
- HCP2800E *msgprocid* is not a CF service machine.
- HCP2805E One or more message processors does not exist in your I/O configuration.
- HCP2806E You are not allowed to control message processors.

## QUERY WRKALLEG

### Authorization

Privilege Class: G

### Purpose

Use QUERY WRKALLEG to display the status of working allegiance for each virtual device given. The device must be a minidisk.

### Operands

#### ALL

will display all the virtual devices in the user's configuration that have WRKALLEG ON.

#### vdev

#### vdev1-vdev2

is the virtual device number or a range of virtual device numbers of the minidisk.

### Usage Notes

1. If no virtual device is specified, all the virtual devices that are simulating working allegiance will be displayed.
2. VM supports a z/OS guest's participation in a Sysplex configuration only if all participating z/OS systems are guests of the same VM host. Environments which include a z/OS system running natively in a separate processor partition, or as a guest of a different VM system are not supported.
3. This command is rejected for full-pack minidisks on a shared real volume. Virtual working allegiance is incompatible with sharing real DASD. WRKALLEG is only for sharing virtual devices.
4. This command is rejected for dedicated DASD. Working allegiance is only necessary for shared minidisks. Virtual working allegiance is incompatible with sharing real DASD. WRKALLEG is only for sharing virtual devices.
5. Working allegiance applies only to users with write access to the minidisk. Furthermore, working allegiance is simulated only when a guest with write access initiates I/O. However, guests with read-only access will be allowed to query the device to determine if another guest issued SET WRKALLEG ON to the minidisk.
6. Working allegiance is always simulated for virtual disks in storage. QUERY WRKALLEG is rejected if the vdev is a virtual disk in storage.
7. The WRKALLEG setting applies to the minidisk, not to an individual virtual device. If two users have links to the same minidisk and one issues SET WRKALLEG, the setting will apply to both users' access to the minidisk.
8. For more information on working allegiance, see the principles of operation manual for your system.

## Responses

Response 1:

```
DASD <vdev> working allegiance is being
simulated among same system guests.
```

is returned for each virtual device specified where WRKALLEG=ON.

Response 2:

```
DASD <vdev> working allegiance is turned off.
```

is returned for each virtual device specified where WRKALLEG=OFF.

Response 3:

```
Working allegiance is being simulated for the
following minidisks:
0100 0200 0300 ...
```

is the response if QUERY WRKALLEG or QUERY WRKALLEG ALL is specified.

Response 4:

```
Working allegiance is not simulated for any
minidisk in your configuration.
```

is the response if QUERY WRKALLEG or QUERY WRKALLEG ALL is specified and no minidisks had WRKALLEG set ON.

## Messages

## READY

---

```
▶▶ READY — vdev ▶▶
```

### Authorization

Privilege Class: G

### Purpose

Use READY to set pending a device-end interrupt for a specified virtual device.

### Operands

*vdev*

identifies the virtual device.

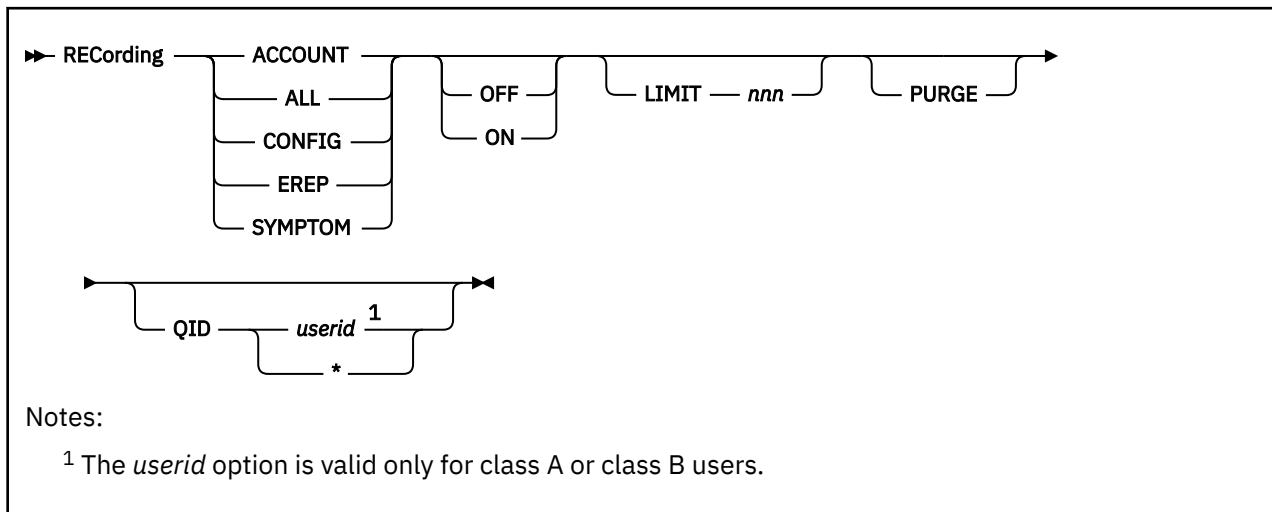

### Usage Notes

1. Use the READY command to clear a previous not-ready condition for a device.
2. Do not use the READY command for a virtual channel-to-channel adapter (CTCA). A not-valid device type error results.

### Messages

- HCP006E Invalid device type - {*rdev/vdev/ldev*}
- HCP022E A virtual device number was not supplied or it was invalid.
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP263E Too many operands were supplied for this command.
- HCP1201E Device *vdev* cannot be readied because it is active.

## RECORDING

## Authorization

Privilege Class: A, B, C, E, F

## Purpose

Use RECORDING to change the processing parameters of the control program (CP) recording facilities.

## Operands

### ACCOUNT

#### ALL

#### CONFIG

#### EREP

#### SYMPTOM

specify the record type for which the parameter change is being requested. Note that the EREP parameter refers to LOGREC error records.

### ON

requests that recording of the specified record type or types be started. The association to the recording function will remain until a cold start of the system is performed.

### OFF

requests that recording of the specified record type or types be stopped.

### LIMIT *nnn*

specifies a decimal value, from 1 to 255, used as a threshold indicating when to notify the system operator and the receiving virtual machine that uncollected records are accumulating.

Uncollected records are records that have been created but not received by the recording virtual machine. Whenever the number of uncollected records of the specified type equals an integral multiple of LIMIT, the system operator and the virtual machine user who normally receives the records are notified.

For example, suppose you specify LIMIT 4. The system operator and the virtual machine user who normally receives the records are notified when four uncollected records accumulate. Notifications are issued when the number of uncollected records reaches 8, 12, 16, and so forth.

The default limit for ACCOUNT records is 20, for EREP records 2, for SYMPTOM records 2, and for CONFIG records 255. Any LIMIT setting that you indicate lasts until VM is restarted with COLD option.

**PURGE**

requests the purging of any records in storage that have been collected but not retrieved.

**QID *userid*****QID \***

identifies the user eligible to retrieve the records of the type specified for which CP's recording queue parameters are to be altered. If you are specifying your own user ID, you can specify *userid* as an asterisk (\*). You may specify your own user ID or asterisk (\*) to limit data selection to your own account.

As part of the z/VM system generation process, your system programmer may have indicated which virtual machines would retrieve records of a designated type. CP recording system services recognize additional virtual machines when the virtual machines connect to them using IUCV facilities. (The RETRIEVE CP utility processing connects to CP system services in order to collect CP records). Once a virtual machine has connected to a CP recording system service, its recording queue is maintained by CP until z/VM is restarted with the COLD option. If the user ID you specify with the QID operand is different from the user ID your system programmer specified at system generation time and the user ID has never connected to the appropriate CP system service with the RETRIEVE utility, the change is not known to the CP recording system service and the user ID will not appear in the query recording output.

**Note:** The QID operand is valid only for class A and B users.

**Usage Notes**

1. If you are a class A or B user and you omit *userid*, the command applies to all records being collected by CP that match the specified record types.
2. If you do not specify any of the optional operands, ON is assumed.
3. Specifying the OFF operand prevents newly generated records from being queued for the relevant virtual machines, but leaves all previously generated records queued. Leaving a large number of these records queued in CP storage could affect system performance and the availability of CP storage. You can purge these records using the PURGE operand (previously described). Also, see [Stopping and Starting the Recording of Accounting Records in z/VM: System Operation](#).
4. If a user has recording set OFF and a non-zero number of records queued, recording cannot be turned ON for that user until the queued records are processed. CP issues message HCP8087I if you try to turn recording on while records are queued. You can use the PURGE operand (previously described) to purge the records, or the RETRIEVE utility to retrieve the records from the queue and then you can turn recording on.

**Responses**

Response 1:

```
COMMAND COMPLETE
```

indicates that the command has completed successfully.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*
- HCP007E Invalid userid - *userid*
- HCP013E Conflicting option - *option*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid

- HCP8072I Recording entry not found
- HCP8087I Records are queued for user *userid* on the {\*LOGREC|\*ACCOUNT|\*SYMPTOM| \*CONFIG} recording queue and must be purged or retrieved before recording can be turned on.

## REDEFINE

### Authorization

Privilege Class: G

### Purpose

Use REDEFINE to change the virtual device number of any existing virtual device in your configuration.

### Operands

#### **vdev1**

is the virtual device number of an existing virtual device.

#### **vdev2**

is the new virtual device number.

### Usage Notes

1. Virtual paging subsystem devices should not be redefined in order to protect the integrity of the user's virtual paging subsystem.
2. When you use the REDEFINE command to alter the configuration of your virtual machine, the changes are temporary and are only in effect for the current session.
3. The virtual device numbers you specify can be no higher than FFFF.
4. Informational responses are sent to your display to confirm that the configuration change you requested has taken place. These responses do not appear if you have issued the SET IMMSG OFF command.
5. If you change the virtual device number of your console while spooling your console, the spool file device number will also change.
6. If the existing virtual device is part of a Concurrent Copy (CONCOPY) session for your virtual machine, the CONCOPY session is terminated in the storage control associated with the device.

### Responses

Response 1:

```
type vdev DEFINED
```

confirms that the device number has been changed.

<b>Type</b>	<b>Meaning</b>
DASD	Direct access storage device
TAPE	Magnetic tape
RDR	Card reader
PRT	Line printer
PUN	Card punch

<b><u>Type</u></b>	<b><u>Meaning</u></b>
GRAF	Display device
CONS	Console
CTCA	Channel-to-channel adapter
CTLR	3745 Communications Controller
MSC	Mass Storage Controller
SWCH	Dynamic switching device
DEV	Any other device.

Response 2:

```

Redefining vdev1 has caused the termination of
CONCOPY session(s) on device(s): vdev...

```

indicates that Concurrent Copy (CONCOPY) sessions have been terminated during the process of changing the existing virtual device number.

***vdev1***

is the existing virtual device number that you are changing.

***vdev...***

is a list of the virtual device numbers that are part of the terminated CONCOPY sessions.

## Messages

- HCP002E Invalid operand - *operand*
- HCP022E A virtual device number was not supplied or it was invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP092E Device *vdev* not defined; *device vdev* already defined
- HCP1150E DASD {*rdev/vdev*} is not a valid base exposure.
- HCP1200E DASD *vdev* has not been redefined because paging subsystem device cannot be redefined.

## REFRESH

### Authorization

Privilege Class: A

### Purpose

Use REFRESH to replace the existing logo configuration file maintained by CP or to tell CP to send new LOGO information to one or more VTAM service machines (VSM).

### Operands

#### LOGOinfo *fn ft*

tells CP to replace the existing logo configuration file with the file specified by *fn* and *ft*. The file must reside on a CMS-formatted minidisk accessed by CP.

#### LOGOVSM *userid*

sends new logo information to one or more VTAM service machines (VSM) specified by *userid*. *userid* is the user ID (or user ID pattern) of the VTAM service machine to which you want to send the new LOGO information. CP supports pattern matching as described in Usage Note [“4” on page 1380](#).

### Usage Notes

1. If CP encounters errors while reading the specified logo configuration file, CP displays an error message on the terminal of the user who issued the REFRESH LOGOINFO command. If errors are found, CP ignores the REFRESH LOGOINFO command.
2. Be careful when you change status area fields on a running system, because certain applications may depend on the status fields remaining constant.
3. If the file you requested does not reside on a CP-accessed minidisk, CP does not delete the previous logo configuration information.
4. Pattern matching follows these rules. Use an asterisk (\*) to match any number of characters. Use a percent symbol (%) to match any single character.
5. For more information on the contents of [The Logo Configuration File](#), see *z/VM: CP Planning and Administration*.
6. For information on CP-accessed minidisks, see [“CPACCESS” on page 89](#) and [“QUERY CPDISKS” on page 824](#).

### Responses

Response 1:

If the command is successful, CP does not issue a response.

Response 2:

If you enter a REFRESH LOGOINFO command and there are errors in the specified logo configuration file, you see error messages. Each error message is preceded by another message that tells you where the error occurs in the file.

Response 3:

If you enter a REFRESH LOGOVSM command and the VTAM service machine you requested is not found, you receive message HCP6784E.

## Messages

- HCP002E Invalid operand - *operand*

- HCP6787E No VSMS support dynamic logo updates.
- HCP6787E VSM *userid* does not support dynamic logo updates.

## RELSPACE

```
▶▶ RELSPACE — vdev — ▶▶
```

### Authorization

Privilege Class: G

### Purpose

Use RELSPACE to return all extents on a device to its associated Extent Space Efficient pool. A user can release the space of any virtual device to which they have write access. This could be a dedicated DASD or a minidisk on a volume attached to the system.

### Operands

#### *vdev*

is the virtual device number of the device to have backing tracks released.

### Usage Notes

1. The RELSPACE command is intended for the release of extents on Extent Space Efficient (ESE) DASD volumes. RELSPACE can be used to return extents to the device's associated ESE pool to be used for expanded usage by other devices.
2. There is no guarantee that all data associated with the released tracks will be erased. If erasure is necessary, a policy such as using the CPFMTXA ERASE function before RELSPACE should be employed.
3. The Query DASD SPACE-EFFICIENT command can be used to check the ESE pool utilization for a given device and its associated pool.
4. Query DASD SPACE-EFFICIENT output will not correlate directly with the release of space of non-fullpack minidisks, when comparing the Query output before and after a release. The Release Allocated Space hardware function, invoked by the RELSPACE command, only releases FULL extents which begin and end on an integral hardware Extent boundary (for example, 21 cylinders). Since a non-fullpack minidisk can start and end on any real cylinder boundary, there may be partial hardware extents at the front and end of the minidisk which will not be released. Minidisks have to be defined to start and end on the real hardware Extent boundaries to circumvent this hardware restriction.
5. RELSPACE to non-fullpack minidisks, including real cylinder 1-to-end minidisks, will fail with I/O errors if issued to Extent Space Efficient volumes with only Phase 1 (Full Volume) Release Allocated Space hardware support. Phase 2 (Partial Volume Extent) or higher Release Allocated Space hardware support is required.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *{option* command contains extra option(s) starting with *option}*
- HCP006E Invalid device type - *rdev*
- HCP022E A virtual device number was not specified or it is invalid.
- HCP026E Operand was missing or invalid
- HCP040E Device *{rdev/vdev/ldev}* does not exist
- HCP263E Too many operands were supplied for this command.
- HCP6432I *vdev* is not on an Extent Space Efficient Volume and is not valid for the RELSPACE command.
- HCP6432I *vdev* is a PAV or HyperPAV alias device and is not valid for the RELSPACE command.

- HCP6432I *vdev* does not have write access and is not valid for the RELSPACE command.

## REPEAT

### Authorization

Privilege Class: D

### Purpose

Use REPEAT to increase the number of output file copies beyond the quantity originally requested.

### Operands

#### *rdev*

identifies the real output device (printer or punch) whose current active spool file is to be repeated.

#### **1**

#### *nnn*

identifies the number of copies to be made. If you do not specify a value, the number of extra copies defaults to 1; the maximum value you may specify for *nnn* is 255.

### Usage Notes

1. This command applies only to files that are currently being written to a real punch or printer.

### Responses

Response 1:

```
{PRT} rdev REPEATED  userid  FILE spoolid
{PUN}

RECS {nnnn} COPY [*] nnn SEQ sss CL c typ
     {nnnK}
     {nnnM}
```

#### *rdev*

identifies the real device whose current output is being repeated.

#### *userid*

identifies the user to receive the output.

#### *spoolid*

identifies the system-assigned file spoolid.

#### **RECS *nnnn***

#### **RECS *nnnK***

#### **RECS *nnnM***

identifies the number of spool file records remaining to be printed. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines rounded to the nearest 1000

records. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines rounded to the nearest million.

**COPY [\*] *nnn***

identifies the number of copies remaining to be created.

When the optional asterisk (\*) is specified, the 3800 printer prints each page from the spooled output files *nnn* times before going on to the next page.

**SEQ *sss***

identifies the (printer or punch) file sequence number.

**CL *c***

is the spool file class.

***typ***

shows the device type that originally produced the spool file. The type can be RDR, PRT, PUN, CON, DMP, or SYS.

**Messages**

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP021E A real device number was not supplied or it is invalid.
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP046E *type rdev* offline
- HCP088E An invalid number was supplied for {COPY|FLASH} - *operand*.
- HCP140E *type {rdev/ldev}* attached to *userid*
- HCP141E *type rdev* not active
- HCP417E {*rdev/vdev*} is not an output spooling device.
- HCP418E {*rdev/vdev*} is not a spooled device.
- HCP6005E Option *option* is not supported by z/VM.

## REQUEST

---

► REQUEST ◄

### Authorization

Privilege Class: G

### Purpose

Use REQUEST to make pending an attention interrupt for your virtual console.

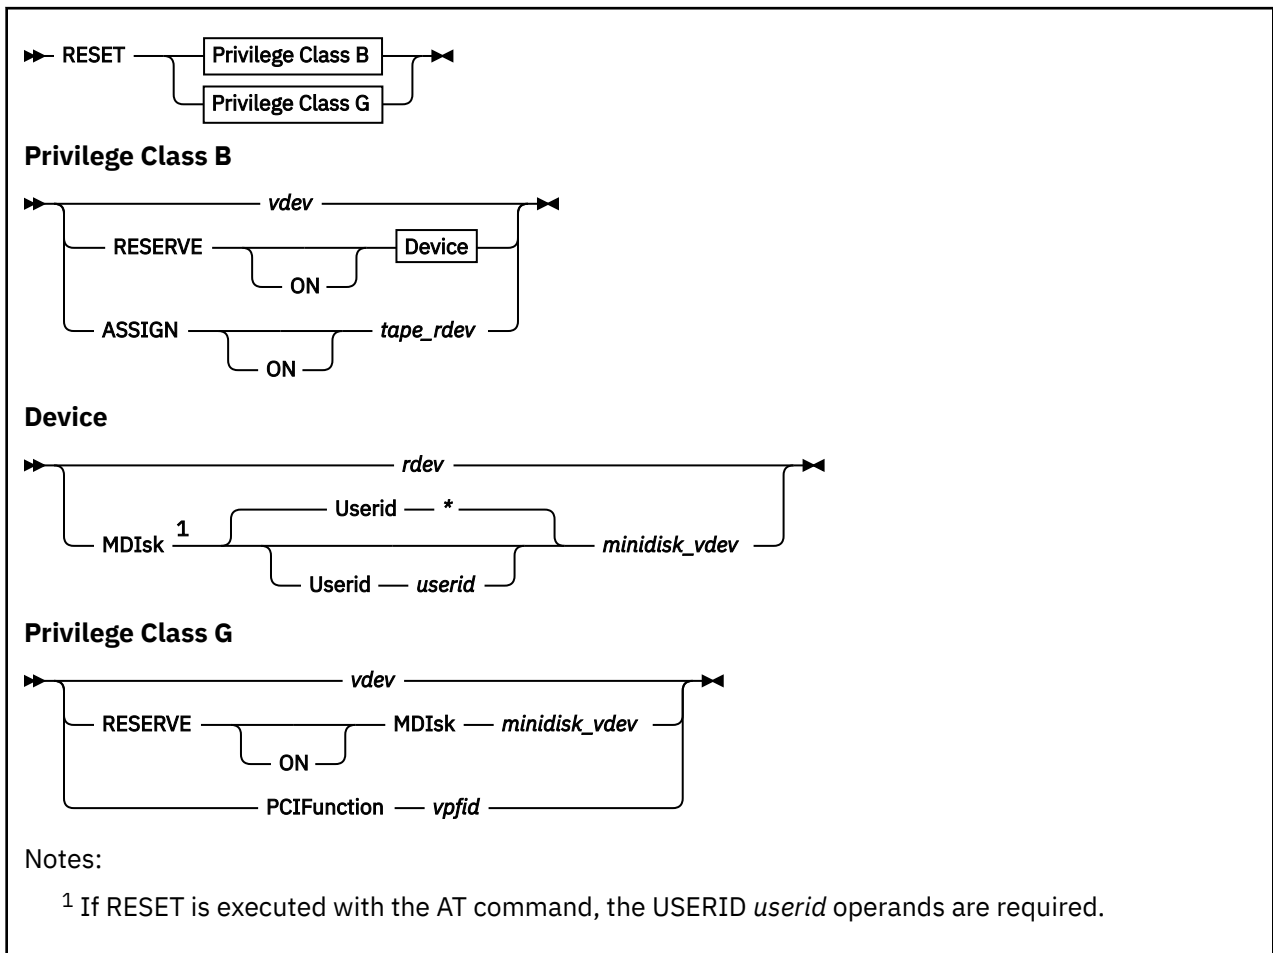

### Usage Notes

1. The REQUEST command performs the same functions as the ATTN command; you can use the two interchangeably.
2. The BEGIN command is not required after you enter REQUEST.
3. CP ignores the ATTN and REQUEST command if another attention interrupt is pending for your virtual machine, or if your virtual machine is not enabled for interrupts.

### Messages

- HCP002E Invalid operand - *operand*

## RESET

### Authorization

Privilege Class: B, G

### Purpose

Use RESET to clear all pending interrupts from a specified device.

A class B user can reset:

- The user's own virtual device to clear all pending interrupts.
- RESERVE on a real device or on another user's minidisk.
- ASSIGN on a real device.

A class G user can reset:

- The user's own virtual device to clear all pending interrupts.
- RESERVE on the user's own minidisk.
- A virtual PCI function to remove the function from the permanent error state.

## RESET

### Operands

#### *vdev*

is the virtual device number of the device to be reset.

#### **RESERVE**

releases the RESERVE status of a system shared DASD.

#### *rdev*

is the real device number of the device to be released.

#### **MDisk** *minidisk\_vdev*

is the virtual device number of the minidisk to be released.

#### **Userid \***

#### **Userid** *userid*

is the user ID of the user that has the *vdev*.

#### **ASSIGN**

unassigns a tape drive.

#### *tape\_rdev*

is the real device number of the tape drive to be released.

#### **PCIFunction**

resets a virtual (guest-attached) PCI function.

#### *vpfid*

specifies the virtual PCI function ID to be reset. Specify a virtual PCI function number as 8 hexadecimal digits. You can omit leading zeros.

### Usage Notes

1.  **Attention:** If you must release a device that is being reserved by CP for some user, you can use the RESET RESERVE command. You should use this command only when you know that the user for whom CP is holding the reserve is hung or is holding the reserve for too long and preventing access to the device by other users.
2. In addition to clearing all pending interrupts, all virtual sense bytes and error conditions occurring as a result of unit checks are reset.
3. The operator of a virtual system can issue the RESET command to return to CP any local displays that were connected to the virtual system using the DIAL command.
4. The reserve status of system DASD can be determined by issuing the Class B QUERY DASD RESERVE command.
5. The reserve status of an MDISK *vdev* can be determined by issuing the QUERY MDISK command.
6. When RESET RESERVE is issued to a device, that device immediately becomes available to the other sharing system.
7. If the specified tape drive is in a GIVEN state the issuer must be the user ID to whom the tape drive was given, or the command is not performed.
8. The RESET RESERVE command can, in some cases, be used to reset a device that is RESERVED BY SYSTEM. Normally a device in this state is in transition, and a subsequent query will indicate the device is reserved by a user, or not reserved. However, if querying the device consistently returns RESERVED BY SYSTEM, and other native systems seem to be unable to access the device, then use the RESET RESERVE command to release the outstanding reserve.
9. If a RESET *vdev* command is issued by a class B user using the AT command, the following message will be issued:

#### **HCP040E**

Device *vdev* does not exist

This is because virtual device addresses are not valid if the RESET command is issued using the AT command.

10.  **Attention:** The RESET ASSIGN command is intended for use in the removal of spurious assignments from a real device. You should use this command only when you know that the virtual machine user of the device, if any, is hung or has otherwise failed, and is thus unable to complete the work being done on the device. Use of this command on a device being actively used can allow the device to be accessed by another real system having shared access to the device, potentially destroying the active work.
11. To reset a real PCI function, use [“SET PCIFUNCTION” on page 1600](#) with privilege class B.

## Responses

Response 1:

```
DEVICE RESET - type vdev
```

is returned when you enter RESET *vdev*.

<b>Type</b>	<b>Meaning</b>
DASD	Direct access storage device
TAPE	Magnetic tape
RDR	Card reader
PRT	Line printer
PUN	Card punch
GRAF	Display device
CONS	Console
CTCA	Channel-to-channel adapter
CTLR	3745 Communications Controller
MSC	Mass Storage Controller
SWCH	Dynamic switching device
DEV	Any other device.

### ***type***

indicates the type of device that has been reset.

### ***vdev***

is the virtual device number.

Response 2:

```
RESERVE ON type rdev RESET
```

is returned when you enter the RESET RESERVE *rdev* command.

Response 3:

```
ASSIGN ON type rdev RESET
```

is returned when you enter the RESET ASSIGN *rdev* command.

Response 4:

```
RESERVE ON userid vdev RESET
```

is returned when you enter the RESET RESERVE *vdev* command.

Response 5:

## RESET

PCI function reset - *vpfid*

is returned when you enter the RESET PCIFUNCTION *vpfid* command.

### Messages

- HCP2000E The reserve was not reset on *rdev* because it is not a shared DASD.
- HCP2001E The reserve was not reset on DASD *rdev* because it was not reserved.
- HCP2009I The system detected I/O errors while attempting to release a real reserve that was held on device *rdev* (by user *userid*, virtual device *vdev*). *{The reserve is now held by the system|The current reserved state of the real device could not be determined}*

# RESTART MSGPROC

► RESTART — MSGProc — *msgprocid* ◄

## Authorization

Privilege Class: A, B, G

## Purpose

The RESTART MSGPROC command allows a user ID to reload and start a message processor in a CF Service Machine.

If you have Class G privilege only, the message processor that you specify must be currently defined in your I/O configuration. A message processor may be defined in your I/O configuration by either the DEFINE MSGPROC command or the SPECIAL directory statement.

The RESTART MSGPROC command will cause the specified CF Service Machine to be loaded with the Coupling Facility Control Code (Licensed Internal Code) from the service element of the processor. Once the CF Service Machine is loaded, the message processor is restarted and all previous structures within the Coupling Facility will be lost.

**Attention:** This command affects all coupled guests connected to the message processor.

## Operands

### *msgprocid*

specifies the user ID of the CF Service Machine to be restarted.

## Usage Notes

1. The CF Service Machine's console may be viewed to verify that the restart completed successfully.
2. To define a virtual message processor and associated virtual message devices, use the DEFINE MSGPROC command.
3. To display information about virtual message processors in your I/O configuration, use the QUERY VIRTUAL MSGPROC command.
4. To display information about the virtual message devices within your I/O configuration, use the QUERY VIRTUAL MSGDEVICES command.
5. To remove all message facility capability from your virtual machine, use the SET MSGFACIL OFF command.
6. To detach a virtual message processor and associated virtual message devices, use the DETACH MSGPROC command.
7. If an IPL directory statement or the IPL operand on the XAUTOLOG command was initially used to load the CF Service Machine, then the same IPL statement will be used by the RESTART MSGPROC command when performing the restart. The CF Service Machine will not be loaded from the service element of the processor.

## Responses

Response 1:

## RESTART MSGPROC

To restart message processor CFCC1 within user SHARE1's I/O configuration, enter the following:

```
restart msgp cfcc1
HCP2809I Restart of message processor CFCC1 by SHARE1 initiated.
Ready;
```

HCP2809I will be displayed on both the message processor and the issuer's console.

### Messages

- HCP002E Invalid operand – *operand*
- HCP003E Invalid option – command contains extra option(s) starting with *option*
- HCP020E Userid missing or invalid
- HCP2805E Message processor *msgprocid* does not exist in your I/O configuration.
- HCP2809I Restart of message processor *msgprocid* by *userid* initiated.

## REWIND

```
▶▶ REWInd — vdev ◀◀
```

### Authorization

Privilege Class: G

### Purpose

Use REWIND to rewind, but not unload, tape on a real tape drive.

### Operands

#### *vdev*

is the virtual tape drive on which the tape is mounted.

### Usage Notes

If the tape drive specified is in a given state, the issuer must be the user ID to whom the tape drive was given, or the command cannot process.

### Responses

Response 1:

```
REWIND NOT PERFORMED
```

is returned when the rewind operation is pending.

Response 2:

```
REWIND COMPLETE
```

is returned when the rewind operation is complete.

### Messages

- HCP006E Invalid device type - *{rdev/vdev/ldev}*
- HCP022E A virtual device number was not supplied or it was invalid.
- HCP040E Device *{rdev/vdev/ldev}* does not exist
- HCP263E Too many operands were supplied for this command.
- HCP1122E *command* was not performed. Tape *vdev* has been given to user *userid*.
- HCP1202E Device *vdev* was not rewound because it is active.

## SAVESEG

```
▶▶ SAVESEG — dcssname ▶▶
```

### Authorization

Privilege Class: E

### Purpose

SAVESEG is the final step of a saved segment build process. This command allows a system administrator or an installation procedure to save the page range areas previously specified by a DEFSEG command. The areas contain the appropriate objects, such as code or data, that were loaded into these defined areas by an install procedure.

Use SAVESEG to save the pages associated with the name of the saved segment into a previously defined class S (skeleton) system data file (SDF). Upon successful completion of SAVESEG, the class S SDF becomes an active class A (available) or class R (restricted available) SDF.

If the saved segment was defined as a member of a segment space, the segment space class S SDF has its member saved segment entry in the segment space's descriptor page updated to saved status. When all members of a segment space indicate saved status, the segment space class S SDF becomes an active class A or class R SDF.

The saved segment may have been defined as a member of several segment spaces. In this case, each segment space having this member would have its descriptor page updated.

### Operands

#### *dcssname*

is the name (a 1- to 8-character alphanumeric string) of the saved segment to be saved. This is the file name of a class S (skeleton) SDF previously defined with the DEFSEG command. When a DEFSEG command using the SPACE operand is issued, the *dcssname* specified in the SAVESEG command is interpreted as the member name specified in the DEFSEG command.

### Usage Notes

1. CP can process only one DEFSEG or SAVESEG command at a time. If CP is already processing a DEFSEG or SAVESEG command, processing of a subsequent DEFSEG or SAVESEG request is delayed. The SAVESEG command writes all page ranges, except those defined as EN or SN, to the associated system data file. The amount of time it takes for the command to complete is directly proportional to the amount of data to be written.
2. Using SAVESEG at off-peak hours on the system will have less impact on users due to I/O contention to the spool DASD.
3. You can interrupt and end a SAVESEG operation before it completes by using the PURGE NSS command. This will not leave a partially-saved system data file on the system. The skeleton system data file will be purged and must be redefined before the saved segment can be resaved.
4. After the execution of this command, the system data file is designated class A or class R. Class A indicates that it is in the unrestricted available state and may be accessed by any user. Class R indicates that the DCSS or segment space is restricted; to load it, the user must have a NAMESAVE statement for the saved segment in the directory entry.
5. Only one available (class A or R) saved segment with a particular name may exist at a given time. If any class A or R saved segment already exists with the same name as the one being saved, and there are no virtual machine users associated with the saved segment, the old copy of the saved segment

is purged, and the new one is made available when it becomes active (see usage note “11” on page 1395).

If users are associated with the old copy and neither the old copy nor the new copy of the saved segment is a CPDCSS (that is, no page ranges were defined with the SC page descriptor code), the old copy is marked as pending purge, and the new copy is saved. Any users associated with the old copy continue to reference the old (now pending purge) saved segment. Subsequent users are associated with the new copy.

If users are associated with the old copy and either the old copy or the new copy of the saved segment is a CPDCSS (that is, one or more page ranges were defined with the SC page descriptor code), the SAVESEG command is not accepted.

6. If there is a copy of the saved segment that is class P pending purge (the PURGE NSS command was used to purge it while there were users associated with it), the same rules apply as described in item “5” on page 1394:
  - If neither the old copy nor the new copy of the saved segment is a CPDCSS, the new copy *may* be saved
  - If either the old or the new copy is a CPDCSS, the new copy *cannot* be saved.
7. Saved segments are loaded through DIAGNOSE X'64'. You can also use the CMS SEGMENT command or macro, which call DIAGNOSE code X'64'. However, CMS does not support saved segments above 2047 MB. A DCSS that contains pages above 2047 MB can be loaded only through DIAGNOSE code X'64', using a 64-bit subcode.
8. A member saved segment cannot be loaded until at least one of the segment spaces of which it is a member is class A or R.
9. The contents of and storage keys for pages defined as or defaulted to "no data saved" on the DEFSEG command are not saved in the saved segment system data file when the SAVESEG command is processed. When referenced by a user who loads the saved segment, the storage contents and keys are zero. In this case, the page contents must be initialized after the DCSS is loaded.
10. When using the collaborative memory management assist, storage in the page ranges of a DCSS should be in the stable block-usage state at the time of the SAVESEG command. Otherwise, the SAVESEG operation might fail (with message HCP445E), or the contents and the block-usage and block-content states of that storage will be unpredictable when the storage is subsequently loaded into a virtual machine by DIAGNOSE X'64'.
11. The SAVESEG command may not be issued for a saved segment represented by *spacename* in a DEFSEG command (see “DEFSEG” on page 246).
12. The segment space SDF is changed from class S to class A when all members within the segment space have been saved.
13. If you use DEFINE STORAGE CONFIGURATION and define more than one storage extent, SAVESEG will save pages in page ranges that are located in the second and higher storage extents. However, if the pages are in a CP segment that has never been referenced (that is, no data was stored in an entire megabyte included within one of the page ranges defined on the DEFSEG command), the SAVESEG will fail.
 

In addition, you cannot load the saved segment after it is saved until the storage configuration is changed so that the saved segment loads below the start of the second defined storage extent.
14. Processing of a SAVESEG command might be delayed if DIAGNOSE code X'64' is concurrently performing the initial load of a large DCSS.

## Messages

- HCP263E Too many operands were supplied for this command.

- HCP1374I The SAVESEG command was terminated by User *userid*. SEGMENT *name* was purged.

## SAVESYS

```
▶▶ SAVESYS — name ◀◀
```

### Authorization

Privilege Class: E

### Purpose

Use SAVESYS to save a named saved system (NSS) into a previously defined system data file (SDF).

### Operands

#### *name*

is the name of the NSS to be saved. This is the file name of a class S (skeleton) system data file previously defined with the DEFSYS command.

### Usage Notes

1. CP can process only one DEFSYS or SAVESYS command at a time. If CP is already processing a DEFSYS or SAVESYS command, processing of a subsequent DEFSYS or SAVESYS command is delayed. The SAVESYS command writes all page ranges, except those defined as EN or SN, to the associated system data file. The amount of time it takes for the command to complete is directly proportional to the amount of data to be written.
2. Using SAVESYS at off-peak hours on the system will have less impact on users due to I/O contention to the spool DASD.
3. You can interrupt and end a SAVESYS operation before it completes by using the PURGE NSS command. This will not leave a partially-saved system data file on the system. The skeleton system data file will be purged and must be redefined before the NSS can be resaved.
4. After the execution of this command, the system data file is designated class A or class R. Class A indicates that it is in the unrestricted available state, and may be accessed by any user. Class R indicates that the NSS is restricted and the users must have a NAMESAVE statement for the NSS in their directory entries in order to load it.
5. Only one available NSS (Class A or R) with a particular name may exist at a given time. If any Class A or R NSS already exists with the same name as the one being saved, and there are no virtual machine users associated with the NSS, then the old copy of the NSS is purged and the new one is made available.

If there are users associated with the old copy and neither the old copy nor the new copy of the NSS is a CP system service NSS (that is, no page ranges were defined with the SC page descriptor code), the old copy is marked as pending purge, and the new copy is saved. Any users associated with the old copy continue to reference the old (now pending purge) NSS. Subsequent users are associated with the new copy.

If there are users associated with the old copy and either the old copy or the new copy of the NSS **is** a CP system service NSS (that is, one or more page ranges were defined with the SC page descriptor code), the SAVESYS command is not accepted.

If there is a CP NSS with the specified name that is class P pending purge (the PURGE NSS command was used to purge it while there were users associated with it), the same rules apply as described in [“5” on page 1397](#):

- If neither the old copy nor the new copy is a system service NSS, the new copy *may* be saved

- If either the old or the new copy is a CP system service NSS, the new copy *cannot* be saved.
6. If a skeleton system data file exists for an NSS with the specified system name, the data is saved into it. If no skeleton NSS file exists, but there is a DCSS skeleton file with the same name, the data and storage keys (but not the virtual machine environment) are saved into the DCSS skeleton file, exactly as if the SAVESEG command had been issued.
  7. The contents of and storage keys for pages defined as or defaulted to "no data saved" on the DEFSYS command are not saved in the NSS system data file when the SAVESYS command is processed. When referenced by a user who IPLs the NSS, the storage contents and keys are zero. In this case, the page contents must be initialized after the NSS is IPLed.
  8. When using the collaborative memory management assist, storage in the page ranges of an NSS should be in the stable block-usage state at the time of the SAVESYS command. Otherwise, the SAVESYS operation might fail (with message HCP445E), or the contents and the block-usage and block-content states of that storage will be unpredictable when the storage is subsequently loaded into a virtual machine by IPL.
  9. An NSS is loaded through the IPL command.
  10. If the MACHMODE operand was used on the DEFSYS command that defined the NSS, then SAVESYS can be used to save the NSS only when the guest's MACHINE setting is one that was specified by the MACHMODE operand. If the NSS was defined without the MACHMODE operand, then SAVESYS can be used regardless of the guest's MACHINE setting.
  11. When an NSS is defined using a MACHMODE operand with more than one value, the NSS is known as a multimode NSS. The following architectural entities are saved by SAVESYS and restored by IPL of a multimode NSS:
    - Storage and storage keys
    - Program Status Word (PSW)
    - General purpose registers
    - Floating-point registers
    - Floating-point control register
    - Prefix register

Note that the saving and restoring of storage is under control of page-descriptor codes, such as EW and EN, specified on the DEFSYS command. Also, the restored general register contents may be replaced with parameter data specified by the PARM operand on the IPL command. See the description of the PARMREG operand of the DEFSYS command and the PARM operand of the IPL command for more information.

Immediately after the NSS is restored by the IPL command, all other architectural entities not mentioned above, such as timers or other registers, have the initial-CPU-reset values appropriate for the MACHINE setting of the guest in which the NSS was IPLed.

12. When an NSS is defined using a MACHMODE operand with a single value, or without the MACHMODE operand, the NSS is known as a single-mode NSS. The data saved and restored by SAVESYS is the same as that for a multimode NSS, but will also include the following:
  - Timers
  - Access registers
  - Control registers
13. The virtual machine's architecture mode is determined by its MACHINE setting. In some cases, the virtual machine's architecture mode is also determined by the architecture mode when the NSS was saved. The interaction of the MACHINE setting and the architecture mode when the NSS was saved has the following outcomes:

**MACHINE setting: ESA**

**Architecture mode when NSS was saved: ESA/390 or ESA/XC**

If the MACHINE setting is ESA and the NSS was saved while in ESA/390 mode or ESA/XC mode, then the architecture mode is ESA/390.

**Architecture mode when NSS was saved: z/Architecture or z/XC**

If the MACHINE setting is ESA and the NSS was saved while in z/Architecture mode or z/XC mode, then the architecture mode is z/Architecture.

**MACHINE setting: XC****Architecture mode when NSS was saved: ESA/390 or ESA/XC**

If the MACHINE setting is XC and the NSS was saved while in ESA/390 mode or ESA/XC mode, then the architecture mode is ESA/XC.

**Architecture mode when NSS was saved: z/Architecture or z/XC**

If the MACHINE setting is XC and the NSS was saved while in z/Architecture mode or z/XC mode, then the architecture mode is z/XC. However, if the virtual machine's relocation domain excludes z/XC capability, then IPL sets the architecture mode to ESA/XC.

**MACHINE setting: Z**

If the MACHINE setting is Z, then the architecture mode is z/Architecture.

The issuer of the SAVESYS command is responsible for ensuring that the saved program can operate correctly if it is resumed with the saved PSW in any of the architecture modes that are allowed by the MACHMODE option.

14. When CMS is built, the SAVESYS must be done in concert with an IPL. The IPL should be done as follows:

```
IPL cuu PARM SAVESYS
```

See *z/VM: Installation Guide* for information on how to SAVESYS the CMS nucleus.

15. If you use DEFINE STORAGE CONFIGURATION and define more than one storage extent, SAVESYS will save pages in page ranges that are located in the second and higher storage extents. However, if the pages are in a CP segment that has never been referenced (that is, no data was stored in an entire megabyte included within one of the page ranges defined on the DEFSYS command), the SAVESYS will fail.

In addition, you cannot load the NSS after it is saved until the storage configuration is changed so that the NSS loads below the start of the second defined storage extent.

16. Processing of a SAVESYS command might be delayed if DIAGNOSE code X'64' is concurrently performing the initial load of a large DCSS.
17. The SAVESYS command does not save vector registers.

**Messages**

- HCP263E Too many operands were supplied for this command.
- HCP300E Save request beyond virtual machine size
- HCP427E *type* {*rdev*/*vdev*/*name*[*userid*]} system spool space full; file {closed|held|purged}
- HCP435E SAVESYS command was not completed because a paging I/O error occurred while writing a page.
- HCP439E {User *userid*|\*NSS|\*IMG|\*UCR|\*NLS} spool fileid limit exceeded
- HCP440I Named Saved System (NSS) *name* was successfully saved in fileid *fileid*.
- HCP445E The Named Saved System (NSS) *name* could not be saved due to an unexpected error.
- HCP446E The Named Saved System (NSS) *name* was not previously defined and cannot be saved.
- HCP448E System *name* not quiesced. Outstanding I/O on device *rdev*.
- HCP448E System *name* was not quiesced due to an outstanding external interrupt.
- HCP1001E An operand is missing for *option*.
- HCP1013E An invalid operand was supplied for *option* - *operand*.
- HCP1350E The saved segment *name* cannot be saved because MP users cannot save a Named Saved System (NSS).

## SAVESYS

- HCP1359E [CP] Named Saved System (NSS) *name* cannot be saved because a [CP] copy is already {active| waiting to be purged}.
- HCP1365E *name1 spoolid* has an entry for *name2* which was not found, [purge *name1*| purge *name1* or define *name3*|*name1* purged].
- HCP1368E Named Saved System (NSS) *name* can not be saved when running in {an ESA|an XC|a Z} virtual machine.
- HCP1374I The SAVESYS command was terminated by User *userid*. SYSTEM *name* was purged.

## SCHEDULE

### Authorization

Privilege Class: A

### Purpose

Use SCHEDULE to assign a user to an already defined resource pool or to remove a user from the resource pool to which the user is currently assigned.

### Operands

*userid*

\*

identifies the user assigned to or removed from a resource pool. If an asterisk (\*) is specified, the user is the user ID issuing the command. The specified user ID must be logged on or disconnected when the SCHEDULE command is issued.

*poolname*

**POOL** *poolname*

**WITHIN** *poolname*

**WITHIN POOL** *poolname*

specifies the resource pool to which the user is assigned. The resource pool must be already defined on the z/VM system and the type of CPU being limited in that resource pool must match the user's primary CPU type. If the specified user is already assigned to another resource pool, the user is removed from the current resource pool and moved to the new resource pool. The CPU resource the user consumed prior to the move is charged against the old pool; future consumption will be charged against the new resource pool, and the user will be subject to the resource limits defined that pool. If the user is unable to move to the new resource pool for any reason, the user remains in the current pool. For information on defining resource pools, see [“DEFINE RESPOOL” on page 205](#)).

**NOPOOL**

specifies that the user is to be removed from whatever resource pool the user is in. After the user is removed from the resource pool, the user will no longer be subjected to pool limits. The remaining users in the resource pool can consume more resources, as there are fewer members in the limited group while the resource pool limit applied to them remains constant.

### Usage Notes

1. When adding a user to a resource pool via the SCHEDULE command, the user's primary virtual CPU type must match the group's virtual CPU type, and CPU affinity must be on for the user. Based on whether there is an IFL processor online for that system, z/VM will run this user ID (and the resource pool to which the user has been added) with CPU affinity set on or suppressed. You are allowed to add an all-IFL user to an IFL virtual CPU type group when there is no IFL processor on that system.
2. After a user is assigned to a resource pool, you cannot issue the SET CPUAFFINITY OFF command for that user, and CPU affinity is suppressed only when that user is running with a virtual IFL on a system where there are no IFL processors online.

## SCHEDULE

3. After a user is assigned to a resource pool, you cannot issue a DEFINE CPU command that would change the user's primary virtual CPU, because the user's primary virtual CPU type must continue to match the group's virtual CPU type.
4. Only a logged on or disconnected user can be assigned to a resource pool. Issuing the SCHEDULE command for a logged on or disconnected user assigns the user to the resource pool immediately, and the assignment remains in effect until another SCHEDULE command is issued for that user, or the user logs off. This allows an administrator to assign a user to a resource pool temporarily.

If a permanent assignment of a user to a resource pool is desired, the SCHEDULE command for the assignment can be placed in the user's directory entry using the COMMAND directory statement. If no other SCHEDULE command is issued, the user will remain in that resource pool until the user logs off. The SCHEDULE command can be placed anywhere where the COMMAND directory statement is allowed, including the directory profile for pooled users, where \* should be specified for the user ID to put the logging on user into the resource pool.

To have an assignment take effect immediately and be permanent, both of these steps must be done.

5. When setting up permanent resource pools and the assignment of users, the order of the commands is very important. To save CPU time at logon, it is recommended that only one SCHEDULE command be included in a user's directory entry. If the directory entry contains multiple SCHEDULE commands, they will all be processed in the listed order, with the user assigned to the resource pool specified on the last SCHEDULE command. The DEFINE RESPOOL command must be issued to create the resource pool before the SCHEDULE command is issued. Any DEFINE CPU or SET CPUAFFINITY commands in the user's directory entry must be executed before the SCHEDULE command in the directory entry, because they are restricted after the SCHEDULE command is executed. Because the defaults are SET CPUAFFINITY ON and SET SRM LIMITHARD CONSUMPTION, resource pooling does not require a lot of setup commands to be issued via the directory.
6. Any individual CPU limits on the user as defined by the SET SHARE command remain in effect. If a user with an individual CPU limit is assigned to a resource pool, both limits will be checked each time the user's CPU use is evaluated, and the more restrictive limit will be applied.
7. Share settings control access to CPU power on a system-wide, per-processor-type basis, but they have no bearing or influence on how the power associated with a RESPOOL is distributed to its members. When the RESPOOL limit is reached, all members of the pool are put onto the limit list for a while, and then, after a delay sufficient to compensate for any excess use, they are all removed. The scheduler makes no effort to distribute the power of the RESPOOL to its members in accordance with the members' share settings.
8. A user assigned to a resource pool can be relocated only to another member of an SSI cluster that contains a resource pool with the same name and the same type of virtual CPU being limited. All users in the resource pool need to use the same underlying CPU resource for resource pooling to work, which is why all users assigned to a resource pool must have CPU affinity on and can relocate only to a resource pool with the same virtual CPU type as the current resource pool. Based on the availability of IFL CPUs on the destination system, z/VM will toggle the relocated user between CPU affinity on and CPU affinity suppressed, as necessary. Because the scope of a resource pool is a single z/VM system, the relocation will essentially remove the user from the resource pool on the source system and assign the user to the resource pool on the destination system. When a VMRELOCATE TEST or MOVE command is issued against a user ID, the SCHEDULE command cannot be issued to move the user to a new resource pool until the VMRELOCATE command processing has ended.

## Responses

Response 1:

```
User userid has been added to resource pool poolname
```

confirms that the user who was not in a resource pool has been added to the pool as requested.

Response 2:

```
User userid has been removed from resource pool poolname
```

confirms that the user has been removed from the resource pool as requested and will now be scheduled as an individual user only.

Response 3:

```
User userid has been removed from resource pool poolname
User userid has been added to resource pool poolname
```

confirms that the user who was already in a resource pool has been moved to a new resource pool as requested. Two responses are issued to indicate that the user was removed from one resource pool and added to another resource pool. However, this action occurs as a single step, and there is no point in time when the user is not in any resource pool.

Response 4:

```
User userid is already in resource pool poolname
```

indicates that the user is assigned to the resource pool as requested. The user was not added to or removed from any resource pool because the user was already in a resource pool before the SCHEDULE command was issued.

Response 5:

```
User userid is not in a resource pool
```

indicates that the user is not assigned to the resource pool as requested and was not in any resource pool when the SCHEDULE command was issued.

## Messages

- HCP002E Invalid operand — *operand*
- HCP003E Invalid option — command contains extra option(s) starting with *option*
- HCP007E Invalid userid — *userid*
- HCP045E *userid* not logged on
- HCP1001E An operand is missing for USER
- HCP1001E An operand is missing for POOL
- HCP3151E Resource pool *poolname* does not exist
- HCP3153E User *userid* is not eligible for resource pool *poolname*
- HCP3156E Resource pool assignment cannot be changed for user *userid* while relocating
- HCP3157E User *userid* must have CPU Affinity ON to be put into a resource pool
- HCP6704E Missing token at end of line

## SCREEN

### Authorization

Privilege Class: G

### Purpose

Use SCREEN to change:

- Screen color definition
- Screen highlight definition.

The initial settings are the default colors green and white.

### Operands

#### *area*

specifies the area of the screen. The area can be:

<b>Area</b>	<b>Meaning</b>
ALL	The entire screen. If you specify this operand, you cannot specify any other area on the same command.
INArea	The input area
STAtarea	The system status area
OUTarea	The output area. If you specify OUTAREA, you cannot specify CPOUT, VMOUT, or INREDISP on the same command line.
CPOut	Output from the CP. You may not specify CPOUT on the same command as OUTAREA.
VMOut	Output from CMS or the virtual machine operating system running in your virtual machine. You may not specify VMOUT on the same command line as OUTAREA.
INRedisp	Your input redisplay. You may not specify INREDISP on the same command line as OUTAREA.

#### *extcolor*

#### **DEFAult**

specifies the color you want to assign to an area of your screen. The choice of colors are:

- BLUe
- TURquois
- RED
- PINK
- GREen
- WHIte
- YELlow
- DEFault (green and white)

***exthilight*****NONE**

specifies the extended highlight value you want to assign to an area of your screen. The *exthilight* value can be:

<b><u>Value</u></b>	<b><u>Meaning</u></b>
BLInk	Blinking
REVvideo	Reverse video
UNDerlin	Underlining
NONE	No extended highlighting

**Usage Notes**

1. If you enter the SCREEN command from a display that does not support extended color or extended highlighting, CP still sets the values you specify for the virtual machine console. If you disconnect from that display and logon at a display that does support extended color or extended highlighting, the values you set are in effect for your virtual machine after the reconnection. These values remain in effect for the duration of the current session unless you alter them with another SCREEN command.
2. You cannot specify a particular *area* operand more than once on the same SCREEN command line.
3. Since the command is not device dependent, you may enter the SCREEN command from any IBM-supported terminal or from a PROFILE EXEC. However, the terminal controller must have the extended color feature installed for the SCREEN command to have an effect on your display.
4. If you enter the SCREEN command for a particular area and you specify only the *extcolor* or default option, the *exthilight* remains unchanged from its previous setting. Likewise, if only the *exthilight* or NONE option is specified, the *extcolor* remains unchanged from its previous setting.
5. If CPOUT uses the default color, then incoming MSGs, WNGs, and MSGNOHs will be displayed in white. If you change the CPOUT color, then incoming MSGs, WNGs, and MSGNOHs are displayed in the CPOUT color you specified.

**Examples**

If you enter

```
screen outarea red none inarea blink green statarea pink underlin
```

CP sets the following values for your terminal:

<b>Area specified</b>	<b>Area affected</b>	<b>Color</b>	<b>Exthilight</b>
outarea	cpout	red	none
	vmout	red	none
	inredisp	red	none
inarea	inarea	green	blinking

## SCREEN

Area specified	Area affected	Color	Exthighlight
statarea	statarea	pink	underlining

### Responses

Response 1:

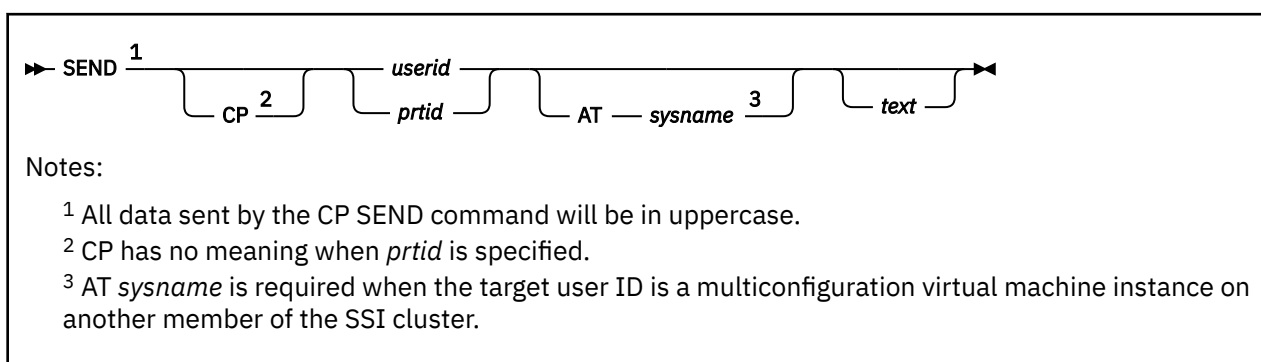

```
Command complete
```

is issued when the command completes successfully.

### Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid

## SEND

### Authorization

Privilege Class: C, G

### Purpose

Use SEND to send console input to a virtual machine. As a Class G user, you can send input to a disconnected virtual machine for which you provide secondary console services. As a Class C user, you can send input to any virtual machine. You may enter the following:

- CP commands
- Virtual machine commands
- Responses to virtual machine or CP messages
- Other virtual machine data, as required.

### Operands

#### CP

indicates that CP should process the input text on behalf of the receiving virtual machine. If the first four characters of the text you want to send are your logical escape character, the receiver's logical line end character, and CP, then you need not specify the CP operand to send a CP command. The same holds true if the receiver's virtual machine is already in CP READ. If you specify the CP operand with no text, the receiving virtual machine is placed in console function mode, just as if a #CP command were entered.

#### *userid*

identifies the virtual machine that is to receive the console input.

#### *prtId*

indicates that the command is to be passed for processing to the print server virtual machine designated by *prtId*. The print server virtual machine that receives and processes the SEND command also provides *prtId*. The operand *prtId* is one to eight alphanumeric characters. If you specify four or fewer characters for the *prtId*, *prtId* cannot contain all hexadecimal characters, because CP then interprets *prtId* as *rdev*.

#### AT

indicates that the target user ID is on another member of the SSI cluster. AT *sysname* is required if the target user ID is a multiconfiguration virtual machine instance on another member of the SSI cluster.

#### *sysname*

is the system name of an active member in the SSI cluster.

## SEND

### *text*

is the data that is passed to the disconnected virtual machine as console input. Mixed DBCS data may be used as input text.

## Usage Notes

1. Use a **send cp userid** command (without *text*) to force a CP READ when no CP READ exists.
2. If you are a secondary user, you might receive one of the following messages from the primary user:

```
HCP150A User userid has issued a CP read
HCP150A User userid has issued a VM read
HCP150A User userid has issued a CP or VM read.
```

To reply to the message, issue one of the following SEND commands:

```
send userid text
send cp userid text
```

Whether you need to specify the CP operand on the SEND command depends on the following principles:

- If there is no CP read or VM read pending on the primary user's console, then SEND (without CP) will be posted as unsolicited input to either CP or the virtual machine, based on the TERM MODE setting. This is analogous to typing input when the screen shows RUNNING status.
- If there is a CP read pending on the primary user's console, then SEND (without CP) will satisfy that CP read. This is analogous to typing input when the screen shows CP READ status.
- If there is a VM read pending but no CP read pending on the primary user's console, then SEND (without CP) will satisfy that VM read. (A CP read supersedes a VM read.) This is analogous to typing input when the screen shows VM READ status.
- SEND CP always either satisfies a CP read, if one is pending, or is presented as an unsolicited CP command. This is analogous to typing input prefixed with #CP.

The different cases are shown in [Table 33 on page 1408](#).

<b>CP Read Pending</b>	<b>VM Read Pending</b>	<b>TERM MODE</b>	<b>Effect of SEND <i>userid text</i></b>	<b>Effect of SEND CP <i>userid text</i></b>
No	No	VM	input goes to virtual machine	input goes to CP
No	No	CP	input goes to CP	input goes to CP
No	Yes	VM	input satisfies VM read	input goes to CP
No	Yes	CP	input satisfies VM read	input goes to CP
Yes	No	VM	input satisfies CP read	input satisfies CP read
Yes	No	CP	input satisfies CP read	input satisfies CP read
Yes	Yes	VM	input satisfies CP read	input satisfies CP read
Yes	Yes	CP	input satisfies CP read	input satisfies CP read

**Notes:**

- a. "input goes to CP" means the input is treated as unsolicited input and therefore is treated the same as a #CP command typed at the console.
- b. "input goes to virtual machine" means the input is treated as unsolicited input; it causes an attention interruption on the virtual console, and is supplied as the response to the line mode read which the guest is expected to post in response to that interruption.

3. If you are a Class G user, then:
  - a. The receiving virtual machine must be disconnected at the time you enter the SEND command.
  - b. You must be authorized as the secondary user on the CONSOLE statement in the directory entry of the receiving virtual machine or authorized as a result of the receiving virtual machine's use of the CP SET SECUSER command.
  - c. The secondary user must not be disconnected when the SEND command is issued, unless the secondary user has a valid path to the \*MSG or \*MSGALL system service.
4. If you are not the receiving virtual machine's secondary user, you do not receive responses to the commands you send it.
5. If both a CP read and a VM read are pending, the CP read is satisfied first, regardless of the order in which they were posted.
6. If you want to send multiple lines of input on a single SEND command, use the receiver's logical-line-end character preceded by your logical-escape character to separate the lines. The receiving virtual machine must also have line editing enabled. This restriction applies to when you SEND a #CP command as well.

If any of your logical-line-editing characters are part of the text to be sent to the disconnected virtual machine, they must be preceded by your logical-escape character.

7. For *prtId*, the virtual machine associated with the *prtId* processes the specified text. Therefore, the text on the SEND command must be valid for the virtual machine that is doing the processing.
8. You cannot use the class C version of this command if an external security manager is installed on your system and security label checking is enabled. For additional information, contact your security administrator.
9. Within a single system, the FOR command is an alternative to the SEND command. The FOR command is used to issue CP commands to other virtual machines and provides responses and return codes to the issuer. The responses can be directed to the console or handled by an IUCV connection to the Asynchronous CP Command Response (\*ASYNCMD) system service. The target virtual machine does not see the command or command responses. See the description of [“FOR” on page 501](#) for further details.
10. If you are using the SEND command to send an AT command, you can preface the AT command with CP to avoid confusion with the SEND command AT operand.
11. In an SSI cluster, the secondary user and primary user can be logged on to different member systems.

If either user is a multiconfiguration virtual machine:

- The secondary user will function in that capacity only when it is local (logged on to the same member as the primary user). If the primary user is a multiconfiguration virtual machine, the secondary user must be logged on to the same member as the instance of the primary user for which the secondary user setting was established:
  - If the setting was established by a CONSOLE statement in the identity entry in the primary user's virtual machine definition, a potential secondary user relationship exists for every member instance of the primary user.
  - If the setting was established by a CONSOLE statement in a subconfiguration entry in the primary user's virtual machine definition, a potential secondary user relationship exists for that member instance of the primary user.
  - If the setting was established by a SET SECUSER command, a potential secondary user relationship exists for the member on which the SET SECUSER command was issued.
- If the secondary user is remote:
  - The secondary user can issue SEND commands to the primary user. The AT *sysname* operands are required if the primary user is a multiconfiguration virtual machine instance.
  - The secondary user will not receive responses to SEND commands or any other output from the primary user.

## SEND

### Examples

1. Enter **send cp user1** to place the disconnected user, USER1, into console function read.
2. Enter **send user3 msg user2 hi** to cause USER2 to receive the message *hh:mm:ss: \*MSG FROM USER3 HI*.
3. If the secondary user receives the message *USER5 CHANGE TOD CLOCK (YES|NO)* and responds by entering **send user5 yes**, the receiving virtual machine accepts this input as if it were entered from the receiver's own terminal.
4. To send information to a specific printer virtual machine, enter **send prtId query prtname options**.

#### **prtId**

identifies the printer.

#### **QUERY prtname options**

identifies the text.

### Messages

- HCP020E Userid missing or invalid
- HCP045E *userid* not logged on
- HCP068E SEND command failed; *text*
- HCP1149E Error communicating with another SSI member. It cannot be determined if *command* executed remotely.
- HCP2970E The SSI cluster member name is missing or invalid.
- HCP2971I Specified SSI cluster member is not joined.

# SET

---

## Purpose

Use the SET command to control various functions associated with your virtual machine or with the z/VM system.

## Usage Notes

1. Use the QUERY SET command to determine the current settings of all the following functions:

ACNT*	NOPDATA
AFFINITY*	NOTRAN*
ASSIST*	PAGEX
AUTOPOLL	RUN
CCWTRAN*	SMSG
CONCEAL	STBYPASS*
CPCONIO	STMULTI*
DIALDROP	SVCACCL*
ECMODE*	SVC76
EMSG	TIMEBOMB
IMSG	TIMER
ISAM*	VMCONIO
LINEDIT	VMSAVE*
MACHINE	WNG
MIH	370ACCOM
MSG	370E*

\* For compatibility purposes only – you cannot use the SET command to change these values, as they are either fixed or no longer valid.

2. SET ECMODE ON is supported for compatibility only. If any option other than ON is specified, the message 'INVALID OPTION' is issued.
3. Use the QUERY command with the appropriate operand to determine the setting of each of the following functions:

## SET ABEND

### Authorization

Privilege Class: B

### Purpose

Use SET ABEND to force soft errors to cause system termination with hard abend format dump, full system snapdumps, or to prevent soft abend dumps from being generated.

### Operands

#### HARD

specifies that any soft abend causes full system termination with a dump and then attempts to restart the system.

#### HARD *aaannn*

specifies the soft abend with abend code *aaannn*, where *aaa* is the three character module identifier and *nnn* is the three character abend code number, causes full system termination, but other soft abends continue to be processed normally.

#### OFF

specifies that any soft abend will not generate a soft abend dump. A symptom record will be created to provide a record of the abend.

#### OFF *aaannn*

specifies the soft abend with abend code *aaannn* will not generate a soft abend dump. A symptom record will be created to provide a record of the abend.

#### SNAPDUMP

specifies that any soft abend causes a full system snapdump.

#### SNAPDUMP *aaannn*

specifies the soft abend with abend code *aaannn* causes a full system snapdump, but other soft abends continue to be processed normally.

#### SOFT

cancels all previous specifications of HARD, HARD *aaannn*, OFF, OFF *aaannn*, SNAPDUMP and SNAPDUMP *aaannn*. All soft abends operate normally as established during system initialization.

#### SOFT *aaannn*

specifies the soft abend with abend code *aaannn* will generate a soft abend. This effectively cancels any previous specification of HARD *aaannn*, OFF *aaannn*, or SNAPDUMP *aaannn*. Also, SOFT *aaannn* will override any global HARD, OFF or SNAPDUMP specification for the soft abend with abend code *aaannn*.

### Usage Notes

1. If any invalid abend code (operand does not have *aaannn* format) is encountered when a specific abend code is specified with any SET ABEND operand, no soft abend settings are changed.
2. You can specify up to 20 unique soft abend codes with one or more invocations of the SET ABEND command.

## SET ABEND

3. The abend codes (*aaannn*) are inspected for format validity. The *aaa* piece consists of three characters that can be any combination uppercase letters A-Z, lowercase letters a-z, or numbers 1-9. The *nnn* piece is a three digit decimal number from 000 to 255. The abend code is not inspected to determine whether it corresponds to a soft abend that is actually present in the system.

Code that is running as part of CP requests abends by using the HCPABEND macro. If the part containing the HCPABEND macro does not start with 'HCP' then the name of the module is stored in lowercase in the HCPABEND macro expansion. When a dump is created, the first three characters of the abend code is in lowercase. This is done because it allows support personnel to quickly identify abends that are not generated from a standard IBM CP nucleus part. This lowercase letter convention affects code that is added to CP via the CPXLOAD command or by using an alternate MDLAT macro and the VMSES/E command GENCPBLS. By using upper or lowercase letters with abend codes specified on SET ABEND, HCP and non-HCP abends can be handled differently.

An abend code containing lowercase characters can be specified on the SET ABEND command that is passed to CP using the DIAGNOSE X'08' programming interface. This could be done in a REXX EXEC or an assembler program. Also, a lowercase abend code can be passed using "Address Command" in a REXX EXEC. However, the simplest way is to use CMS Pipelines. A pipe command like the following could be passed to CMS to invoke a CP command.

```
PIPE CP SET ABEND HARD bcd001 efg002 | console
```

Note that the "SET ABEND HARD" part of the command must be specified in uppercase so that it passes tests in the CP parsing code. Specify abend code(s) in upper or lowercase, as necessary.

4. There may be some unique circumstances which will prevent a dump from being created despite having the ABEND set to SNAPDUMP. This will only occur if SNAPDUMP cannot get the resource which guarantees that no other processor in the configuration will force the abending processor offline. If a dump was to be taken at this time, its contents would not accurately reflect the abending environment.
5. When SET ABEND is issued for HARD, OFF, or SNAPDUMP, the soft abend dump spool file is automatically closed. This is a class D spool file that is normally opened during system initialization and is owned by the user ID specified with the DUMP operand on the SYSTEM\_USERIDS configuration statement. It has a file type of "HCPDUMP". Once closed, it can be reopened by issuing SET ABEND SOFT or SET ABEND SOFT *aaannn*.

### Examples

Specific invocations are cumulative. For example:

```
SET ABEND HARD ABC001 BCD002
```

Will add soft abends ABC001 and BCD002 to the abend table, indicating that they should cause a hard abend if hit.

```
SET ABEND SNAP BCD002 CDE003 DEF004
```

The abend table will now have 1 soft abend set to hard (ABC001), and 3 soft abends set to snapdump (BCD002, CDE003 and DEF004).

```
SET ABEND SOFT CDE003
```

Will reset soft abend CDE003 from generating a snapdump abend back to a soft abend. The other abends are not affected.

Global invocations (no specific abend specified) reset all previously set specific abends. For example (assuming the preceding invocations are still in effect), suppose the following command is entered:

```
SET ABEND OFF
```

The preceding soft abends that have been set to hard, soft, and snapdump, along with all of the remaining soft abends, will not generate a dump.

## Messages

- HCP002E Invalid operand - *operand*

## SET ACCOUNT

---

```
► Set — ACCount — nnnnnnnn ◄
```

### Authorization

Privilege Class: G

### Purpose

Use SET ACCOUNT to change the current session account number.

### Operands

**nnnnnnnn**

is the 1- to 8-character account number that replaces the current session account number.

### Usage Notes

1. The account number you specify on the command line must be the same as one contained in your entry in the system directory.
2. If the account number you specify is valid, an accounting record is created for your session under the current accounting number.

### Messages

- HCP026E Operand missing or invalid
- HCP266E An account number was not supplied or is invalid.
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]

## SET ADJUNCTS

### Authorization

Privilege Class: A

### Purpose

The adjunct support for a system can be enabled or disabled with this command. It allows dynamic alteration of the setting established at system initialization or by the FEATURE ENABLE ADJUNCTS or FEATURE DISABLE ADJUNCTS statement in the system configuration file. If no such FEATURE statement exists, the support is enabled by default.

### Operands

#### ON

Enable adjunct support.

#### OFF

Disable the ability for users to create adjunct configurations via the ADJUNCT START command. If an adjunct configuration already exists when this command is issued, it can continue to operate; all ADJUNCT command options except START will be accepted until the adjunct is ended.

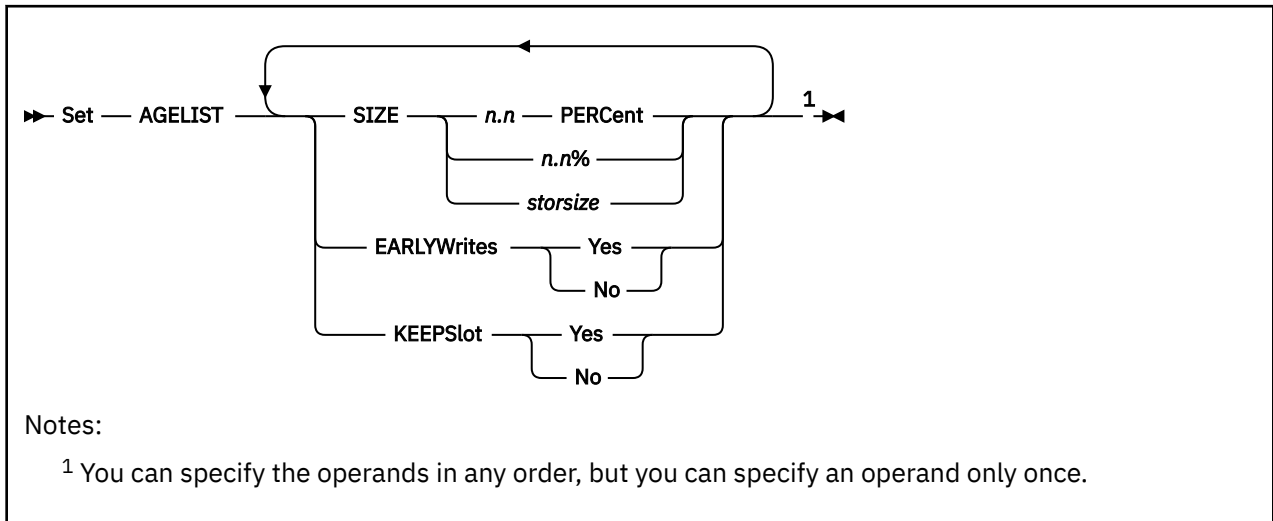

### Usage Notes

1. See the ADJUNCT directory statement in *z/VM: CP Planning and Administration* for more information on configuring an adjunct.
2. For a user to create an adjunct, ADJUNCTS must be set ON, and an ADJUNCT statement must exist in the user's directory entry (for example, ADJUNCT CMSADJ).

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid

## SET AGELIST

### Authorization

Privilege Class: A

### Purpose

Use SET AGELIST to modify the target size of the global aging list used by the system's frame replenishment algorithm and to tailor the algorithm's behavior in managing guest pages on auxiliary storage.

To satisfy the system's need for real storage, the frame replenishment algorithm selects candidate frames from the user and system frame-owned lists. The pages associated with the selected frames are put in the invalid-but-resident (IBR) state. Any access to a page in the IBR state by the guest results in a re-validation. Otherwise, after a period of aging on the local frame-owned list, the frame associated with an IBR page is added to the global aging list.

If a page is referenced while its frame is on the aging list, the page is re-validated and the frame moves back to the appropriate frame-owned list. Before a frame can be reclaimed from the aging list, the page content must be backed in auxiliary storage.

The target size of the aging list is a guideline to CP. The actual amount of storage in the global aging list at any point in time may differ significantly below the target amount, and at times may rise above the value.

### Operands

#### SIZE

is the target size of the global aging list used by the frame replenishment algorithm, specified as an amount of storage in one of the following formats.

#### *n.n* PERCent

#### *n.n%*

is the target size of the global aging list used by the frame replenishment algorithm, specified as a percentage of the current size of the dynamic paging area (DPA). The size of the DPA varies over time and it includes available frames and those that contain pageable content. When a percent value is specified, the system recalculates the target storage size periodically to adjust to the changing size of the DPA. The computed value is rounded up to the next megabyte boundary.

The decimal percentage can have at most one decimal place, and be in the range of .1 through the maximum allowed percentage of 5%. Regardless of the size of the configuration, CP never sets a target size smaller than 1M.

### **storsize**

The format of the storage size is *nu* where *n* is a 1-7 digit decimal number greater than 0 and *u* is the 1-character storage unit suffix (M,G,T,P,E). The specified storage size may not exceed 5% of the current size of the dynamic paging area.

### **EARLYWrites**

when Yes, the frame replenishment algorithm backs up page content to auxiliary storage in advance of frame reclaim to maintain a pool of readily reclaimable frames. When No is specified, pages are backed up only when the system is in need of frames.

### **KEEPSlot**

when Yes is specified, the auxiliary storage address (ASA) to which a page is written during frame replenishment will remain allocated to that page when it is read into real memory upon access by the guest. Preserving a copy of a page on auxiliary storage eliminates the need to rewrite the contents if the page is unchanged prior to the next steal operation. However, it could result in more fragmentation on the device over time.

When No is specified, the ASA for the page is unallocated during page fault processing. Releasing a paging ASA makes it available for reallocation and reduces the size of the auxiliary storage footprint.

## **Usage Notes**

1. It is suggested that the STORAGE AGELIST statement in the system configuration file be used to set the size of the aging list and the behavior of the frame replenishment algorithm to make sure the values are in effect during IPL. Any changes made to these settings after IPL using the SET AGELIST command will occur gradually. See the [STORAGE Statement in z/VM: CP Planning and Administration](#), for more information about the configuration statement and applicable defaults.
2. It is preferable to specify the target size of the aging list as a percentage of the DPA rather than a fixed amount. This allows CP to periodically adjust the size in response to system behavior.
3. If you increase the amount of real storage available to z/VM using the SET STORAGE command, you may also want to consider adjusting the target size of the aging list, especially when you have defined the size as a fixed amount.
4. Because specification of the aging list target size as a percentage of the DPA is rounded up to the next megabyte boundary, the resulting calculation may exceed the maximum value allowed as a fixed-size specification.
5. See QUERY AGELIST in *z/VM: CP Commands and Utilities Reference* for guidelines to determine an appropriate aging list size for your storage configuration and workload.
6. When the SET AGELIST command is used after IPL to change KEEPSlot from Yes to No, the auxiliary storage locations associated with any pages that are currently resident are not released. The new setting applies only to future reads from auxiliary storage. For this reason, it is recommended that you use the STORAGE AGELIST statement in the system configuration file to set KEEPSlot to No, rather than doing this after IPL using the SET AGELIST command.

To further eliminate copies of resident pages on auxiliary storage, you might want to also set EARLYWrites to No. However, doing so could reduce performance on a storage-constrained system because frame replenishment will not have a readily-available pool of frames to reclaim.

7. When a SET STORAGE command is issued to decrease the size of the storage configuration, a fixed AGELIST size will be reduced, if necessary, to equal the maximum allowed size of 5% of the dynamic paging area (DPA) size. If an adjustment is made, message HCP2597I is issued to the system operator. There is no automatic increase in the fixed AGELIST size when a SET STORAGE command is used to add storage to the configuration. If you want the AGELIST size to vary based on the size of the storage configuration, set the AGELIST size to be a percentage of the DPA size.

## Responses

```

Target size      = nU (mU) x.x% of pageable storage
In use          = nU
Pending writes  = nU
Early writes    = Yes|No
Sizing         = Fixed|Variable
Keep slot      = Yes|No

```

where:

### Target size *nU*

identifies the maximum expected amount of pageable storage to be contained in the global aging list. The target size is displayed in a storage unit (K,M,G,T,P,E) suitable to represent the values displayed in the remaining lines of the command response.

### (*mU*)

the target size in a storage unit with a precision of no more than 7 significant digits. This value may be rounded if the aging list size is defined as a percentage of pageable storage. When the aging list is empty this value is omitted.

### *x.x%* of pageable storage

identifies the target size as a percentage of pageable storage. The value may be rounded to the nearest tenth of a percent if the aging list size is defined as a fixed storage size.

### In use *nU*

identifies the amount of storage currently within the global aging list in storage units (K,M,G,T,P,E). Usage of the aging list is at the discretion of CP based on storage constraints. The amount of storage currently within the aging list may be significantly less than the target size, or in some cases slightly higher.

### Pending writes *nU*

identifies the portion of the global aging list in storage units (K,M,G,T,P,E), that must be backed up in auxiliary before the associated frames can be reclaimed.

### Early writes = Yes

indicates the frame replenishment algorithm backs up page content to auxiliary storage in advance of frame reclaim to maintain a pool of immediately reclaimable frames.

### Early writes = No

indicates the frame replenishment algorithm backs up page content to auxiliary storage only when the system is in need of frames.

### Sizing = Fixed

indicates the size of the aging list was specified on the SET AGELIST command as a fixed storage size.

### Sizing = Variable

indicates the size of the aging list was specified on the SET AGELIST command as a percentage of pageable storage. Since the number of real frames containing pageable content varies over time, so will the size of the aging list.

### Keep slot = Yes

indicates the auxiliary storage address (ASA) to which a page is written during frame replenishment will remain allocated to that page when it is read into real memory upon access by the guest.

### Keep slot = No

indicates the ASA to which a page is written during frame replenishment is unallocated during page fault processing.

## Messages

- HCP003E Invalid option - *option*|command contains extra option(s) starting with *option*
- HCP6704E Missing token at end of line

## SET AUTOPOLL

### Authorization

Privilege Class: G

### Purpose

Use SET AUTOPOLL to control how CP detects changes to virtual autopolling channel programs:

- The system itself tests for the change
- Your virtual machine notifies the system of the change.

**Note:** In general, the guest operating system issues the notifying command without your intervention.

### Operands

**ON**

**OFF**

controls whether CP tests for changes to virtual autopolling channel programs. ON indicates that your virtual machine must notify CP when a change is made to a virtual autopolling channel program. OFF indicates that CP tests for changes to virtual autopolling channel programs.

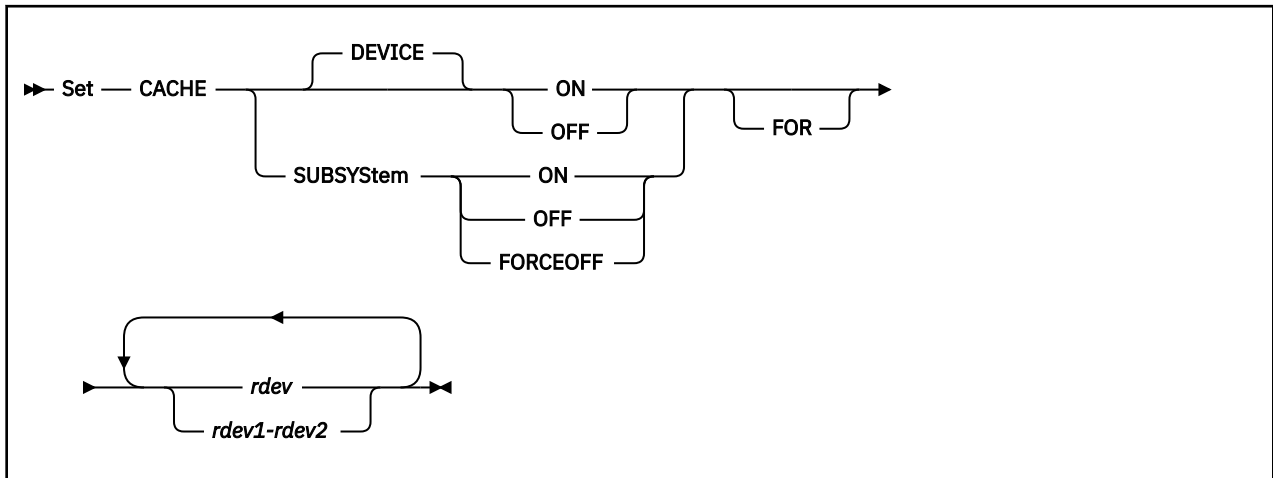

### Usage Notes

1. Do not enter this command arbitrarily. If you enter the command while a guest operating system is running, you may cause the system to stop or to end abnormally.
2. If SET AUTOPOLL ON is required for your virtual machine, the operating system running in your virtual machine is using DIAGNOSE X'28' to notify the system whenever a virtual autopolling channel program has been modified.
3. SET AUTOPOLL OFF is required if the operating system running in your virtual machine does NOT use the DIAGNOSE X'28' interface.

### Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid
- HCP263E Too many operands were supplied for this command.

## SET CACHE

### Authorization

Privilege Class: B

### Purpose

Use SET CACHE to activate or deactivate the cache function by device or by subsystem. The subsystems are IBM DASD subsystems.

### Operands

#### DEVICE ON

indicates that caching is to be activated for the specified devices. DEVICE is the default.

#### DEVICE OFF

indicates that caching is to be deactivated for the specified devices. Any user to whom the device was attached bypasses the cache.

#### SUBSYStem ON

indicates that caching is to be made available for the entire subsystem to which the device is attached.

#### SUBSYStem OFF

indicates that caching is to be made unavailable for the entire subsystem to which the device is attached.

#### SUBSYStem FORCEOFF

indicates that the cache is to be forced to be unavailable to subsystems to which the devices are attached.

*rdev*

*rdev1-rdev2*

is the real device number, a list of real device numbers, or a range of real device numbers of devices in the subsystem.

### Usage Notes

1. All SET CACHE operands are nonpositional except that if FOR is specified, it must precede the device list.
2. Device caching and subsystem cache availability are both required for the caching function to be used, but they are controlled independently. Caching can be turned on for a device, but unless the

subsystem cache is available, caching does not occur. The subsystem remembers the caching state of each device even when the subsystem cache is not available.

3. The caching function is always enabled on RAID (Redundant Array of Independent Disks) technology DASD such as an IBM DASD subsystem. For these types of DASD, the device accepts but ignores this command; the caching function cannot be modified by the user. The caching function for these types will always appear as ON in related query commands.
4. Error message HCP296E appears if the subsystem is not in the correct mode to accept the QUERY CACHE command.
5. SET CACHE SUBSYSTEM FORCEOFF is a recovery command. It can be issued only after a SET CACHE SUBSYSTEM OFF has been issued and the subsystem could not make the cache unavailable because of internal errors.
6. If SET CACHE SUBSYSTEM FORCEOFF is issued, the subsystem causes all current channel programs operating on caching devices to fail.
7. SET CACHE SUBSYSTEM OFF and SET CACHE SUBSYSTEM FORCEOFF halt, but do not end, Concurrent Copy (CONCOPY) sessions on the subsystem. Because the CONCOPY function requires that caching be available for the subsystem, applications that had active CONCOPY sessions on the subsystem must end and then restart the CONCOPY function after a SET CACHE SUBSYSTEM OFF or SET CACHE SUBSYSTEM FORCEOFF command has been issued.
8. This command may produce delayed responses. See [“Delayed Responses to CP Commands”](#) on page 7 for more information.
9. This command may be issued to offline devices.
10. When specifying a real device number (*rdev*), do not use the secondary device in a duplex pair. The QUERY DUPLEX and QUERY DASD DETAILS commands can be issued to determine if a device is a secondary device in a duplex pair.
11. Error message HCP263E appears if too many devices are specified.

### Examples

To activate device 340 for caching, enter SET CACHE DEVICE ON 340.

### Responses

Response 1:

```
rdev CACHE activated for device
```

If the originator of the command is not the system operator, the following response is issued to the system operator and is also repeated for each device specified on the command line.

```
rdev CACHE was activated for device by userid.
```

#### ***rdev***

is the real device number of the device that had been given access to the cache.

#### ***userid***

is the ID of the user who issued the command.

Response 2:

**Immediate Response:** If the cache was deactivated immediately, the following response is displayed for each specified device when you enter SET CACHE DEVICE OFF:

```
rdev CACHE deactivated for device
```

**Delayed Response:** If the cache is not deactivated immediately, the following response is displayed when you enter SET CACHE DEVICE OFF:

```
Command started: SET CACHE DEVICE OFF rdev.
```

## SET CACHE

When the cache is deactivated, the following response is issued:

```
rdev CACHE deactivated for device
```

Under certain circumstances, it is possible that a cache storage subsystem does not notify CP when it has completed deactivating the cache. When this occurs, the appropriate command response cannot be generated. Under these circumstances, command processing ends after generating the following response:

```
Command results lost: SET CACHE DEVICE OFF rdev.
```

In this case the QUERY CACHE command can be issued to determine the state of the cache.

If errors occur during the asynchronous processing of the command which prevent the successful completion of the command, the following response is displayed:

```
Command failed: SET CACHE DEVICE OFF rdev.
```

### **rdev**

is the real device number of a specified device for which the subsystem cache is available.

**Response to System Operator:** If the originator of the command is not the system operator, the following response is issued to the system operator and is also repeated for each device specified on the command line.

```
rdev CACHE was deactivated for device by userid.
```

### **rdev**

is the real device number of a device for which caching has been deactivated.

### **userid**

is the ID of the user who issued the command.

Response 3:

**Immediate Response:** If the subsystem cache is made available immediately, the following response is repeated for each *unique subsystem* that is associated with the devices specified when you enter SET CACHE SUBSYSTEM ON:

```
rdev CACHE available for subsystem
```

### **rdev**

is the real device number of a specified device for which the subsystem cache has been activated.

**Delayed Response:** If the cache is not made available immediately, the following response is displayed when you enter SET CACHE SUBSYSTEM ON:

```
Command started: SET CACHE SUBSYSTEM ON rdev.
```

When the cache is made available, the following responses are issued:

```
rdev CACHE available for subsystem
```

Under certain circumstances, it is possible that a cache storage subsystem does not notify CP when it has completed making the cache available. When this occurs, the appropriate command response cannot be generated. Under these circumstances, command processing is ended after generating the following response:

```
Command results lost: SET CACHE SUBSYSTEM ON rdev.
```

In this case, the QUERY CACHE command can be issued to determine the state of the cache.

If errors occur during the asynchronous processing of the command preventing the successful completion of the command, the following response is displayed:

```
Command failed: SET CACHE SUBSYSTEM ON rdev.
```

***rdev***

is the real device number of a specified device for which the subsystem cache has been made available.

**Response to System Operator:** If the originator of the command is not the system operator, the following response is issued to the system operator when the subsystem cache has been made available. This response is also repeated for each *unique subsystem* identified by the devices specified on the command line.

```
rdev CACHE was made available for subsystem by userid.
```

***rdev***

is the real device number of one of the specified devices in a subsystem for which the cache has been made available.

***userid***

is the ID of the user who issued the command.

Response 4:

**Immediate Response:** If you enter SET CACHE SUBSYSTEM FORCEOFF, or if the cache is made unavailable immediately when you enter SET CACHE SUBSYSTEM OFF, the following response is repeated for each *unique subsystem* that is associated with the devices specified.

```
rdev CACHE unavailable for subsystem
```

***rdev***

is the real device number of a specified device for which the subsystem cache has been made unavailable.

**Delayed Response:** If the cache is not made unavailable immediately, the following response is displayed when you enter SET CACHE SUBSYSTEM OFF:

```
Command started: SET CACHE SUBSYSTEM OFF rdev.
```

When the cache is made unavailable, the following responses are issued:

```
rdev CACHE unavailable for subsystem
```

Under certain circumstances, it is possible that a cache storage subsystem does not notify CP when it has completed making the cache unavailable. When this occurs, the appropriate command response cannot be generated. Under these circumstances, command processing ends after generating the following response:

```
Command results lost: SET CACHE SUBSYSTEM OFF rdev.
```

In this case, the QUERY CACHE command can be issued to determine the state of the cache.

If errors occur during the asynchronous processing of the command that prevent the successful completion of the command, the following response is displayed:

```
Command failed: SET CACHE SUBSYSTEM OFF rdev.
```

***rdev***

is the real device number of a specified device for which the subsystem cache has been made unavailable.

**Response to System Operator:** If the originator of the command is not the system operator, the following response is issued to the system operator when the subsystem cache has been made unavailable. This

## SET CACHE

response is also repeated for each *unique subsystem* identified by the devices specified on the command line.

```
rdev CACHE was made unavailable for subsystem by userid.
```

### ***rdev***

is the real device number of one of the specified devices in a subsystem for which the cache has been made unavailable.

### ***userid***

is the ID of the user who issued the command.

## SET CACHEFW

### Authorization

Privilege Class: B

### Purpose

Use the SET CACHEFW command to activate or deactivate the cache fast write function in a DASD subsystem. This command is valid for cache storage subsystems that support the cache fast write function.

### Operands

#### SUBSYSstem

specifies that the entire storage subsystem is affected by this command, regardless of which device within the subsystem receives the order. This is the default (and only) value.

#### ON

indicates that the cache fast write function is to be activated for the subsystem.

#### OFF

indicates that the cache fast write function is to be deactivated for the subsystem.

#### rdev

#### rdev1-rdev2

is the real device number, a list of real device numbers, or a range of real device numbers of devices in the subsystems.

### Usage Notes

1. The SET CACHEFW function is only valid for storage subsystems that support the cache fast write function.
2. If the subsystem cache is unavailable when the SET CACHEFW ON command is issued, cache fast write data access begins when the cache is made available (through SET CACHE SUBSYSTEM ON).
3. When SET CACHEFW OFF is issued, the cache fast write data for all devices in the subsystem is destaged to the appropriate DASD.
4. There are certain error messages that may result if the subsystem is not in the correct mode to accept the SET CACHEFW ON command. See error message HCP296E for more information.
5. SET CACHEFW OFF may produce delayed responses. See [“Delayed Responses to CP Commands” on page 7](#) for more information.

### Responses

Response 1:

## SET CACHEFW

The following response is displayed when you enter SET CACHEFW ON and is repeated for each *unique subsystem* identified by the devices specified on the command line.

```
rdev Cache fast write function has been activated.
```

If the originator of the command is not the system operator, the following response is issued to the system operator and is also repeated for each *unique subsystem* identified by the devices specified on the command line.

```
rdev Cache fast write function was activated by userid.
```

### **rdev**

is the real device number of one of the specified devices in a subsystem for which the cache fast write function has been activated.

### **userid**

is the ID of the user who issued the command.

Response 2:

**Immediate Response:** If you enter the SET CACHEFW OFF command and the cache fast write function is deactivated immediately, the following response is displayed. This response is repeated for each *unique subsystem* identified by the devices specified on the command line.

```
rdev Cache fast write function has been deactivated.
```

### **rdev**

is the real device number of one of the specified devices in a subsystem for which the cache fast write function has been deactivated.

**Delayed Response:** If the cache fast write function is not deactivated immediately, the following response is issued:

```
Command started: SET CACHEFW OFF rdev.
```

When the cache fast write function is deactivated, the following responses are issued:

```
rdev Cache fast write function has been deactivated.
```

Under certain circumstances, it is possible that a cache storage subsystem does not notify CP when it has deactivated the cache fast write function. When this occurs, the appropriate command response cannot be generated. Under these circumstances, command processing is ended after generating the following response:

```
Command results lost: SET CACHEFW OFF rdev.
```

In this case, the QUERY CACHEFW command can be issued to determine the state of the cache fast write function.

If errors occur during the asynchronous processing of the command that prevent the successful completion of the command, the following response is displayed:

```
Command failed: SET CACHEFW OFF rdev.
```

### **rdev**

is the real device number of one of the specified devices in a subsystem for which the cache fast write function has been deactivated.

**Response to System Operator:** If the originator of the command is not the system operator, the following response is issued to the system operator when the cache fast write function has been deactivated. This

response is also repeated for each *unique subsystem* identified by the devices specified on the command line.

```
rdev Cache fast write function was deactivated by userid.
```

***rdev***

is the real device number of one of the specified devices in a subsystem for which the cache fast write function has been deactivated.

***userid***

is the ID of the user who issued the command.

**Messages**

## SET CFLINK

### Authorization

Privilege Class: A, B, G

### Purpose

The SET CFLINK command logically connects or disconnects a coupling facility link using the message processor user ID and channel path ID to identify the link.

### Operands

#### *msgprocid*

is the user ID of the coupling facility virtual machine that owns the link.

#### **CHPID** *chpid*

Specifies the channel path ID of the link, which is known by the coupling facility virtual machine that owns the link.

#### **CONNect**

Enable and logically connect the link.

#### **DISConnect**

Disable and logically disconnect the link.

### Usage Notes

1. The issuing user must either be class A or class B. If class G only, the user must be coupled to the indicated coupling facility virtual machine.
2. The user ID specified by *msgprocid* must be logged on and must be a coupling facility virtual machine.
3. For the CONNect operand, the link specified by *chpid* must already exist. If it is already connected, no action is taken.
4. For the DISCONNect operand, the link specified by *chpid* must already exist. If it is already disconnected, no action is taken.

### Messages

- HCP001E Unknown CP command: *command*
- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP013E Conflicting option - *option*
- HCP020E Userid missing or invalid
- HCP022E A virtual device number was not supplied or it was invalid.
- HCP045E *userid* not logged on
- HCP047E CFLINK with this CHPID does not exist
- HCP260E *command* command processing cannot complete due to errors.
- HCP846E Invalid channel path identifier.
- HCP1014E A required option is missing.

- HCP2800E *msgprocid* is not a CF Service Machine.
- HCP2805E One or more message processors does not exist in your I/O configuration.
- HCP2806E You are not allowed to control message processors.
- HCP6704E Missing token at end of line
- HCP6706E Invalid string - *string*

## SET CMDLIMIT

### Authorization

Privilege Class: B

### Purpose

Use SET CMDLIMIT to limit the number of incorrect passwords to be processed with the AUTOLOG and XAUTOLOG commands. When a user exceeds this limit, CP disables the commands for the rest of the user logon session.

### Operands

**AUTOLOG *nnn***

**XAUTOLOG *nnn***

sets the system limit for incorrect passwords entered on the AUTOLOG or XAUTOLOG command. The maximum limit is 255, the minimum limit is 1, and the default limit is 4.

### Usage Notes

1. For security reasons, CP limits the number of incorrect passwords allowed on the AUTOLOG and XAUTOLOG commands in each user's logon session. The SET CMDLIMIT lets you raise or lower that limit.
2. Use the QUERY CMDLIMIT command to determine the current system limit value.
3. AUTOLOG is an accepted synonym for XAUTOLOG. The minimum truncation is AUTOL.
4. The initial system setting depends on how the JOURNALING system configuration statement is specified at system generation. If the FACILITY ON operand is specified, and no value is specified for the number of logon attempts, the initial setting of the limit is 4.
5. If a user exceeds the value specified by *nnn* and logon journaling is enabled, the user will not be able to enter the AUTOLOG or XAUTOLOG commands as long as logon journaling is enabled, even if the CMDLIMIT value *nnn* is increased with the SET CMDLIMIT command.

If a user exceeds the value specified by *nnn* and logon journaling is not enabled, the user will not be able to enter the AUTOLOG or XAUTOLOG commands. However, if the value *nnn* is increased with the SET CMDLIMIT command, the user will be allowed additional attempts to use the AUTOLOG or XAUTOLOG commands.

If a user exceeds the value specified by *nnn* and logon journaling is enabled (and is prevented from executing the AUTOLOG or XAUTOLOG commands) and then the SET JOURNAL LOGON OFF command is issued, the number of invalid password attempts accrued when logon journaling was enabled will not be reset. Consequently, if the *nnn* value of SET CMDLIMIT is not increased, the user will still not be able to run the AUTOLOG or XAUTOLOG commands. However, if the *nnn* value of SET CMDLIMIT is increased, the user will be allowed additional attempts to use the AUTOLOG or XAUTOLOG commands.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

- HCP1014E A required option is missing.
- HCP1826E The system limit of incorrect passwords was specified with an invalid number - *number*

## SET CONCEAL

### Authorization

Privilege Class: G

### Purpose

Use SET CONCEAL to turn on and off the protected application environment. This environment protects a session from unexpectedly entering CP READ.

### Operands

#### ON

specifies that the virtual machine is to operate in the protected application environment. This environment is intended for the application end user who does not want to interact with CP. Instead of presenting the user with an unexpected CP READ on occurrence of certain error conditions (for example, paging error, soft abend, disabled wait PSW loaded), the protected application facility forces an automatic re-IPL of the virtual machine without issuing any error messages to the user. The IPL is initiated using the IPL command last used for the virtual machine.

To prevent a re-IPL loop, CP does not force re-IPL if a previous automatic re-IPL occurred less than a minute before. No more than 10 automatic re-IPLs are attempted between activation and deactivation of the protected application environment. If a re-IPL is not attempted or if the attempt fails, CP issues the same message as when the protected application environment is not active and puts the terminal into CP READ state. For 3270 terminals, SET CONCEAL ON disables the break key. If you subsequently deactivate the protected application environment using the SET CONCEAL OFF command, the break key and the PA1 key are reenabled. You may also enable the break key by issuing a TERMINAL BRKKEY command while in the protected application environment.

#### OFF

specifies that the virtual machine should no longer operate in the protected application environment. Certain error conditions (such as a paging error, a soft abend, or a disabled wait PSW in the virtual processor) cause CP to take control of the virtual machine and display CP READ on the terminal. No re-IPL is initiated. The terminal break key, PA1 key, and ASCII double break or attention are reenabled when you enter SET CONCEAL OFF.

### Usage Notes

1. With your break key disabled, you cannot enter the CP READ state while running in full screen mode unless your guest (operating system or application) provides a way. The guest can use DIAGNOSE X'08' to pass either the CP command or no command at all to enter CP READ. In addition, the TERMINAL MODE command allows entry to CP on a console attention interrupt when in line mode.
2. An application can establish the protected application environment for itself by issuing a SET CONCEAL ON command using DIAGNOSE X'08'.
3. You may not specify SET CONCEAL ON if you have defined a multiprocessor configuration. The protected application facility only supports virtual uniprocessor systems.
4. If you use an application that runs with the protected application environment active, be aware that an automatic re-IPL resets your virtual machine. If you IPL a named saved system, storage is also cleared; therefore, data in virtual machine storage is lost.

5. If the protected application environment is already active, the SET CONCEAL ON command has no effect. Thus, if the break key has been reenabled using the TERMINAL BRKKEY command, this second SET CONCEAL ON command does not disable the break key.
6. For ASCII devices, hitting a double break or attention while in the protected application environment posts an attention to the virtual machine rather than presenting a CP READ. The only way to enable the double break or attention again is to SET CONCEAL OFF.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP5780E Adjunct does not support the *command subcommand* command
- HCP6026E Operand missing or invalid.

## SET CONFIGMODE

### Authorization

Privilege Class: B

### Purpose

Use SET CONFIGMODE to turn configuration mode on or off. Configuration mode is a machine state that is used to change your I/O configuration dynamically. You can use this command to issue a group of dynamic I/O commands together. Otherwise, each command enters and exits configuration mode at the beginning and ending of each dynamic I/O command.

Note that the SET DYNAMIC\_I/O OFF and SET LSYSTEM commands are an exception to the above. See Usage Note “3” on page 1437.

The dynamic I/O commands are:

DEFINE CHPID	DEFINE PATH
DELETE CHPID	DELETE PATH
MODIFY CHPID	MODIFY PATH
DEFINE CU	DEFINE CNTLUNIT
DELETE CU	DELETE CNTLUNIT
MODIFY CU	MODIFY CNTLUNIT
DEFINE DEVICE	DEFINE IODEVICE
DELETE DEVICE	DELETE IODEVICE
MODIFY DEVICE	MODIFY IODEVICE
DEFINE LPAR	
DELETE LPAR	
SETCONFIGMODE	SET DYNAMIC_I/O
SET LSYSTEM	

### Operands

#### ON

tells CP to enter configuration mode.

#### OFF

tells CP to exit configuration mode.

#### RESET

tells CP to enter or exit configuration mode even if there is a mismatch between the system's and the hardware's view of the I/O configuration.

### Usage Notes

1. Whenever you issue one of the dynamic I/O commands, CP puts you in configuration mode, processes the dynamic I/O command, and then takes you out of configuration mode.
2. Whenever you dynamically change your I/O configuration using one of the dynamic I/O commands, CP must perform a certain amount of overhead. If you want to issue several dynamic I/O commands in succession and you are concerned about performance, issue the SET CONFIGMODE ON command,

issue your dynamic I/O commands, and then issue the SET CONFIGMODE OFF command. This method causes CP to perform the overhead once at the beginning and once at the end, rather than before and after each individual command.

3. There are two dynamic I/O commands that you cannot issue while in configuration mode: the SET DYNAMIC\_I/O OFF command and the SET LSYSTEM command. You must issue SET DYNAMIC\_I/O OFF and SET LSYSTEM as individual commands. For more information about the SET DYNAMIC\_I/O command, see [“SET DYNAMIC\\_I/O” on page 1502](#). For more information about the SET LSYSTEM command, see [“SET LSYSTEM” on page 1553](#).
4. When you use the dynamic I/O commands, you are changing the I/O configuration as the software (CP) understands it. You must also change the I/O configuration as the hardware understands it. To do so, you must update the IOCP source file and issue the SET IOCDs\_ACTIVE command (see [“SET IOCDs\\_ACTIVE” on page 1525](#)).
5. If you are in configuration mode and you issue a dynamic I/O command that does not complete successfully, CP automatically takes you out of configuration mode.
6. If you are in configuration mode and any of the following occur:
  - The system abends,
  - The system loses power,
  - You issue a SHUTDOWN REIPL command,
  - You issue a CLEAR RESET from the hardware console, or
  - You issue a LOAD CLEAR from the hardware console.

CP takes you out of configuration mode before shutting down the system.
7. To display whether the processor is currently in configuration mode, use the QUERY CONFIGMODE command (see [“QUERY CONFIGMODE” on page 806](#)).

## Responses

### Response 1:

To turn configuration mode on, enter the following SET CONFIGMODE command:

```
set configmode on
System is now in configuration mode
Ready;
```

If configuration mode is on when you issue the SET CONFIGMODE ON command, you see the following response:

```
set configmode on
System is already in configuration mode
Ready;
```

### Response 2:

To turn configuration mode off, enter the following SET CONFIGMODE command:

```
set configmode off
System is no longer in configuration mode
Ready;
```

If configuration mode is off when you issue the SET CONFIGMODE OFF command, you see the following response:

```
set configmode off
System is not in configuration mode
Ready;
```

### Messages

## SET CPCHECKING

### Authorization

Privilege Class: A, C

### Purpose

Use SET CPCHECKING to activate or deactivate CP internal checking.

#### ON

indicates that internal CP checking should be activated. The action to be taken when an untrue assertion is encountered is controlled by the subsequent parameters.

#### ABEND

indicates that an abend should occur. Whether it is a hard abend or a soft abend is controlled by the specific assertion case. It is typically a hard abend. This is the default when CP internal checking is activated.

#### VMSTOP

this parameter is permitted only when CP is itself running in a virtual machine, and is generally useful only for debugging CP. Specifying this parameter causes CP to issue a DIAGNOSE X'08' instruction when an untrue assertion is encountered, specifying a command string length of zero. This causes the virtual machine to stop and for CP to post a read to the console. Messages are sent to the console (from a DIAGNOSE X'08' MESSAGE \* command) providing information about the cause of the stop.

#### OFF

Indicates that CP internal checking should be deactivated.

### Messages

- HCP1007E The VMSTOP option is only permitted when CP itself is running in a virtual machine.
- HCP6010I The CPCHECKING setting has been changed to OFF to avoid a possible abend loop. It may be set ON again if desired.

## SET CPCONIO

---

### Authorization

Privilege Class: G

### Purpose

Use SET CPCONIO to control the destination of all CP output. At LOGON, CPCONIO is set OFF.

### Operands

#### IUCV

specifies that responses are to be passed to the virtual machine through IUCV if a connection to the message system service exists. If the console is being spooled, the responses are also placed in the console spool file, as well as being sent through IUCV. If no IUCV connection exists, data is handled as if SET CPCONIO OFF had been issued.

#### OFF

specifies that responses are displayed at the terminal.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid

## SET CPLANGUAGE

Notes:

<sup>1</sup> SYSTEM is valid only for class B.

### Authorization

Privilege Class: B, G

### Purpose

Use SET CPLANGUAGE to change the language of your virtual machine or the entire system.

### Operands

#### *langid*

is the language to which the virtual machine is to be set; *langid* must be 1 to 5 characters long and must consist of CMS file system characters only.

#### **USER**

specifies that the default language is being set for the user.

#### **SYSTEM**

specifies that the default language is being set for the entire system.

### Usage Notes

1. Be aware of the language-related terminal restrictions when you specify a language. If you are not sure what characters your terminal can display, check with your system administrator.
2. The QUERY CPLANGLIST command displays all the valid language IDs that you can set in CP. To display the language that is currently active for CP in your virtual machine, enter the QUERY CPLANGUAGE command. Contact your system administrator if you have any questions about the languages available on your system.
3. The system default language is set with the CPLANGUAGE operand of the USER\_DEFAULTS system configuration statement or with the CP SET CPLANGUAGE command. The order of precedence, from highest priority to lowest, that determines an individual user's language is:
  - SET CPLANGUAGE command specified by the individual user
  - the value specified for the LANG operand of the OPTION statement in the user's directory
  - the system default language, and then
  - the language that is built into the CP nucleus.
4. If the system default language is changed, the response to QUERY CPLANGLIST will show the new system default language. If the user is using the system default language, the user's current language will not change until the user either logs off and logs back on, or issues the CP SET CPLANGUAGE command or CMS SET LANGUAGE command to switch to the new system default language.
5. CP uses the message repository that is built into the CP nucleus even when a message repository file for the same language exists. The QUERY NLS command can be used to display the message repository files that exist on the system.

## SET CPLANGUAGE

### Examples

If your virtual machine is set to American English for CP, and you want to change your language to German, enter `set cplanguage ger`. To change it back to American English, enter `set cplanguage ameng`.

### Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid
- HCP413E Command processing cannot complete due to a spool paging error.
- HCP1831E The command could not be completed because of a temporary condition. Try again later.
- HCP2575E The message repository for *langid* cannot be found.
- HCP2576E The command processing cannot complete and a soft abend has been taken because an unrecoverable system error has occurred.
- HCP2577E Message repository file *name* is damaged
- HCP6525E External Security Manager is unavailable

## SET CPPROTECT

### Authorization

Privilege Class: C

### Purpose

Use SET CPPROTECT to control enablement of certain security modes in z/VM, such as limiting speculative execution in the machine. Speculative execution is an optimization mechanism designed into the processor to improve system performance.

The standard virtual machine isolation and protection mechanisms in z/VM are designed to prevent code being run in an unprivileged virtual machine from interfering with or gaining unauthorized access to resources or data owned by the z/VM Control Program or by other guests. Setting CPPROTECT modes ON offers additional protections against information leak attacks that might be attempted by malicious or compromised code running in an untrusted virtual machine. Running the system with MODE1 ON or MODE2 ON might increase system overhead, reduce capacity, or reduce throughput.

z/VM maintains a system-wide MODE1 setting and a MODE2 default setting. When z/VM is IPLed, MODE1 is ON and the default for MODE2 is OFF. In addition to changing the MODE1 setting and the default MODE2 setting, SET CPPROTECT can also establish per-user MODE2 override settings.

In choosing CPPROTECT settings, the system programmer might want to consider the degree to which the code running in virtual machines is known and controlled, the level of risk from unauthorized discovery of data in the memory of CP or other virtual machines, and the performance cost associated with the various protections. For example, an open multitenant cloud platform might call for greater protection than an isolated internal company system.

Details on the protection modes are not provided in this publication. Authorized personnel of IBM clients can consult the IBM Z Security Portal for further information and guidance. To request access to the portal, go to [Register for IBM Z Security Portal \(www.ibm.com/systems/campaignmail/z/capabilities/system-integrity/register-zsecurity-portal\)](http://www.ibm.com/systems/campaignmail/z/capabilities/system-integrity/register-zsecurity-portal). Scroll and review information on that page including the Terms and Conditions section. The IBM Z Security Portal section of the page includes links to request access and to obtain the required IBMid.

### Operands

#### MODE1

refers to a system-wide mitigation mechanism that is either ON or OFF.

**MODE2**

refers to a mitigation mechanism that the z/VM Control Program (CP) can apply when it interacts with some users but not with others. MODE2 protection can be enabled or disabled against all users or against specific users.

**DEfault**

specifies that the system-wide default is to be set.

**AGainst ALL DEfault**

specifies that every logged-on user will be set to the default MODE2 setting. All user overrides will be removed.

**AGainst userid****AGainst \***

specifies that a user-specific override is to be set, taking precedence over the system default when the specified virtual machine is run. An asterisk refers to the virtual machine of the command issuer.

**AGainst userid DEfault**

cancels the user-specific override for the specified user. Subsequent handling of this virtual machine will be governed by the system-wide default MODE2 setting.

**ON****OFF**

indicates that a level of protection should be enabled (ON) or disabled (OFF) under the specified conditions.

**Usage Notes**

1. At z/VM IPL, the MODE1 setting is ON and the default MODE2 setting is OFF. These settings apply to all users on the system. To change these IPL settings, insert the following statement(s) into the directory of the primary system operator user ID (usually OPERATOR):

```
COMMAND SET CPPROTECT MODE1 OFF
COMMAND SET CPPROTECT MODE2 DEFAULT ON
```

Because the operator is the first user automatically logged on at IPL, this will put the setting into effect before any virtual machine can run.

2. At logon, each user receives the system default MODE2 setting.
3. A user-specific MODE2 override remains in effect until the user logs off. To establish a persistent override for a user, insert the following statement into either the USER or IDENTITY directory entry, or the PROFILE entry included by this entry:

```
COMMAND SET CPPROTECT MODE2 AGAINST * {ON|OFF}
```

This will ensure that the setting is put into effect as soon as the user logs on.

4. If APAR VM65414 or its precursor, VM65396, is installed on the source and destination systems, VMRELOCATE will preserve a user-specific override set for the relocated virtual machine. If either APAR is installed on the source system but neither is installed on the destination system, a user override will be lost in relocation. If either APAR is installed on the destination system but neither is installed on the source system, the relocated guest will inherit the default MODE2 setting on the destination system.
5. Machine support is required to implement MODE1 ON and MODE2 ON. If the support is not available, the requested ON setting will be recorded and will be preserved by VMRELOCATE as described above but will not be effective on this system. If the necessary machine service is applied dynamically, you can then issue QUERY CPPROTECT to cause CP to recognize the machine support and put the requested settings into effect.

**Examples**

Assuming a freshly IPLed system with the required machine support and no CP directory COMMAND statements, consider the following sequence of commands:

```
set cprotect mode1 on
set cprotect mode2 default off
set cprotect mode2 against alice on
set cprotect mode2 against bob off
```

MODE1 will be ON system-wide. MODE2 will be OFF with respect to all users except ALICE: with respect to BOB because of the user-specific override, and with respect to all others because of the system default.

If the following command is subsequently issued:

```
set cprotect mode2 default on
```

MODE2 remains OFF with respect to user BOB, because of the user-specific override. MODE2 remains ON to protect against ALICE, because of the user-specific override. The rest of the users now run with MODE2 ON, because of the changed system default.

To remove all user overrides, in other words ALICE's and BOB's overrides:

```
set cprotect mode2 against all default
```

The user-specific overrides for ALICE and BOB are removed. All users now run with the system default, which in this example is MODE2 ON.

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on
- HCP1056I {MODE1|MODE2} ON request set, but required machine support not available.

## SET CPTRACE

### Authorization

Privilege Class: A, C

### Purpose

Use SET CPTRACE to activate or deactivate the trace function for real machine events. (Trace information is logged in trace tables.)

### Operands

#### CPTRACE

enables or disables tracing of real machine events in the CP trace tables.

#### NONSPECIFIC

indicates that the specified tracing applies to all virtual machines not specifically set or named by a previous SET CPTRACE command. This is the default. All virtual machines begin in the NONSPECIFIC group. All members of the NONSPECIFIC group have the same codes traced.

#### SPECIFIC

#### SYSTEM

#### ALL

#### *userid*

specifies the target for the subsequent tracing changes.

SPECIFIC indicates that the specified tracing applies only to those virtual machines specifically set or named by a previous SET CPTRACE command. Members of the SPECIFIC group may each have a unique set of codes traced.

SYSTEM indicates that the specified tracing applies to system work. SYSTEM becomes a member of the SPECIFIC group, even though the specified tracing may not match the virtual machines already in the group. Therefore, SYSTEM is similar to *userid* in that it names the work for which tracing applies, and SYSTEM can also be a part of either the SPECIFIC or NONSPECIFIC groups, but not both.

ALL indicates that the specified tracing applies to both the SPECIFIC and NONSPECIFIC groups of virtual machines and to system work.

*userid* indicates that the specified tracing applies only to this specific virtual machine. The operand *userid* becomes a member of the SPECIFIC group, even though the specified tracing may not match others in the group.

**ON****OFF**

enables or disables tracing of the specified trace categories or codes. ON is the default. ON and OFF may be intermixed in the same trace category list to enable and disable trace categories in the same command. The trace category list is processed from left to right.

**ALLcodes**

sets or resets tracing of all events. This is the default.

**category  
code**

is either a single 4-digit hexadecimal code for an event to be traced or the name of a category of trace codes. The system displays only the setting of this code or category.

The category names, subcategory names, and the trace codes in each category are listed below in system hierarchical order. For a full numeric list of trace codes regardless of category, refer to [Trace Table Codes](#) in *z/VM: Diagnosis Guide*.

**EXT**

**1957**

Userid socket reply error occurred

**1958**

Userid join wrap-up received

**VAA**

Virtual architecture trace codes:

**2000**

Acquire VAAXLK lock locally

**2001**

Acquire VAAXLK lock globally

**2002**

Release VAAXLK lock

**2003**

Relocation domain synchronization received an SSI state change notification

**2004**

HCPXLKUU successful call

**2005**

HCPXLKUU failed call

**LGRMM**

Live Guest Relocation (LGR) Memory Move Trace Codes:

**2100**

End-to-end throttle: Activation message received (LGR source)

**2101**

End-to-end throttle: Deactivation message received (LGR source)

**2102**

End-to-end throttle: Memory move has resumed (LGR source)

**2103**

Logical link throttle: "Pages on aux" processor has resumed (LGR source)

**2104**

Logical link throttle: PGMBK walker has resumed (LGR source)

**2105**

Logical link throttle: DAT walk has resumed (LGR source)

**2106**

"Pages on aux" processor has finished, allowing DAT walk to resume (LGR source)

**2107**

Paging overrun resolved; PGMBK walker resumed (LGR source)

**RESET**

ends specific tracing for the indicated virtual machine, system work, or the entire SPECIFIC group. The virtual machine or machines (and/or SYSTEM) become members of the NONSPECIFIC group. SET CPTRACE FOR SPECIFIC RESET, therefore, ensures that all virtual machines and SYSTEM are in the NONSPECIFIC group.

**Usage Notes**

1. You may combine several commands into one command as long as the FOR qualifier is the same. For example, `set cptrace for nonspecific on svc off ext`.

**Note:** FOR NONSPECIFIC is the default; the following command has the same result: `set cptrace on svc off ext`.

2. If you start a SPECIFIC trace, you must be aware of the initial state of the trace, or you get whatever the initial state was, modified by the NONSPECIFIC trace. To find out the initial trace state, enter `query cptrace for specific`; then, check the response and enter `query cptrace`.

(QUERY CPTRACE gives you the NONSPECIFIC state.)

3. You cannot disable tracing for entries that can occur at the time of a CP trace table full condition. The two entry conditions that can occur are "PROGRAM INTERRUPTION" (0300) for trace table page full, program interrupt X'16', and "TRACE TABLE PAGE FULL DURING MACHINE CHECK HANDLING" (F40F). The TIME STAMP TRACE ENTRY (FFFD) cannot be disabled by the SET CPTRACE command either.
4. The SET CPTRACE command processes categories sequentially from left to right; tracing for the first category begins before the second category is processed. Therefore, it may be possible to have trace settings in effect during command processing that are different from the trace settings before and after command processing.

The NONSPECIFIC trace setting, modified by the command initially creating the SPECIFIC trace, is the initial state of a SPECIFIC trace setting.

To get an initial state of ALLCODES enabled, enter: `set cptrace for userid on allcodes`, combined with, or followed by, the desired trace settings.

5. SPINLOCK trace entries are generated only for spin locks whose obtain and release macros indicate they should be traced.

**Examples**

To disable the trace for IUCV instructions, enter: `set cptrace off iucv`. As an example, assume that when your system is IPLed, all users are in the NONSPECIFIC category. If you want to put all users in the NONSPECIFIC category and you want to trace all trace codes, enter: `set cptrace for nonspecific on allcodes`. If you enter the command with all its defaults and truncations specified, the command looks like this: `set cptr`. If you want to put some users in the SPECIFIC category, enter the following commands: `set cptrace for nonspecific off all`. This turns off all trace codes for users in the NONSPECIFIC category.

Perhaps you want to set a SPECIFIC trace for users CMS000 and SYSTEM. For CMS000 you want to set ON code categories I/O and IUCV, and for SYSTEM you want to set ON only the code categories SVC and IUCV. (See the trace code category listings in [“category” on page 1447](#).)

To do this, enter the following commands:

```
set cptrace for cms000 off on i/o
set cptrace for system off on svc
set cptrace for specific on iucv
```

If you now want to put the user CMS000 back into the NONSPECIFIC group, enter: `set cptrace for cms000 reset`. The system traces SYSTEM for SVC and IUCV trace code categories.

**Note:** You can only use RESET to set users or SYSTEM back into the NONSPECIFIC group. In order to set codes for a NONSPECIFIC user off, enter `set cptrace for userid off code/category`.

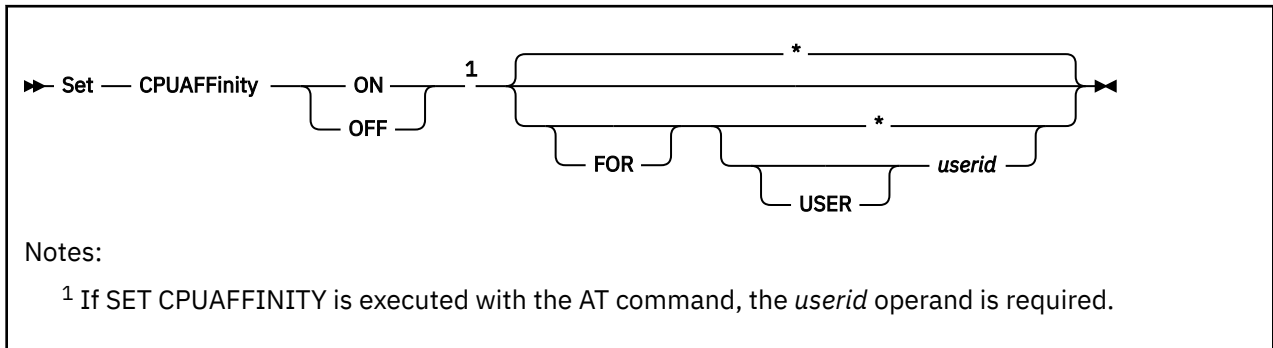

If you want to trace ALLCODES for one SPECIFIC user (a user ID) only, enter the following commands:

```
set cptrace for all off allcodes  
set cptrace for userid on allcodes
```

## Messages

- HCP1033E No SPECIFIC CP TRACE is in effect.
- HCP1034I No SPECIFIC CP TRACE is in effect for *userid*.

## SET CPUAFFINITY

### Authorization

Privilege Class: A

### Purpose

Use SET CPUAFFINITY to change the CPU affinity setting for a user.

### Operands

#### USER *userid*

identifies the virtual machine whose CPU affinity you are setting.

\*

specifies that CPU affinity is to be set for the *userid* issuing the command.

#### ON

#### OFF

specifies if CPU affinity should be turned ON or OFF. Initially, CPU affinity is set to ON for users at logon time. ON means the virtual CPUs are dispatched on only real CPUs of matching type. When CPU affinity is OFF, the guest's virtual processors of secondary type always get dispatched on host real processors of primary type.

### Usage Notes

1. CPU affinity is a global setting for the entire virtual CPU configuration. CPU affinity is achieved when there is a real CPU with the same type as the virtual secondary processor trying to obtain affinity. If no real CPU of the same type exists, then CPU affinity is suppressed for that virtual processor type.
2. The resource pooling function requires all users in a resource pool to use the same CPU type that is being limited by the resource pool. By requiring CPU affinity to be on for a user ID to be assigned to a resource pool, z/VM handles all users in the resource pool in an identical manner in cases where CPU affinity needs to toggle between on and suppressed, and ensures this change occurs for all affected users at the same time. After a user is assigned to a resource pool, CPU affinity cannot be set off for that user.

### Responses

Response 1:

```
CPU Affinity is suppressed for CPU type type
```

There was no real processor with the same type as the virtual secondary processor.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - {*option* | command contains extra option(s) starting with *option*}
- HCP045E *userid* not logged on
- HCP1014E A required option is missing.
- HCP1463I CPU Affinity is suppressed for CPU type *type*.
- HCP1473E CPU Affinity cannot be turned OFF for a user in a resource pool
- HCP5780E Adjunct does not support the *command subcommand* command

## SET CPUID

---

►► Set — CPUid — *number* ◄◄

### Authorization

Privilege Class: G

### Purpose

Use SET CPUID to change the processor identifier for the virtual processor from which the command is issued.

### Operands

#### *number*

changes the virtual processor identifier. The 6 hexadecimal digits you specify in *number* become the new processor identifier number or processor serial number.

1. The SET CPUID command changes bits 8 through 31 of the CPU identifier that is set by the STIDP instruction to the value you specify.
2. If the guest owning the virtual processor is relocated, the serial number of the virtual processor does not change as a result of the relocation, even if the FORCE ARCHITECTURE or FORCE DOMAIN options were used on the VMRELOCATE command.

### Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid
- HCP263E Too many operands were supplied for this command.
- HCP1005E An invalid character was encountered.

## SET CPUPOOL

---

### **Purpose**

SET CPUPOOL has been superseded by SET RESPOOL. See [“SET RESPOOL”](#) on page 1679.

## SET CRYPTO

### Authorization

Privilege Class: B

### Purpose

Use SET CRYPTO APVIRTUAL POLLING to specify whether CP uses polling or interruptions to drive the processing of crypto work that is assigned to the shared pool.

### Operands

#### POLLing ON

CP uses polling to drive the processing of APVIRT crypto work.

#### POLLing OFF

CP uses crypto interruptions to drive the processing of APVIRT crypto work. CP does not use polling to drive the processing of APVIRT crypto work.

### Usage Notes

1. The command is allowed even if no shared pool is defined. The setting becomes active as soon as a shared resource is attached to the system.
2. The command affects CP's processing of work for APVIRT crypto users. The command does not affect the way that a virtual machine places work in the shared pool or receives replies from crypto work that is processed by shared crypto resources.
3. Use the QUERY CRYPTO POLLING command to determine the current setting. See [QUERY CRYPTO](#) in *z/VM: CP Commands and Utilities Reference*.
4. Use the CRYPTO APVIRTUAL POLLING statement in the system configuration file to specify the setting that takes effect at system IPL time. See [CRYPTO APVIRTUAL Statement](#) in *z/VM: CP Planning and Administration*.
5. If a POLLING setting is not specified on a CRYPTO APVIRTUAL statement in the system configuration file, then the default setting is OFF.

### Examples

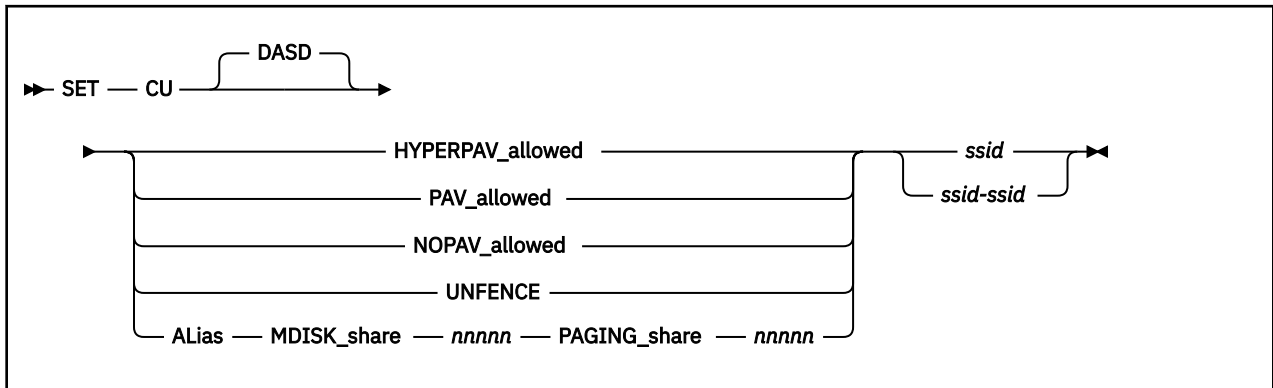

- SET CRYPTO APVIRTUAL POLLING ON
- SET CRYPTO POLLING OFF

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra options starting with *option*
- HCP1014E A required option is missing
- HCP1713E A required facility is not available to allow Crypto to operate with polling off. Polling remains on.

- HCP1728E AP Crypto resources are not installed on this system.

## SET CU

### Authorization

Privilege Class: B

### Purpose

Use SET CU to change the functional level at which a specified control unit is allowed to operate with respect to your z/VM system (the system on which you issue the command). For the parameters you specify, you can permit the control unit to operate below, at, or (for PAV\_allowed) above its currently-installed functional level. You can allow the control unit to reset soft fence state for the DASDs on it. You can also specify the relative share of system-attached HyperPAV aliases to be used for minidisk I/O and paging I/O.

### Notes:

- The command applies only to first-level z/VM systems. When z/VM is running as a guest of another z/VM system, the guest z/VM system does not control the operation of the control unit. If the command is issued to a guest z/VM system, the command is rejected.
- The control unit that is associated with an EDEVICE HyperPAV pool has a subsystem identifier (SSID) that cannot be referenced by the SET CU command and thus cannot be affected by the SET CU command.

### Operands

#### HYPERPAV\_allowed

tells CP to allow a specified control unit to operate with HyperParallel Access Volume (HyperPAV) devices in your z/VM system.

**Note:** All alias devices in a specified control unit must be offline to CP if changing to the HYPERPAV\_allowed setting.

#### PAV\_allowed

tells CP to allow a specified control unit to operate with Parallel Access Volume (PAV) devices in your z/VM system.

**Note:** All alias devices in a specified control unit must be offline to CP if changing from the HYPERPAV\_allowed setting.

#### NOPAV\_allowed

tells CP to not allow a specified control unit to operate with PAV or HyperPAV devices with respect to your z/VM system.

**Note:** All alias devices in a specified control unit must be offline to CP if changing to the NOPAV\_allowed setting. After the command, all alias devices will become non-operational.

**UNFENCE**

tells CP to allow a specified control unit to reset soft fence state for all the devices on it.

**Alias**

tells CP the command applies to aliases that are associated with the control unit. When this operand is specified, MDISK\_share and PAGING\_share are also required in the order shown in the command syntax diagram.

**MDISK\_share *nnnnn***

specifies the relative share that minidisk I/O will use when it competes for system-attached HyperPAV aliases in the control unit. The fraction of the total number of system-attached HyperPAV aliases that CP will attempt to make available for use by minidisk I/O is *nnnnn* divided by the sum of the values of the MDISK\_share and PAGING\_share operands. The value of *nnnnn* ranges from 0 to 10000. When this operand is not specified, the value of MDISK\_share is 0. When the value of MDISK\_share is 0, minidisk I/O is not promised any share of the control unit's system-attached HyperPAV aliases.

**PAGING\_share *nnnnn***

specifies the relative share that paging I/O will use when it competes for system-attached HyperPAV aliases in the control unit. The fraction of the total number of system-attached HyperPAV aliases that CP will attempt to make available for use by paging I/O is *nnnnn* divided by the sum of the values of the MDISK\_share and PAGING\_share operands. The value of *nnnnn* ranges from 0 to 10000. When this operand is not specified, the value of PAGING\_share is 0. When the value of PAGING\_share is 0, paging I/O is not promised any share of the control unit's system-attached HyperPAV aliases.

***ssid******ssid-ssid***

is the subsystem identifier (SSID) of a control unit as established in a control unit during its installation. The SET CU command operates on the control unit that is identified. The variable *ssid* must be a hexadecimal number between X'0000' and X'FFFF'. You can specify a single subsystem identifier, a list, a range, or any combination thereof.

**Usage Notes**

1. The actual capabilities of control units that support the PAV or HyperPAV functions (such as the IBM DS6000™ and DS8000® series) are defined by the presence or absence of the applicable features in these control units. CP's default value for a control unit's allowed operational level is PAV\_allowed. However, if a control unit can function at the HYPERPAV level, then the default value is HYPERPAV\_allowed. The allowed level can be changed by CU statements in your system configuration file or by SET CU commands you issue. For example, if a control unit has the HyperPAV feature installed but a CU statement in the system configuration file specifies PAV\_allowed, then any alias devices defined in the control unit will operate as PAV devices and not as HyperPAV devices.
2. The allowed level cannot be higher than the installed level, except that the allowed level can be PAV\_allowed when neither the PAV nor the HYPERPAV features are installed in a control unit. In this latter case, if you later install the PAV feature in a control unit while it continues in normal operation, any defined alias devices will become available to CP without the need for a SET CU command. If you additionally install the HYPERPAV feature, a SET CU command is necessary to raise the allowed functional level to HYPERPAV\_allowed.
3. If an allowed level is lower than the installed level, the control unit will function (with respect to your z/VM system) at the allowed level only.
4. If the HYPERPAV feature is removed from a control unit while HYPERPAV alias devices are being used, they become unusable and the control unit notifies CP of the change. The error recovery for these devices is to take them offline to CP and to lower the allowed functional level for the control unit to PAV\_allowed.
5. If the PAV feature is removed from a control unit while PAV alias devices are being used, they become non-operational. If the PAV feature is subsequently restored, the alias devices become operational again as long as you did not change the PAV\_allowed setting.
6. When SET CU is used to change the PAV state of a control unit and the applicable features are already installed, the following occurs:

- *NOPAV-to-PAV transition* - previously-defined alias devices can be brought online and become associated with their applicable base pools.
  - *NOPAV-to-HyperPAV transition* - previously-defined alias devices can be brought online and become associated with their applicable HyperPAV pools.
  - *PAV-to-HyperPAV transition* - affected alias devices are disassociated from their base devices; when brought online, they become associated with their applicable HyperPAV pools.
  - *HyperPAV-to-PAV transition* - affected alias devices are disassociated from their HyperPAV pools; when brought online, they become associated with their applicable base devices.
  - *HyperPAV-to-NOPAV transition* - affected alias devices are disassociated from their HyperPAV pools and taken offline; they cannot be VARYed ONline.
  - *PAV-to-NOPAV transition* - affected alias devices are disassociated from their base pools and taken offline; they cannot be VARYed ONline.
7. The UNFENCE operand will reset the soft fence state of every configured DASD on the control unit regardless of whether or not they are defined to the VM LPAR.
  8. The MDISK\_share and PAGING\_share operands influence CP in choosing an I/O operation to be executed on a system-attached HyperPAV alias device. The settings of these operands have meaning to CP only when all system-attached HyperPAV aliases associated with the control unit are currently busy executing I/O and an alias becomes available.

The default behavior for CP when an alias becomes available is to scan for I/O queued on the HyperPAV base devices on the control unit. The first I/O operation found that can be executed on a system-attached HyperPAV alias device is chosen for execution (this is the behavior when the values of MDISK\_share and PAGING\_share are 0). By specifying a non-zero value for MDISK\_share, PAGING\_share, or both, you specify an entitlement for the respective use. CP makes sure an entitlement is met before resorting to its default behavior.

The entitlement computation rounds the value to the nearest whole number. Specifically:

- A value with a decimal component of less than .5 is rounded down.
- A value with a decimal component of .5 or greater is rounded up.

However, if the sum of the resulting entitlements for minidisk I/O and paging I/O exceeds the number of system-attached HyperPAV aliases, both entitlements are rounded down and the default algorithm applies to the residual alias.

To determine the alias activity for a HyperPAV base device, examine the device monitor data. To see minidisk I/O's and paging I/O's current shares and entitlements for a control unit, use the QUERY CU command with the ALIAS\_Share operand. To obtain a complete list of alias devices that are associated with a control unit, use the QUERY CU command with the ALIASES operand.

For ECKD CUs, some performance specialists suggest not mixing paging I/O and minidisk I/O in the same CU, even though SET CU ALIAS mediates alias use correctly. Results will vary from one workload to another. If the results that you get when mixing do not meet expectations, try placing paging I/O and minidisk I/O in separate LCUs.

For EDEVICE CUs, the SET CU ALIAS command does not apply, so it is possible in theory for one type of I/O to starve another type's exploitation of aliases. For such CUs, IBM recommends not mixing I/O types when I/O rates are high enough to exhaust the alias pool routinely. To watch the alias pool, use Performance Toolkit FCX327 HPALIAS or equivalent.

9. The z/VM system programmer and the DASD management programmer must work together to make sure each logical subsystem (LSS) that is being used on the system has a unique SSID.

## Examples

Example 1:

To allow the operation of HyperPAV devices on a control unit, enter the following:

```
set cu hyperpav 4343
Command complete
Ready;
```

**Example 2:**

To disallow the operation of PAV or HyperPAV devices on a range of control units, enter the following:

```
set cu nopav 4400-4410
Command complete
Ready;
```

**Example 3:**

To reset soft fence state for the devices on a control unit, enter the following:

```
set cu unfence 0409
Command complete
Ready;
```

**Example 4:**

To set a minidisk alias share of 100 and a paging alias share of 200 for control unit 4343, specify the following:

```
set cu alias mdisk_share 100 paging_share 200 4343
Command complete
Ready;
```

In this example, if the number of HyperPAV system-attached aliases is 17, the minidisk entitlement is 6 and the paging entitlement is 11.

The minidisk entitlement calculation is:

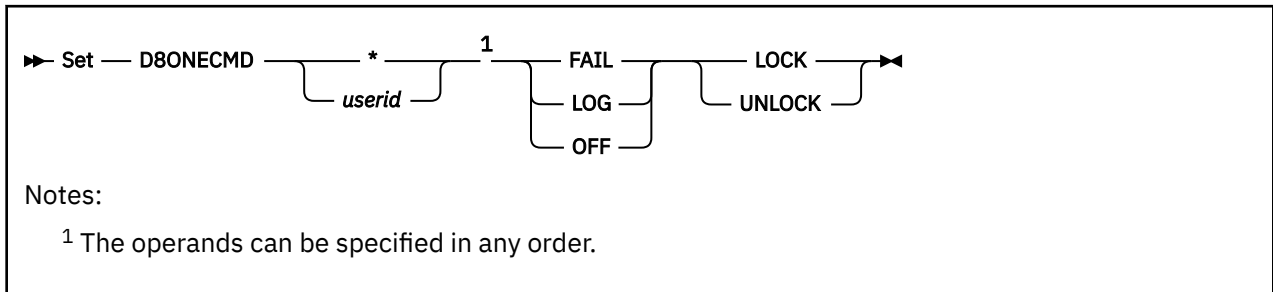

$$(100 / (100 + 200)) * 17 = 17 / 3 = 5.67 \text{ (rounded up to 6)}$$

The paging entitlement calculation is:

$$(200 / (100 + 200)) * 17 = 34 / 3 = 11.33 \text{ (rounded down to 11)}$$
**Messages**

## SET D8ONECMD

### Authorization

Privilege Class: A, G

### Purpose

Use SET D8ONECMD to change the D8ONECMD settings for your own virtual machine or another user's virtual machine. D8ONECMD settings determine whether CP accepts multiple CP commands imbedded in a single CP command issued through DIAGNOSE code X'08'.

When a user uses a general VMCF-capable program to send a request that contains imbedded X'15' characters to a service user ID, the service user ID assumes the request was issued with the CP SMSG facility. The CP SMSG facility is trusted because CP ensures the service user ID does not receive any imbedded X'15' characters. When the service user ID uses DIAGNOSE code X'08' to issue a CP command that contains the request, CP interprets the X'15' characters as command separators and breaks what the service user ID thought was a single command into several commands.

SET D8ONECMD lets you to prevent the execution of "Trojan Horse" commands (commands hiding inside legitimate requests) and records any attempt to process such commands.

For information on how to display the D8ONECMD settings of your virtual machine or another user's virtual machine, see ["QUERY D8ONECMD"](#) on page 865.

### Operands

#### *userid*

indicates that you wish to change another virtual machine's D8ONECMD settings. If you are a class G user, you can specify only your own user ID.

\*

indicates that you wish to change your own virtual machine's D8ONECMD settings.

#### **FAIL**

tells CP to reject any attempt to process a DIAGNOSE code X'08' containing multiple CP commands and send a message to operations personnel. If you specify FAIL, you cannot specify LOG or OFF.

#### **LOG**

tells CP to send a message to operations personnel every time the specified user tries to process a DIAGNOSE code X'08' containing multiple CP commands. If you specify LOG, you cannot specify FAIL or OFF.

#### **OFF**

tells CP the specified user can process a DIAGNOSE code X'08' containing multiple CP commands with no restrictions. If you specify OFF, you cannot specify FAIL or LOG.

#### **LOCK**

tells CP to only let a privileged user, who is also not the command issuer, change the settings. If you specify LOCK, you cannot specify UNLOCK.

**UNLOCK**

tells CP to let a privileged user change the command filtering level for the selected virtual machine (even if the target virtual machine is the command issuer's virtual machine). If you specify UNLOCK, you cannot specify LOCK.

**Usage Notes**

1. The initial D8ONECMD settings for your virtual machine are determined by options set in your user directory entry.
2. This command does not affect the user's ability to enter multiple commands by typing them at the console; it affects only multiple commands issued by programs.
3. This facility does not affect a user's ability to use a Program Function Key to enter more than one command at once, nor does it keep a program from establishing a value for a Program Function Key that issues multiple commands when the user at the terminal presses the Program Function Key.
4. If you are running an earlier level of CMS and D8ONECMD is set to FAIL:
  - some CMS commands (such as SENDFILE, NETDATA, DISK LOAD, and READCARD) may not work properly
  - an earlier level of the programmable operator facility will not initialize.

**Messages**

- HCP003E Invalid option - *option*
- HCP013E Conflicting option - *option*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on
- HCP6889E *userid*'s DIAGNOSE X'08' options are locked.

## SET DASD

### Authorization

Privilege Class: B

### Purpose

Use SET DASD to reset soft fence state for one or more real devices.

### Operands

*rdev*

*rdev1-rdev2*

is the real device number, a list of real device numbers, or a range of real device numbers. The variable *rdev* must be a hexadecimal number between X'0000' and X'FFFF'.

### FENCE RESET

tells CP to reset soft fence state for the specified device or devices.

### Usage Notes

1. The FENCE RESET function is allowed only for dedicated DASD and fullpack minidisks. If this command is issued from a second-level system to reset soft fence state for the specified device, it will work only when the underlying first-level disk is a dedicated DASD or a fullpack minidisk. Additionally, for a guest to issue this function, the guest must have OPTION DEVMAINT or MAINTCCW user authority.

### Examples

Example 1:

To reset a soft fence state for devices 8001-8004, enter the following:

```
set dasd 8000-8004 fence reset
Command complete;
Ready;
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *option*
- HCP006E Invalid device type - {*rdev/vdev/ldev*}
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP1172E No action for device *rdev* because control unit does not support soft fence
- HCP1173E Reset soft fence operation failed for device *rdev*
- HCP1173E Reset soft fence operation failed for devices: *rdev-rdev*

## SET DASDFW

### Authorization

Privilege Class: B

### Purpose

Use SET DASDFW to activate or deactivate the DASD fast write function for devices in a DASD subsystem. This command is valid for cache storage subsystems that support the DASD fast write function.

**Note:** Although the SET DASDFW ON command activates the DASD fast write function, it does not necessarily cause immediate DASD fast write operation. For the DASD fast write function to operate, both the subsystem cache and nonvolatile storage must be available and both caching and DASD fast write must be activated for the device.

### Operands

#### DEVICE

specifies that the DASD fast write function is to be activated or deactivated for the specified devices. It is the default (and only) value.

#### ON

indicates that the DASD fast write function is to be activated for the specified devices.

#### OFF

indicates that the DASD fast write function is to be deactivated for the specified devices.

#### FORCEOFF

indicates that the DASD fast write function is to be unconditionally deactivated for the specified device, regardless of any internal subsystem errors. This operand should only be used when absolutely necessary, because there is a possibility of loss of data.

#### *rdev*

#### *rdev1-rdev2*

is the real device number, a list of real device numbers, or a range of real device numbers of devices for which the DASD fast write function is to be activated or deactivated.

### Usage Notes

1. The SET DASDFW command is only valid for storage subsystems that contain nonvolatile storage (NVS) and support the DASD fast write function. An error message is generated if the subsystem containing a specified device does not support this function.
2. If the NVS or cache is not available when the SET DASDFW ON command is issued, the DASD fast write function begins when these resources become available. (For information on making these resources available to the subsystem, see [“SET CACHE”](#) on page 1422 and [“SET NVS”](#) on page 1588.)
3.  **Attention:** The FORCEOFF operand is intended only for recovery purposes and can result in a loss of data. It should only be used after SET DASDFW OFF has been issued to the device and the subsystem could not deactivate the DASD fast write function because of internal errors.

4. SET DASDFW OFF may produce delayed responses. See [“Delayed Responses to CP Commands”](#) on page 7 for more information.
5. This command may be issued to offline devices.
6. The caching function is always enabled on RAID (Redundant Array of Independent Disks) technology DASD such as an IBM DASD subsystem. For these types of DASD, the device accepts but ignores this command; the caching function cannot be modified by the user. The caching function for these types will always appear as ON in related query commands.

## Responses

Response 1:

The following response is displayed when you enter SET DASDFW ON and is repeated for each device specified on the command line.

```
rdev DASD fast write function has been activated.
```

If the originator of the command is not the system operator, the following response is issued to the system operator and is also repeated for each device specified on the command line.

```
rdev DASD fast write function was activated by userid.
```

### **rdev**

is the real device number of a device for which the DASD fast write function has been activated.

### **userid**

is the ID of the user who issued the command.

Response 2:

**Immediate Response:** If you enter SET DASDFW FORCEOFF, or if the DASD fast write function is deactivated immediately when you enter SET DASDFW OFF, the following response is repeated for each device specified on the command line.

```
rdev DASD fast write function has been deactivated.
```

### **rdev**

is the real device number of a device for which the DASD fast write function has been deactivated.

**Delayed Response:** If you issued the SET DASDFW OFF command and the DASD fast write function was not deactivated immediately, the following response is displayed:

```
Command started: SET DASDFW OFF rdev.
```

When the DASD fast write function is deactivated, the following response is issued:

```
rdev DASD fast write function has been deactivated.
```

Under certain circumstances, it is possible that a cache storage subsystem does not notify CP when it has deactivated the DASD fast write function. When this occurs, the appropriate command response cannot be generated. Under these circumstances, command processing is ended after generating the following response:

```
Command results lost: SET DASDFW OFF rdev.
```

In this case the QUERY DASDFW command can be issued to determine the state of the DASD fast write function.

If errors occur during the asynchronous processing of the command that prevent the successful completion of the command, the following response is displayed:

```
Command failed: SET DASDFW OFF rdev.
```

**rdev**

is the real device number of a device for which the DASD fast write function failed to deactivate.

**Response to System Operator:** If the originator of the command is not the system operator, the following response is issued to the system operator when the DASD fast write function has been deactivated. This response is also repeated for each device specified on the command line.

```
rdev DASD fast write function was deactivated by userid.
```

**rdev**

is the real device number of a device for which the DASD fast write function has been deactivated.

**userid**

is the ID of the user who issued the command.

**Messages**

- HCP006E Invalid device type - {rdev/vdev/ldev}
- HCP009E Invalid range - range
- HCP021E A real device number was not supplied or it is invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {rdev/vdev/ldev} does not exist
- HCP046E type rdev offline
- HCP319E Error processing subsystem command - cmd for DASD rdev
- HCP332E Invalid control unit type - rdev
- HCP1109E The command command cannot be processed for device rdev because the device is the secondary in a duplex pair.

## SET DATEFORMAT

### Authorization

Privilege Class: B, G

### Purpose

Use SET DATEFORMAT to set the default date format for commands which provide multiple date formats. Default date formats may be set for individual users or the entire system.

### Operands

#### SHOrtdate

specifies that dates will be displayed in *mm/dd/yy*, *mm/dd*, or *yy/mm/dd* format, where *mm* is the month, *dd* is the day of the month, and *yy* is the 2-digit year.

#### FULLdate

specifies that dates will be displayed in *mm/dd/yyyy* or *yyyy/mm/dd* format, where *mm* is the month, *dd* is the day of the month, and *yyyy* is the 4-digit year.

#### ISOdate

specifies that dates will be displayed in *yyyy-mm-dd* format, where *yyyy* is the 4-digit year, *mm* is the month, and *dd* is the day of the month.

#### SYSdefault

specifies that the default date format for this user will be set to the system-wide default.

#### USER

specifies that the default date format is being set for the user.

#### SYSTEM

specifies that the default date format is being set for the entire system.

### Usage Notes

1. If SET DATEFORMAT is not specified for an individual user and there is no DATEFORMAT statement in the user's directory entry, the default date format for that user is the system-wide default.
2. SYSDEFAULT is not valid with SYSTEM.
3. If the default date format for a user is set to (or defaults to) the system-wide default date format, and the system-wide default is changed, the user continues to see the old system-wide default as the user default until the user either logs off and logs back on or issues SET DATEFORMAT SYSDEFAULT to switch to the new system-wide default.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - Invalid option - command contains extra option(s) starting with *option*
- HCP013E Conflicting option - *option*
- HCP6704E Missing token at end of line

## SET DEVICES

### Authorization

Privilege Class: C

### Purpose

Use SET DEVICES to define or change the settings that CP will use if a device is added dynamically to the I/O configuration or is powered on after IPL.

**Note:** Before using this command, you must enable it by specifying a FEATURES ENABLE SET\_DEVICES statement in your system configuration file. See *z/VM: CP Planning and Administration* for more information on the [FEATURES Statement](#).

### Operands

#### ACCEPTed

tells CP to accept the specified device or devices.

#### *rdev*

#### *rdev-rdev*

is the real device number of the device or devices that you are affecting. The variable *rdev* must be a hexadecimal number between X'0000' and X'FFFF'. You can specify a single device, a range of devices, or any combination thereof.

#### NOTACCEPTed

tells CP not to accept the specified device or devices when the devices are dynamically added to VM from another partition. When VM is running second level, it prevents a device from being accepted when the device is attached to the virtual machine in which VM is running. If VM dynamically defines a device for its own partition, the NOTACCEPTed designation is overridden.

#### DYNamic\_i/o

tells CP to allow dynamic I/O changes on the specified device or devices.

**Note:** If you want to allow dynamic I/O changes on **any** devices, do not forget to specify FEATURES ENABLE DYNAMIC\_I/O in your system configuration file. This FEATURES operand enables or disables

dynamic I/O changes for your system's processor. So, if you do not enable dynamic I/O changes on the processor, CP prevents dynamic I/O changes on any individual device or devices.

#### **NOTDYNAMIC\_i/o**

tells CP not to allow dynamic I/O changes on the specified device or devices.

#### **SENSEd**

tells CP to use the information that is returned from a sense ID request to determine the device class or type.

#### **NOTSENSEd**

tells CP not to use the information that is returned from a sense ID request to determine the device class or type.

#### **THROTTled**

tells CP to limit (throttle) the rate of I/O coming from the specified device or devices.

#### **NOTTHROTTled**

tells CP not to limit (throttle) the I/O rate of the specified device or devices.

### **Usage Notes**

1. If multiple subchannel set support is enabled, DEVICES settings that are defined by the SET DEVICES command or the DEVICES system configuration statement apply to all subchannel sets. For example, if device 1234 is NOTACCEPTED, then so is device 11234. If device 01234 is NOTACCEPTED and device 11234 is added dynamically, it is ignored.

### **Responses**

Response 1:

To have CP accept a device, enter the following:

```
set devices accept 701
The Devices bit map was updated successfully
Ready;
```

Response 2:

To have CP not permit throttling for a range of devices, enter the following:

```
set devices notthrottled 700-710
The Devices bit map was updated successfully
Ready;
```

### **Messages**

- HCP002E Invalid operand - *operand*
- HCP643E Command not enabled in system configuration file

## SET DIALDROP

---

### Authorization

Privilege Class: G

### Purpose

Use SET DIALDROP to control when devices DIALED to your virtual machine are dropped.

### Operands

#### ON

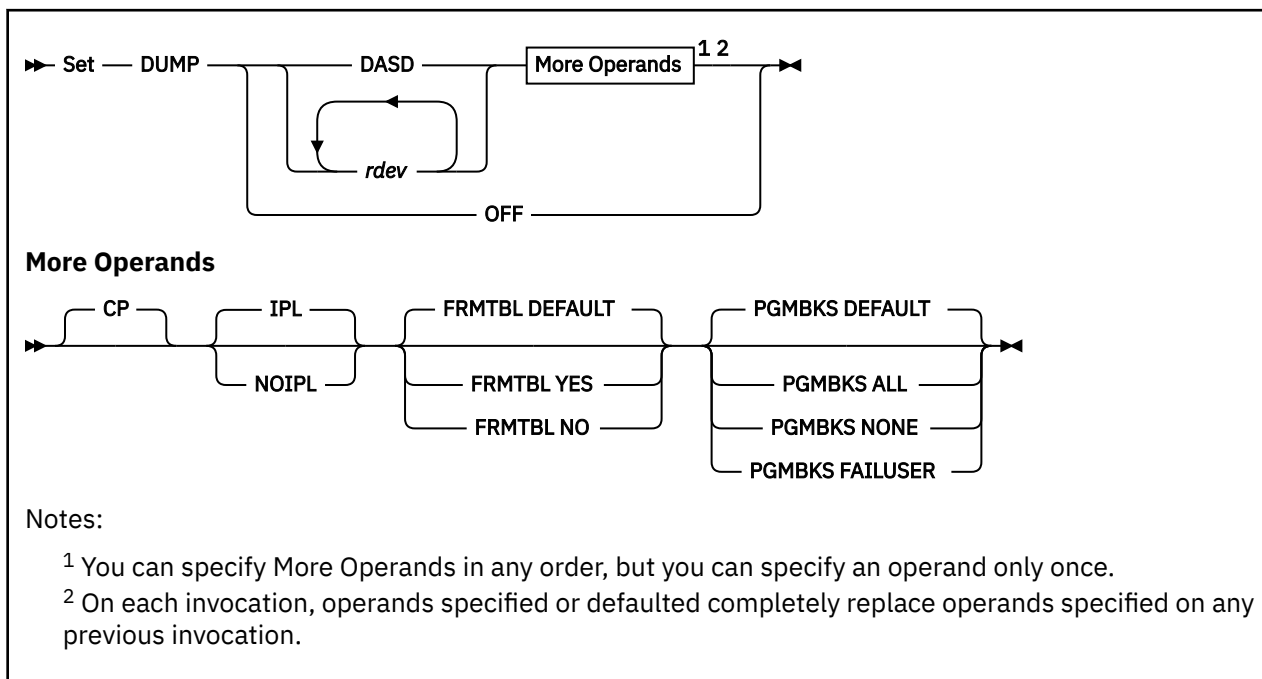

#### OFF

establishes whether devices DIALED to your virtual machine are dropped (ON) or stay connected (OFF) when a reset occurs (for example, when an IPL or SYSTEM CLEAR command is issued). Such a device is always dropped when an explicit DETACH or RESET command is issued for the associated virtual device. When you log on, DIALDROP is set ON.

### Messages

- HCP003E Invalid operand - *operand*
- HCP026E Operand missing or invalid

## SET DUMP

### Authorization

Privilege Class: B

### Purpose

Use SET DUMP to assign the unit or units to receive a system abend dump, to control the contents of a hard abend dump, and to specify whether the system should restart after dumping.

**Note:** Each invocation of SET DUMP completely replaces all settings from previous invocations of the command. Any option not specified on the new command is set to its default value.

### Operands

#### DASD

specifies that the system dump is written to one or more disks. The DASD dump space is released when the dump setting is changed. Clusters are allocated from spooling space on CP-owned DASD devices sufficient to hold a system abend dump.

#### rdev...

is the real device number, or a list of real device numbers of CP-owned DASD that contain spooling space to which the dump is written. A list of up to 32 real device numbers can be specified. The order in which you specify the DASD is the order in which they are searched for spooling space to be assigned as system abend dump space.

NVMe EDEVICES cannot be used to hold system hard abend dumps or snapdumps.

#### CP

is an obsolete keyword and no longer controls what memory is dumped. It is retained for compatibility.

**IPL  
NOIPL**

indicates whether the system is to be automatically restarted after a failure. At system initialization, the value is IPL; if you do not want your system automatically restarted, you must explicitly change the setting to NOIPL.

**OFF**

indicates that in the event a dump is attempted, either by a CP abend, a System Restart, or SNAPDUMP command, no dump will be created.

**FRMTBL DEFAULT****FRMTBL YES****FRMTBL NO**

specifies whether the full CP frame table is included in a hard abend dump. If you specify DEFAULT, the frame table is included in the cases for which IBM believes the frame table is needed to debug the problem. Otherwise, the dump includes a correlation table describing only the frames whose contents were dumped. YES forces inclusion of the frame table and NO forces the dump to have a correlation table. IBM recommends using the DEFAULT setting unless IBM support personnel instruct you to do otherwise in order to diagnose a specific problem.

**PGMBKS DEFAULT****PGMBKS ALL****PGMBKS NONE****PGMBKS FAILUSER**

specifies whether user PGMBKS are included in a hard abend dump. If you specify DEFAULT, PGMBKS are included in the cases for which IBM believes they are needed to debug the problem. ALL forces inclusion of all PGMBKS that aren't paged out, and NONE omits user PGMBKS. FAILUSER causes PGMBKS to be included for the guest that was running on the failing processor at the time of the abend, and for PGMBKS owned by the system. IBM recommends using the DEFAULT setting unless IBM support personnel instruct you to do otherwise in order to diagnose a specific problem.

PGMBKS owned by the system are always dumped, even if you specify PGMBKS NONE or PGMBKS FAILUSER. These PGMBKS are necessary in order to find data in address spaces owned by the system for certain VMDUMPTL commands.

**Usage Notes**

1. When the system is initialized, the dump device is set to DASD if there is enough spooling space to hold it. If there is not enough spooling space, a 'no dump unit' indicator is set. No dump will be generated.
2. When extending the amount of dump space during normal system execution, the system may be forced to set the 'no dump unit' indicator because there is insufficient contiguous SPOOL space.
3. The frame table and PGMBKS together constitute the vast majority of CP-owned frames, because they contain entries describing each 4K unit of real and virtual memory, respectively. The CP frame table is 1/128th the size of configured memory (8 GB per TB). PGMBKS take up 8K for each 1MB of virtual memory; though they are pageable, a PGMBK must remain resident as long as any page of that megabyte is resident. Omitting these structures from dumps when they are not likely to be needed for diagnosis dramatically reduces dump size and dumping time. With you specify the DEFAULT operand, CP determines whether or not to include the structures based on the abend code and failing module.
4. Specifying PGMBKS NONE/FAILUSER or FRMTBL NO does not affect the amount of space allocated for the dump. Dump space is allocated for a dump of maximum size because a SNAPDUMP command could occur at any time and could specify PGMBKS ALL and/or FRMTBL YES.
5. Use the OFF option only when you truly do not wish to receive a system dump. Use of this option stops the system dump capability until the command is reissued to specify an actual device.
6. When SET DUMP OFF has been specified, and the SET ABEND command was used to redefine a soft abend as HARD, an occurrence of that redefined soft abend will still cause a hard abend and a system re-IPL. But because of the SET DUMP settings, no dump will be generated. If the soft abend

was redefined as SNAPDUMP, the snapdump will not be generated because the only purpose of a snapdump is to create a dump.

7. When SET DUMP OFF is specified, the hard abend dump spool file is automatically closed. This is a class D spool file that is normally opened during system initialization and is owned by the user ID specified with the DUMP operand on the SYSTEM\_USERIDS configuration statement. It has a file type of "CPDUMP". Once closed, it can be reopened by issuing SET DUMP DASD or SET DUMP *rdev*.
8. See *z/VM: CP Planning and Administration* for information on [Allocating Space for CP Hard Abend Dumps](#) including recommendations from IBM.
9. Although CP limits the command length to 240 characters, not all terminal configurations allow that much input. It is possible that specifying all of the operands permitted by this command would exceed the input limits on some terminals. There are two ways to circumvent this limitation. First, it might be possible to change the line length of your terminal definition. For example, your terminal emulation software may permit you to define a terminal that has line 160 characters long, as opposed to the common line length of 80 characters. A second alternative is to create a simple REXX EXEC that contains the SET DUMP command that you wish to issue. This method has the added benefit of minimizing typographic errors because the REXX EXEC can be edited and rerun many times.

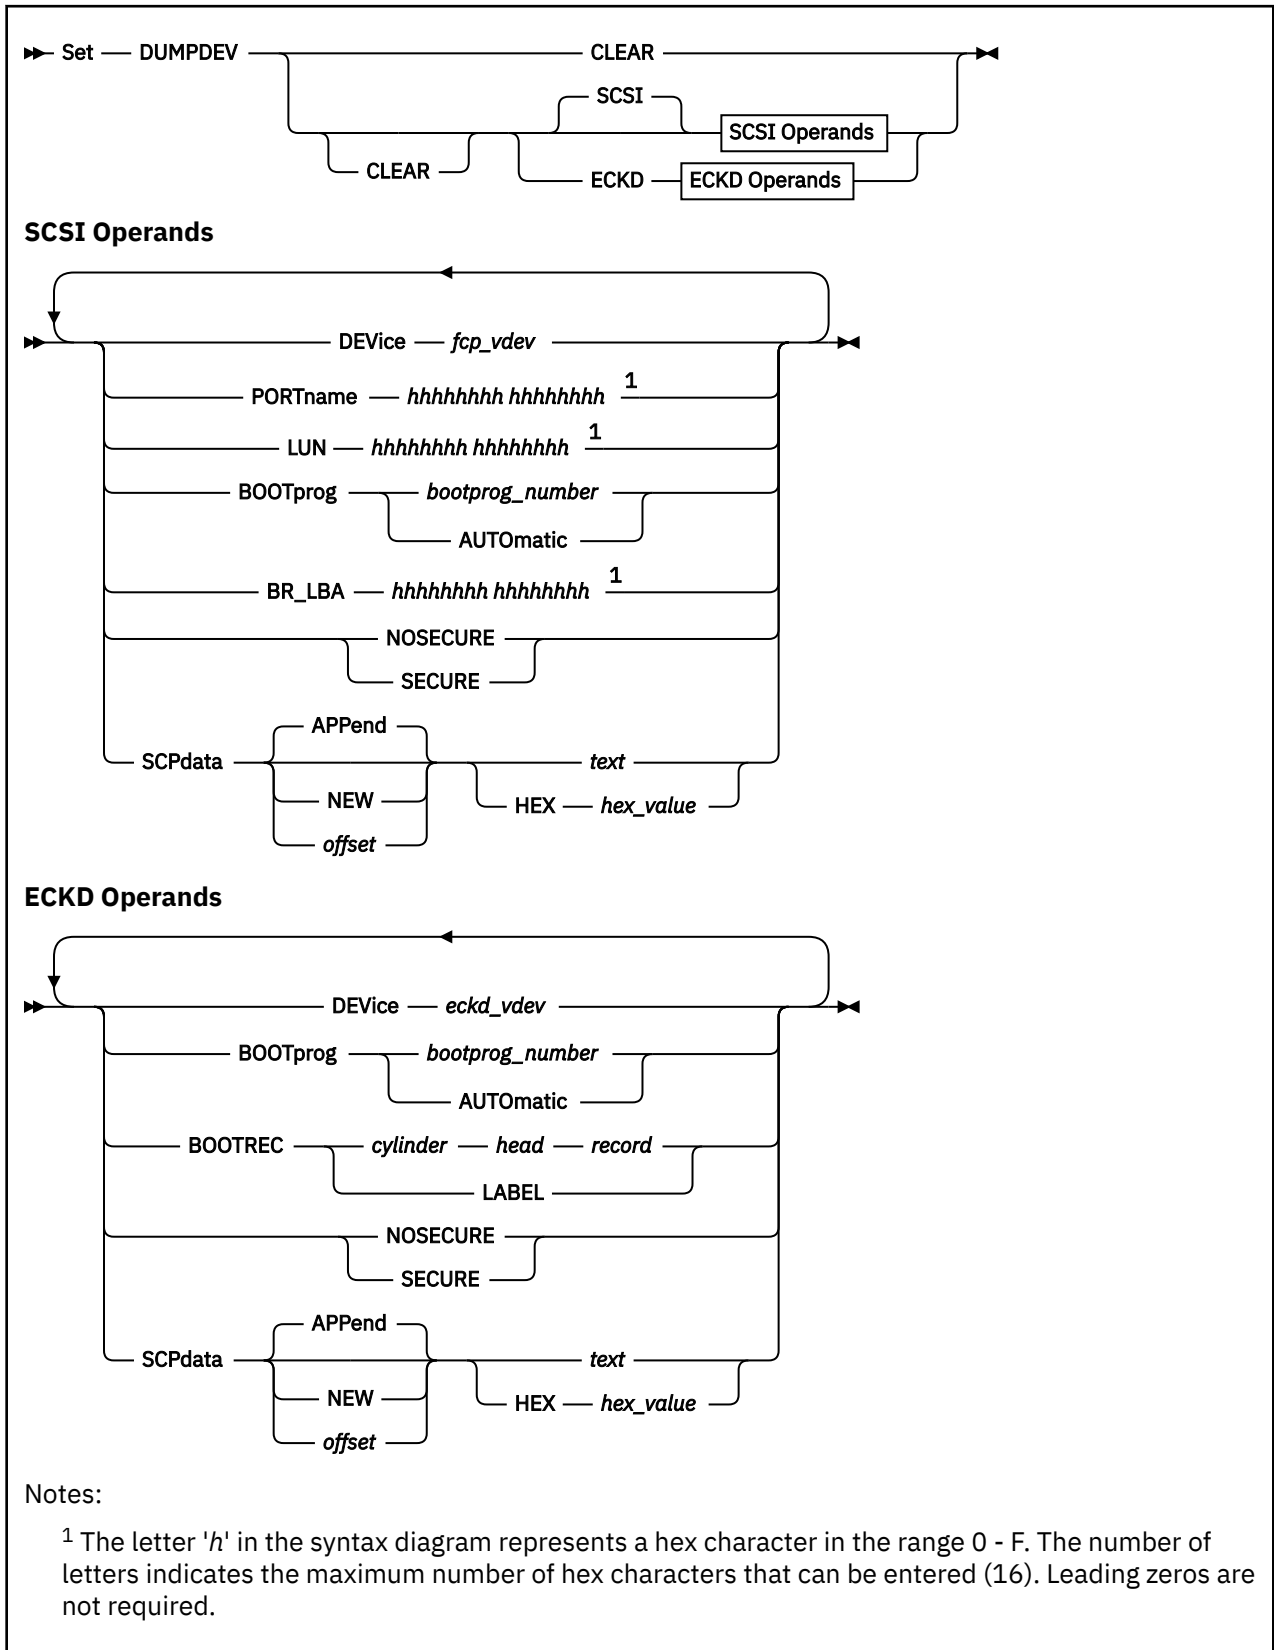

## Responses

The SET DUMP command responses are the same as the QUERY DUMP command responses. For more information, see the QUERY DUMP Responses section (see [“QUERY DUMP”](#) on page 887).

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

- HCP6005E Option *option* is not supported by z/VM.
- HCP9255I Excessive fragmentation of DASD dump space; unable to obtain additional clusters.
- HCP9259I No dump unit is set. No system abend dump will be generated. To assign a device, enter the SET DUMP command.

## SET DUMPDEV

## Authorization

Privilege Class: G

## Purpose

Use the **SET DUMPDEV** command to set parameters for a guest IPL with dump from a SCSI or ECKD disk. The parameters can identify the virtual device number and specify whether the IPL is a secure IPL. The parameters can identify the location of a system dumper program and information to pass to the program. The device that is IPLed is used to store the dump data.

The parameters that are set by using the **SET DUMPDEV** command are called DUMPDEV parameters and are used only for list-directed IPLs, which occur in the following cases:

- The **IPL** command specifies the *fcv\_vdev* operand and the DUMP operand.
- The **IPL** command specifies the DUMPDEV operand.

See usage note [“1” on page 1499](#).

The settings are temporary. The settings persist after an IPL but not after the user logs off. For more information, see [“IPL” on page 566](#).

## Operands

### CLEAR

The CLEAR operand clears all DUMPDEV parameters for all device types (SCSI and ECKD). Operands that follow the CLEAR operand are not cleared.

After DUMPDEV parameters are cleared, a guest IPL from SCSI or ECKD disk cannot be initiated until all required parameters for the SCSI or ECKD device type are set. The parameters that are required for each load device type are explained in usage note [“1” on page 1499](#).

### SCSI

The SCSI operand indicates that the DUMPDEV parameters are for IPL of a SCSI device. Other operands on the command must be operands for a SCSI device.

If you do not specify the SCSI or ECKD operand, the device type defaults to SCSI.

After the SCSI parameter is set, subsequent **SET DUMPDEV** commands cannot set ECKD parameters until a **SET DUMPDEV** command with the CLEAR operand is specified. Likewise, DUMPDEV parameters for an ECKD device must be cleared before you can set DUMPDEV parameters for a SCSI device.

### ECKD

The ECKD operand indicates that the DUMPDEV parameters are for IPL of an ECKD device. Other operands on the command must be operands for an ECKD device.

Because SCSI is the default device type, the ECKD operand must be specified on every command that sets DUMPDEV parameters for an ECKD device.

After the ECKD parameter is set, subsequent **SET DUMPDEV** commands cannot set SCSI parameters until a CLEAR operand is specified. Likewise, DUMPDEV parameters for a SCSI device must be cleared before you can set DUMPDEV parameters for an ECKD device.

### DEVICE *fcv\_vdev*

The DEVICE value (*fcv\_vdev*) specifies the virtual device number of the FCP device to IPL.

The DUMPDEV DEVICE parameter must be set before you can issue the **IPL DUMPDEV** command. A secure IPL with dump from a SCSI device can be initiated only by issuing the **IPL DUMPDEV** command.

If the **IPL** command specifies the *fcv\_vdev* operand, then the DUMPDEV DEVICE parameter must match that value or must not be set.

### DEVICE *eckd\_vdev*

The DEVICE value (*eckd\_vdev*) specifies the virtual device number of the ECKD device to IPL.

## SET DUMPDEV

The DUMPDEV DEVICE parameter must be set before you can issue the **IPL DUMPDEV** command. A secure IPL with dump from an ECKD device can be initiated only by issuing the **IPL DUMPDEV** command.

### **PORTname** *hhhhhhhh hhhhhhhh*

The PORTNAME value (*hhhhhhhh hhhhhhhh*) specifies the 8-byte fibre channel port name of the SCSI device that is IPLed. The value must be a hexadecimal value in the range 0 - FFFFFFFF FFFFFFFF. For values longer than eight hex characters, at least one separator blank is required after the eighth character.

If you do not set the PORTNAME parameter, it defaults to 0.

### **LUN** *hhhhhhhh hhhhhhhh*

The LUN value (*hhhhhhhh hhhhhhhh*) specifies the 8-byte logical unit number of the SCSI device that is IPLed. The value must be a hexadecimal value in the range 0 - FFFFFFFF FFFFFFFF. For values longer than eight hex characters, at least one separator blank is required after the eighth character.

If you do not set the LUN parameter, it defaults to 0.

### **BOOTprog** *bootprog\_number*

The *bootprog\_number* value specifies the boot program that is loaded from the SCSI or ECKD device that is IPLed. The value must be a decimal value in the range 0 - 30.

If you do not set the BOOTPROG parameter, it defaults to 0.

### **BOOTprog** **AUTOMATIC**

The BOOTPROG AUTOMATIC operand loads the first system dumper program (not an operating program) that is listed in the program table of the device that is IPLed.

If you do not set the BOOTPROG parameter, it defaults to 0.

### **BR\_LBA** *hhhhhhhh hhhhhhhh*

The BR\_LBA value (*hhhhhhhh hhhhhhhh*) specifies the logical-block address of the boot record of the SCSI device that is IPLed. The value must be a hexadecimal value in the range 0 - FFFFFFFF FFFFFFFF. For values longer than eight hex characters, at least one separator blank is required after the eighth character.

If you do not set the BR\_LBA parameter, it defaults to 0.

### **BOOTREC** *cylinder head record*

The BOOTREC values (*cylinder head record*) specify the boot record location on the ECKD device that is IPLed. Use hexadecimal values and separate the values by blank space. Leading zeros are not required. The following ranges are allowed when you specify the boot record location:

- Cylinder: 0 - FFFFFFFF
- Head (or track): 0 - F
- Record: 1 - FF

### **BOOTREC** **LABEL**

The BOOTREC LABEL operands specify that the boot record is the record that is identified in the volume label of the ECKD device that is IPLed.

If you do not set the BOOTREC parameter, it defaults to LABEL.

### **SECURE**

#### **NOSECURE**

The SECURE operand specifies that the IPL is a secure IPL.

The NOSECURE operand specifies that the IPL is not a secure IPL.

If you do not set the SECURE or NOSECURE parameter, the parameter defaults to NOSECURE.

The SECURE parameter is not valid unless the DEVICE parameter (virtual device number) is set.

**Note:** A secure IPL is required in the following situations:

- If a user's OPTION directory statement includes the SECUREIPLREQUIRED option, a secure IPL is required.
- If the program to be dumped was IPLed with the SECURE parameter, then the DUMPDEV parameters must include the SECURE parameter.

**SCPDATA ... text****SCPDATA ... HEX *hex\_value***

The SCPDATA keyword designates data to be passed to the program that is loaded for a list-directed IPL. If the program does not require any data, then the SCPDATA parameter is optional.

The HEX keyword indicates that the data (*hex\_value*) is UTF-8 encoded hex (characters 0-F). The hex string must be an even number of digits.

If the HEX keyword is not specified, the data is assumed to be EBCDIC text (code page 924).

Quotation marks are necessary only if the text includes blanks, mixed case, is a valid keyword (NEW or APPEND), or is all numeric (a valid offset).

Up to 4096 (4K) characters of data (text or hexadecimal) can be entered. The actual number of input characters might be less than 4096 depending on the translation to UTF-8. Because two hex characters are required to represent each UTF-8 data byte, the maximum number of UTF-8 data bytes that can be defined by using the HEX option is 2048 (1/2 of the 4K character input limit).

There is no default value for SCPDATA.

**NEW**

The parameter value that follows the NEW keyword replaces any previously specified SCPDATA data.

**APPEND**

The parameter value that follows the APPEND keyword is appended to the end of any previously specified SCPDATA data.

**offset**

The *offset* value indicates an offset of the previously specified SCPDATA data. The parameter value that follows the *offset* value overlays the previously defined SCPDATA data beginning at the specified offset. The *offset* value must be a value from 0 to the current length of the SCPDATA data.

**Usage Notes**

1. LOADDEV and DUMPDEV parameters are used for list-directed IPLs. [Table 34 on page 1499](#) shows which DUMPDEV parameters have default values that must be set (changed from the default) before each type of guest IPL with dump can be started. Other parameters might need to be set if the default values are not appropriate for your environment.

IPL type	DEVICE parameter	PORTNAME parameter	LUN parameter	SECURE parameter
IPL <i>fcv_vdev</i> DUMP	The DEVICE parameter is not set or matches <i>fcv_vdev</i> on the <b>IPL</b> command	Required	Required	The SECURE parameter is not allowed when the <i>fcv_vdev</i> operand is used
IPL <b>DUMPDEV</b> from SCSI device	Required	Required	Required	Required if the previous IPL used the SECURE parameter or if the SECUREIPLREQ option is specified in the OPTION directory statement
IPL <b>DUMPDEV</b> from ECKD device	Required	Not applicable	Not applicable	

## SET DUMPDEV

Note that a list-directed IPL with dump uses DUMPDEV parameters. A list-directed IPL without dump uses LOADDEV parameters. See [“IPL” on page 566](#) and [“SET LOADDEV” on page 1544](#).

2. To prepare for a secure IPL, the program that is loaded must be signed. The appropriate certificate must be loaded in the HMC and assigned to any LPAR on which the IPL might occur.
3. DUMPDEV parameters can be set only by using the **SET DUMPDEV** command.
4. The DUMPDEV settings of a user can be displayed by using the **QUERY DUMPDEV** command. See [“QUERY DUMPDEV” on page 890](#).
5. The initial **SET DUMPDEV** command or the first **SET DUMPDEV** command after a **SET DUMPDEV CLEAR** command establishes the device type (SCSI or ECKD) until another **SET DUMPDEV CLEAR** command is issued. Until another **SET DUMPDEV CLEAR** is issued, **SET DUMPDEV** commands with operands for a different device type are not valid. Because the default device type is SCSI, when you set an ECKD load device you must specify the ECKD operand on every **SET DUMPDEV** command issued. For example:

```
SET DUMPDEV CLEAR ECKD DEVICE 1234
SET DUMPDEV ECKD BOOTREC 0 0 5
```

6. After a DUMPDEV parameter is set, it can be changed by issuing the **SET DUMPDEV** command with a new value for the same parameter. It is not necessary to issue a **SET DUMPDEV CLEAR** command before you change a parameter value.

The one exception is the device type parameter (SCSI or ECKD). You must issue a **SET DUMPDEV CLEAR** command before you change the device type parameter.

7. The z/VM stand-alone dump utility does not support list-directed IPL from ECKD, and does not support secure IPL from SCSI or ECKD. Therefore, you cannot set the following DUMPDEV parameters to IPL z/VM stand-alone dump in a virtual machine:

- ECKD
- SECURE

More information about IPLing the z/VM stand-alone dump utility is available. See [The Stand-Alone Dump Utility in z/VM: CP Planning and Administration](#).

8. The default DUMPDEV value for the PORTNAME and LUN parameters is 0, which is not a valid device port name and not a valid device LUN. An IPL attempt that uses the default value for the PORTNAME or LUN parameter will fail.

### Examples

1. The following command identifies port a20, logical unit number 03 as the SCSI device, and passes the SCPDATA=x'74657374' to the system dumper program that is loaded during a guest IPL.

```
set dumpdev port a20 lun 03 scpdata hex 74657374
```

2. After the command in the previous example completes, the following command replaces '57' in the SCPDATA with '75'. The offset of 3 indicates where the data overlay begins. The resulting SCPDATA value is 74675374.

```
set dumpdev scpdata 3 hex 75
```

## SET DYNAMIC\_I/O

### Authorization

Privilege Class: C

### Purpose

Use SET DYNAMIC\_I/O or SET DYNAMIC\_IO to enable or disable CP's ability to dynamically change the processor's I/O configuration.

### Operands

#### ON

tells CP to allow dynamic changes to the I/O configuration on this processor.

#### OFF

tells CP not to allow dynamic changes to the I/O configuration on this processor.

### Usage Notes

1. You can also allow or prevent dynamic I/O changes to this processor's I/O configuration using the ENABLE or DISABLE DYNAMIC\_I/O operands of the FEATURES statement in the system configuration file. For more information about the [FEATURES Statement](#), see *z/VM: CP Planning and Administration*.
2. After you enable dynamic I/O changes for the system (using either this command or the FEATURES statement), you can decide whether to allow dynamic I/O changes on a device by device basis using the DYNAMIC\_I/O operand of the SET DEVICES command or the DEVICES statement in the system configuration file. For more information about the SET DEVICES command, see [“SET DEVICES” on page 1490](#). For more information about the [DEVICES Statement](#), see *z/VM: CP Planning and Administration*.

### Responses

Response 1:

To allow dynamic I/O changes on the system, enter the following SET DYNAMIC\_I/O command:

```
set dynamic_i/o on
System is now enabled for dynamic I/O changes
Ready;
```

If CP is already allowing dynamic I/O changes when you issue the SET DYNAMIC\_I/O ON command, you see the following response:

```
set dynamic_i/o on
System is already enabled for dynamic I/O changes
Ready;
```

Response 2:

To prevent dynamic I/O changes on the system, enter the following SET DYNAMIC\_I/O command:

```
set dynamic_i/o off
System is now disabled for dynamic I/O changes
Ready;
```

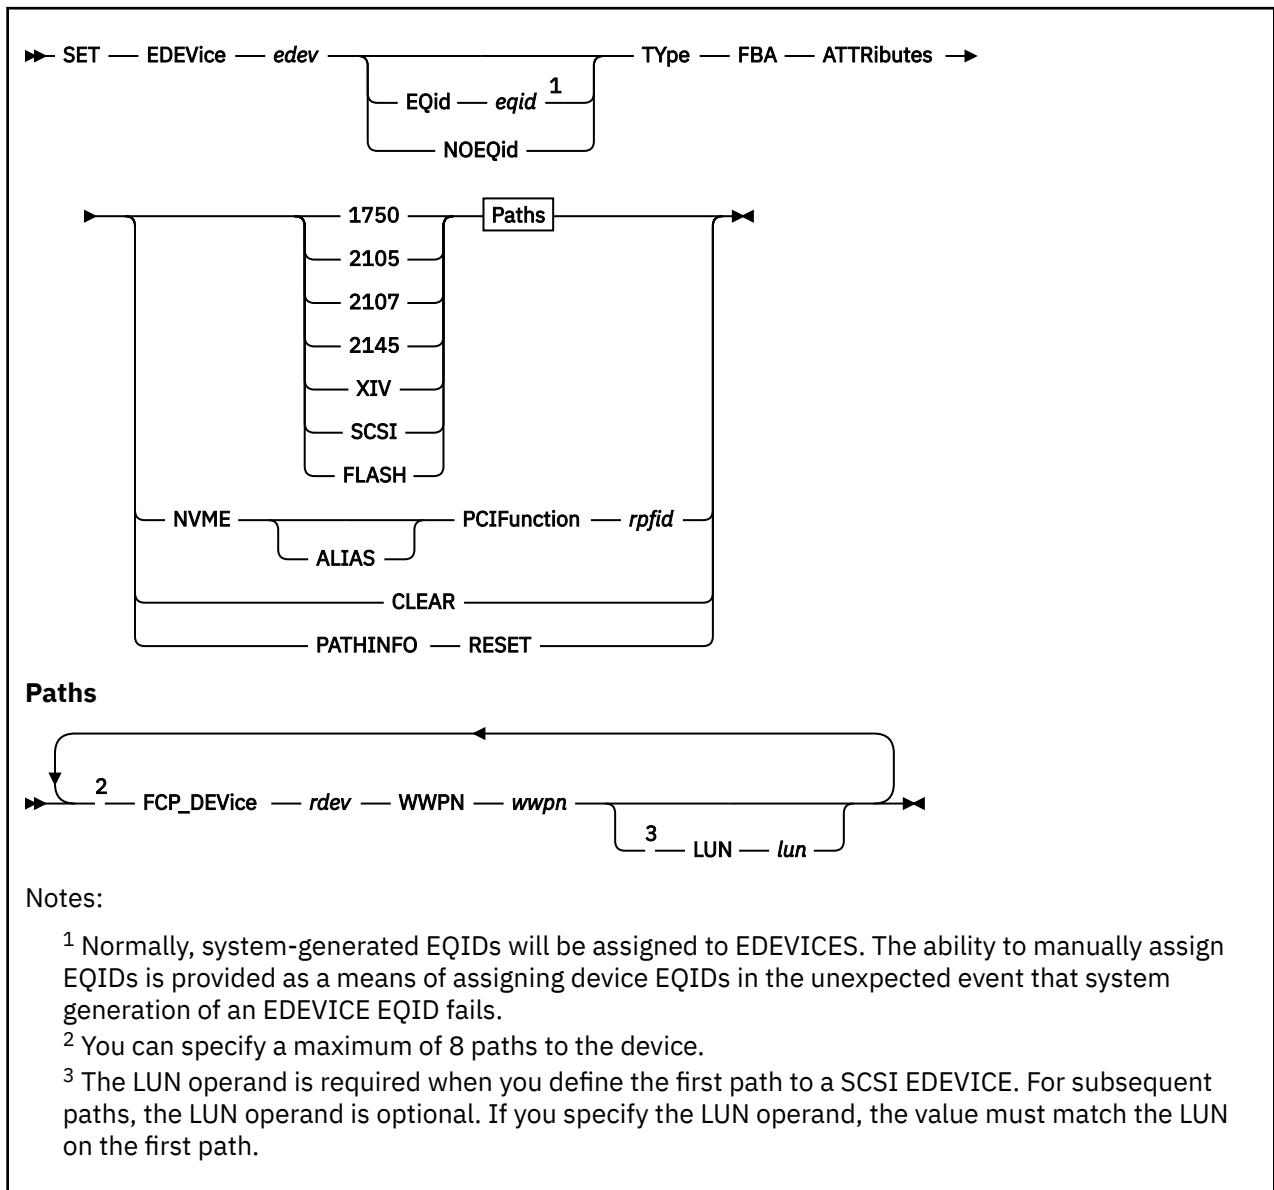

If CP is already preventing dynamic I/O changes when you issue the SET DYNAMIC\_I/O OFF command, you see the following response:

```
set dynamic_i/o off
System is already disabled for dynamic I/O changes
Ready;
```

## Messages

- HCP6850E Cannot disable dynamic I/O changes System is in configuration mode

## SET EDEVICE

### Authorization

Privilege Class: B

### Purpose

Use the SET EDEVICE command to define, modify, or clear the definition of an emulated device that represents a real SCSI device or a real NVMe device that is connected to a PCIe adapter.

**Note:** The device number of an emulated device must not conflict with the device number of a real device.

### Operands

#### *edev*

specifies the device number that is associated with the emulated device. The *edev* number corresponds directly with an *rdev* number. Thus, a new *edev* number cannot be defined where an *rdev*

number already exists. An *edev* in the active configuration can be entered as a 4-digit hexadecimal number between X'0000' and X'FFFF'. For an *edev* in the active or standby configuration, the device number can be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set of the device defined, modified or cleared.

**EQid eqid**

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1 to 8 alphanumeric characters. If the CLEAR option is specified, the EQID will be ignored. The EQID must be unique across all devices on the system.

**NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID. If the CLEAR option is specified, the NOEQID option is not necessary.

**TYPe**

specifies the emulated device type, selected by the immediately following parameter.

**FBA**

identifies the emulated device as an FBA DASD.

**ATTRIBUTES**

specifies the name of an attribute set to be associated with the real device.

**1750**

specifies that IBM 1750 device attributes are to be used for the real device that is being emulated. This attribute should be used for all DS6000 hardware. See Usage Note [“6” on page 1507](#) for more information.

**2105**

specifies that IBM 2105 device attributes are to be used for the real device that is being emulated. This attribute should be used for all Enterprise Storage Server (ESS) hardware.

**2107**

specifies that IBM 2107 device attributes are to be used for the real device that is being emulated. This attribute should be used for all DS8000 hardware.

**2145**

specifies that IBM 2145 device attributes are to be used for the real device that is being emulated. This attribute should be used for all SAN Volume Controller hardware, including Storwize® models. See Usage Note [“7” on page 1507](#) for more information.

**XIV**

specifies that IBM XIV® device attributes are to be used for the real device that is being emulated.

**SCSI**

specifies that general SCSI device attributes are to be used for the real device that is being emulated.

**Note:** When specifying this value, you should exercise caution in defining more than one path to the device. Be sure that the device actually supports multiple paths. Defining multiple paths to a device that does not support multiple paths could result in data-integrity problems on the device.

**FLASH**

specifies that IBM FLASH device attributes are to be used for the real device that is being emulated. This attribute is used for IBM Flash Systems hardware and does not require a SAN Volume Controller (2145) in use.

**NVME**

specifies that NVMe device attributes are to be used for the device that is emulated. This attribute is used for NVMe devices that are connected via PCIe functions.

**FCP\_DEVICE rdev**

specifies the real device number of the FCP device to be used for a specific path to a SCSI device. The *rdev* must be a 1- to 4-digit hexadecimal number between X'0000' and X'FFFF'.

**WWPN wwpn**

specifies the world wide port name for a specific path to a SCSI device. The *wwpn* must be a 16-digit hexadecimal number between X'0000000000000000' and X'FFFFFFFFFFFFFFFF'.

## SET EDEVICE

**Note:** If fewer than 16 digits are specified for the *wwpn*, the number will be padded with leading zeroes to make it a 16-digit number.

### LUN *lun*

specifies the logical unit number for a specific path to a SCSI device. The *lun* must be a 16-digit hexadecimal number between X'0000000000000000' and X'FFFFFFFFFFFFFF'.

**Note:** If fewer than 16 digits are specified for the *lun*, the number will be padded with leading zeroes to make it a 16-digit number.

### ADD PATH

indicates that one or more additional paths are to be added to the real SCSI device.

### DELeTe PATH

indicates that one or more paths are to be deleted from the real SCSI device.

### ALIAS

specifies that an alias device is to be defined.

### PCIFunction *rpfid*

is the ID of a real PCI function that is associated with an NVMe adapter. Specify the ID as eight hexadecimal digits. You can omit leading zeros. If an EDEVICE is already associated with the PCI function, another EDEVICE is defined. One base device can be defined for roughly each one terabyte of device capacity. A combination of up to 127 base and alias devices can be defined for a single NVMe PCIe function.

### CLEAR

specifies that the information in the real device control block (RDEV) and the emulated device control block (EDEV) associated with the specified emulated device is to be cleared such that the emulated device can no longer be used without another SET EDEVICE command to redefine it.

The CLEAR operand is meaningless for an NVMe EDEVICE and is rejected if used with an NVMe EDEVICE.

### PATHINFO RESET

clears the current error and failure counters associated with each path. Also resets the timestamps and reason fields.

## Usage Notes

1. When defining emulated devices to represent real SCSI devices, there should be a one-to-one relationship between an emulated device and a real SCSI device. All paths defined for an emulated device should represent paths to the same real SCSI device. If the paths for one emulated device are associated with more than one real SCSI device or if more than one emulated device is associated with the same real SCSI device, data integrity problems could occur.
2. Path validation for an emulated device occurs when the emulated device is varied online or when a path is added to an online emulated device. Any invalid path will be deleted from the EDEV. A path is considered to be invalid for any of the following reasons:
  - The device specified by the FCP\_DEVICE parameter does not exist.
  - The device specified by the FCP\_DEVICE parameter is not an FCP device.
  - The device specified by the FCP\_DEVICE parameter is an offline FCP device.
  - The device specified by the FCP\_DEVICE parameter is dedicated to a virtual machine.
  - The value specified by the WWPEN parameter is not a valid world wide port name in your configuration.
  - The value specified by the LUN parameter is not a valid logical unit number for the specified world wide port name.
3. You must use the VARY command to take an emulated device offline before you can clear it.
4. The ADD PATH and DELETE PATH parameters are only valid when the command is issued to a previously defined emulated device, but cannot be used on a command issued to a cleared emulated device.

5. The last path to an emulated device cannot be deleted except via the CLEAR parameter.
6. Devices (LUNs) on an IBM 1750 (DS6000) storage controller can be configured through any of the I/O ports on the controller, but the access times for a given device through different ports can be different. For a given device, half of the ports will provide faster access times than the other half of the ports. The channel paths connected to the ports with faster access are called "preferred paths" for the device, and the remaining channel paths are called "non-preferred paths".

Previous releases of z/VM required knowledge of the preferred/non-preferred value for each path on a SET EDEV command when using the 1750 attribute. Now, z/VM is able to determine during device initialization which paths are preferred and which are not, so operands on the SET EDEV command that explicitly state the preferred/non-preferred value for such a device will be ignored. Preferred paths will still be given preference over non-preferred paths during the path selection for an I/O request.

7. When using an IBM 2145, a host that has a LUN mapping for a virtual disk will normally be able to access that virtual disk via any of the ports connected to either of the two nodes in the I/O group supporting that virtual disk. Each virtual disk has a set of preferred ports. These ports will give slightly better performance than the ports that are non-preferred. By default, the cache component assigns ownership of even numbered virtual disks to one node of a caching pair and the ownership of odd numbered virtual disks to the other node. To provide flexibility, the ownership for a given virtual disk can be explicitly assigned to a given node when the virtual disk is created. A node that is explicitly assigned as an owner of a virtual disk is known as the preferred node.

Previous releases of z/VM required knowledge of the preferred/non-preferred value for each path on a SET EDEV command when using the 2145 attribute. Now, z/VM is able to determine during device initialization which paths are preferred and which are not, so operands on the SET EDEV command that explicitly state the preferred/non-preferred value for such a device will be ignored. Preferred paths will still be given preference over non-preferred paths during the path selection for an I/O request.

8. If an EQID is specified along with the CLEAR parameter, the EQID is ignored and the EDEV is cleared without setting an EQID. Similarly, if an EQID is specified with the PATHINFO RESET parameters, the EQID is ignored and the path information is reset without setting an EQID.
9. When setting an EQID for an EDEV, no other device can have the same EQID assigned to it. Furthermore, when the device is brought online, if a system-generated EQID can be assigned to the device, the user-defined EQID will be removed and the system-generated ID will be used.
10. Normally, system-generated EQIDs will be assigned to EDEVICES. The ability to manually assign EQIDs is provided as a means of assigning device EQIDs in the unexpected event that system generation of an EDEVICE EQID fails.
11. When using IBM Flash Systems and specifying the FLASH attribute, a SAN Volume Controller should not exist in the configuration. In this case a round-robin path algorithm is used. However, if a SAN Volume Controller is configured with Flash Systems hardware, the 2145 attribute must be specified instead of the FLASH attribute, because a preferred path algorithm is used.
12. For system attached paging EDEVICES, z/VM has an optimized path for issuing SCSI I/O requests directly without any simulation overhead. For non-paging EDEVICES, there is simulation overhead incurred with every I/O request. Therefore, it is recommended that EDEVICES only be used for disks which are accessed infrequently, such as a system disk used to store z/VM kernel images. z/VM has industry leading virtualization support for FCP subchannel attachment, which should be considered the primary approach for configuring any I/O intensive environments.
13. When configuring a single LUN on an XIV, SVC (2145), or a device incorporating SVC technology (such as V7000, V840, and V9000) as an EDEVICE, each associated FCP (source) subchannel should be configured to only one target port (WWPN) of the storage system. In addition, it is recommended that each (source) FCP subchannel be defined on a different (source) FCP channel path (or CHPID). This provides for best LUN availability in the event of a link failure.
14. Due to hardware differences between a Flash device and other SCSI devices, the FLASH attribute must be specified in order for an EQID to be generated. Otherwise, the device cannot be used in an SSI environment. The exception is: if the FlashSystem is used as an IPL device, the attributes FLASH, XIV, and SCSI will be recognized as valid for generating an EQID.

## SET EDEVICE

15. Specifying a 5-digit hexadecimal device number on defining an EDEV will place it into the active configuration as well, if there is not already a matching device number active.
16. When you vary on the device, the device attribute is checked dynamically. If the wrong value was set, the ATTR value will be updated to the correct device attribute. Any further paths added or deleted using the SET EDEVICE command will require specifying the correct ATTR operand. When setting the ATTR operand for non-IBM devices, the above behavior is ignored, and the specified ATTR value will be used as the specified device attribute for the emulated device.
17. When the ADD PATH or DELETE PATH option is specified, the value set for the ATTR operand is ignored, and the attribute of the existing EDEV is used to add or delete the path instead.

### Responses

Response 1:

To define an emulated device 8181 for a 2105 SCSI device with one path, enter the following:

```
set edev 8181 type fba attr 2105
  fcp_dev 900 wwpn 200400A0B80BA987 lun 0002000000000000
EDEV 8181 was created.
Ready;
```

Response 2:

To define an emulated device 8181 for a 2105 SCSI device with one path, and an EQID of ABCDEFGH, enter the following:

```
set edev 8181 eqid ABCDEFGH type fba attr 2105
  fcp_dev 900 wwpn 200400A0B80BA987 lun 0002000000000000
EDEV 8181 was created.
Ready;
```

Response 3:

To define an emulated device 8181 for a 2105 SCSI device with one path, and remove any previously existing EQID for the EDEV, enter the following:

```
set edev 8181 noeqid type fba attr 2105
  fcp_dev 900 wwpn 200400A0B80BA987 lun 0002000000000000
EDEV 8181 was created.
Ready;
```

Response 4:

To define an emulated device 4343 for a general SCSI device with two paths, enter the following:

```
set edev 4343 type fba attr scsi
  fcp_dev 800 wwpn 200400A0B80BA687 lun 0001000000000000
  fcp_dev 801 wwpn 200400A0B80BA688 lun 0001000000000000
EDEV 4343 was created.
Ready;
```

Response 5:

To add a path to an existing emulated device 8181, enter the following:

```
set edev 8181 type fba attr 2105 add path
  fcp_dev 901 wwpn 200400A0B80BA988 lun 0002000000000000
EDEV 8181 was modified.
Ready;
```

Response 6:

To delete a path from an existing emulated device 4343, enter the following:

```
set edev 4343 type fba attr scsi delete path
  fcp_dev 800 wwpn 200400A0B80BA687 lun 0001000000000000
```

```
EDEV 4343 was modified.
Ready;
```

## Response 7:

To clear an existing emulated device 4343, enter the following:

```
set edev 4343 clear
EDEV 4343 was cleared.
Ready;
```

## Response 8:

To define an emulated device 5004 for a 2145 device with two paths where the LUN is optional on the second path, enter the following:

```
set edev 5004 type fba attr 2145
  fcp_dev 800 wwpn 200400A0B80BA687 lun 0002000000000000
  fcp_dev 801 wwpn 200400A0B80BA688
EDEV 5004 was created.
Ready;
```

## Response 9:

To reset the error and failure information displayed with the PATHINFO option, enter the following:

```
set edev 400 pathinfo reset
```

The path information should now be cleared:

```
query edev 400 pathinfo
EDEV 0400 TYPE FBA ATTRIBUTES 2107 ALUA SUPPORTED: YES
PATHS:
FCP_DEV: 1D1D WWPN: 5005076306081588
LUN: 4064401600000000 ALUA OPTIMIZED: NO
SELECTED: 0
ADAPTER ERRORS: 0
SOFTWARE: 0
HARDWARE: 0
TRANSPORT: 0
OTHER: 0
TIMEOUT ERRORS: 0
SCSI ERRORS: 0
RESERVATION: 0
QUEUE FULL: 0
DEVICE BUSY: 0
ACA ACTIVE: 0
ABORT TASK: 0
CHECK CONDITIONS: 0
MEDIUM: 0
HARDWARE: 0
NOT READY: 0
ABORTED: 0
OTHER: 0
LAST ERROR TIME: NONE
LAST ERROR TYPE: NONE
LAST FAILURE TIME: NONE
LAST FAILURE REASON: NONE
```

The counters are reset to 0 and the error and failure types are set to NONE.

## Response 10:

The following commands and responses show the definition of emulated base devices (0F80, 0F81) and emulated alias devices (0F90, 0F91, 0F92) for a real PCIe function 00000071 that is associated with an NVMe adapter.

```
set edev f80 type fba attr nvme pcif 00000071
EDEV 0F80 was created.

vary on f80
```

## SET EDEVICE

```
0F80 varied online

attach f80 system
DASD 0F80 ATTACHED TO SYSTEM MYNVME HYPERPAV BASE

set edev f81 type fba attr nvme pcif 00000071
EDEV 0F81 was created.

vary on f81
0F81 varied online

attach f81 system
DASD 0F81 ATTACHED TO SYSTEM MYNV2 HYPERPAV BASE

set edev f90 type fba attr nvme alias pcif 00000071
EDEV 0F90 was created.

vary on f90
0F90 varied online

attach f90 system
DASD 0F90 ATTACHED TO SYSTEM          HYPERPAV ALIAS

set edev f91 type fba attr nvme alias pcif 00000071
EDEV 0F91 was created.

vary on f91
0F91 varied online

attach f91 system
DASD 0F91 ATTACHED TO SYSTEM          HYPERPAV ALIAS

set edev f92 type fba attr nvme alias pcif 00000071
EDEV 0F92 was created.

vary on f92
0F92 varied online

attach f92 system
DASD 0F92 ATTACHED TO SYSTEM          HYPERPAV ALIAS
```

- HCP8704E EDEV *rdev* was not modified because the device could not be unloaded.
- HCP8704E EDEV *rdev* was not cleared because the device could not be unloaded.
- HCP8704E Device *rdev* is an NVMe emulated device and cannot be cleared.

## SET EMSG

### Authorization

Privilege Class: G

### Purpose

Use SET EMSG to control error message handling. The initial setting for EMSG is installation dependent and is defined in the system configuration file.

### Operands

#### ON

specifies that both error code and error message text are displayed on your display screen.

#### CODE

specifies that only the error code is displayed.

#### IUCV

specifies that both the error code and text are to be passed to the virtual machine through IUCV if a connection to the message system service exists. If no IUCV connection exists, the message is handled as if SET EMSG ON had been issued.

#### OFF

specifies that no error messages are displayed.

#### TEXT

specifies that only the message text is displayed.

### Usage Notes

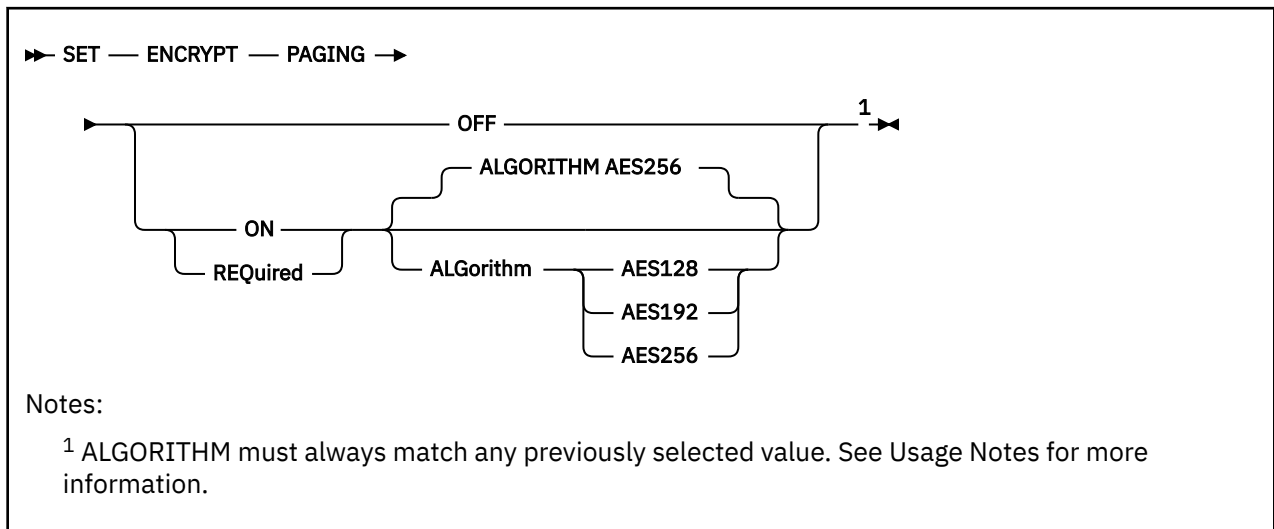

1. If you specify the TEXT option, the number of the message is not displayed. The lack of a message number makes it difficult to locate the message in the [z/VM: CP Messages and Codes](#). Therefore, use the TEXT option with caution.
2. The full message is spooled (code and text) if SET EMSG is set OFF; otherwise an error message is spooled according to the setting.
3. CMS recognizes EMSG settings for all error (E) and information (I) messages, but ignores the EMSG setting and displays the complete message (error code and text) for all other system messages.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid

## SET ENCRYPT

### Authorization

Privilege Class: A

### Purpose

Use SET ENCRYPT to enable or disable host level encryption for the z/VM hypervisor if the appropriate hardware support is available to the LPAR.

### Operands

#### PAGing

indicates the hypervisor function modified by this command is CP paging of guest memory and virtual-disk-in-storage (VDISK).

#### OFF

disables the host encryption for the hypervisor function indicated. You cannot use this operand if the ENCRYPT value was previously set to REQUIRED (via either the SET ENCRYPT command or the ENCRYPT configuration statement).

#### ON

enables host encryption for the hypervisor function indicated, if appropriate hardware is available. You cannot use this operand if the ENCRYPT value was previously set to REQUIRED (via either the SET ENCRYPT command or the ENCRYPT PAGING system configuration statement).

#### REQUIRED

enables host encryption for the hypervisor function indicated, if appropriate hardware is available, and locks this setting until the next system IPL. That is, once you set the ENCRYPT value to REQUIRED, the SET ENCRYPT command cannot be used for this CP function.

#### ALGorithm

Specifies the symmetric encryption cipher to be used by this host function. All algorithms currently supported require a specific level of CPACF (hardware feature 3863) to be enabled for the system. For more information, see *z/VM: Migration Guide*.

## SET ENCRYPT

### AES128

### AES192

### AES256

indicates the Advanced Encryption Standard (AES) algorithm is to be used for this hypervisor function, in Cipher Block Chaining (CBC) mode. The key length in bits determines the strength of the encryption to be performed.

## Usage Notes

1. A value for ALGORITHM can be selected only when ENCRYPT PAGING is enabled for the first time. The algorithm can be set either with the SET ENCRYPT command or with the ENCRYPT statement in the system configuration file. Once an algorithm is selected, it cannot be changed without a system IPL.
2. The algorithm must always match any previously selected value. SET ENCRYPT returns an error if a different algorithm is requested.
3. The system operator receives an informational message after a successful SET ENCRYPT command if there is a change in encryption status.
4. Caution should be exercised when using the REQUIRED option, because after using this option further changes are not permitted until the next system IPL. For more information, see [Pervasive Encryption for z/VM](#) in *z/VM: CP Planning and Administration*.
5. Enabling encryption will increase CPU utilization relative to the strength of the encryption algorithm selected. For more information, see [Major Factors Affecting Performance](#) in *z/VM: Performance*.

## Responses

Response 1:

```
Encrypt Paging set on to algorithm AES192
Encrypt Paging Settings:
  Currently: On AES192
  At IPL: Off
```

This response is issued when ON is specified with a valid algorithmic value.

Response 2:

```
Encrypt Paging set off
Encrypt Paging Settings
  Currently: Off
  At IPL: Off
```

This response is issued when encryption has never been enabled.

Response 3:

```
HCPENC1394I Encryption of paging changed from {on|off} to {on|off|required},
[with algorithm AESnnn,] by user userid
```

This message is issued to the primary system operator when a user ID other than the system operator uses SET ENCRYPT to change the state of host-level encryption of a particular function. This message does not require operator intervention, but should be noted for auditing and automation purposes.

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *{option|command}* contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid
- HCP1390E Encrypt Paging cannot be enabled due to missing hardware support
- HCP1391E Encryption algorithm previously set to *algorithm*; no change made

- HCP1392E Encrypt Paging is required; no change made
- HCP1394I Encryption of paging changed from *state* to *state*, [with algorithm *algorithm*,] by user *userid*
- HCP2768E Missing algorithm type

## SET HOTIO

### Authorization

Privilege Class: B

### Purpose

Use SET HOTIO to change the maximum number of consecutive, unsolicited interrupts per second that CP should allow from an I/O device (the hot I/O rate) before refusing to accept input from it. For information on how to display the hot I/O rate settings for your system, see [“QUERY HOTIO” on page 938](#).

### Operands

#### ALL

tells CP to change the hot I/O rate for all the devices in the active I/O configuration.

#### DASD

tells CP to change the hot I/O rate for all the DASDs in the active I/O configuration.

#### Graf

tells CP to change the hot I/O rate for all the graphic display devices in the active I/O configuration.

#### rdev

tells CP to change the hot I/O rate for a device at a specific real device number in the active I/O configuration. The variable *rdev* must be a hexadecimal number between X'0000' and X'FFFF'. If you specify a real device number that does not exist, CP issues an error message and ignores your command.

#### rdev1-rdev2

tells CP to change the hot I/O rate for devices in a range of specific real device numbers in the active I/O configuration. The variable *rdev* must be a hexadecimal number between X'0000' and X'FFFF'. The first real device number in the range must be less than the second real device number; otherwise, CP issues an error message and ignores your command. If you specify a range of real device numbers that do not exist, CP issues an error message and ignores your command. However, if there are some valid real device numbers in the range, CP accepts the command.

**SPecial**

tells CP to change the hot I/O rate for all the special devices (3088s, CTCAs, 37x5s) in the active I/O configuration.

**SWCH****SWitch**

tells CP to change the hot I/O rate for all the switching devices in the active I/O configuration.

**TApe**

tells CP to change the hot I/O rate for all the tape drive devices in the active I/O configuration.

**TErминаl**

tells CP to change the hot I/O rate for all the terminals in the active I/O configuration.

**Unit\_record****UR**

tells CP to change the hot I/O rate for all the unit record devices in the active I/O configuration.

**Default**

tells CP to use the default rate of 16 unsolicited interrupts per second for the specified device or devices.

**Off**

turns hot I/O detection off and tells CP to accept all unsolicited interrupts for the specified device or devices.

**Warning!**

We do not recommend that you specify the OFF operand to turn off the hot I/O detection for a device or devices for any length of time. Hot I/O detection protects CP from broken hardware that floods the system with unsolicited interrupts. If you turn hot I/O detection off, you may experience performance degradation or a system abend.

**nnnnn**

tells CP how many unsolicited interrupts per second to accept for the specified device or devices before CP stops accepting input from the device or devices. The variable *nnnnn* is a decimal number from 1 to 62500.

**Usage Notes**

1. CP processes SET HOTIO commands in the order that you enter them. If you enter more than one SET HOTIO command for a specific device or devices, the last command you enter is the one that CP uses for that device or devices. For example, if you issued the following commands:

```
set hotio all 25
set hotio 2ff 50
set hotio switch 75
```

CP sets the hot I/O rate for all devices in the active I/O configuration to 25, then CP sets the hot I/O rate for device X'2FF' to 50, and lastly, CP sets the hot I/O rate for all special switching devices to 75. If device X'2FF' is a special switching device, the third command overrides the second command and CP sets the hot I/O rate for device X'2FF' to 75, instead of 50.

2. If you want to set the hot I/O rate before the system IPLs, use the [HOT\\_IO\\_RATE Statement](#) in the system configuration file. For more information, see *z/VM: CP Planning and Administration*.
3. All real I/O devices have a hot I/O rate of 16 consecutive unsolicited interrupts per second, unless you override the default using the HOT\_IO\_RATE statement or the SET HOTIO command.
4.  **Attention:** We do not recommend that you specify the OFF operand to turn off the hot I/O detection for a device or devices for any length of time. Hot I/O detection protects CP from broken hardware that floods the system with unsolicited interrupts. If you turn hot I/O detection off, you may experience performance degradation or a system abend.

## SET HOTIO

### Examples

Example 1:

To change the hot I/O rate for all DASD devices in the active I/O configuration to 100 and to change the hot I/O rate for all devices in the range X'200' to X'300' in the active I/O configuration to 50, use the following SET HOTIO commands:

```
set hotio dasd 100
set hotio 200-300 50
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP013E Conflicting option - *option*

## SET IMSG

### Authorization

Privilege Class: G

### Purpose

Use SET IMSG to control the display of certain informational responses. The affected CP commands are:

- CHANGE
- CLOSE
- DEFINE
- DETACH
- ORDER
- PURGE
- REDEFINE
- SPOOL
- SPXTAPE
- TRANSFER

**Note:** The affected response is identified in each command description.

### Operands

#### ON

specifies that the responses are displayed.

#### OFF

specifies that the responses are not displayed.

#### IUCV

specifies that informational messages are to be passed to the virtual machine through IUCV if a connection to the message system service exists. If no IUCV connection exists, the message is handled as if SET IMSG ON had been issued.

### Usage Notes

1. The SET IMSG ON or OFF command has no effect on the handling of error messages set by the SET EMSG command. The initial setting for IMSG is installation dependent and is defined in the system configuration file.
2. DETACH RDEV will still display informational messages when IMSG is set OFF. The other DETACH commands will not display informational messages when IMSG is set OFF.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

## **SET IMSG**

- HCP026E Operand missing or invalid

## SET IO\_OPT

### Authorization

Privilege Class: B, G

### Purpose

Use SET IO\_OPT to control whether or not virtual machine I/O options will be used for a virtual machine.

### Operands

#### UID

indicates guest PCI UID uniqueness enforcement will be affected.

#### ENFORCE\_BY\_VOLID

indicates the enforcing of attachment of DASD devices by VOLID will be affected.

#### ON

#### OFF

turns I/O options on or off for a virtual machine or system setting.

#### \*

asterisk represents the default. The default is that the command affects the virtual machine (User ID) only from where the command is issued.

#### ALLUsers

enables or disables I/O options for all virtual machines, independent of the individual settings for each user. The individual settings are not changed. When ALLUSERS is specified by a class B user, the specified I/O option is allowed or disallowed for all virtual machines, including any new users that might log on. When this global setting is OFF, it overrides any individual user's setting to enable the I/O option.

If SET IO\_OPT is executed with the AT command, the ALLUSERS or *userid* operand is required.

#### USER *userid*

specifies an individual user whose I/O option settings will be changed. If SET IO\_OPT is executed with the AT command, the ALLUSERS or *userid* operand is required.

### Usage Notes

1. If an IO\_OPT is set ON for ALLUSERS, an individual user can set that option OFF without changing the setting for other users.  
**Note:** The reverse is not true; setting OFF for ALLUSERS overrides individual user settings.
2. The QUERY IO\_OPT command can be used to see the current option settings for a given virtual machine.
3. The default for the UID option for the all users and each virtual machine is to be set ON.
4. No checks or changes to PCI functions already attached to virtual machines are made when the UID option is changed. Functions may need to be detached from virtual machines when the UID option is turned on to remove functions with identical UID values.
5. The ENFORCE\_BY\_VOLID option only affects the system wide setting which is initially determined by the ENFORCE\_BY\_VOLID configuration statement. See *z/VM: CP Planning and Administration* for more information on the [ENFORCE\\_BY\\_VOLID Statement](#) and its affects.

### Examples

Example 1:

The following command will disable userid test1 from using virtual machine UID I/O option.

```
set io_opt uid off test1
```

### Responses

Response 1:

```
IO_OPT is already {enabled }  
                  {disabled}
```

indicates that the IO\_OPT specified is already enabled or disabled.

### Messages

- HCP002E Invalid operand - *operand*
- HCP007E Invalid userid - *userid*
- HCP020E Userid missing or invalid
- HCP045E *userid* not logged on
- HCP263E Too many operands were supplied for this command
- HCP1014E A required option is missing

## SET IOASSIST

### Authorization

Privilege Class: B, G

### Purpose

Use SET IOASSIST to control whether or not virtual machine I/O assists will be used for a virtual machine.

To use any virtual machine I/O assists, the following are required:

- z/VM must be running in a logical partition and not as a guest.
- I/O assists must be globally enabled with the CP SET IOASSIST ON FOR ALLUSERS command.
- The virtual machine must be enabled with the CP SET IOASSIST ON FOR USER command.
- The virtual machine must not be using the CP TRACE command.
- Only the I/O assists that the processor supports will be enabled.

### Operands

#### ALL

indicates all I/O assists will be affected.

#### ON

#### OFF

turns I/O assists on or off for a virtual machine.

#### \*

asterisk represents the default. The default is that the command affects the virtual machine (User ID) only from where the command is issued.

#### ALLUsers

enables or disables eligibility for all virtual machines to use I/O assists, independent of the individual settings for each user. The individual settings are not changed. When ALLUSERS is specified by a class B user, access to I/O assists are allowed or disallowed for all virtual machines, including any new users that might log on. When this global setting is OFF, it overrides any individual user's setting to allow I/O assists.

## SET IOASSIST

If SET IOASSIST is executed with the AT command, the ALLUSERS or *userid* operand is required.

### USER *userid*

specifies an individual user whose assist settings will be changed. If SET IOASSIST is executed with the AT command, the ALLUSERS or *userid* operand is required.

## Usage Notes

1. If IOASSIST is set ON for ALLUSERS, an individual user can set IOASSIST OFF without changing the setting for other users.

**Note:** The reverse is not true; setting OFF for ALLUSERS overrides individual user settings.

2. Setting IOASSIST ON or OFF for all users may not immediately enable or disable the assist for all users. The command will take effect as soon as possible. Use the QUERY IOASSIST to determine when the user's virtual machine is in the desired state.

3. The SET QIOASSIST command and the SET IOASSIST command both disable all virtual machine I/O assists. Setting QIOASSIST ON/OFF for a virtual machine also performs the SET IOASSIST ALL ON/OFF command for the target virtual machine.

## Examples

Example 1:

The following command will disable *userid* test1 from using virtual machine I/O assists.

```
set ioassist off test1
```

## Responses

Response 1:

```
IOASSIST is already {enabled }  
                   {disabled}
```

indicates that the IOASSIST is now already enabled or disabled.

## Messages

- HCP002E Invalid operand - *operand*
- HCP007E Invalid *userid* - *userid*
- HCP020E *userid* missing or invalid
- HCP045E *userid* not logged on
- HCP263E Too many operands were supplied for this command
- HCP1014E A required option is missing
- HCP2162I IOASSIST is not available

## SET IOCDS\_ACTIVE

►► Set — IOCDS\_active —<sup>1</sup>— An ◄◄

Notes:

<sup>1</sup> You must specify one IOCDS file in the range A0 through A3.

### Authorization

Privilege Class: B

### Purpose

Use SET IOCDS\_ACTIVE to change the input/output configuration data set (IOCDS) file that the processor will use during the next power-on reset (POR).

### Operands

**An**

is the file type of the IOCDS file that you want the processor to use during the next POR. The variable *n* is a decimal number between 0 and 3.

### Usage Notes

1. Once you issue the SET IOCDS\_ACTIVE command to change the active IOCDS file, the SE automatically puts the new IOCDS file in write-protect mode for you. This means that no one can make changes to the active IOCDS file.
2. If the current hardware configuration does not match the IOCDS file that you specify, CP issues error message HCP6814E and terminates command processing.
3. Whenever you issue one of the following dynamic I/O commands:

DEFINE CHPID	DEFINE PATH
DELETE CHPID	DELETE PATH
MODIFY CHPID	MODIFY PATH
DEFINE CU	DEFINE CNTLUNIT
DELETE CU	DELETE CNTLUNIT
MODIFY CU	MODIFY CNTLUNIT
DEFINE DEVICE	DEFINE IODEVICE
DELETE DEVICE	DELETE IODEVICE
MODIFY DEVICE	MODIFY IODEVICE

CP puts you in configuration mode, processes the dynamic I/O command, and then takes you out of configuration mode.

4. Before you can use any I/O devices, you must include those devices in the hardware's and software's view of the I/O configuration.

The software creates its view of the I/O configuration at initialization either by sensing the I/O device, by reading RDEVICE statements in the system configuration file, or some combination thereof. After initialization, you can change the software's view of the I/O configuration using the SET RDEVICE command (see [“SET RDEVICE” on page 1627](#)) or the dynamic I/O commands listed in Usage Note [“3” on page 1525](#).

The hardware creates its view of the I/O configuration at power-on reset (POR) time. The I/O configuration is defined in the I/O configuration program (IOCP) source file that is stored on a user's

## SET IOCDS\_ACTIVE

minidisk (or SFS directory). You run the IOCP utility against the IOCP source file to create an I/O configuration data set (IOCDS) file that is stored on the support element (SE) hard disk. You can have multiple IOCDS files stored on the SE hard disk. At power-on reset time, you choose the IOCDS file that you want to use. The specified IOCDS file is copied to the hardware system area (HSA) storage and becomes the active hardware I/O configuration. Thus, there are 2 parts to the hardware's view of the I/O configuration: the active IOCDS file in HSA storage and the IOCDS file on the SE hard disk.

After the machine is up and running, you can change the hardware's view of the active I/O configuration using the dynamic I/O commands listed in Usage Note “3” on page 1525. However, these commands only change the active I/O configuration in the HSA. They do not change the IOCDS file on the SE hard disk.

To change the IOCDS file on the SE hard disk, you must:

- a. Update the IOCP source file.
- b. Run the IOCP utility (see “IOCP” on page 2203) against the updated IOCP file. Specify all options you normally specify including WRTxx (to write the newly generated IOCDS file to the SE hard disk). If the IOCP utility runs without errors, it downloads the new IOCDS file to the SE hard disk.
- c. Issue the SET IOCDS\_ACTIVE command to make the new IOCDS file the active file that the processor will use during the next power-on reset (POR).

## Responses

Response 1:

To change the active IOCDS file to A3, enter the following:

```
set iocds_active a3
The active IOCDS file is now A3
Ready;
```

## Messages

- HCP026E Operand missing or invalid
- HCP6812E Set IOCDS\_active command failed with return code *nnnn*
- HCP6814E Command is not valid on this processor

## SET IOPRIORITY

### Authorization

Privilege Class: A

### Purpose

Use SET IOPRIORITY to change a user's I/O priority settings.

### Operands

#### *userid*

\*

is the user identification of the virtual machine whose I/O priority range changed. That virtual machine must be logged on to the system. You can specify your user ID as an asterisk (\*).

#### **ABSolute**

indicates the type of I/O priority range. If LPAR I/O Priority Facility is enabled, the I/O priority range specified must fit onto the range available to CP. If the range specified falls outside of the range available to CP, an informational message is displayed and the requested range is clipped to fall within the range available to CP.

If LPAR I/O Priority Facility is not enabled or not installed, CP simulates an I/O priority range from 0 to 255.

#### **RELative**

indicates the type of I/O priority range. The maximum I/O priority range is 0 to 255. If LPAR I/O Priority Facility is installed and enabled, the maximum I/O priority range maps proportionately onto the range available to CP with the highest I/O priority mapping directly to the highest value available to CP. The requested RELATIVE I/O priority range is used to calculate a percentage of the maximum I/O priority range, and the user's effective I/O priority range is the corresponding percentage of the I/O priority range available to CP.

The following formula is used to calculate an effective I/O value:

$$\text{Eff\_Val} = \text{TRUNC}\left(\frac{(\text{Rel\_Val} - \text{Rel\_Lo}) * (\text{CP\_Hi} - \text{CP\_Lo})}{255}\right) + \text{CP\_Lo}$$

where

<b><u>Value</u></b>	<b><u>Meaning</u></b>
Eff_Val	Effective I/O priority
Rel_Val	Relative I/O priority
Rel_lo	Relative low priority
CP_Hi	High I/O priority available to CP
CP_Lo	Low I/O priority available to CP

## SET IOPRIORITY

If LPAR I/O Priority Facility is not enabled or not installed, CP simulates an I/O priority range from 0 to 255. Thus, the maximum I/O priority range maps directly onto the range simulated by CP.

### **low**

is the low value of the I/O priority range. It must be a number from 0 to 255.

### **high**

is the high value of the I/O priority range. It must be a number from 0 to 255 and greater than or equal to the low value. If not specified, the high value is equal to the low value.

## Usage Notes

1. The initial I/O priority settings for a user can be specified by the IOPRIORITY statement in the user's directory entry. If an IOPRIORITY statement is not found and LPAR I/O Priority Facility is enabled, LOGON processing requests RELATIVE I/O priority range with a low value of 0 and a high value of 0. The user's effective range is computed based on the I/O priority range available to CP.
2. The I/O priority settings of a user can be displayed by the QUERY IOPRIORITY command. For more information on this command, see [“QUERY IOPRIORITY”](#) on page 952.

## Responses

Response 1:

To set I/O priority of user USER1 to an absolute range with a low value of 3 and a high value of 3, enter the following:

```
set iopriority user1 abs 3
Command complete
```

## Examples

1. Suppose a user requests a RELATIVE I/O priority range of 40 to 100, and the I/O priority range available to CP is 0 to 15. For relative ranged, the maximum I/O priority range (0–255) maps proportionately onto the range available to CP with the highest I/O priority mapping directly to the highest value available to CP. The following table shows how the entire range of relative I/O priorities map onto the range available to CP:

Relative Value	Maps to CP's Priority
0 to 16	0
17 to 33	1
34 to 50	2
51 to 67	3
68 to 84	4
85 to 101	5
102 to 118	6
119 to 135	7
136 to 152	8
153 to 169	9
170 to 186	10
187 to 203	11
204 to 220	12

Relative Value	Maps to CP's Priority
221 to 237	13
238 to 254	14
255	15

Therefore, a user requesting relative I/O priority range of 40 to 100 would have effective I/O priority range of 2 to 5.

2. As in the previous example, suppose a user requests a relative I/O priority range of 40 to 100 but this time the I/O priority range available to CP is 8 to 14. The following table shows how the entire range of relative I/O priorities map onto the range available to CP:

Relative Value	Maps to CP's Priority
0 to 42	8
43 to 84	9
85 to 127	10
128 to 169	11
170 to 212	12
213 to 254	13
255	14

A user requesting relative I/O priority range of 40 to 100 would have effective I/O priority range of 8 to 10.

## SET IPLPARMS

►► Set — IPLparms ◄◄

### Authorization

Privilege Class: A

### Purpose

Use SET IPLPARMS to change the IPL parameters currently in CP storage that CP will use for a shutdown re-IPL or a software restart.

### Usage Notes

1. The SET IPLPARMS command prompts the user for up to 3 lines of data. Each line is either truncated to 80 characters or padded with blanks out to 80 characters. These lines are joined together with no intervening blanks to form the IPL parameters.
2. Specify all of the IPL parameters you want CP to use, even if they are already in CP storage. The SET IPLPARMS command replaces all the IPL parameters in CP storage. For example, if you IPLed with the IPL parameter to override the default console address (CONS) and then issued a SET IPLPARMS command to override the default file name of the system configuration file (FN), CP storage would contain only the new value for FN. The next shutdown re-IPL or software restart would use the default console address because you did not specify it on the SET IPLPARMS command.
3. The IPL parameters (listed below) are described in *z/VM: System Operation*.

Parameter	Purpose
CLEARPDR	Reinitialize the PDR when all other SSI members are down.
CONS= or CON=	The operator console address.
FN=	The system configuration file name.
FT=	The system configuration file type.
IPLVAR=	The value of the CP.IPLPARMS.IPLVAR system environment variable.
NOEXITS	Do not pass certain options in the configuration file.
NOHCD	Ignore the IODF statement in the system configuration file.
PDNUM=	The parm disk number.
PDOFF=	The parm disk offset in the IPL volume.
PDVOL=	The real address of the parm disk.
PROMPT	The prompt for startup options at IPL.
REPAIR	Bypass SSI cluster initialization and management functions. For non-SSI, this is equivalent to specifying the NOAUTOLOG and DISABLE IPL options.
<i>selector:value (IPL parameter substring)</i>	Define conditional IPL parameters based on the value of the specified <i>selector</i> .
STORE=	The storage amount.

4. After all of the IPL parameter data has been accepted, CP checks each parameter for syntax errors. If you make a syntax error (typing the name of an IPL parameter incorrectly, specifying a non-numeric value for an IPL parameter that is expecting a number, and so forth), CP issues error message HCP6770E and ignores your SET IPLPARMS command. CP does not change the IPL parameters in CP storage unless the SET IPLPARMS completes without errors. See **Response 3** for an example of making a typographical error in the name of an IPL parameter.
5. To display the IPL parameters in CP storage, use the QUERY IPLPARMS command (see [“QUERY IPLPARMS”](#) on page 954).

## Responses

### Response 1:

To set or reset the IPL parameters that CP will use after the next SHUTDOWN REIPL command or CP abend, enter the following SET IPLPARMS command:

```
set iplparms
ENTER UP TO 3 LINES. ENTER A NULL LINE TO END.
FN=SYSTEM FT=CONFIG CONS=08E6
PROMPT

IPL parameters have been replaced.
Ready;
```

### Response 2:

To clear the IPL parameters in CP storage so that CP will use the default values, use the following SET IPLPARMS command:

```
set iplparms
ENTER UP TO 3 LINES. ENTER A NULL LINE TO END.

IPL parameters have been replaced.
Ready;
```

### Response 3:

If you enter a mistake after the prompt, CP does not replace any of the IPL parameters, even the ones that were not in error. For example, suppose you wanted to set (or reset) the IPL parameters as in **Response 1**, but you made a typographical error. CP would ignore your entire SET IPLPARMS command, not just the IPL parameter in error:

```
set iplparms
ENTER UP TO 3 LINES. ENTER A NULL LINE TO END.
FN=SYSTEM FT=CONFIG CONS=08E6
PRIMPT

HCP6770E IPL parameters: Unrecognized option - PRIMPT
IPL parameters have not been replaced.
Ready(06770);
```

### Response 4:

If you enter an IPL parameter more than once, CP stores the last occurrence in CP storage and ignores all previous occurrences. For example, suppose you wanted to set (or reset) the IPL parameters as in **Response 1**, but you specified the wrong file name for the system configuration file. If you catch the mistake before you enter the null line that ends the SET IPLPARMS command, you can enter another file name:

```
set iplparms
ENTER UP TO 3 LINES. ENTER A NULL LINE TO END.
FN=SYSTM FT=CONFIG CONS=08E6
PROMPT
FN=SYSTEM
```

IPL parameters have been replaced.  
Ready;

### Messages

- HCP003E Invalid option - {command|statement} contains extra option(s) starting with *option*

## SET JOURNAL

### Authorization

Privilege Class: A

### Purpose

Use SET JOURNAL to start or stop the journal security function.

### Operands

#### LOGON ON

#### LOGON OFF

indicates whether the LOGON, AUTOLOG, and XAUTOLOG thresholds established in the system configuration file at system generation are observed. The default is ON.

#### LINK ON

#### LINK OFF

indicates whether type 05, 06 and 08 accounting records are generated and messages are sent to operations personnel when the LINK thresholds established in the system configuration file at system generation are violated. The default is ON.

### Usage Notes

1. The SET JOURNAL command can be used only if the FACILITY ON operand and SET\_AND\_QUERY ON operand are specified on the JOURNALING statement in the system configuration file.
2. SET JOURNAL LINK OFF changes to 10 the limit for incorrect password LINK attempts that a particular user can enter.
3. SET JOURNAL LOGON OFF disables the logon inductor and discards the count of logon attempts associated with terminals and user IDs that are not logged on at the time. If SET JOURNAL LOGON ON is then issued, no information about previous logon attempts is available.

**Note:** The logon inductor is the CP facility that responds to excessive logon attempts with a bad password. It temporarily prohibits a terminal or user ID from logging on.

4. Users who exceed the AUTOLOG/XAUTOLOG not-valid-password limit and are not permitted to use these commands for the remainder of their logon session, have their ability to use these commands restored after SET JOURNAL LOGON OFF is issued. If SET JOURNAL LOGON ON is issued later, these users again are unable to enter AUTOLOG or XAUTOLOG. Refer to Usage Note “5” on page 1432 in SET CMDLIMIT for details on what will happen when SET JOURNAL LOGON OFF is issued for invalid password attempts.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid

## SET KEYALIAS

### Authorization

Privilege Class: B

### Purpose

Use SET KEYALIAS to associate a shorter or more meaningful alias name with a key label. Key label aliases are used on the ATTACH and SET RDEV commands to identify the key label(s) to be used for encrypting data written to a tape.

### Operands

#### *aliasname*

a 1 to 32 character string alias name. Imbedded blanks and lowercase characters are permitted. Enclose the string in single quotation marks to include blanks in the alias name. Alias names are not case sensitive.

#### **Label**

indicates the key label encoding mechanism. The key label is to be used as is. This is the default.

#### **Hash**

indicates the key label encoding mechanism is a hashed value of the key label.

#### *keylabel*

a 1 to 64 character key label known to the key manager being used for tape encryption. Imbedded blanks and lowercase characters are permitted. Enclose the string in single quotation marks to include blanks in the key label. Key labels are not case sensitive.

#### **CLEAR**

indicates the existing *aliasname* definition is to be deleted.

### Usage Notes

1. If the alias name being defined already exists it will be replaced by the new definition.
2. Use the CLEAR option to delete a key alias definition.

### Responses

Response 1:

To define an alias called "myalias" which does not contain imbedded blanks and uses the default encoding mechanism, enter:

```
set keya myalias key1 e3rw33rssesyqypsftqpx0539
Ready;
```

Response 2:

To define an alias called "THIS IS MY ALIAS" which contains imbedded blanks and uses HASH encoding, enter:

```
set keya 'this is my alias' hash keyl e3rw33rssesyqypsftqpx0539
Ready;
```

Response 3:

Although key aliases and labels are case insensitive, it is possible to assign mixed cased values. An alias containing lowercase characters can be defined using a REXX EXEC as shown below. Note that the CP commands within the command string being executed must be uppercase.

```
(a simple REXX exec)
/* This comment format indicates the REXX interpreter is to be used */
address command "CP SET KEYA 'ABC Co' KEYL e3rw33rssesyqypsftqpx05399"
```

## Messages

- HCP9968E The key alias contains leading or trailing blanks or an empty string.
- HCP9968E The key label contains leading or trailing blanks, invalid characters, or an empty string.

## SET LAN

### Authorization

Privilege Class: B, G

### Purpose

Use SET LAN to modify the attributes of a guest LAN. The current owner of the LAN (or a Class B user) can:

- Grant permission for a user to connect (COUPLE)
- Revoke permission for a user to connect (COUPLE)
- Modify the IPTimeout value for the guest LAN
- Modify the MAC protection setting for the guest LAN

The Class B form of the command allows the invoker to modify a LAN owned by another user. Only a Class B user can specify OWNERid SYSTEM (modifying a SYSTEM LAN). Only a Class B user can specify ACCOUNTING to turn accounting on or off for a LAN.

### Operands

#### *lanname*

is the name of the guest LAN to be modified. Both *lanname* and *ownerid* must be known to fully qualify a LAN.

#### OWNERid \*

#### OWNERid *ownerid*

#### OWNERid SYSTEM

identifies the owner of the subject LAN. When OWNERID \* is specified, it indicates the invoker is the owner of the LAN. This is the default when OWNERID is omitted.

The Class G form of the command only accepts \* or the user ID of the invoker.

The Class B form of the command accepts another user ID (like OWNERID SYSTEM).

#### **IPTimeout *nnn***

indicates the length of time in minutes that a remote IP address table entry remains in the IP address table for the guest LAN.

*nnn* is a number from 1 to 240.

#### **GRANT *userid***

specifies *userid* is added to the access list for this LAN. This allows user *userid* to connect an adapter to LAN *lanname* (if it is a RESTRICTED LAN). If an External Security Manager (ESM) is in control of the LAN, it may override the CP access list.

#### **PROMiscuous**

specifies that the *userid* from the grant is authorized for PROMISCUOUS Mode.

#### **NOPROMiscuous**

specifies that the *userid* from the grant is NOT authorized for PROMISCUOUS Mode.

If an External Security Manager (ESM) is in control of the LAN, it may override the PROMISCUOUS authority.

#### **REVOKE *userid***

specifies *userid* is removed from the access list for this LAN. This prevents user *userid* from connecting an adapter to a RESTRICTED LAN *lanname*. If an External Security Manager (ESM) is in control of the LAN, it may override the CP access list. Existing connections to the LAN are not affected.

#### **ACCOUNTing ON**

#### **ACCOUNTing OFF**

allows a Class B user to control whether accounting records are created for the LAN specified.

#### **MACProtect**

modifies the MAC address protection for devices coupled to this guest LAN. Turning MAC address protection on prevents a guest from using a MAC address that is not assigned to the user's network device. MACPROTECT is valid only for an ETHERNET guest LAN.

There are three levels of inheritance used when determining the MAC address protection level for a MAC address assigned to a network device. The highest is the system level, followed by the guest LAN (or virtual switch) level. The lowest level is the protection set for a specific network data device.

The MAC address protection level assigned is determined first at the device, then guest LAN and lastly the system level. If MAC address protection is set at the device level using the SET NIC CP command, then its current setting is used. When the device is set to UNSPECIFIED, it will inherit the guest LAN's MACPROTECT setting. When the guest LAN MACPROTECT setting is set to UNSPECIFIED, the SYSTEM's MAC address protection specified by the SET VMLAN CP command or VMLAN configuration statement is assigned.

#### **UNSPECified**

allow the MAC address protection to be determined by the SYSTEM level setting. UNSPECIFIED is the default setting for a guest LAN.

If MAC address protection is set to UNSPECIFIED by the SET NIC CP command for a specific device, then the device's MAC address protection will be set to the SYSTEM level defined by the SET VMLAN CP command or the VMLAN configuration statement.

#### **OFF**

set the MAC address protection level off for coupled devices defined with a MAC address protection set to UNSPECIFIED.

If MAC address protection is set to UNSPECIFIED by the SET NIC CP command for a specific device, then the device's MAC address protection will be set off.

#### **ON**

set the MAC address protection level on for coupled devices defined with a MAC address protection set to UNSPECIFIED.

## SET LAN

If MAC address protection is set to UNSPECIFIED by the SET NIC CP command for a specific device, then the device's MAC address protection will be set on.

### Usage Notes

1. If the guest LAN is defined with the UNRESTRICTED attribute, any user can connect a virtual adapter to that LAN. The CP access list has no meaning for an UNRESTRICTED LAN. This will be overridden if an External Security Manager (ESM) is in control of the guest LAN.

### Examples

The following examples apply when CP, not an ESM, is protecting the guest LAN:

1. SET LAN - Class G:

To modify a user LAN named TECHINFO by adding user REYNOLDS to the access list, enter:

```
cp set lan techinfo grant reynolds
command complete
```

2. SET LAN - Class B:

To modify a SYSTEM LAN named ADMIN by adding user MAINT to the access list, enter:

```
cp set lan admin ownerid system grant maint
command complete
```

**Note:** This must be done by a user with Class B privileges since the LAN is not owned by the invoker.

3. SET LAN - Class B:

To begin generating account records for a SYSTEM LAN named ADMIN enter:

```
cp set lan BKT614 accounting on
command complete
```

**Note:** This must be done by a user with Class B privileges since the ACCOUNTING option is specified.

### Responses

Response 1:

```
command complete
```

is the normal response from this command.

### Messages

- HCP2783E LAN *ownerid lanname* does not exist
- HCP2795E Promiscuous Mode can not be used with a HiperSockets device
- HCP2795E You are not authorized to override LAN ACCOUNTING
- HCP2795E You are not authorized to SET LAN *lanname* for OWNERID *ownerid*
- HCP2858I *userid* connection to *lanowner lanname* has been [revoked | updated] by *userid1*.
- HCP2858I *userid* connection to *lanowner lanname* is not affected by this update.
- HCP3022E SET LAN not performed; MACPROTECT is not valid for the IP transport type.

## SET LINEDIT

### Authorization

Privilege Class: G

### Purpose

Use SET LINEDIT to control logical line edit functions.

### Operands

#### ON

#### OFF

controls the logical line editing functions for your virtual machine. If you specify ON, the system line editing functions and symbols are used for editing virtual console input requests. If you specify OFF, no character or line editing is used for the virtual machine operating system. When you log on, LINEDIT is set ON.

### Usage Notes

1. The character displayed depends on the code page used by the terminal emulator. The following characters are from code page 037 United States:

Character	Meaning
# X'7B'	SYSLEND LINEND
¢ X'4A'	SYSLDEL LINEDEL
@ X'7C'	SYSLCEL CHARDEL
" X'7F'	SYSLESCP ESCAPE
X'6A'	SYSTAB TABCHAR
[ X'AD'	SYSALDEL LINEDEL

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid

## SET LKFAC

### Authorization

Privilege Class: G

### Purpose

Use SET LKFAC to connect or disconnect a user to a specified Multi-Path Lock Facility RPQ (MPLF) simulation configuration.

Once connected, the user is identified as a member of that configuration. This means that the user's attached minidisk DASDs will be included in the specified MPLF I/O configuration and assigned a virtual MPLF DASD controller subsystem identifier (SSID). While a user is connected to a MPLF configuration, all MPLF locking functions are simulated for the user's attached minidisk devices.

MPLF device simulation is based on the assumption of 32 device numbers per block or storage director range. The range shares a virtual subsystem identifier and common lock space.

### Operands

#### *config\_name*

is the 1- to 8-character alphanumeric name of the MPLF configuration to be connected to or disconnected from.

### Usage Notes

1. If you specify *config\_name*, CP searches for that name in the configuration name table which contains currently defined MPLF configurations. If the name is found, the user is connected to the configuration. If the name is not found, it is added to the table and the user is then connected to the configuration.
2. If you enter SET LKFAC without *config\_name*, the user is disconnected from the MPLF configuration. If the user is the last connected user, the MPLF configuration is deleted.
3. There is a maximum of 25 configurations and a maximum of 32 userids assigned to each configuration.

### Responses

Response 1:

```
LKFAC CONFIGURATION config_name CREATED
```

is issued if this is the first time a user is connecting to the configuration.

#### *config\_name*

is the name of the configuration specified on the SET LKFAC command.

Response 2:

```
userid ADDED TO LKFAC CONFIGURATION config_name
```

tells you that the specified configuration already exists and connects the user to the configuration.

#### *userid*

is the user ID of the user issuing the SET LKFAC command.

***config\_name***

is the name of the configuration specified on the SET LKFAC command.

Response 3:

```
userid REMOVED FROM LKFAC CONFIGURATION config_name
```

is issued if the SET LKFAC command is issued without parameters; the user is disconnected from the configuration previously connected to.

***userid***

is the user ID of the user issuing the SET LKFAC command.

***config\_name***

is the name of the configuration from which the user was disconnected.

Response 4:

```
LKFAC CONFIGURATION config_name DELETED
```

is issued when the last user is disconnected from the specified configuration.

***config\_name***

is the name of the configuration specified on the SET LKFAC command.

**Messages**

- HCP9951E Invalid LKFAC configuration name entered
- HCP9952E Maximum (32) users assigned to LKFAC configuration *config\_name*
- HCP9954E Maximum LKFAC configurations defined, *config\_name* not created
- HCP9955E No change,LKFAC configuration same as entered
- HCP9964E User not authorized to use LKFAC simulation support

## SET LKFACR

### Authorization

Privilege Class: G

### Purpose

Use SET LKFACR to control whether a full-pack minidisk is to use the real multi-path lock facility (MPLF) of an IBM DASD storage controller.

### Operands

#### ON

indicates that the device will use the real MPLF facility

#### OFF

indicates that the device will not use the real MPLF facility.

#### vdev

#### vdev1-vdev2

is the virtual device number or range of virtual device numbers of the devices to be enabled or disabled for real MPLF.

### Usage Notes

- 
**Attention:** SET LKFACR ON causes a SYSTEM RESET of your virtual machine whenever one or more of the specified virtual devices have been enabled for MPLF simulation through the SET LKFACR command. Use the QUERY LKFACR command just before issuing SET LKFACR ON to see a current list of the virtual devices that would cause such a SYSTEM RESET of your virtual machine.
- SET LKFACR ON will prevent the virtual device from using simulated MPLF until the next SYSTEM RESET.
- The virtual machine must have lock facility authorization in order to use the real MPLF facility. See [OPTION Directory Statement \(LKFAC\)](#) in *z/VM: CP Planning and Administration*.
- SET LKFACR ON is only valid for full-pack minidisks. Non-full-pack minidisks can only use the simulated MPLF facility. For more information, see [“SET LKFAC” on page 1540](#). Dedicated DASD always use the real MPLF facility, provided that the virtual machine has the proper authorization. See [OPTION Directory Statement \(LKFAC\)](#) in *z/VM: CP Planning and Administration*.

### Responses

Response 1:

```
Real MPLF is {enabled } for DASD vdev
           {disabled}
```

is issued when the command completes successfully.

## Response 2:

```
Real MPLF is already enabled for DASD vdev - this device is
dedicated and always has access to the real MPLF.
```

is issued when the target device is dedicated.

## Response 3:

```
Real MPLF remains enabled for DASD vdev - this device is
dedicated and always has access to the real MPLF.
```

is issued when the target device is dedicated.

## Response 4:

```
Real MPLF remains disabled for DASD vdev - this device is
a non-full-pack minidisk and cannot access a real MPLF.
```

is issued when the target device is a non-full-pack minidisk.

## Response 5:

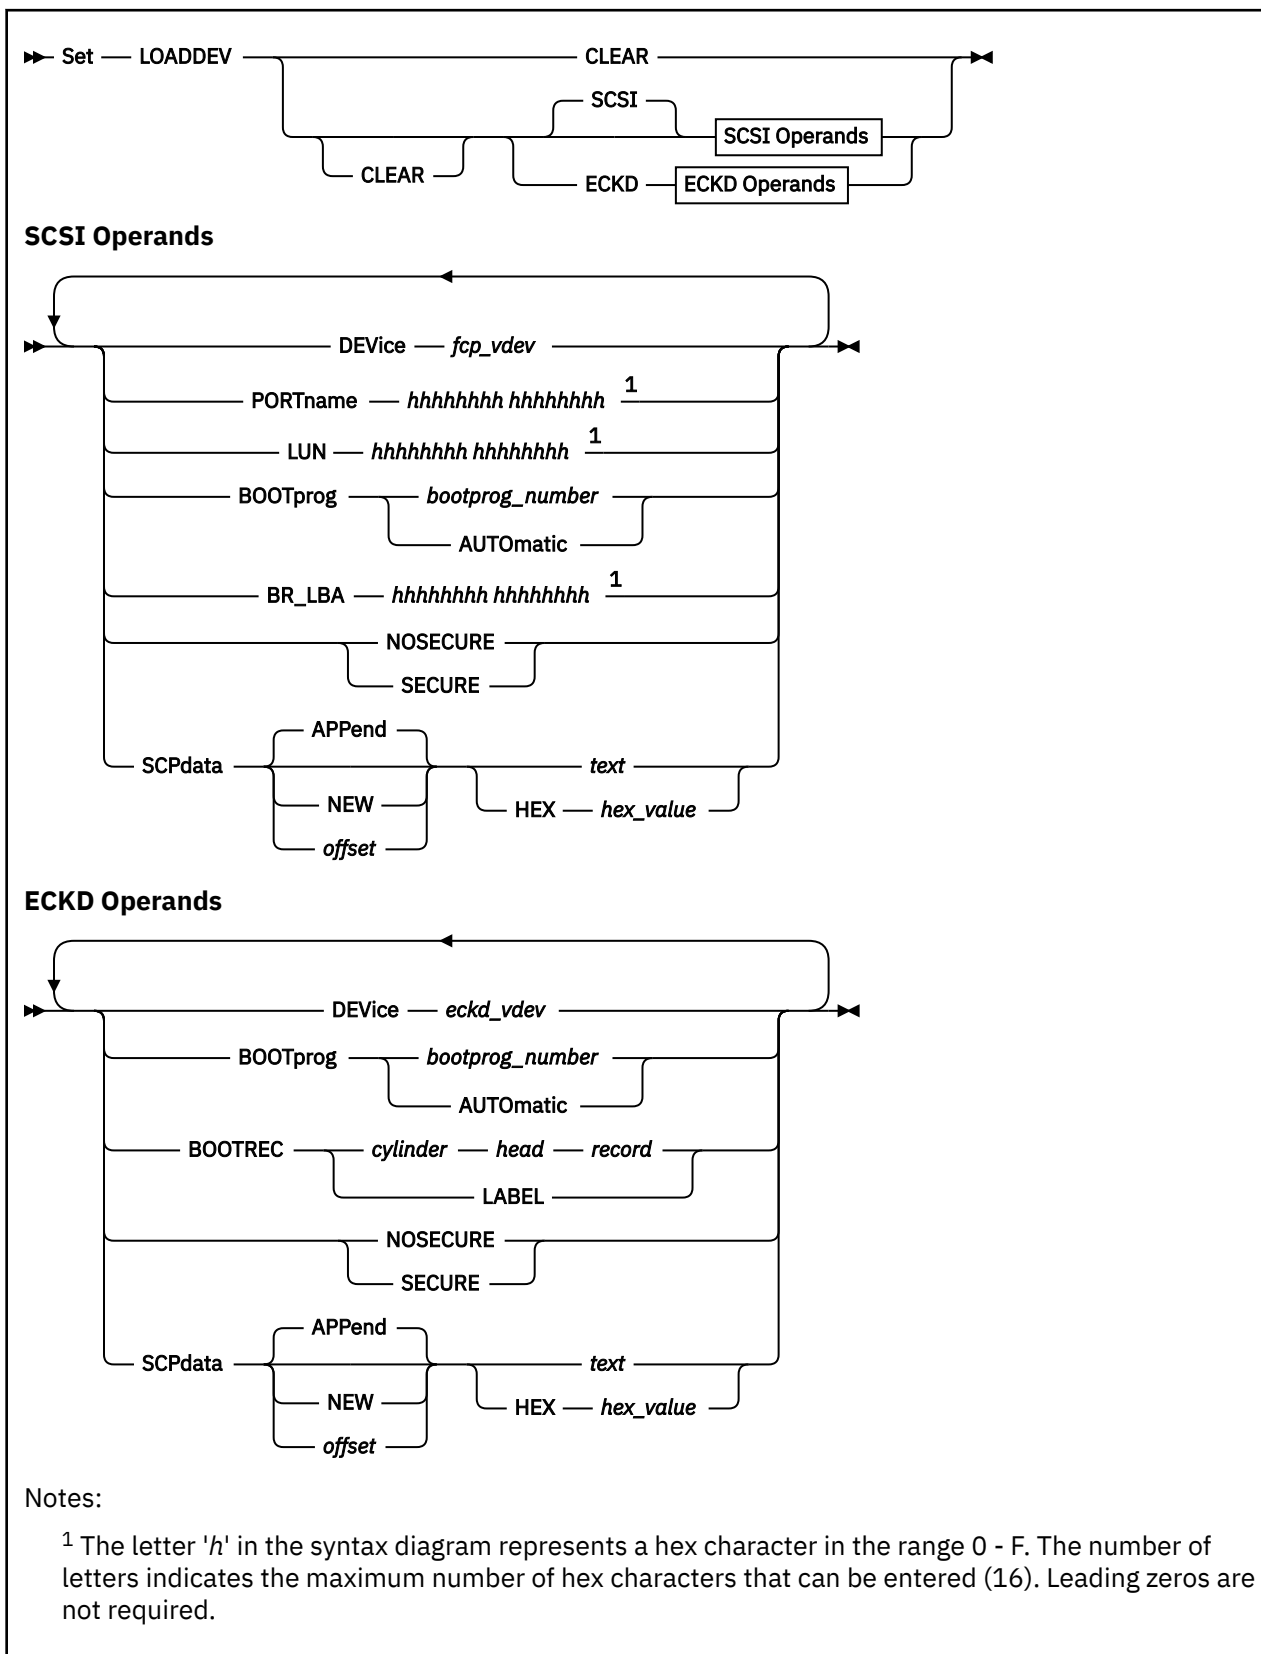

```
Real MPLF remains disabled for DASD vdev - Real MPLF
is not available when CHPID virtualization is active.
```

is issued when this command is invoked with CHPID virtualization on.

## Messages

- HCP003E Invalid option - *{option|command contains extra option(s) starting with option}*
- HCP013E Conflicting option - *option*
- HCP026E Operand missing or invalid
- HCP040E Device *{vdev}* does not exist
- HCP6706E Invalid address range - *range*
- HCP9966E You do not have LKFAC directory authorization
- HCP9967E *type vdev* LKFACR cannot be used - no real MPLF is available

## SET LOADDEV

## Authorization

Privilege Class: G

## Purpose

Use the **SET LOADDEV** command to set LOADDEV parameters for a guest IPL (without dump) from a SCSI or ECKD disk. The parameters can identify the virtual device number and specify whether the IPL is a secure IPL. The parameters can identify the location of an operating system program and data to pass to the program.

The parameters that are set by using the **SET LOADDEV** command are called LOADDEV parameters and are used only for list-directed IPLs, which occur in the following cases:

- The **IPL** command specifies the *fcp\_vdev* operand but not the DUMP operand.
- The **IPL** command specifies the LOADDEV operand.

See usage note [“1” on page 1547](#).

The settings are temporary. The settings persist after an IPL but not after the user logs off. LOADDEV statements in the user directory file are not changed. For more information, see [“IPL” on page 566](#).

## Operands

### CLEAR

The CLEAR operand clears all LOADDEV parameters for all device types (SCSI and ECKD). Operands that follow the CLEAR operand are not cleared.

After LOADDEV parameters are cleared, a list-directed IPL from SCSI or ECKD disk cannot be initiated until all required parameters for the SCSI or ECKD device type are set. The parameters that are required for each load device type are explained in usage note [“1” on page 1547](#).

### SCSI

The SCSI operand indicates that the LOADDEV parameters are for IPL of a SCSI device. Other operands on the command must be operands for a SCSI device.

If you do not specify the SCSI or ECKD operand, the device type defaults to SCSI.

After the SCSI parameter is set, subsequent **SET LOADDEV** commands cannot set ECKD parameters until a **SET LOADDEV** command with the CLEAR operand is specified. Likewise, LOADDEV parameters for an ECKD device must be cleared before you can set LOADDEV parameters for a SCSI device.

### ECKD

The ECKD operand indicates that the LOADDEV parameters are for IPL of an ECKD device. Other operands on the command must be operands for an ECKD device.

Because SCSI is the default device type, the ECKD operand must be specified on every command that sets LOADDEV parameters for an ECKD device.

After the ECKD parameter is set, subsequent **SET LOADDEV** commands cannot set SCSI parameters until a CLEAR operand is specified. Likewise, LOADDEV parameters for a SCSI device must be cleared before you can set LOADDEV parameters for an ECKD device.

### DEVICE *fcp\_vdev*

The DEVICE value (*fcp\_vdev*) specifies the virtual device number of the FCP device to IPL.

The LOADDEV DEVICE parameter must be set before you can issue the **IPL LOADDEV** command. A secure IPL without dump from a SCSI device can be initiated only by issuing the **IPL LOADDEV** command.

If the **IPL** command specifies the *fcp\_vdev* operand, then the LOADDEV DEVICE parameter must match that value or must not be set.

A table of restrictions and requirements for using the DEVICE parameter is presented in usage note [“1” on page 1547](#).

## SET LOADDEV

There is no default value for the DEVICE parameter.

### **DEVICE** *eckd\_vdev*

The DEVICE value (*eckd\_vdev*) specifies the virtual device number of the ECKD device to IPL.

The LOADDEV DEVICE parameter must be set before you can issue the **IPL LOADDEV** command. A secure guest IPL without dump from an ECKD device can be initiated only by issuing the **IPL LOADDEV** command.

### **PORTname** *hhhhhhhh hhhhhhhh*

The PORTNAME value (*hhhhhhhh hhhhhhhh*) specifies the 8-byte fibre channel port name of the SCSI device that is IPLed. The value must be a hexadecimal value in the range 0 - FFFFFFFF FFFFFFFF. For values longer than eight hex characters, at least one separator blank is required after the eighth character.

If you do not set the PORTNAME parameter, it defaults to 0.

### **LUN** *hhhhhhhh hhhhhhhh*

The LUN value (*hhhhhhhh hhhhhhhh*) specifies the 8-byte logical unit number of the SCSI device that is IPLed. The value must be a hexadecimal value in the range 0 - FFFFFFFF FFFFFFFF. For values longer than eight hex characters, at least one separator blank is required after the eighth character.

If you do not set the LUN parameter, it defaults to 0.

### **BOOTprog** *bootprog\_number*

The *bootprog\_number* value specifies the boot program that is loaded from the SCSI or ECKD device that is IPLed. The value must be a decimal value in the range 0 - 30.

If you do not set the BOOTPROG parameter, it defaults to 0.

### **BOOTprog** **AUTOMATIC**

The BOOTPROG AUTOMATIC operand loads the first operating system program (not a dump program) that is listed in the program table of the device that is IPLed.

If you do not set the BOOTPROG parameter, it defaults to 0.

### **BR\_LBA** *hhhhhhhh hhhhhhhh*

The BR\_LBA value (*hhhhhhhh hhhhhhhh*) specifies the logical-block address of the boot record of the SCSI device that is IPLed. The value must be a hexadecimal value in the range 0 - FFFFFFFF FFFFFFFF. For values longer than eight hex characters, at least one separator blank is required after the eighth character.

If you do not set the BR\_LBA parameter, it defaults to 0.

### **BOOTREC** *cylinder head record*

The BOOTREC values (*cylinder head record*) specify the boot record location on the ECKD device that is IPLed. Use hexadecimal values and separate the values by blank space. Leading zeros are not required. The following ranges are allowed when you specify the boot record location:

- Cylinder: 0 - FFFFFFFF
- Head (or track): 0 - F
- Record: 1 - FF

### **BOOTREC** **LABEL**

The BOOTREC LABEL operands specify that the boot record is the record that is identified in the volume label of the ECKD device that is IPLed.

If you do not set the BOOTREC parameter, it defaults to LABEL.

### **SECURE**

#### **NOSECURE**

The SECURE operand specifies that the IPL is a secure IPL.

The NOSECURE operand specifies that the IPL is not a secure IPL.

If you do not set the SECURE or NOSECURE parameter, the parameter defaults to NOSECURE.

The SECURE parameter is not valid unless the DEVICE parameter (virtual device number) is set.

If a user's OPTION directory statement includes the SECUREIPLREQUIRED option, the SECURE operand must be set.

#### SCPDATA ... *text*

#### SCPDATA ... HEX *hex\_value*

The SCPDATA keyword designates data to be passed to the program that is loaded for a list-directed IPL. If the program does not require any data, then the SCPDATA parameter is optional.

The HEX keyword indicates that the data (*hex\_value*) is UTF-8 encoded hex (characters 0-F). The hex string must be an even number of digits.

If the HEX keyword is not specified, the data is assumed to be EBCDIC text (code page 924).

Quotation marks are necessary only if the text includes blanks, mixed case, is a valid keyword (NEW or APPEND), or is all numeric (a valid offset).

Up to 4096 (4K) characters of data (text or hexadecimal) can be entered. The actual number of input characters might be less than 4096 depending on the translation to UTF-8. Because two hex characters are required to represent each UTF-8 data byte, the maximum number of UTF-8 data bytes that can be defined by using the HEX option is 2048 (1/2 of the 4K character input limit).

There is no default value for SCPDATA.

#### NEW

The parameter value that follows the NEW keyword replaces any previously specified SCPDATA data.

#### APPEND

The parameter value that follows the APPEND keyword is appended to the end of any previously specified SCPDATA data.

#### offset

The *offset* value indicates an offset of the previously specified SCPDATA data. The parameter value that follows the *offset* value overlays the previously defined SCPDATA data beginning at the specified offset. The *offset* value must be a value from 0 to the current length of the SCPDATA data.

## Usage Notes

- LOADDEV and DUMPDEV parameters are used for list-directed IPLs. Table 36 on page 1547 shows which LOADDEV parameters have default values that must be set (changed from the default) before each type of list-directed IPL without dump can be started. Other parameters might need to be set if the default values are not appropriate for your environment.

IPL type	DEVICE parameter	PORTNAME parameter	LUN parameter	SECURE parameter
IPL <i>fcp_vdev</i>	The DEVICE parameter is not set or matches <i>fcp_vdev</i> on the <b>IPL</b> command	Required	Required	The SECURE parameter is not allowed when the <i>fcp_vdev</i> operand is used
IPL LOADDEV from SCSI device	Required	Required	Required	Required if the SECUREIPLREQ option is specified in the OPTION directory statement
IPL LOADDEV from ECKD device	Required	Not applicable	Not applicable	

## SET LOADDEV

Note that a list-directed IPL without dump uses LOADDEV parameters. A list-directed IPL with dump uses DUMPDEV parameters. For more information, see [“IPL” on page 566](#) and [“SET DUMPDEV” on page 1496](#).

2. To prepare for a secure IPL, the program that is loaded must be signed. The appropriate certificate must be loaded in the HMC and assigned to any LPAR on which the IPL might occur.
3. LOADDEV parameters can be set by either of the following methods:

- **SET LOADDEV** command.
- LOADDEV directory statement. The LOADDEV parameters that are set by the LOADDEV directory statement can be used at logon and persist after the logon. Those parameters can be used by a list-directed IPL of a running guest.

The LOADDEV user directory statement can be modified by a directory management tool such as IBM Directory Maintenance (DirMaint). To set load parameters by using DirMaint, use the **DIRM LOADDEV** command. The LOADDEV user directory statement can be modified also by the Image\_IPL\_Characteristics\_Define\_DM API function.

For more information, see **DIRM LOADDEV** in *z/VM: Directory Maintenance Facility Commands Reference* and **LOADDEV Directory Statement** in *z/VM: CP Planning and Administration*.

4. The LOADDEV settings of a user can be displayed by using the **QUERY LOADDEV** command. See [“QUERY LOADDEV” on page 985](#).
5. The initial **SET LOADDEV** command or the first **SET LOADDEV** command after a **SET LOADDEV CLEAR** command establishes the device type (SCSI or ECKD) until another **SET LOADDEV CLEAR** command is issued. Until another CLEAR is issued, **SET LOADDEV** commands with operands for a different device type are not valid. Because the default device type is SCSI, when you set load parameters for an ECKD device you must specify the ECKD operand on every **SET LOADDEV** command that is issued. For example:

```
SET LOADDEV CLEAR ECKD DEVICE 1234
SET LOADDEV ECKD BOOTREC 0 0 5
```

6. After a LOADDEV parameter is set, it can be changed by issuing the **SET LOADDEV** command with a new value for the same parameter. It is not necessary to issue a **SET LOADDEV CLEAR** command before you change a parameter value.

The one exception is the device type parameter (SCSI or ECKD). You must issue a **SET LOADDEV CLEAR** command before you change the device type parameter.

7. z/VM does not support list-directed IPL of a z/VM system from ECKD or a secure IPL of a z/VM system from SCSI or ECKD. Therefore, you cannot set the following LOADDEV parameters to IPL a second-level z/VM system:

- ECKD
- SECURE

To IPL a second-level z/VM system non-securely from a SCSI disk, specify the following information:

- Specify the virtual device number to IPL (DEVICE *fcv\_vdev*).
- Specify the world wide port name (PORTNAME).
- Specify the logical unit number (LUN).
- For the BOOTPROG operand, specify 0 (or let it default to 0).
- If the IPL device is a CP-formatted device, specify C8 for the BR\_LBA operand. The SALIPL utility writes the SCSI boot record to block 200 (X'C8') of a CP-formatted device.

For a CMS-formatted device, SALIPL writes the SCSI boot record at block 200 (X'C8') into the RECOMP area. Set BR\_LBA to the hexadecimal value of decimal 200 plus the number of blocks in the CMS area of the minidisk. The value is 200 plus the "noblk" value that is used on the CMS command to prepare the disk:

```
FORMAT vdev fm noblk (RECOMP
```

See example “4” on page 1549.

- Specify NOSECURE.
  - For the SCPDATA operand, optionally specify a console device number where you want the Stand Alone Program Loader screen to appear. The console device number can also be specified on the LOADPARM operand of the IPL command. Note that if both the SCPDATA operand and the LOADPARM operand are specified, the Stand Alone Program Loader uses the value that is specified by the LOADPARM operand.
8. The default LOADDEV value for the PORTNAME and LUN parameters is 0, which is not a valid device port name and not a valid device LUN. An IPL attempt that uses the default value for the PORTNAME or LUN parameter will fail.

## Examples

1. The following command identifies port a20, logical unit number 03 as the SCSI device, and passes the SCPDATA=x'74657374' to the program that is loaded during a guest IPL.

```
set loaddev port a20 lun 03 scpdata hex 74657374
```

2. After the command in the previous example completes, the following command replaces '57' in the SCPDATA with '75'. The offset of 3 indicates where the data overlay begins. The resulting SCPDATA value is 74675374.

```
set LOADDEV scpdata 3 hex 75
```

3. The following commands set the load device information for a SCSI disk that is CP-formatted and was initialized by using the SALIPL utility. The BR\_LBA value is the hexadecimal equivalent of 200.

```
set loaddev clear port 50050763 00ce04da
set loaddev lun 51460000 00000000 br_lba C8
```

4. The following commands set the load device information for a SCSI disk that is CMS-formatted and was initialized by using the SALIPL utility. It is a 50000 block minidisk with a RECOMP area that starts at block 48000. The BR\_LBA value is the hexadecimal equivalent of 48000 + 200. The Stand Alone Program Loader screen appears on the console at device number 9.

```
set loaddev clear port 50050763 00ce04da
set loaddev lun 51460000 00000000 br_lba bc48 scpdata new 09
```

## Messages

- HCP002E Invalid operand - *operand*

- HCP6706E Invalid record number - *record*

## SET LOGMSG

### Authorization

Privilege Class: B

### Purpose

Use SET LOGMSG to:

- Set the log message line you specify to the text you enter on the command line.
- Delete a specified line from the log message.
- Delete the entire log message.

The SET LOGMSG setting is temporary and disappears with any reset other than a warm start.

**Note:** If you enabled the file-based LOGMSG support using the FEATURES statement in the system configuration file, you cannot use the SET LOGMSG command to alter the log message. In this case, you need to edit log message files on CP-accessed minidisks and notify CP of the changes using the CPACCESS command.

### Operands

#### *nn*

is the line number in the log message you want changed. The variable *nn* is a decimal number between 0 and 50.

#### \* *text*

is the text that you want placed at line *nn* of the log message. If you want the line automatically displayed on each user's console during logon, you must precede the text with an asterisk (\*). The maximum number of bytes per line is 76, which includes blanks and the asterisk, if specified. In DBCS, if *text* is longer than 76 bytes, CP truncates the text to 76 bytes, but the SO/SI pair will be maintained. You can use mixed DBCS strings as message text. If line *nn* already has text, it is replaced. Otherwise, the text is inserted for line *nn*.

#### NULL

indicates that the current text for line *nn* is deleted from the log message. If NULL is not preceded by a line number, the entire log message is deleted.

### Usage Notes

1. CP only sends the response and redisplayed input lines to the terminal, not to the virtual machine.
2. If you do not specify any operands after SET LOGMSG, the system prompts you to enter a line of text. This line of text is inserted into the log message after the last line that already has text. For example, if the highest line number in the log message to have text is 37, the new line of text is inserted at line 38. If line 50 already has text defined, you receive an error message and the text is not inserted.
3. The maximum number of lines you can include in your log message is 50, including blank lines; the highest line number in the log message is 50.

## SET LOGMSG

4. If you specify a line number with nothing following it (for example, SET LOGMSG *nn*), the system prompts you to enter a line of text. The text entered is placed in the log message at the line specified in the command. If you press ENTER without entering any text, the line is deleted from the log message.
5. Enter SET LOGMSG 0 to allow yourself to insert a new line into the log up to a maximum of 50 lines.
6. If the text of a line in the log message does not start with an asterisk (\*), the user must enter QUERY LOGMSG to see the text. (The text is not displayed automatically when the user logs on to the system.)
7. If more than 76 characters of text are entered for a line, the text is truncated after the 76th character without any message being issued.
8. The LOGMSG area is checkpointed at system termination.

### Responses

Response 1:

```
LOGMSG:
```

prompts you to enter a line of text when you enter either SET LOGMSG or SET LOGMSG *nn*. Type the desired line of text in response to the prompt and press the ENTER key.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid
- HCP041E Logmsg *nn* does not exist.
- HCP1506E The last line (50) in the log message is already in use.

## SET LSYSTEM

```
▶ SET — LSYStem — lsysname ▶
```

### Authorization

Privilege Class: B

### Purpose

Use SET LSYSTEM to set or change the machine name of the local system. This name is used when identifying two machines connected by CIB (coupling over InfiniBand) channel paths.

### Operands

#### LSYStem *lsysname*

is the machine name of the local system. The variable *lsysname* must be a 1- to 8-character alphanumeric string.

### Usage Notes

1. CP must be enabled to allow dynamic-I/O configuration changes (by the FEATURES ENABLE DYNAMIC\_I/O statement in the system configuration file or the SET DYNAMIC\_I/O operator command) in order for this command to be allowed.
2. When you execute this command, the machine enters and exits configuration mode.
3. This command cannot be issued while the machine is in configuration mode.
4. If you are going to use the SET CONFIG ON command to make dynamic-I/O changes that involve the use of the local system name, and you also want to change that name, use this SET LSYSTEM command to change the name before using the SET CONFIG ON command.
5. The local system name can be defined in your IOCP configuration definition using the LSYSTEM keyword on the ID statement. You must define this name in the IOCP definition if CIB-type channel paths are defined.

### Responses

Response 1:

To set your local system name to CPCSYS43, enter the following:

```
set lsys cpcsys43
The local system name was set as requested.
Ready;
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP1006E Command processing cannot complete because the system does not support the coupling over InfiniBand channel-path facility.
- HCP6545E HCD currently controls the hardware configuration. All CP hardware configuration commands are disabled.
- HCP6704E Missing token at end of line.

## SET LSYSTEM

- HCP6805E Cannot find RDEV for TYPE 1 subchannel
- HCP6806E Dynamic I/O change request failed with return code *nnnn*
- HCP6808E Cannot find the configuration token on the system
- HCP6808E System disabled for dynamic I/O changes
- HCP6808E The configuration mode setting of the hardware and software do not match
- HCP6808E The dynamic I/O support was disabled at the service console
- HCP6808E The VM configuration token does not match the hardware configuration token
- HCP6809E This processor does not support dynamic I/O changes
- HCP6815E Command failed in channel subsystem.
- HCP6815E Cannot find configuration token in the system
- HCP6816E Dynamic I/O changes are not allowed on this system
- HCP6819E A dynamic I/O command is currently executing for user *userid*
- HCP6850E Cannot set local system name. A dynamic I/O change is in progress.
- HCP6850E Cannot set local system name. System is in configuration mode.
- HCP6851E I/O configuration cannot be changed because VM is not the controlling partition

## SET MACHINE

### Authorization

Privilege Class: G

### Purpose

Use SET MACHINE to change the architecture in effect for your virtual machine. When you select an architecture mode, your virtual machine must obey that particular mode's architecture conventions.

### Operands

#### ESA

designates an ESA virtual machine, which can simulate either ESA/390 architecture or z/Architecture. See [Table 37 on page 1555](#). Also see usage note “7” on [page 1556](#).

#### XA

designates an XA virtual machine, which is functionally equivalent to an ESA virtual machine.

#### XC

designates an XC virtual machine, which simulates ESA/XC architecture and which can be switched into z/XC architecture.

#### Z

designates a Z virtual machine, which simulates a z/Architecture-only environment.

*Table 37. Virtual Machine Architecture Modes*

Virtual Machine Designation	Virtual Machine Architecture	Address Width	Addressable Storage
ESA, XA	ESA/390 or z/Architecture <sup>1</sup>	31-bit or 64-bit <sup>1</sup>	2 GB or 16 EB <sup>1</sup>
XC	ESA/XC or z/XC <sup>2</sup>	31-bit or 64-bit <sup>2</sup>	2 GB or 16 EB <sup>3</sup>
Z	z/Architecture	64-bit	16 EB

#### Note:

1. An ESA virtual machine simulates ESA/390 architecture when initially defined. However, a guest can switch the virtual machine between ESA/390 and z/Architecture mode. A z/Architecture virtual machine supports 64-bit addressing and addressable storage beyond 2 GB.
2. An XC virtual machine simulates ESA/XC architecture when the virtual machine is initially defined. However, a guest can switch the virtual machine between ESA/XC and z/XC architectures. z/XC supports 64-bit addressing and storage beyond 2GB.
3. Data spaces are limited to 2 GB.

## Usage Notes

1. If the SET MACHINE command changes your virtual machine architecture mode, a system-reset-clear function is performed on your virtual machine as if you had issued a SYSTEM CLEAR command. The effects of a system-reset-clear function are explained in detail in the description for the SYSTEM CLEAR command. Because a system-reset-clear function sets all of your virtual machine's storage to binary zeros, you must repeat your IPL procedure to continue operation.  
  
If you enter the command but it does not change your virtual machine architecture mode, no system-reset-clear function is performed on your virtual machine, and your virtual machine's environment remains as it is.
2. If the SET MACHINE command places your virtual machine in the ESA/XC architecture mode, the time-of-day (TOD) clock for your virtual machine is reset to match the TOD clock on the real processor.
3. A default virtual machine architecture mode can be specified on the user directory MACHINE statement. If no machine statement is used, the machine definition on the GLOBALOPTS statement of the directory is used. If no GLOBALOPTS statement is used, the default is XA.
4. For compatibility, z/VM continues to accept the virtual machine designation XA and continues to report XA as the virtual machine type in response to QUERY SET and INDICATE USER commands when the virtual machine has been defined using the XA designation. However, whether the virtual machine is defined using SET MACHINE XA or SET MACHINE ESA makes no difference when running on z/VM. A virtual machine defined with SET MACHINE XA has the capabilities of an ESA virtual machine and is considered by CP to be an ESA virtual machine.
5. CP does not support System/370 mode virtual machines. A SET MACHINE 370 command will be rejected with message HCP1016E.
6. If an attempt is made to SET MACHINE Z by a guest whose relocation domain does not support the facility, the command will be rejected with message HCP1016E.
7. An ESA (or XA) virtual machine will be put into either full ESA/390 mode or ESA/390 compatibility mode, depending on the level of ESA/390 capability available in the machine where the virtual machine is logged on or in the virtual machine's relocation domain. ESA/390 compatibility mode allows a subset of ESA/390 functionality sufficient for CMS and GCS, but lacks advanced functions like dynamic address translation (DAT). For details on ESA/390 compatibility mode, see [z/Architecture Principles of Operation](#).

## Responses

Response 1:

```
SYSTEM RESET
```

indicates that the virtual machine has been cleared.

Response 2:

```
SYSTEM =[ESA]
         [XA ]
         [XC ]
         [Z  ]
```

### ESA

indicates that the virtual machine mode has been set to ESA.

### XA

indicates that the virtual machine mode has been set to XA.

### XC

indicates that the virtual machine mode has been set to XC.

### Z

indicates that the virtual machine mode has been set to Z.

**Messages**

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid
- HCP1016E Command rejected; CP does not support System/370 mode virtual machines.
- HCP1016E Command rejected; SET MACHINE Z is not available in the current relocation domain.

## SET MAXLDEV

---

```
▶▶ Set — MAXLdev — nnnnn ▶▶
```

### Authorization

Privilege Class: E

### Purpose

Use SET MAXLdev to change the maximum number of logical devices that can exist at the same time.

### Operands

#### *nnnnn*

is the maximum number of logical devices allowed at one time. The default is 4096. The range is from 4096 to 32768.

### Usage Notes

1. The count of logical devices on the system may be greater than the maximum specified. This can happen when the limit is lowered to a value less than the current number of logical devices in existence. If this occurs, the existing logical devices will be unaffected, but no new logical devices can be created until the number of logical devices is less than the maximum allowed.

### Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid

## SET MAXUSERS

### Authorization

Privilege Class: A

### Purpose

Use SET MAXUSERS to control the number of users able to log on.

### Operands

#### *nnnnn*

is the maximum number of users allowed to log on. The range is between 1 and 99,999.

#### **OFF**

indicates that a maximum number of logged on users has not been explicitly set, so the system default limit of 99,999 is in effect.

### Usage Notes

1. If the maximum number of users is set to a number lower than the current number of logged-on users, the system allows the users to log off, to be forced off the system, and to disconnect and reconnect. However, it does not allow any users to log on until the current number of logged on users is lower than the number specified by MAXUSERS unless the user directory for the virtual machine that is logging on was created with the IGNMAXU operand of the OPTION control statement.

### Responses

Response 1:

```
MAXUSERS = nnnnn
```

is the normal response for this command.

Response 2:

```
REQUEST ACCEPTED. MAXIMUM USERS VALUE IS CURRENTLY EXCEEDED
```

is returned when the number of users already logged on exceeds the limit just set.

Response 3:

```
THE MAXUSERS LIMIT CHECKING HAS BEEN TURNED OFF
```

is returned when SET MAXUSERS OFF is entered and the maxusers limit was on. The response means the system default of 99,999 users is now in effect.

Response 4:

```
NO MAXUSERS LIMIT IS SET
```

is returned when SET MAXUSERS OFF is entered and the maxusers limit was already off. The response means the system default of 99,999 users is now in effect.

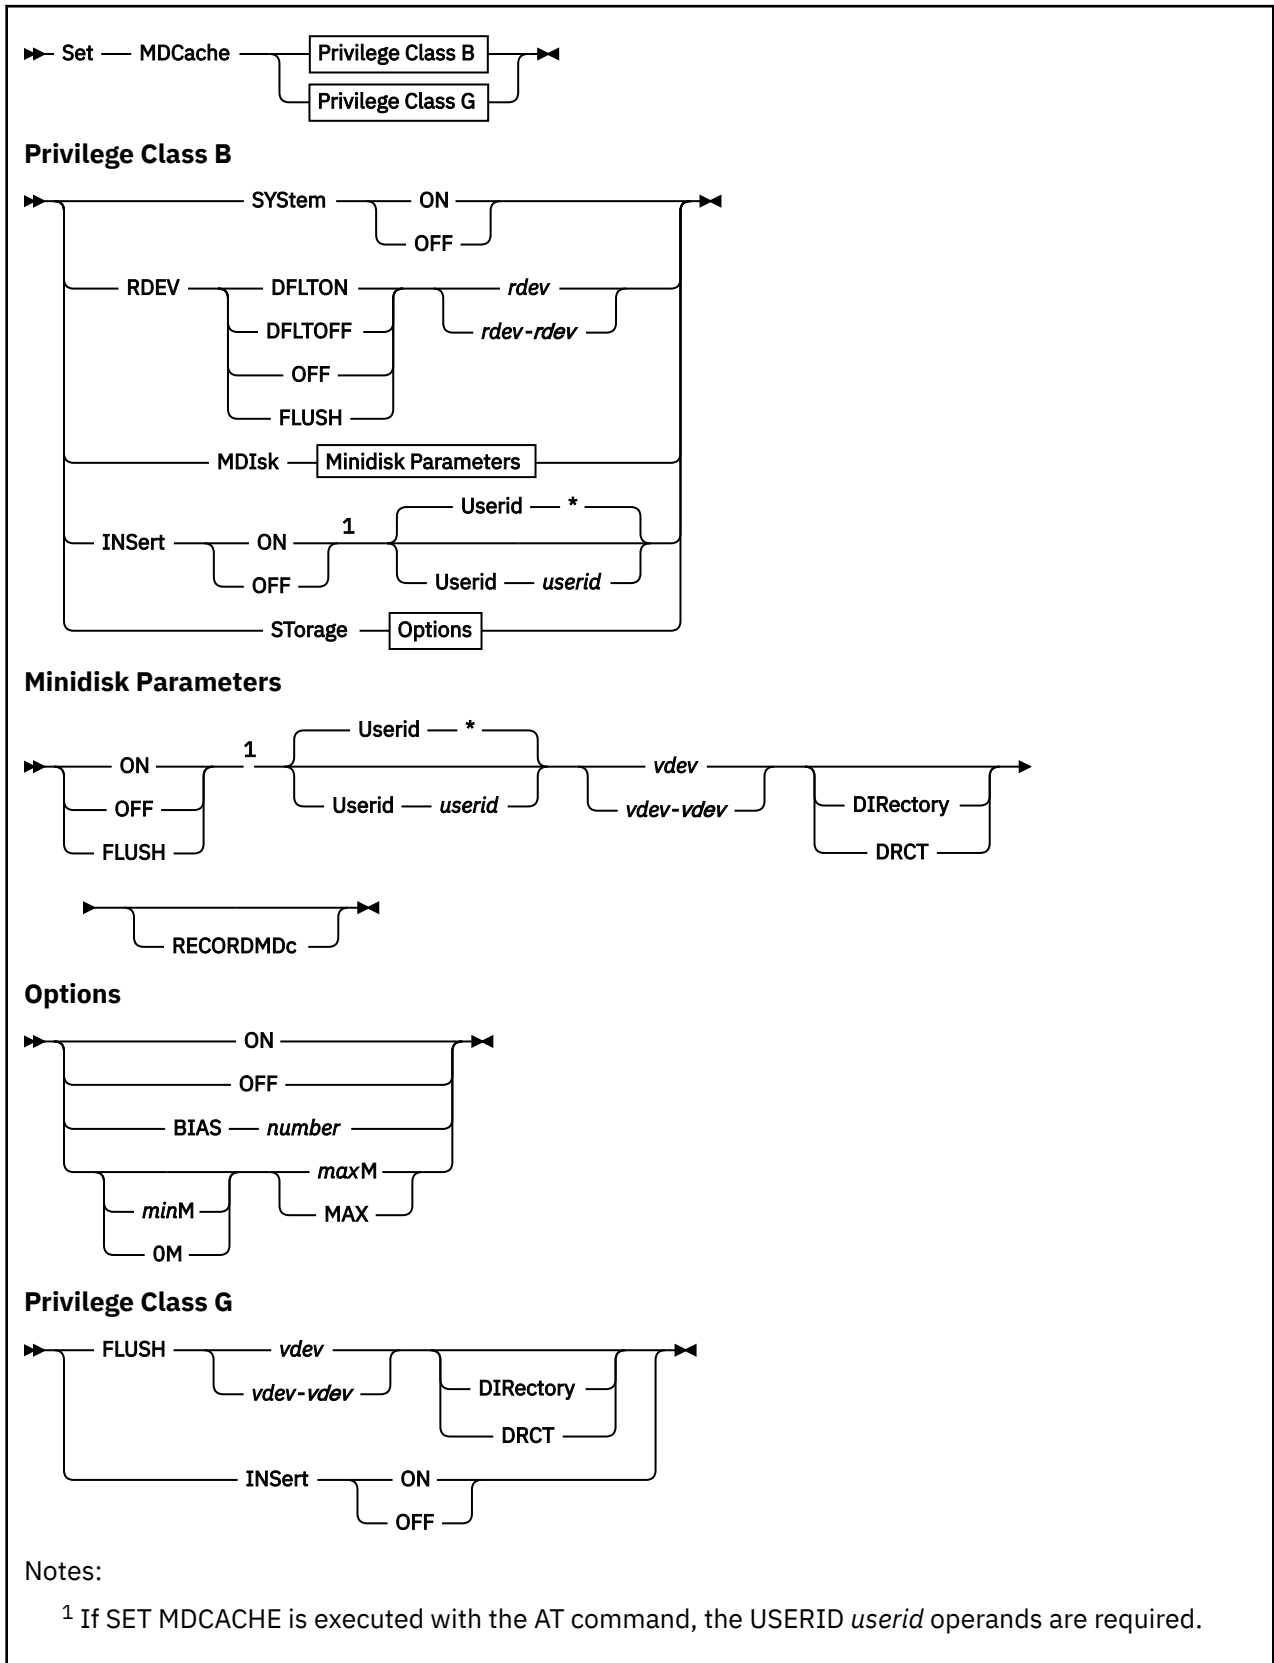

## SET MAXUSERS

### Messages

- HCP002E Invalid operand - *operand*
- HCP1001E An operand is missing for *option*.

# SET MDCACHE

## Authorization

Privilege Class: B, G

## Purpose

Use SET MDCache to change minidisk cache settings or change a user's ability to insert data into the cache.

A class B user can:

- Set caching on or off for all minidisks accessed on this system.
- Control minidisk caching at the real device or minidisk level.
- Purge the cache of data from a real device or an active minidisk.
- Change any user's ability to insert data into the cache.
- Specify the maximum and minimum amounts of real storage that can be used by a minidisk cache. The actual size of the minidisk cache varies and is determined dynamically by the paging and I/O load.

A class G user can:

- Purge the data in the cache pertaining to an active minidisk or a minidisk defined in the user's directory entry.
- Change the user's ability to insert data into the cache.

## Operands

### SYSTEM

### RDEV

### MDisk

defines the hierarchy level to which the command pertains, which determines whether a given virtual I/O will be cached.

### SYSTEM

specifies the highest level of control of the minidisk cache. With the SYSTEM option, minidisk caching can be globally turned on (enabled) or off (disabled) for the entire system via SET MDCACHE SYSTEM ON and SET MDCACHE SYSTEM OFF. If minidisk caching is on at the system level, it can be further controlled at the real device and minidisk level.

### RDEV

specifies the next highest level of control of the cache. If minidisk caching is on for the system, the installation can change the cache eligibility for a given real device, and hence, all minidisks that reside on that device via SET MDCACHE RDEV *action rdev* (or SET MDCACHE RDEV *action rdev-rdev*) where *action* is either DFLTON, DFLTOFF, OFF, or FLUSH.

### MDisk

specifies the lowest level of control of the cache. If minidisk caching is on for the system, the installation can change the cache eligibility for an active minidisk via SET MDCACHE MDISK *action USERID userid vdev* (or SET MDCACHE MDISK *action USERID userid vdev-vdev*). Note that for a minidisk to be cached, the system must be enabled for caching, the real device on which it resides must be set to DFLTON or DFLTOFF for caching, and the minidisk itself must be enabled for caching.

Class G users can use the SET MDCACHE FLUSH *vdev* (or SET MDCACHE FLUSH *vdev-vdev*) to purge the cache of data pertaining to minidisks defined in their directory.

The duration of cache control at the minidisk level is not permanent when set by the SET MDCACHE command. Permanent cache control at the minidisk level is achieved by the use of the MDC and NOMDC options of the MINIOPT directory statement. For the SET MDCACHE command to be successful for a minidisk, the minidisk must be active (that is, the minidisk must be linked by at least one user who is logged on the system). If at a later time, all links to the minidisk are

dropped, then the cache eligibility of the minidisk is determined from the directory entry for any subsequent link to the minidisk.

**ON**

is valid at the SYSTEM and MDISK levels.

- At the SYSTEM level, the ON option enables minidisk caching for the entire system without changing any real device or minidisk cache settings.
- At the MDISK level, the ON option enables minidisk caching for a minidisk. Note that the real device on which the minidisk resides must be set to DFLTON or DFLTOFF also before caching will occur. If specified without the RECORDMDC option and record caching is enabled, record caching is turned off for the minidisk.

**OFF**

is valid at the SYSTEM, RDEV, and MDISK levels.

- At the SYSTEM level, the OFF option disables minidisk caching for the entire system without changing any real device or minidisk cache settings.
- At the RDEV level, the OFF option disables minidisk caching for an entire real device. This command overrides any minidisk MDC setting set by the MINIOPT directory statement or the SET MDCACHE MDISK command.
- At the MDISK level, the OFF option disables minidisk caching for a minidisk. It also turns off RECORDMDC for the minidisk if it is active.

**DFLTON**

is valid at the RDEV level.

The DFLTON option enables minidisk caching for an entire real device, yet allows the installation to disable cache eligibility for any minidisk that resides on that device via the MINIOPT NOMDC directory statement or the SET MDCACHE MDISK OFF command

**DFLTOFF**

is valid at the RDEV level.

The DFLTOFF option disables cache eligibility for the entire real device, yet allows the installation to enable cache eligibility for any minidisk that resides on that device via the MINIOPT MDC directory statement or the SET MDCACHE MDISK ON command.

**FLUSH**

is valid at the RDEV and MDISK levels.

- At the RDEV level, the FLUSH option temporarily purges the data in the cache belonging to a real device. It does not change cache eligibility settings.
- At the MDISK level, the FLUSH option temporarily purges the data in the cache belonging to a minidisk. It does not change cache eligibility settings. Class G users can use the SET MDCACHE FLUSH *vdev-vdev* command for active minidisks defined in their directory entry.

***rdev******rdev-rdev***

identifies the real device numbers whose cache eligibility is to be changed.

**Userid \*****Userid *userid***

is the user ID of the virtual machine for which you want to change minidisk cache settings. If omitted or specified as an asterisk (\*), CP uses the user ID of the virtual machine issuing the command. For the class B command, if DRCT or DIRectory is not specified, the userid specified must be logged on.

***vdev******vdev-vdev***

identifies the virtual device number or the range of virtual device numbers for which cache settings are to be changed. For the class B command, the virtual device numbers specified correspond to the userid's current configuration if the DIRECTORY or DRCT option is not specified and to the userid's directory entry if the DIRECTORY or DRCT option is specified.

**DIRectory****DRCT**

indicates that the virtual device numbers correspond to the userid's directory entry. For the class B command, if DRCT or DIRectory is not specified, the userid specified must be logged on.

**RECORDMDC**

indicates that the minidisk's data should be cached using 4 KB record caching instead of normal full track caching. Only non-FBA 4 KB CMS formatted I/O via Diagnose X'18', X'A4', X'250', and \*BLOCKIO CP System Service is cached. All other I/O results in I/O direct to the minidisk. This option is only valid for SET MDCACHE MDISK ON.

**Attention:** Use of this option is a last resort for very special and unusual circumstances. It should only be used as the result of consultation with IBM support personnel who have concluded that no other performance problem exists. Using this option for any other reason may mask a performance problem which when corrected allows normal full track minidisk cache to perform better than with the RECORDMDC option.

**INSert**

changes a user's ability to insert information into the cache.

- The ON option allows a user to insert data into the cache.
- The OFF option prevents a user from inserting data into the cache. The user will continue to use data that is already in the cache, but cannot insert data. This option is useful when doing a scan of multiple files to avoid corrupting the cache with data that will only be referenced once.

**STorage**

used to control the size of the real storage portion of the minidisk cache or enable/disable caching to real storage.

**ON**

indicates that CP uses the amount of minidisk cache that best balances I/O and paging performance. This is the default. The minidisk cache size can range from 0 to the size of real storage, although the actual maximum is really limited to the size of the dynamic paging area (DPA).

**OFF**

indicates that CP does not use any of the identified storage for minidisk caching. The minidisk cache size is set to 0 for the specified storage type.

**BIAS number**

designates a number (value) that the MDC arbiter will use to adjust the target size for the indicated storage. The number must be within the range .01 to 100.00. For whole numbers, the decimal point is optional. The arbiter will multiply its selected target size by number and use the product (subject to the specialized min and max ranges) as the new target size. Therefore, if the number is greater than one, the effective target size will be larger than the one chosen by the arbiter and if the number is smaller, the target will be correspondingly smaller.

**OM****minM**

indicates the minimum size of the minidisk cache in megabytes if OM or minM. If *min* is greater than the amount of real storage on the system, the value is decreased to the amount of real storage on the system. If *minM* is specified, *maxM* must also be specified. If *minM* is not specified, the current minimum does not change unless it is now larger than the maximum in which case it is set to equal the maximum.

**MAX****maxM**

indicates the maximum storage size in megabytes for the indicated storage. If *max* is greater than the amount of real storage on the system, the value is decreased to the amount of real storage on the system. If *minM* is specified, *max* must be greater than or equal to *min*. If MAX is specified for the maximum real storage size, the upper limit of the real storage portion of the minidisk cache is set to the size of online real storage.

If the value specified as *max* is 0, the minidisk caching is turned off for that type of storage. Setting the maximum value to 0 is likely to degrade performance. The smallest recommended value is 2.

When *min* equals *max*, the size of the minidisk cache is fixed for that type of storage. It does not vary dynamically.

## Usage Notes

1. In z/Architecture mode, minidisk cache uses real storage above the 2 GB line.
2. If the amount specified via SET MDCACHE STORAGE is greater than the amount available, the amount specified is rounded down to the amount available.
3. Issuing SET MDCACHE STORAGE OFF or SET MDCACHE SYSTEM OFF prevents caching from occurring on the system. However, issuing SET MDCACHE SYSTEM OFF immediately purges all cache data, disables caching on the system, cleans up all internal minidisk cache structures, and releases all storage used by caching. Issuing SET MDCACHE STORAGE OFF causes a gradual reduction in cache data and does not clean up internal structures or storage. Furthermore, caching is still considered enabled for the system.
4. When SET MDCACHE STORAGE is issued with any option other than OFF, minidisk caching is enabled.
5. If SET MDCACHE STORAGE *maxM* is issued when *max* is greater than the current size of the minidisk cache in real storage, a gradual reduction in the use of real storage for CP paging occurs until the minidisk cache attains the new size. This does not cause a rapid migration of paging data to auxiliary storage. Similarly, when *max* is less than the current size of the minidisk cache, a gradual reduction in the use of minidisk cache occurs until the minidisk cache attains the new size.
6. Using the DIRECTORY or DRCT options is highly recommended as the user's current virtual configuration could vary between the time a user's virtual device is queried and the time the SET MDCACHE command is issued. The SET MDCACHE command could end up being issued for the wrong virtual device.
7. It is recommended that if minidisk caching is used, STORAGE should not be set to OFF. Even if it is set to OFF, up to 2 MB of real storage can be used for minidisk caching.
8. A minidisk, including a temporary disk, is not eligible for minidisk cache if it has been defined with greater than 32767 cylinders. This does not apply to FBA devices. It applies only to ECKD devices.
9. The RECORDMDC option of the SET MDCACHE MDISK ON command should only be used when directed to do so by IBM support personnel. RECORDMDC is for use only when DASD cache as well as real storage minidisk cache are all being overwhelmed by excessive unreferenced records being read by the full track cache support.
10. Use the SET MDCACHE INSERT command to temporarily disable minidisk cache operation for a minidisk (for example: during backup for the minidisk). Do not use SET MDCACHE MDISK as this causes unnecessary overhead and may cause a change in the caching mode for this minidisk.
11. The SET MDCACHE command is not valid for an alias Parallel Access Volume. Cache settings for an alias Parallel Access Volume are inherited from its associated base Parallel Access Volume.
12. The SET MDCACHE command is not valid for an alias HyperParallel Access Volume. Cache settings are only applicable for base HyperParallel Access Volumes.
13. When SET MDCACHE RDEV ON or SET MDISK ON is issued, a minidisk will not be eligible for cache until all write links on other systems in the SSI cluster are dropped, if any exist.

## Responses

Response 1:

The following response is issued when you specify SET MDCache SYStem ON.

```
Minidisk cache ON for system
Storage MDC min=nnnM max=nnnM, usage=ppp%, bias=b.bb
```

**min=nnnM**

indicates the current minimum value for the size of minidisk cache in megabytes.

## SET MDCACHE

### **max=nnnM**

indicates the current maximum value for the size of minidisk cache in megabytes.

### **usage=ppp%**

indicates the percentage of real storage in use by minidisk cache.

### **bias=b.bb**

indicates the bias factor used by the arbiter to determine the target size for the storage type.

Response 2:

The following response is issued when you specify SET MDCACHE SYSTEM OFF.

```
Minidisk cache OFF for system
```

Response 3:

The following response is issued when you specify SET MDCACHE RDEV DFLTON/DFLTOFF/OFF/FLUSH *rdev*.

```
Minidisk cache {DFLTON } for rdev
                {DFLTOFF}
                {OFF     }
                {FLUSHED}
```

### ***rdev***

identifies the real device number.

Response 4:

The following response is issued when you specify SET MDCACHE RDEV DFLTON/DFLTOFF/OFF/FLUSH for a range of real device numbers.

```
Minidisk cache {DFLTON } for rdev-rdev
                {DFLTOFF}
                {OFF     }
                {FLUSHED}
```

### ***rdev-rdev***

identifies the first and last real device numbers in the range.

Response 5:

The following response is issued when you specify SET MDCACHE MDISK ON/OFF/FLUSH USERID *userid* *vdev* or the class G command SET MDCACHE FLUSH *vdev*.

```
Minidisk cache {ON      } for userid vdev [recordmdc enabled]
                {OFF     }
                {FLUSHED}
```

### ***userid***

identifies the userid.

### ***vdev***

identifies the virtual device number.

### **recordmdc enabled**

indicates that record level minidisk caching is in effect for this minidisk rather than normal full track minidisk caching.

Response 6:

The following response is issued when you specify SET MDCACHE MDISK ON/OFF/FLUSH FOR USERID *userid vdev-vdev* or the class G command SET MDCACHE FLUSH *vdev*.

```
Minidisk cache {ON      } for userid vdev-vdev [recordmdc enabled]
                {OFF     }
                {FLUSHED}
```

**userid**

identifies the userid.

**vdev-vdev**

identifies the first and last virtual device numbers in the range.

**recordmdc enabled**

indicates that record level minidisk caching is in effect for this minidisk rather than normal full track minidisk caching.

Response 7:

The following response is issued when you specify SET MDCACHE INSERT ON/OFF.

```
Minidisk cache inserts {ON } for userid
                       {OFF }
```

**userid**

identifies the userid whose insert capability has been changed.

**Messages**

- HCP003E Invalid option - *{option|command}* contains extra option(s) starting with *option*
- HCP0013E Conflicting option - *option*
- HCP0026E Operand missing or invalid
- HCP0045E *userid* not logged on
- HCP1401I Expanded storage is not supported.
- HCP1920E Minidisk cache not enabled for system
- HCP1921E Cache settings could not be {changed | queried} for {*rdev code cc* | *userid vdev code cc* | *rdev-rdev* | *userid vdev-vdev* | system code *cc*}
- HCP6630E Minidisk Cache will be enabled later for *userid vdev*; write links exist in the SSI cluster.

**Note:** In message HCP1921E, the meanings of the value *cc* are:

**4**

device is not attached to system or not a cacheable device type

**8**

device does not exist

**12**

information could not be obtained from the directory

**16**

userid not in the directory

**20**

not enough storage to initialize cache

**24**

start or end of FBA minidisk not on full page boundary

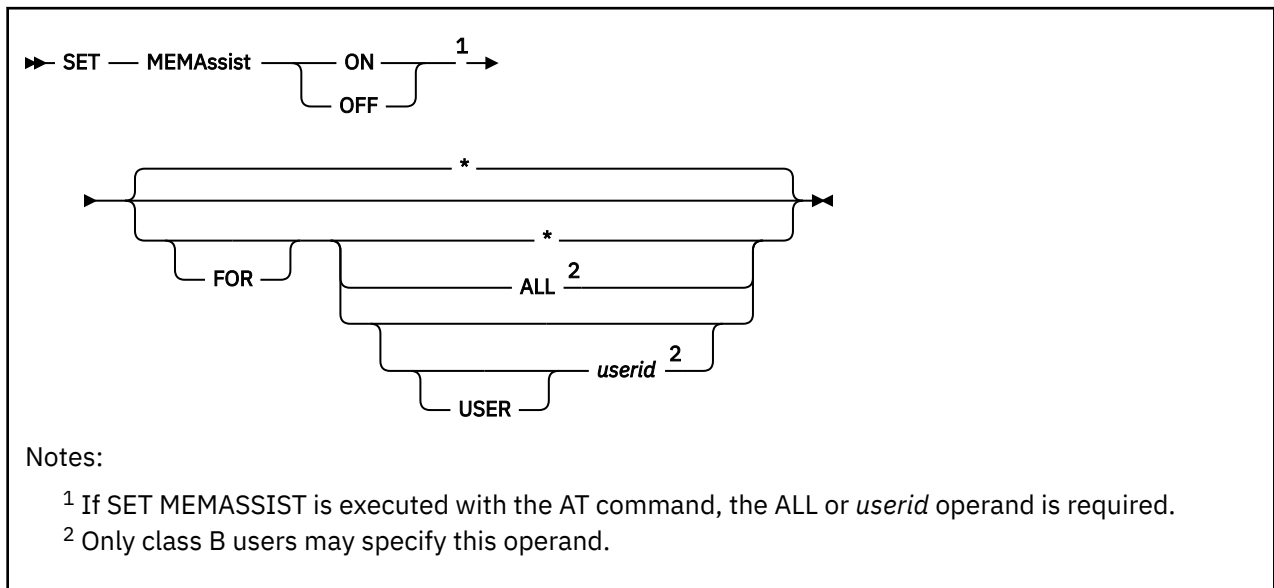

**28**

device is an alias Parallel Access Volume. Cache settings are inherited from its associated base Parallel Access Volume.

**32**

device is an alias HyperParallel Access Volume. Cache settings are only applicable for base HyperParallel Access Volumes.

## SET MEMASSIST

### Authorization

Privilege Class: B, G

### Purpose

Use SET MEMASSIST to control the collaborative memory management assist for a virtual machine. This interpretive-execution assist applies to guests that use the EXTRACT AND SET STORAGE ATTRIBUTES (ESSA) instruction.

The following are required to use the collaborative memory management assist:

- The assist must have been permitted for the system, either by default or with the MEMASSIST ON FOR ALL setting.
- The assist must not be forbidden for the virtual machine with the MEMASSIST OFF setting.

### Operands

#### ON

#### OFF

enables or disables the assist for a virtual machine.

#### \*

indicates you want to set your own virtual machine's MEMASSIST setting.

#### ALL

permits or disallows eligibility for all virtual machines to use the assist. Current individual virtual machine settings are not changed. When ALL is specified by a class B user, all new accesses to the assist are permitted or disallowed for all virtual machines, including any new users that might log on. See usage notes “3” on page 1569 and “4” on page 1569.

#### USER *userid*

specifies the user ID of the specific virtual machine for which you want to set the assist.

### Usage Notes

1. The initial MEMASSIST settings for your virtual machine are determined as follows:

- a. If the collaborative memory management assist is installed on the system, the initial setting will be ON unless the NOMEMASSIST directory option is specified.
  - b. If the assist is not installed, the initial setting is OFF.
2. At z/VM IPL, the initial setting for MEMASSIST FOR ALL is ON, even if the assist is not installed on the machine. This allows a virtual machine to SET MEMASSIST ON, causing the assist to be simulated by z/VM for guest testing purposes.
  3. If your virtual machine's MEMASSIST setting is ON, then SET MEMASSIST OFF does not immediately disable the assist. Instead, the assist is placed into a PENDING OFF state and is disabled at the next virtual machine reset (such as a re-IPL).
  4. A SET MEMASSIST OFF FOR ALL command does not affect any user who might be currently using the assist. The command merely prevents any user from issuing the SET MEMASSIST ON command, and places users with MEMASSIST ON into a PENDING OFF state.
  5. You can use the class G QUERY MEMASSIST command to inspect the current MEMASSIST setting for your own virtual machine. You can use the class B QUERY MEMASSIST command to inspect another virtual machine's MEMASSIST settings. For more information, see [“QUERY MEMASSIST” on page 1008](#).
  6. If the collaborative memory management assist is not installed on the machine, guests can still use it by means of the simulation that is built into CP. However, because of the overhead incurred by simulation, this mode of operation is recommended for testing purposes only.

## Messages

- HCP003E Invalid option - *option*
- HCP020E Userid missing or invalid
- HCP045E *userid* not logged on
- HCP1014E A required option is missing
- HCP2163I MEMASSIST is not permitted

## SET MIH

---

### Authorization

Privilege Class: G

### Purpose

Use SET MIH to specify whether missing interrupt conditions should be handled for I/O operations involving devices dedicated to your virtual machine.

### Operands

#### ON

indicates that CP automatically handles missing interrupt conditions to the virtual machine's dedicated devices.

#### OFF

indicates that the missing interrupt conditions to the virtual machine's dedicated devices are detected but are not handled.

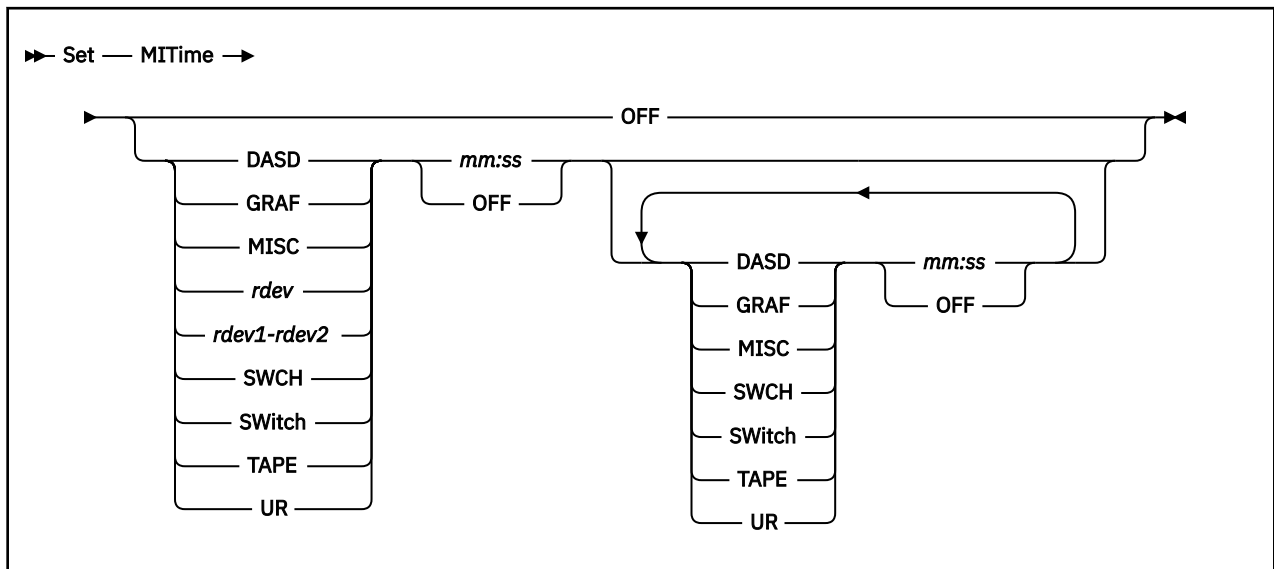

### Usage Notes

1. SET MITIME OFF overrides any setting of the MIH. Missing interrupts can be handled only if they are detected.
2. The default, which is to not handle missing interrupt conditions detected for the virtual machine's dedicated devices, is in effect when MIH is not specified on the user directory OPTION statement or the SET command is not issued.

### Messages

- HCP026E Operand missing or invalid

## SET MITIME

### Authorization

Privilege Class: A, B

### Purpose

Use SET MITIME to control the time interval at which the device specified is checked for missing interrupts.

### Operands

#### DASD

specifies that all real devices generated as DASD during system generation are to be monitored using the new time interval. Devices used by the mass storage subsystem (MSS) are not included.

#### GRAF

specifies that all real devices generated as display devices during system generation are to be monitored with the new time interval, an exception being device TYP328X.

#### MISC

specifies that real devices TYP328X, TYP3800, and any mass storage device are to be monitored with the new time interval.

#### *rdev*

#### *rdev1-rdev2*

is a real device number or range of real device numbers that are to be monitored with the new time interval.

#### SWCH

#### SWitch

specifies that all real devices generated as switch devices during system generation are to be monitored with the new time interval.

#### TAPE

specifies that all real devices generated as tape devices during system generation are to be monitored with the new time interval.

## SET MITIME

### UR

specifies that all real devices generated as spooling devices during system generation are to be monitored with the new time interval, an exception being device TYP3800.

### mm:ss

specifies the rate in minutes and seconds at which the device is to be examined for missing interrupts. The maximum value for *mm* is 99 and for *ss* is 59. The value is rounded up to the next multiple of five seconds.

### OFF

specifies that missing interrupts are not to be detected for any devices within the specified range. If you specify this operand without any device, missing interrupt monitoring for all devices is stopped.

## Usage Notes

1. If z/VM is running virtually, missing interrupt detection defaults to OFF at IPL. The default value is SET MITIME OFF.

When a real and a virtual system share a display device, the virtual system should leave missing interrupt detection off for the shared display device. Under certain circumstances, if the missing interrupt detector is active in the virtual machine for the shared display device, the virtual machine operator may be logged off.

2. The system default values at IPL time are:

<u>Device</u>	<u>Default Value</u>
SET MITIME DASD	00:15*
SET MITIME GRAF	01:10
SET MITIME UR	01:00
SET MITIME TAPE	10:00
SET MITIME SWITCH	05:00
SET MITIME MISC	12:00

\*The DASD and TAPE system default values will be used only if the device subsystems do not return a primary time-out value for the missing interrupt handler.

3. If you specify a range of devices, *rdev-rdev*, it must be in ascending sequence; otherwise, the command is invalid.
4. If you specify a value for *:ss* that is greater than 59, the command is considered not valid. If you specify 00:00, missing interrupt detection for the devices is stopped.
5. It may take up to 5 seconds longer than the interval specified to detect a missing interrupt.
6. When SET MITIME is issued, the new time interval is applied to any current operation.
7. The most recent interval specified for a device is the interval currently in effect. Keep in mind that when you enter the SET MITIME command for an entire class of devices (such as all DASD or all tape devices), the system monitors *all* members of that class at the new time interval.

For example, assume that the valid range of DASD addresses at your installation is 190 through 400<sup>®</sup>. If you enter **set mitime 250-255 00:59** and at some later point in time enter **set mitime dasd 00:20** the current interval for devices 190 through 400 is 20 seconds.

8. Changes can be made to several device classes with a single command. The command is processed from left to right so that the time interval specified last on the command line for a device class is the interval currently in effect.
9. Only device classes may be repeated on a single command line. If real device numbers are detected along with device classes on a single command line, the command is rejected.
10. The SET MITIME command has no effect on EDEVICES. The SCSI device driver has a separate mechanism and set of timers for managing missing interrupts. The values for those timers are not

configurable. SET MITIME commands that would include EDEVICES in their specification, either with the DASD class or by RDEV, will result in an informational message and will impact only devices in the specification that are not EDEVICES. Device ranges that include EDEVICES will be modified to have the EDEVICES removed, which will result in multiple ranges being displayed on the QUERY MITIME command.

Valid examples of multiple requests:

```
set mitime dasd 00:30 tape off ur 01:00 misc
1:40
set mitime tape 01:50 dasd 02:35 misc 02:30 tape 00:50
set mitime dasd 00:00 ur 05:00 misc 1:40 dasd off
```

Nonvalid examples:

```
set mitime dasd 00:30 tape off ur 01:00 190
01:40
set mitime 225-260 02:35 tape 00:50
set mitime dasd 01:00 ur 05:00 255 00:30 dasd off
```

## Messages

- HCP026E Operand missing or invalid
- HCP287I One or more EDEVICES exist that match the specification. SET MITIME will be ignored for all EDEVICES.

## SET MODE

### Authorization

Privilege Class: A, F

### Purpose

Use SET MODE to set the error-recording mode for system-recovery machine checks (soft errors).

**Note:** When the hardware recovers from an error without software assistance, it issues a system recovery machine check interrupt to report the incident.

### Operands

#### RETRY

is an optional keyword provided for compatibility with earlier systems.

#### Quiet

turns off error recording of system recovery machine checks.

#### Record

turns on error recording of system recovery machine checks. The next 12 system recovery machine checks are recorded. After that, the system automatically returns to QUIET mode and you receive a message informing you of that condition.

When a warning machine check occurs, a message is issued and further warning machine checks are disabled. The system then runs disabled for further warning machine checks until the SET MODE RECORD command is issued.

### Usage Notes

1. In addition to turning on and off system recovery machine check recording, you can use this command to reenables warning machine checks.

### Responses

Response 1:

```
SYSTEM RECOVERY {QUIET } MODE ACCEPTED
                 {RECORD}
```

indicates that the command has been accepted.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid
- HCP6005E Option *option* is not supported by z/VM.

## SET MONDATA

### Authorization

Privilege Class: C

### Purpose

Use SET MONDATA to control whether display device input and output data appear in the monitor records.

### Operands

#### ON

indicates that input from, and output to, user display devices is to be included with the terminal event records.

#### OFF

indicates that input from, and output to, user display devices is not to be included with the terminal event records.

### Usage Notes

1. The MONDATA option is set to OFF when the system is IPLed and is not changed unless a user issues SET MONDATA ON.
2. To obtain the setting of the MONDATA option, enter the QUERY MONDATA command.
3. It is the responsibility of the installation to protect the security of the data if MONDATA is set ON.

### Responses

Response 1:

```
Command complete
```

is issued when the command completes successfully.

### Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid

## SET MSG

---

### Authorization

Privilege Class: G

### Purpose

Use SET MSG to control whether the MESSAGE command messages are to be received at your display. The initial setting for MSG is installation dependent and is defined in the system configuration file.

### Operands

#### ON

#### OFF

controls the display of messages. If you specify ON, the messages are displayed. If you specify OFF, no messages are displayed.

#### IUCV

specifies that messages are to be passed to the virtual machine through IUCV if a connection to the message system service exists. If messages are passed through IUCV, they are not placed in the virtual console spool file. If no IUCV connection exists, messages are handled as if SET MSG ON had been issued.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid

## SET MSGFACIL

---

```
▶▶ Set — MSGFacil — OFF ▶▶
```

### Authorization

Privilege Class: G

### Purpose

Use the SET MSGFACIL OFF command to remove all message facility capability from the issuing virtual machine. All virtual message processors and message devices are detached from the virtual machine.

### Operands

#### OFF

removes all virtual message capability from your virtual machine

### Usage Notes

1. To define a virtual message processor and associated virtual message devices, use the DEFINE MSGPROC command.
2. To display information about virtual message processors in your I/O configuration, use the QUERY VIRTUAL MSGPROC command.
3. To display information about the virtual message devices within your I/O configuration, use the QUERY VIRTUAL MSGDEVICES command.
4. To restart a virtual message processor that is within your I/O configuration, use the RESTART MSGPROC command.
5. To detach a virtual message processor and associated virtual message devices, use the DETACH MSGPROC command.

### Responses

Response 1:

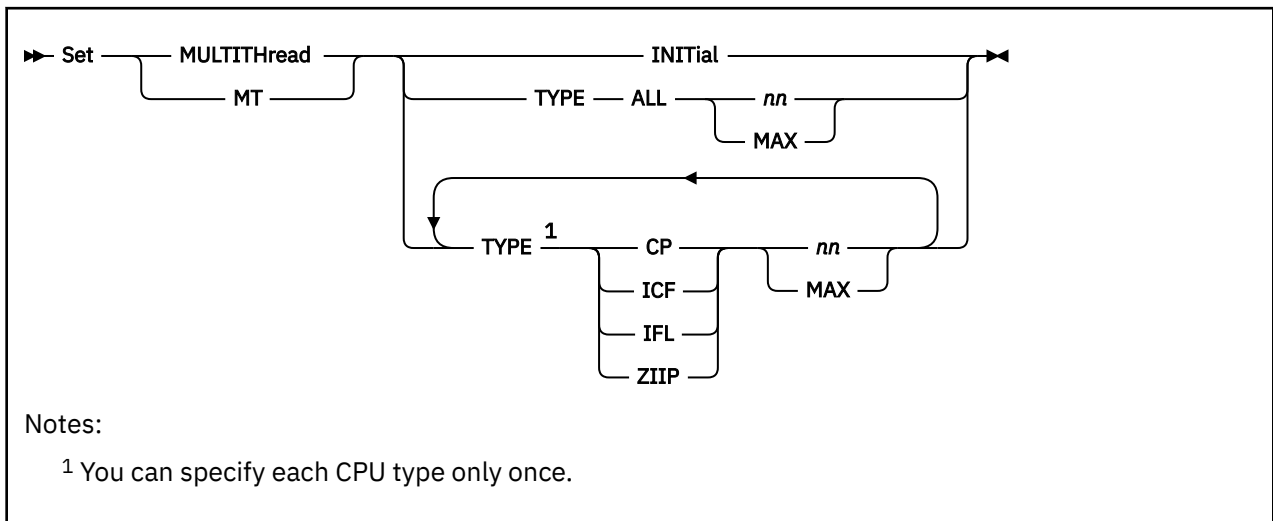

To remove all virtual message facility capability from your virtual machine, enter the following:

```
set msgf off
Command complete
Ready;
```

### Messages

- HCP002E Invalid operand – *operand*
- HCP003E Invalid option – command contains extra option(s) starting with *option*
- HCP003E Invalid option – *option*

## SET MULTITHREAD

### Authorization

Privilege Class: A

### Purpose

Use SET MULTITHREAD to change the multithreading (MT) characteristics of the system. The command allows the activated thread count per CPU type to be changed if multithreading is enabled.

When the result of the command changes the number of activated threads of a CPU type, then logical processors might be activated or deactivated to match the new setting.

### Operands

#### INITIAL

This operand requests that the configuration be restored to the values specified on the MULTITHREADING statement in the system configuration file at the time the system was IPLed. If it is specified, no other operands are allowed.

#### TYPE ALL {nn/MAX}

specifies the CPU type and the requested number of threads for that type. If ALL is specified, no individual CPU types may be specified. The value specified by this operand tells z/VM the number of threads to activate on each CPU type. The value *nn* must be a decimal number 1 - 32 and cannot be greater than the effective maximum threads value. If MAX is specified the activated thread count will be set to the effective maximum threads value. Refer to usage note [2](#) for an explanation of the effective maximum threads value, and usage note [4](#) for an explanation of how it influences the activated thread count.

When ALL is not specified and some of the individual CPU types are not specified, then the unspecified CPU types retain their prior values.

### Usage Notes

1. The activated thread count per CPU type can be changed only if multithreading is enabled.
2. The effective maximum threads value is the maximum number of threads any CPU type can use given the MAX\_THREADS setting requested on the MULTITHREADING statement, hardware limits and software limits. This value is displayed in the Activated Threads column of the MAX\_THREADS row of the QUERY MULTITHREAD command output. For an explanation of the MAX\_THREADS setting, see the [“QUERY MULTITHREAD”](#) on page 1026 command.

3. The number of online logical processors per core is determined by the activated thread count for the corresponding CPU type.
4. The actual activated thread count for a CPU type might be less than what was requested if the hardware or z/VM has a limit less than the effective maximum threads value. This level of z/VM supports up to 2 threads for IFL and 1 thread for all other CPU types.
5. For each CPU type, the resulting activated threads number will be the least of the following:
  - The effective maximum threads value
  - The requested threads value for that CPU type as specified on this command
  - The number of threads per core supported for that CPU type on the hardware or the configuration where z/VM is running
  - The number of threads for that CPU type supported by z/VM
6. The SET MULTITHREAD command is an asynchronous command. The initial synchronous stage of processing parses the command and determines whether or not it is valid. If valid, and it is not necessary to activate or deactivate processors, a "Command complete" response is issued. If it is necessary to activate or deactivate processors then a "Command accepted" response will be issued and control will be returned to the caller after scheduling the asynchronous processing to process the requested transition.
7. During the asynchronous processing step informational messages are displayed:
  - HCP6514I and HCP6517I which indicate the beginning and end of the asynchronous processing are sent to the command issuer and the primary system operator if not the issuer of the SET MULTITHREAD command.
  - HCP6515I and HCP6516I identify each of the processors that have been activated or deactivated as a result of the SET MULTITHREAD command. The primary system operator is also notified if not the issuer of the SET MULTITHREAD command.

These messages are generated after completion of the synchronous portion of the command, they are not treated as command responses. Therefore they will not be returned through interfaces like the AT or FOR command, Diagnose 8, or \*ASYNCMD.
8. Any additional SET MULTITHREAD commands will be rejected until the asynchronous processing has completed. The QUERY MULTITHREAD command can be used to determine when the asynchronous portion of the SET MULTITHREAD command processing has completed. The rejection will be indicated by message HCP6513I and corresponding return code.
9. The QUERY MULTITHREAD INITIAL command can be used to determine what the initial multithreading configuration settings were which would be restored by SET MULTITHREAD INITIAL.

## Responses

Response 1:

```
Command complete
```

Response 2:

```
Command accepted
```

After this response, asynchronous processing will complete the request. During that processing the following informational messages will be issued:

HCP6514I Processor reconfiguration for a multithreading configuration change has started.

HCP6517I Processor reconfiguration for a multithreading configuration change has completed.

One or more of the following information messages may be displayed between HCP6514I and HCP6517I when the SET MULTITHREAD command causes one or more CPU types with online cores to change activated thread counts.

HCP6515I Processor nnnn online due to thread activation

HCP6516I Processor *nnnn* offline due to thread deactivation

### Examples

1. To change the system to run single-threaded, use the following command:

```
SET MULTITHREAD TYPE ALL 1
```

### Messages

- HCP6517I Processor reconfiguration for a multithreading configuration change has completed.
- HCP6704E Missing token at end of line
- HCP6706E Invalid number - *number*
- HCP9152E Core *mmmm* is being varied offline because processor *nn* is not responsive during thread activation.
- HCP9152E Core *mmmm* is being varied offline because processor *nn* is not responsive during thread deactivation.

## SET NEW\_DEVICES

►► Set — NEW\_DEVICES — INITialize\_when\_added — ON — OFF —

### Authorization

Privilege Class: B

### Purpose

Use SET NEW\_DEVICES to change the way CP handles new real devices as they are added to a running system.

### Operands

#### INITialize\_when\_added ON

tells CP to automatically create a real device control block (RDEV) and initialize (bring online) the associated I/O device when you add a new device to the system.

#### INITialize\_when\_added OFF

tells CP to create a real device control block (RDEV) for a new I/O device, but not to initialize (bring online) that device when your system receives an I/O machine check (IOMCK) for adding a new device to the system. To bring the device online, use the CP VARY (Real Device) command (see [“VARY \(Real Device\)”](#) on page 2063).

### Usage Notes

1. You can also tell CP how to handle new devices using the FEATURES statement in your system configuration file. The FEATURES statement allows you to specify ENABLE (or DISABLE) NEW\_DEVICES\_INITIALIZED\_WHEN\_ADDED. For more information about the [FEATURES Statement](#), see *z/VM: CP Planning and Administration*.
2. To display whether CP initializes new real devices as they are added to a running system, use the QUERY NEW\_DEVICES command (see [“QUERY NEW\\_DEVICES”](#) on page 1033).
3. For more information about adding new devices to a running system, see the [FEATURES Statement](#) in *z/VM: CP Planning and Administration*.

### Responses

Response 1:

To have your devices initialized when they are added to the configuration, enter the following SET NEW\_DEVICES command:

```
set new_devices init on
Command accepted
Ready;
```

Response 2:

To prevent your devices from being initialized when they are added to the configuration, enter the following SET NEW\_DEVICES command:

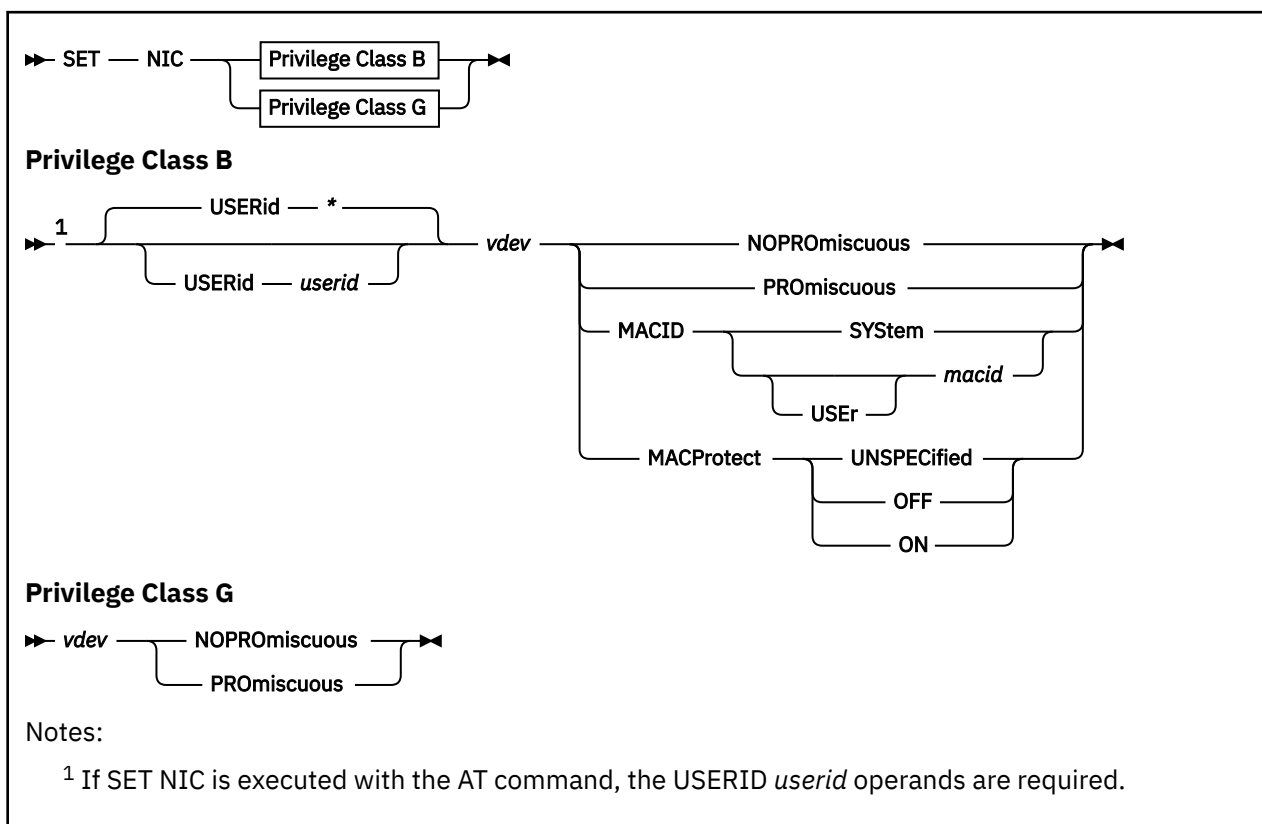

## SET NEW\_DEVICES

```
set new_devices init off  
Command accepted  
Ready;
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP0003E Invalid option - command contains extra option(s) starting with *option*
- HCP6704E Missing token at end of line

## SET NIC

### Authorization

Privilege Class: B, G

### Purpose

Use SET NIC to perform various settings for a specific network device.

A class B user can:

- Toggle promiscuous mode ON or OFF for a specified user ID's virtual network data device. In order for the guest to participate in promiscuous mode, the NIC must be authorized for promiscuous mode and coupled to a guest LAN or virtual switch.
- Specify the mechanism to be used when assigning a MAC address to a real or simulated network data device.
- Enable or disable MAC address protection for a specific network data device. Enabling MAC address protection ensures only the MAC address assigned by z/VM or the system administrator is used when a guest establishes a layer 2 (ETHERNET) network connection.

A class G user can only toggle promiscuous mode ON and OFF for a particular virtual network data device.

### Operands

**USERid *userid***

**USERid \***

is the user ID of the virtual machine for which you want to set NIC settings. If omitted or specified as an asterisk (\*), CP uses the user ID of the virtual machine issuing the command. The *userid* specified must be logged on.

**vdev**

is the virtual device number to be modified. Typically, this is required to be the device number of what is the data device (or what will be the data device) for the NIC.

**NOPROMiscuous****PROMiscuous**

specifies if promiscuous mode is to be toggled ON or OFF. Current Linux distributions enable or disable Promiscuous mode as part of the device driver alleviating the need for this SET command. Authorization to enable Promiscuous mode is still required using SET VSWITCH.

**MACID SYSTEM****MACID [USER] macid**

specifies the mechanism to be used when assigning a MAC address to a real or simulated network data device.

Specify SYSTEM to have a locally administered MAC address automatically assigned to this device number. The first 3 bytes (6 hexadecimal digits) of the MAC address will be the MACPREFIX value set on the VMLAN system configuration statement and the last 3 bytes will be the next available number in the MACIDRANGE SYSTEM range specified on the VMLAN statement.

Specify USER *macid* to have a static MAC address assigned. The *macid* value must be a unique 3-byte (6 hexadecimal digits) identifier. It will be appended to the system MACPREFIX or USERPREFIX value set on the VMLAN system configuration statement to form a unique user-defined locally administered MAC address for this device.

When MACPREFIX and USERPREFIX are set to the identical value, the value specified for *macid* must be in the USER subset of the MACIDRANGE SYSTEM range.

When MACPREFIX and USERPREFIX are set to different values, the MACIDRANGE settings are ignored. This allows the entire range of MACIDs (000001 - FFFFFFF) to be used by either the system or the user when making MAC address assignments.

Use SET NIC with the SYSTEM operand to remove a previously assigned USER MACID.

**MACProtect UNSPECified|ON|OFF**

turns MAC address protection on or off for the specified network device number. Turning MAC address protection on prevents a guest from using a MAC address that is not assigned to the user's network device. MAC address protection is valid only for simulated network devices when coupled to an ETHERNET virtual switch or guest LAN. MAC address protection is not supported for HiperSockets Bridge Capable guest ports that are being bridged by this virtual switch.

There are three levels of inheritance used when determining the MAC address protection level for a MAC address assigned to a network device. The highest is the system level, followed by the virtual switch or guest LAN level. The lowest level is the protection set for a specific network data device.

The MAC address protection level assigned is determined first by the device, then virtual switch or guest LAN and lastly the system level. If MAC address protection is set at the device level using the SET NIC CP command, then its current setting is used. When the device is set to UNSPECIFIED, it will inherit the MACPROTECT setting of the virtual switch. When the virtual switch MACPROTECT setting is set to UNSPECIFIED, the SYSTEM's MAC address protection specified by the SET VMLAN CP command or VMLAN configuration statement is assigned.

**UNSPECified**

allows the MAC address protection to be determined by the next higher level. UNSPECIFIED is the default setting for a network device.

**OFF**

will set the device MAC address protection level to unrestricted or off. The MAC address assigned to this device is not protected. A guest can override the assigned MAC address when establishing a network connection.

**ON**

will set the device MAC address protection level to restricted or on. The MAC address assigned to this device is protected and cannot be overridden by the guest when establishing a network connection.

## Usage Notes

1. The virtual device number (*vdev*) does not have to exist to set a MACID or the MACPROTECT option. In this case, the option will be preassigned and will be inherited when the virtual NIC is created comprising the device number.
2. A SET NIC *vdev* MACID command has no effect when a real device is attached as *vdev*, unless the device driver uses VM MAC address support. That is, the device driver must make a call to subcode X'30' of Diagnose X'26C' to retrieve a MAC address from CP and use that MAC address on link initialization.  
  
The z/VM TCP/IP stack's OSD device driver provides this support for a link defined to use the ETHERNET transport type. The link must be restarted in order to use the new MAC address. Until the link is restarted, a QUERY VIRTUAL OSA or QUERY VIRTUAL NIC command issued for the device shows a status of "Pending" for the newly assigned MAC address.
3. A SET NIC *vdev* MACID command sets the MAC ID for a virtual device. For the z/VM OSD device driver, the link must be restarted in order to use the newly assigned MAC address, unless it is SET before the link is first initialized..
4. For the z/VM TCP/IP stack, the *network data device number* is the first device number in a network adapter triplet. That is, a DEFINE NIC 501 creates an adapter with devices 501, 502, and 503. 501 is the data device number and should be used in the SET NIC command. (This information applies to z/VM stacks with code from release z/VM 5.4.0 and later.)

## Responses

Response 1:

```
Promiscuous Mode has been enabled for device vdev
```

Response 2:

```
Promiscuous Mode has been disabled for device vdev
```

Response 3:

```
MAC address macaddr has been assigned to device vdev
```

Response 4:

```
A MAC address is automatically assigned to device vdev
```

are the normal responses from this command.

## Messages

- HCP006E Invalid device type - *vdev*.
- HCP0045E *userid* not logged on
- HCP022E A virtual device number was not supplied or it was invalid
- HCP026E Operand missing or invalid
- HCP040E Device *vdev* does not exist.
- HCP2795E Promiscuous Mode can not be used with a HiperSockets device.
- HCP2795E Promiscuous Mode must be used on a data device
- HCP2850E MACID is not set for *vdev*. MAC address *macaddr* is already in use [by *user ID*]
- HCP2850E MACID is not set for *vdev*. Suffix for MAC address *macaddr* is not within USER MACIDRANGE.
- HCP2850E MACID is not set for *vdev*. SSI cluster mode not stable.

## SET NIC

- HCP2850E MACID is not set for *vdev*. Guest relocation active.
- HCP3022E SET NIC not performed; MACPROTECT is not valid for the IP transport type.
- HCP6704E Missing token at end of line

## SET NOPDATA

---

### Authorization

Privilege Class: G

### Purpose

Use SET NOPDATA to control the simulation of NOP CCWs in your virtual printer and punch channel programs.

### Operands

#### ON

#### OFF

controls the simulation of NOP CCWs. If you specify ON and if you specify more than one byte of data, CP attempts to transfer the data addressed by a NOP CCW to the spool file. If you specify OFF, CP simulates the NOP the same way a real device and channel would. The initial setting for a virtual machine is OFF.

### Usage Notes

1. This command allows programs that need to embed control information in CP spool files (such as RSCS) to operate under z/VM.
2. Do not use data chaining with NOP CCWs.

### Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid
- HCP263E Too many operands were supplied for this command.

## SET NVS

### Authorization

Privilege Class: B

### Purpose

Use SET NVS to make nonvolatile storage (NVS) available or unavailable within a DASD subsystem. This command is valid for cache storage subsystems that contain nonvolatile storage.

### Operands

#### SUBSYSstem

is an optional keyword that specifies that the entire storage subsystem is affected by this command, regardless of which device within the subsystem receives the order. This is the default (and only) value.

#### ON

indicates that the nonvolatile storage is to be made available to the subsystem.

#### OFF

indicates that the nonvolatile storage is to be made unavailable to the subsystem.

#### rdev

#### rdev1-rdev2

is the real device number, a list of real device numbers, or a range of real device numbers of devices in the subsystem.

### Usage Notes

1. SET NVS is valid only for cache storage subsystems that have nonvolatile storage installed. An error message is generated for storage subsystems that do not have nonvolatile storage installed.
2. The caching function is always enabled on RAID (Redundant Array of Independent Disks) technology DASD such as an IBM DASD subsystem. For these types of DASD, the device accepts but ignores this command; the caching function cannot be modified by the user. The caching function for these types will always appear as ON in related query commands.
3. Certain error messages may result if the subsystem is not in the correct mode to accept the SET NVS command. See error message HCP296E for more information.
4. If DASD fastwrite has previously been activated for any device, the DASD fastwrite function becomes operational when nonvolatile storage is made available for subsystem use.
5. Making nonvolatile storage unavailable for subsystem use causes a destage of all modified DASD fastwrite data in the subsystem.
6. This command may produce delayed responses. For more information see [“Delayed Responses to CP Commands”](#) on page 7.

### Responses

Response 1:

**Immediate Response:** If you enter the SET NVS ON command and the NVS is made available to the subsystem immediately, the following response is displayed. This response is repeated for each *unique subsystem* identified by the devices specified on the command.

```
rdev Nonvolatile storage has been activated.
```

**rdev**

is the real device number of one of the specified devices in a subsystem for which NVS has been activated.

**Delayed Response:** If the NVS is not made available to the subsystem immediately, the following response is displayed:

```
Command started: SET NVS ON rdev.
```

When the NVS is made available to the subsystem, the following responses are displayed:

```
rdev Nonvolatile storage has been activated.
```

Under certain circumstances, it is possible that a cache storage subsystem does not notify CP when it has made the NVS available to the subsystem. When this occurs, the appropriate command response cannot be generated. Under these circumstances, command processing is ended after generating the following response:

```
Command results lost: SET NVS ON rdev.
```

In this case, the QUERY NVS command can be issued to determine the state of the nonvolatile storage.

If errors occur during the asynchronous processing of the command that prevent the successful completion of the command, the following response is displayed:

```
Command failed: SET NVS ON rdev.
```

**rdev**

is the real device number of one of the specified devices in a subsystem for which the command has failed.

**Response to System Operator:** If the originator of the command is not the system operator, the following response is issued to the system operator when the NVS has been made available to the subsystem. This response is also repeated for each *unique subsystem* identified by the devices specified on the command line.

```
rdev Nonvolatile storage was activated by userid.
```

**rdev**

is the real device number of one of the specified devices in a subsystem for which the NVS has been activated.

**userid**

is the ID of the user who issued the command.

Response 2:

**Immediate Response:** If you enter the SET NVS OFF command and the NVS is made unavailable to the subsystem immediately, the following response is displayed. This response is repeated for each *unique subsystem* identified by the devices specified on the command

```
rdev Nonvolatile storage has been deactivated.
```

**rdev**

is the real device number of one of the specified devices in a subsystem for which the NVS has been deactivated.

**Delayed Response:** If the NVS is not made unavailable to the subsystem immediately, the following response is displayed:

```
Command started: SET NVS OFF rdev.
```

When the NVS is made unavailable to the subsystem, the following responses are displayed:

```
rdev Nonvolatile storage has been deactivated.
```

Under certain circumstances, it is possible that a cache storage subsystem does not notify CP when it has made the NVS unavailable to the subsystem. When this occurs, the appropriate command response cannot be generated. Under these circumstances, command processing is ended after generating the following response:

```
Command results lost: SET NVS OFF rdev.
```

In this case, the QUERY NVS command can be issued to determine the state of the nonvolatile storage.

If errors occur during the asynchronous processing of the command that prevent the successful completion of the command, the following response is displayed:

```
Command failed: SET NVS OFF rdev.
```

#### **rdev**

is the real device number of one of the specified devices in a subsystem for which the command has failed.

**Response to System Operator:** If the originator of the command is not the system operator, the following response is issued to the system operator when the NVS has been made unavailable to the subsystem. This response is also repeated for each **unique subsystem** identified by the devices specified on the command line.

```
rdev Nonvolatile storage was deactivated by userid.
```

#### **rdev**

is the real device number of one of the specified devices in a subsystem for which the NVS has been deactivated.

#### **userid**

is the ID of the user who issued the command.

## Messages

## SET OBSERVER

### Authorization

Privilege Class: A, C, G

### Purpose

Use SET OBSERVER to change the observer setting for a virtual machine. The observer is a virtual machine that receives the line-mode output produced on another virtual machine's console. If you are a class G user, you can change the observer setting for your own virtual machine. If you are a class A or C user, you can change the observer setting for any virtual machine.

### Operands

#### *targetid*

is the user ID of the virtual machine whose observer status is to be set or reset. If you are a class A or C user and you do not specify *targetid*, CP sets or resets the secondary user for your user ID. If you are a class G user, you can stop being the observer for *targetid* by specifying *targetid* OFF.

#### *userid*

is the user ID of the observer virtual machine.

#### RESET

sets the observer for *targetid* or the command issuer to the user ID specified on the CONSOLE statement in the user's directory entry.

#### OFF

removes the user from observation.

#### \*

sets the observer to the virtual machine that issues the command.

## Usage Notes

1. If observer support is used with large console messages that are close to the free storage limit of X'1FD' doublewords, it is possible that the message could be truncated at the end in order to add the header at the beginning which indicates the user ID from which the message originated.
2. A virtual machine cannot have both an observer and a secondary user defined by any combination of the SET OBSERVER and SET SECUSER commands and the CONSOLE directory statement.
3. If the designated observer is currently unable to function in that capacity (for example, not logged on, or disconnected with no connection to \*MSG or \*MSGALL), the setting is nevertheless accepted by CP, and the relationship is established when the specified user ID meets the necessary criteria.
4. In an SSI cluster, the observer and the target (observed) user can be logged on to different member systems.

If either user is a multiconfiguration virtual machine, the observer will function in that capacity only when it is local (logged on to the same member as the observed user). If the observed user is a multiconfiguration virtual machine, the observer must be logged on to the member where the SET OBSERVER command was issued.

## Examples

Example 1:

USERA (a general user) designates USERB (another general user) as its observer by issuing the following command:

```
set observer userb
```

USERB can stop observing USERA by issuing the following command:

```
set observer usera off
```

If USERC is the observer for USERD, USERD can remove its observer by issuing the following command:

```
set observer off
```

Example 2:

USERC (a class A or class C user) issues the following command to assign USERD as the observer for USERB:

```
set observer userb userd
```

USERD receives the following message:

```
HCP6768I Observation of USERB initiated for you by USERC
```

At the same time, USERB receives one of the following messages:

```
HCP6768I Your observation by USERD set by USERC
```

-or-

```
HCP6769I Your observation terminated by USERC
```

Example 3:

USERC can remove the observer for USERB by issuing the following command:

```
set observer userb off
```

This causes the user ID that was the secondary user (USERD) to receive the message:

```
HCP6769I Observation of USERB terminated for you by USERC
```

#### Example 4:

If the command issuer becomes the observer, the message issued at initiation is:

```
HCP6768I Observation of target initiated
```

When the secondary user option is terminated, the message issued is:

```
HCP6769I Observation of target terminated
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) beginning with *option*
- HCP007E Invalid userid - *userid*
- HCP017E User *userid* has a SECUSER and cannot be observed
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on
- HCP053E *userid* not in CP directory
- HCP1149E Error communicating with another SSI member. It cannot be determined if *command* executed remotely.
- HCP6768I Observation of *target* by *observer* is not functional
- HCP6768I Observation of *target* initiated
- HCP6768I Observation of *target* initiated for you by *userid*
- HCP6768I Your observation by *observer* set by *userid*
- HCP6769I Observation of *target* terminated
- HCP6769I Observation of *target* terminated for you by *userid*
- HCP6769I Your observation terminated by *userid*

## SET PAGEX

### Authorization

Privilege Class: G

### Purpose

Use SET PAGEX to turn on or off the pseudo-page-fault facility for your virtual machine.

When the facility is on, your virtual machine can dispatch a task while waiting for CP to satisfy a page-in request for another task. When the facility is off, your virtual machine must wait until CP has satisfied a pending page-in request before dispatching another task.

**Note:** In general, your virtual machine guest operating system issues this command without your intervention. The guest operating system will do this explicitly using DIAGNOSE code X'08', which implies that the guest already knows (from STIDP) that it is running in a virtual machine.

### Operands

**ON**

**OFF**

controls whether the pseudo-page-fault facility is activated or deactivated for your virtual machine. ON activates the facility. OFF deactivates it.

### Usage Notes

1. In general, do not enter this command arbitrarily. If you enter the command while a guest operating system is running, you may cause the system to be stopped or to end abnormally.
2. The pseudo-page-fault facility is an interface consisting of a special CP program interrupt code (X'14'). The guest operating system must have this special program interrupt handler to switch to another task while CP resolves the host page fault that triggered the PAGEX interruption. When the host page fault has been resolved, CP presents a second interruption to the virtual machine for each task that previously received a PAGEX interruption for an address in the page where the fault occurred. See [“Pseudo-Page-Fault Interruption” on page 1595](#) below for details.

If the pseudo-page-fault facility is not activated for an operating system that supports the PAGEX interface feature, you may cause performance degradation. On the other hand, if the pseudo-page-fault facility is activated for an operating system that does *not* support the handshaking feature, results are unpredictable as the guest program interrupt handler will not recognize the special PAGEX program interrupts.

3. For ESA/XC and z/XC virtual machines, SET PAGEX governs handling of faults to only the host-primary address space. Page-fault handshaking of access register (AR)-specified references, as controlled by the PFAULT macro, is not affected by SET PAGEX in any way, nor is SET PAGEX affected by this support. See [PFAULT Macro -- Page-Fault Handshaking Services in z/VM: CP Programming Services](#) for details on page-fault handshaking for AR-specified references.
4. PAGEX is used by the following IBM operating systems:

VSE/ESA  
GCS

5. If the virtual configuration executes a SIGP Set-Architecture instruction, the pseudo-page-fault facility is reset.
6. SET PAGEX ON may not be issued when the asynchronous page-fault handshaking facility for the host-primary address space is in effect (when the VERSION=2 parameter of the PFAULT TOKEN macro has been specified).

## Pseudo-Page-Fault Interruption

A pseudo-page-fault (PPF) interruption is a program interruption with interruption code X'0014'. There are two types of PPF interruptions, initial and completion. When PPF interruptions are enabled and a guest instruction encounters a CP page fault which can not be resolved immediately, a PPF initial interruption is presented to the virtual CPU. This allows the guest supervisor to suspend the running thread and dispatch another. For each initial interruption, a completion interruption specifying the same fault address is presented to the same virtual CPU when the page fault has been resolved. This signals the guest supervisor to unblock the affected thread.

If the virtual CPU is disabled for PPF interruptions when a page fault occurs, the fault is handled synchronously; that is, execution of the virtual CPU is suspended until the fault is resolved. If the virtual CPU is disabled for PPF interruptions when a previous asynchronous page fault is completed, the completion interruption remains pending until the virtual CPU enables.

PPF interruptions are enabled on a virtual CPU when all of the following are true:

- PAGEX is set ON for the virtual machine.
- The PSW is enabled for I/O interruptions. (PSW bit 6 is one.)

In addition, if the virtual machine is in z/Architecture or z/XC mode, PPFs are presented only for faults on guest real addresses below 2 GB. Faults on higher addresses are handled synchronously, as if PPF interruptions were disabled.

When a PPF interruption is presented, an interruption parameter is stored at guest real locations 144-147 (X'90'-X'93'), as follows:

- Bit 0 is zero for a PPF initial interruption, or one for a PPF completion interruption.
- Bits 1-31 are the guest real starting address of the page on which the fault occurred. (Bits 20-31 are zero.)

## Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid
- HCP1404E Asynchronous page-fault handshaking for the host-primary space is already in effect. PAGEX cannot be activated.

## SET PAGING

### Authorization

Privilege Class: B

### Purpose

Use the SET PAGING command to modify settings for the paging subsystem.

### Operands

#### ALIAS ON

indicates that system-attached HyperPAV aliases should be used for paging I/O. HyperPAV aliases allow concurrent I/O requests to the same physical volume by using alias devices. Aliases do not have associated storage and can be bound dynamically to base volumes. Using HyperPAV can increase throughput by reducing queuing at the device level.

#### ALIAS OFF

indicates that system-attached HyperPAV aliases should not be used for paging I/O. This is the default behavior, unless aliases are activated on a PAGING or FEATURES statement in the system configuration file (see Usage Note “1” on page 1597), or through a previous SET PAGING command.

#### HPF ON

indicates that transport mode channel program format should be used for paging I/O. With transport mode, less overhead occurs between the channel subsystem and the FICON adapter than with traditional command-mode I/O. This results in higher I/O rates and less CPU overhead.

Specifying SET PAGING HPF ON is not recommended unless all paths to paging devices are High Performance FICON for IBM Z (zHPF) capable.

#### HPF OFF

indicates that command-mode channel program format should be used for paging I/O. This is the default behavior, unless HPF is activated on a PAGING or FEATURES statement in the system configuration file (see Usage Note “1” on page 1597), or through a previous SET PAGING command.

#### WARNING

defines the allocation warning level for paging volumes. The *nnn* value is a decimal integer in the range of 0 to 100. If the number of allocated slots reaches this percentage of total slots on all paging volumes, message HCP401I is issued to alert the system operator.

This warning level is in addition to the default 90% warning message (issued via message HCP401I). Setting the WARNING value to 90% does not result in a second warning message.

This value also serves as the default MAXPAGEFULL setting for a SET STORAGE command to make sure a storage removal does not cause paging volumes to exceed this level of allocation. See “[SET STORAGE](#)” on page 1722 for more information.

## Usage Notes

1. Use the PAGING statement in the system configuration file to establish the paging subsystem's settings at IPL.

For compatibility, the Alias and HPF settings can also be specified on the FEATURES statement in the system configuration file using the PAGING\_ALIAS and PAGING HPF operands. However, it is recommended that you consolidate your paging options on the PAGING statement.

2. Setting a PAGING WARNING value of 0% results in message HCP401I as soon as the system starts paging operations. After paging slots have been allocated, it is unlikely that the total number of paging slots allocated will revert to 0, even if all guests with slots on DASDs are logged off. This is because some CP-pageable pages (system-owned utility address space pages, for example) might remain allocated.

To reduce paging slot allocations, you could consider specifying STORAGE AGELIST KEEPSLOT NO in the system configuration file, or on the SET AGELIST command, to cause paging slots to be unallocated when the corresponding page is read into memory. KEEPSLOT NO can reduce the number of slot allocations on paging volumes. However, it can also increase paging I/O during page-steal operations because every page needs to be written, even those that are unchanged since the last read from DASD.

## Responses

Response 1:

```
PAGING_ALIAS: {ON}          PAGING_HPF= {ON}          WARNING: nnn%
               {OFF}                {OFF}
```

### PAGING\_ALIAS

indicates the state of the HyperPAV alias feature of the paging subsystem.

### PAGING\_HPF

indicates the state of the HPF feature of the paging subsystem.

#### ON

the feature is active

#### OFF

the feature is not active

### Warning *nnn%*

specifies the allocation warning level for paging volumes.

## Messages

- HCP003E Invalid option - *{option | command contains extra option(s) starting with option}*
- HCP026E Operand missing or invalid

## SET PASSWORD

### Authorization

Privilege Class: B

### Purpose

Use SET PASSWORD to indicate whether users of commands requiring passwords must enter the passwords separately from the command.

### Operands

**AUTOLOG SEPARATE**  
**XAUTOLOG SEPARATE**  
**AUTOLOG INCLUDE**  
**XAUTOLOG INCLUDE**

sets the system-wide password suppression facility for the AUTOLOG and XAUTOLOG commands. (Specifying either AUTOLOG or XAUTOLOG changes the setting for both commands.) Specify SEPARATE to indicate that passwords cannot be entered as part of the command line. Specify INCLUDE to indicate that passwords *must* be part of the AUTOLOG command line and are permitted as part of the XAUTOLOG command line.

**LINK SEPARATE**  
**LINK INCLUDE**

sets the system-wide password suppression facility for the LINK command. Specify SEPARATE to indicate that passwords cannot be entered as part of the command line. Specify INCLUDE to indicate that passwords are permitted as part of the command line.

**LOGON SEPARATE**  
**LOGON INCLUDE**

sets the system-wide password suppression facility for the LOGON command. Specify SEPARATE to indicate that passwords cannot be entered as part of the command line. Specify INCLUDE to indicate that passwords are permitted as part of the command line.

### Usage Notes

1. For security reasons, the password suppression facility permits your installation to require that issuers of commands that require passwords do not include the password in the command line. Instead, after the user enters the command without the password, the system prompts the user to enter the password, and the input field is masked.
2. The initial (default) system setting for the password suppression facility for the AUTOLOG, XAUTOLOG, LINK, and LOGON commands is the equivalent of SEPARATE. The default system setting can be overridden by the PASSWORDS\_ON\_CMDs operand of the FEATURES system configuration statement. The SET PASSWORD command changes the current setting. Password suppression settings that are not explicitly reset with SET PASSWORD retain their previous values.

3. SET PASSWORD changes the syntax allowed for the specified command, because it indicates whether the password may be included on the command line. Therefore, changing this setting may affect EXECs that use the command.
4. System programmers responsible for z/VM security should examine the usage notes for the `PASSWORDS_ON_CMDs` operand of the [FEATURES Statement](#) in *z/VM: CP Planning and Administration*.

**Messages**

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid

## SET PCIFUNCTION

### Authorization

Privilege Class: B

### Purpose

Use SET PCIFUNCTION to reset or deconfigure a real PCI function or to report an error with the function to the Support Element.

### Operands

#### *rpfid*

is a real PCI function ID to be set. Specify the ID as eight hexadecimal digits. You can omit leading zeros.

#### **RESET**

resets the real PCI function.

#### **DECONFIGure**

removes the real PCI function from the z/VM LPAR configuration.

#### **REPORT**

reports device errors to the Support Element.

### Usage Notes

1. The REPORT operand provides device information for any function type. However, the device information includes the detail information that is displayed by the QUERY PCIF DETAILS command only for NVMe PCI functions that are associated with an EDEVICE.
2. An operation that uses the RESET operand places the PCI function in an error state. After the reset function completes successfully for an NVMe function, the function returns to the operational state and the following message is issued:
  - HCPNVM1164I PCI function *rpcf* recovery was successful.
3. An operation that uses the DECONFIGURE operand for an NVMe function removes the PCI function from the z/VM LPAR configuration. The following operator messages might be issued asynchronously:
  - HCPPCI1164I - PCI Function *rpcf* is no longer available for use by the configuration.
  - HCPPCH1165I - PCI Function *rpcf* has been deleted from the configuration.

Recovery requires that you add the PCI function to the configuration again by using the Support Element or the Hardware Management Console.
4. An operation that uses the RESET or DECONFIGURE operand for an NVMe function places any associated NVMe EDEVICES in an error state. Guests and z/VM might not operate effectively. Recovery requires that you delete and re-create the NVMe EDEVICES.

### Responses

There is no direct response to a successful SET PCIFUNCTION command.

**Messages**

- HCP021E A real PCI function ID was not supplied or it is invalid.
- HCP040E PCI function *rpfid* does not exist
- HCP1003E *rpfid* not found.
- HCP1170E Support Element notification failed for PCI function *rpfid*
- HCP1170E Support Element operation failed for PCI function *rpfid*

## SET PFnn

### Authorization

Privilege Class: G

### Purpose

Use SET PFnn to:

- Assign a program function to a program function key
- Specify when the program function is to be processed.

**Note:** PF keys are part of the terminal display keyboard.

### Operands

#### PFnn

identifies the program function key you are defining; the operand *nn* is a number from 1 (or 01) to 24 that corresponds to a program function key on the display. The program function is a programming capability you create by defining a series of commands you want run. This series of commands runs when you press the appropriate program function key.

#### SUBSTITU

indicates that the PF data may contain one or more substitution place holders.

A substitution place holder is identified by an ampersand followed by an asterisk (&\*) or an ampersand followed by a decimal number comprised of 1 to 8 digits (&n, where n=1,2,3...). The value of the number must be greater than zero. The end of the place holder is delimited by a period, blank, line end, or data end.

Any other ampersand that is not a substitution place holder must be specified within the PF data as two ampersands.

If a single ampersand is detected that is not a valid substitution place holder, the ampersand and what follows to the ending delimiter is translated to a null within the PF data when the PF key is processed.

If SUBSTITU is not specified, no substitution is made.

If SUBSTITU is specified, any &n (for example, &1, &2,...) in PF data is substituted with a token from the input area. The value &1 is substituted with the first token, &2 is substituted with the second token, and so on. &\* is substituted with all the data past the highest token referenced in PF data.

The SUBSTITU operand supports mixed DBCS strings. If you are using DBCS data, SUBSTITU will not look for a substitution character within the DBCS data.

If no corresponding token is found for an &n, it is translated as a null. If a token is not referred to in the PF data, it is ignored.

A token can be delimited by blanks or single quotation marks. If you want single quotation marks imbedded in the token, double the number of quotation marks.

For example, assume you enter **set pf1 substitu msg &1 please attach &2 to me as &3, &4**. If you then enter **operator 135 246 'as soon as possible'** and press the PF1 key, the following appears in your input area:

```
MSG OPERATOR PLEASE ATTACH 135 TO ME AS 246,
AS SOON AS POSSIBLE
```

Specifying a period after a substitution place holder concatenates the substitution place holder with the following data. (The data can be text or another substitution character.) For example, assume you set PF2 by entering:

```
set pf2 substitu immed display Lt&1..&2
```

If you enter:

```
1fd000 90
```

and press PF2, the following command is processed immediately after being displayed:

```
DISPLAY LT1fd000.90
```

CP does not read double-byte characters as tokens.

### **DElayed**

### **IMMed**

### **NODisp**

indicates when the program function is processed. If you specify IMMED, the program function is processed when you press the PF key. If you specify DELAYED, the PF data is displayed in the input area when you press the PF key. The data may then be modified if necessary and the ENTER key pressed when you want the function to be processed. If you specify NODISP, the program function is processed when you press the PF key, but the function is not redisplayed on the terminal. DELAYED is the default.

### ***pfdata***

defines the command or data lines that constitute the program function. If you are entering more than one command line as program function data, use the line end symbol to separate the lines. The default line end symbol is the pound sign (#); you can define your own line end symbol with the TERMINAL LINEND command.

If you use the line end symbol to separate commands that you want run with a designated PF key, you must precede each line end symbol with the logical escape character. The default logical escape character is a double quotation mark symbol (""); you can define your own logical escape character with the TERMINAL ESCAPE command.

If you do not enter any command lines, the SET PFnn command resets a PF key to undefined or resets the IMMED or DELAY status of an existing PF key function to the value you have specified.

Mixed DBCS strings can be used for the data defined for a PF key.

## **Usage Notes**

1. If your keyboard has 24 PF keys, specify the PF key number, *nn*, as a value from 1 (or 01) to 24. If your keyboard has only 12 PF keys, specify *nn* as a value from 1 (or 01) to 12.
2. For DELAYED, if the length of the saved data is longer than the input area, it is truncated to the input area length. The input area length is twice the terminal line size minus 21. The QUERY TERMINAL command returns the LINESIZE field used in this calculation.

## SET PFnn

For IMMED and NODISP, the length of the data is limited to the greater of either the input area length or 240.

**Note:** Remember that this applies to the terminal where you will be pressing the PF key.

3. You can use the line end symbol to separate commands that you want to run with the designated program function key.

For example, suppose your virtual machine has the line editing function set ON, and is using the pound sign (#) as the logical line end symbol.

While in CMS mode, enter **set linedit off**. Then enter **set pf02 immed q rdr:#q pun** or **cp set pf02 immed q rdr:#q pun**. (CP assigns the two QUERY commands as functions of the PF02 key.) Then enter **set linedit on**. (Pressing the PF02 key runs the two QUERY commands.)

Since the entire input line is accepted as valid program function data, do not specify further SET command functions on the SET PFnn command line.

4. On a DELAY PF key, if SUBSTITU is not specified, the cursor is positioned at the end of the data. If SUBSTITU is specified and all of the &ns are substituted with tokens, the cursor is also positioned at the end. If some &ns are not substituted, the cursor is positioned over the first &n that is not substituted.
5. If you press a PF key that has not been set, the following message is displayed:

```
PFnn UNDEFINED
```

6. To use the DELAY function on a 3101, you must be in block mode.
7. On a 3101 device, if you press a PF key that has been defined using SUBSTITU, the &ns are always substituted with nulls.

## Messages

- HCP026E Operand missing or invalid

## SET PFnn COPY

### Authorization

Privilege Class: G

### Purpose

Use SET PFnn COPY to copy your display screen to a printer.

### Operands

#### PFnn

identifies the program function key to perform the COPY function for your 3270 or 3290 display.

#### rdev

#### ldev

The operand *rdev* represents the real device number of the display printer to be used; *ldev* is the logical device number of the logical display printer to be used.

#### luname

identifies a printer controlled by the same VTAM service machine that controls the display whose screen is being copied. It is the name from the VTAM definition of the printer as an SNA logical unit. If the *luname* is omitted, it is assumed that the associated control unit supports the local copy function.

#### netname.luname

identifies the network qualified logical unit to be used as the copy device.

### Usage Notes

1. If your keyboard has 24 PF keys, specify the PF key number, *nn*, as a value from 1 (or 01) to 24. If your keyboard has only 12 PF keys, specify *nn* as a value from 1 (or 01) to 12. When you press the PF key, the COPY function produces a printed output of the entire 3270 or 3290 display screen except for the status field, which is replaced by blanks.
2. After you press the PF key, you receive a NOT ACCEPTED message in the status field of your display if any of the following situations occur:
  - The printer is already busy
  - The printer is turned off
  - The printer is operational but has not been varied online or enabled by the system operator
  - The printer is out of paper or is in any other condition that requires intervention
  - The designated device is not a 3286/3287/3288/3289 printer
  - The SET PFnn COPY command format is not valid.

You may include your own identification on the printed output by entering the data into the user input area of the screen before you press the PF key. The identification appears on the last two lines of the printed copy.

## SET PFnn COPY

3. To ensure the definition of a PF key for the COPY function, you must start with the keyword COPY, followed by at least one blank, followed by the device identifier (*rdev*, *ldev* or *luname*).
4. The existence of more than one data field (*rdev*, *ldev*, or *luname*) following the keyword COPY identifies the string as PF key data rather than a hard copy request.
5. The following conditions cause the string to be interpreted as PF key data rather than as a hard-copy request:
  - No operand after COPY
  - No *rdev* or *ldev* defined in the range X'0'-X'FFFF'
  - The presence of an operand after *rdev*, *ldev*, or *luname*.
6. SET PFnn COPY is an immediate (nondisplaying) command; its function is processed immediately upon pressing the appropriate program function key. If you insert the keyword DELAY after the PFnn operand, it is ignored; the program function still processes immediately when the PF key is pressed.
7. On all logical display printers, a maximum of 1920 bytes are printed.
8. A copy from a larger display screen to a smaller print buffer produces unpredictable results.
9. The COPY function is not supported on a 3101 device. The 3101 can have an attached printer and the screen can be copied using the PRINT key.
10. If you press a PF key that has not been set, the following message is displayed:

```
PFnn UNDEFINED
```

### Messages

- HCP026E Operand missing or invalid

## SET PFnn RETRIEVE

### Authorization

Privilege Class: G

### Purpose

Use SET PFnn RETRIEVE to assign a RETRIEVE function to a PF key. Use the PF key to retrieve commands and search forward and backward through the RETRIEVE buffers.

### Operands

*nn*

is the number of the program function key for which you are setting the RETRIEVE function.

**Backward *i***

**Forward *i***

indicates the direction that CP skips through the RETRIEVE buffers. When this program function key is pressed, CP searches through the RETRIEVE buffers *i* positions (or 1 if *i* is not specified) and displays the command saved in that RETRIEVE buffer only.

**CLEAR**

causes CP to discard the contents of any existing RETRIEVE buffers. This option also causes CP to define this program function key as if you had entered the command SET PFnn RETRIEVE BACKWARD 1.

### Usage Notes

1. If your keyboard has 24 PF keys, specify the PF key number, *nn*, as a value from 1 (or 01) to 24. If your keyboard has 12 PF keys, specify *nn* as a value from 1 (or 01) to 12.
2. After you define a RETRIEVE program function key or run the SET RETRIEVE command, CP starts saving your input lines. If you enter SET PF11 RETRIEVE BACKWARD 5 and then SET PF12 RETRIEVE FORWARD 3, pressing PF11 will move a pointer to the RETRIEVE buffer five buffers back. If you then press PF12, CP moves the pointer up three buffers to the second one back. Once you press ENTER to enter what was in the RETRIEVE buffer you selected, CP resets the pointer back to the most recent buffer.
3. As a default, CP keeps track of seven input lines. See the SET RETRIEVE command for modifying the number of input lines that are saved and for the effects that SET PFnn can have on the SET RETRIEVE command. Any input line that is an exact duplicate of the previous input line is not saved. For security reasons, input lines that are not displayed on the display device, such as passwords, are not saved.
4. If the saved line is longer than the input area, the line is truncated to the input area length.
5. Do not use any operands before RETRIEVE. If you do so, CP interprets the RETRIEVE as PF data rather than the RETRIEVE function.
6. To use the RETRIEVE function on a 3101, you must be in block mode.

7. If you press a PF key that has not been set, the following message is displayed:

```
PFnn UNDEFINED
```

### Messages

- HCP026E Operand missing or invalid
- HCP6892E Invalid number of buffer positions - *nnn*

## SET PFnn TAB

### Authorization

Privilege Class: G

### Purpose

Use SET PFnn TAB to set values for the TAB function.

### Operands

#### PFnn

is the program function key to perform the TAB function for your virtual machine.

#### n

identifies the tab settings that you want to associate with the PF key.

### Usage Notes

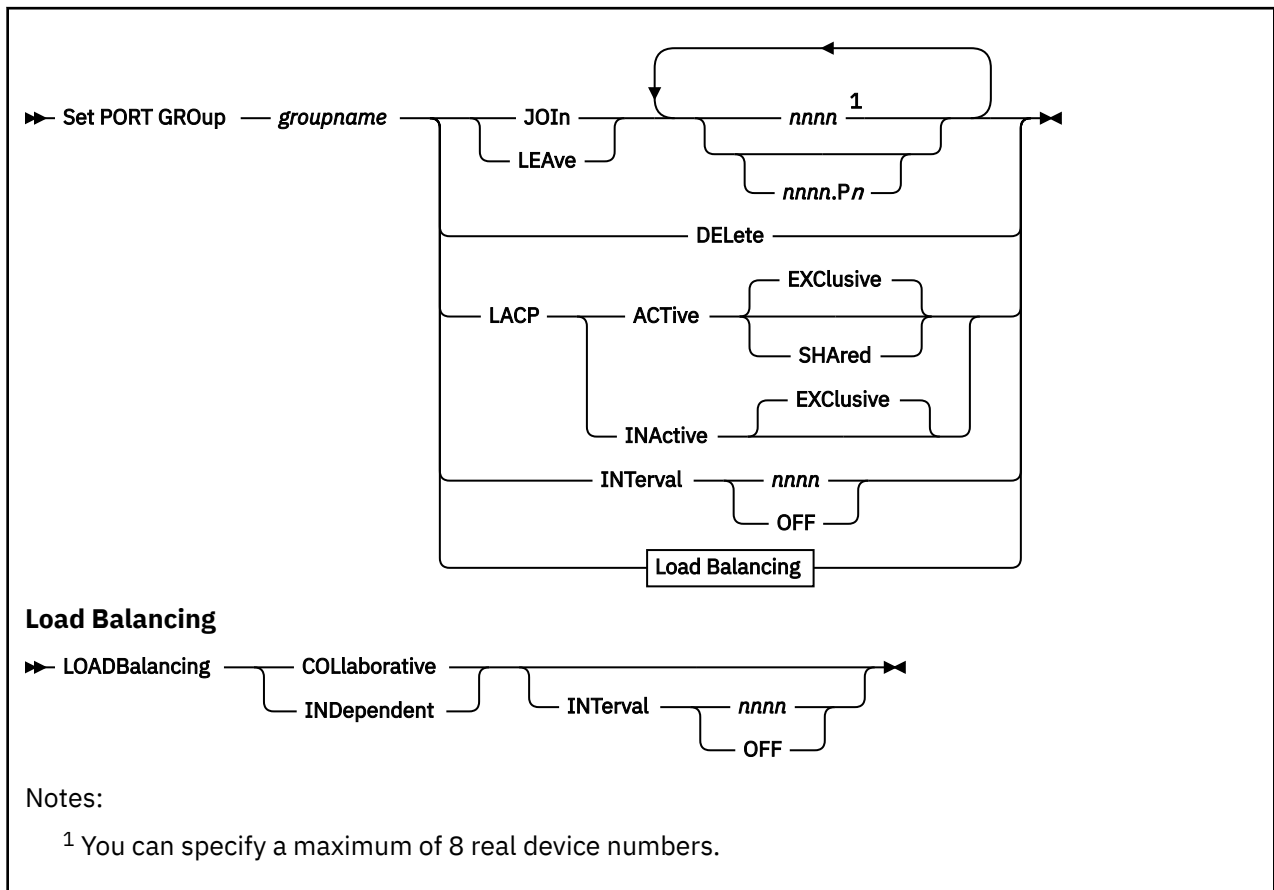

1. If your keyboard has 24 PF keys, specify the PF key number, *nn*, as a value from 1 (or 01) to 24. If your keyboard has only 12 PF keys, specify *nn* as a value from 1 (or 01) to 12.
2. SET PFnn TAB is not supported on a 3101 device. The 3101 has a tab function incorporated in its hardware.
3. SET PFnn TAB is an immediate (nondisplaying) command: its function is processed immediately upon pressing the appropriate program function key. If you insert the keyword DELAY after the PFnn operand, it is ignored; the program function is processed immediately.
4. To ensure the definition of a PF key for the TAB function, you must start with the keyword TAB, followed by at least one blank, followed by at least one tab setting that you want to associate with the PF key. The lack of a tab setting identifies the string TAB as PF key data.
5. If you press a PF key that has not been set, the following message is displayed:

```
PFnn UNDEFINED
```

## SET PORT GROUP

### Authorization

Privilege Class: B

### Purpose

Use the SET PORT command to define or change the OSA-Express devices that make up a link aggregation group and to set the attributes of a link aggregation group. For more information about [Virtual Networking Options](#) in VM, see *z/VM: Connectivity*.

If the SET PORT GROUP command is issued with the JOIN, LACP or INTERVAL operand, and the group does not exist, it will be created and will remain until the next time z/VM is IPLed or the group name is deleted with a SET PORT groupname DELETE command. For options not specified, the following defaults will be used: LACP ACTIVE EXCLUSIVE INTERVAL 300.

### Operands

#### *groupname*

is the name of the link aggregation group to be affected. The *groupname* is a single token (1-8 alphanumeric characters) that identifies a link aggregation group. This groupname is associated with a virtual switch via the DEFINE VSWITCH command or statement in the System Configuration file. The association can be changed with the SET VSWITCH command.

#### **JOIN**

indicates that the devices (*nnn* or *nnnn.Pn*) specified will join the specified group. If the group does not exist, it will be created and will remain until the next time z/VM is IPLed or the group name is deleted with a SET PORT *groupname* DELETE command.

**nnn****nnnn.Pn**

is a real device number or a real device number and OSA-Express port number of a QDIO OSA-Express device to be affected within the specified group. Specify each real device number as a hexadecimal number. If specifying a real device and an OSA-Express port number, specify the real device number as a hexadecimal number between X'0001' and X'FFFD' followed by a period (.), the letter 'P' (or 'p') followed by the port number as a hexadecimal number between X'0' and X'F'. For example, to specify port 1 for RDEV 300, specify "300.P1". The value of the port number depends on how many ports the OSA-Express hardware adapter supports. If the port number is not specified, it will default to port 0.

You can specify a maximum of 8 real device numbers. If you specify more than one device number, each must be separated from the others by at least one blank. Each real device number represents a trio of devices. For example, specifying JOIN 111 means that devices 111-113 are used to provide the connection to the real hardware LAN segment.

When the port group has been defined with the SHARED option, some devices on the adapters containing the specified devices are reserved for system use. See usage note [3](#) for information about device number assignment for shared port groups.

See Usage Note [“1” on page 1612](#). for more information about the requirements for the OSA-Express devices.

**LEAve**

indicates that the devices (*rdev*) specified will leave the specified group.

**DELeTe**

indicates that the *groupname* definition will be removed from the system. You can not delete a group that is being used for an active virtual switch. Use SET VSWITCH DISCONNECT to make the virtual switch inactive and then SET VSWITCH NOGROUP to drop the association with the group.

A SET PORT GROUP DELETE for a port group configured with the SHARED option has global scope. A copy of the shared port group exists in each member of the IVL domain and ALL port groups with that name are deleted. You can not delete a shared port group that is in use on any other system.

**LACP ACTIVE****LACP INACTIVE**

LACP ACTIVE mode indicates that the virtual switch will initiate negotiations with the physical switch via the Link Aggregation Control Protocol (LACP) and will respond to LACP packets sent by the physical switch. LACP INACTIVE indicates that aggregation is to be performed, but without LACP. It is only useful when the physical switch is also operating without LACP. In this mode, there is no negotiation between the physical switch and the virtual switch.

Ensure the same LACP setting exists on both the virtual switch and the physical switch.

LACP ACTIVE is the default for a *groupname* until changed by a SET PORT GROUP LACP command.

You cannot change the LACP mode when the port group is associated with an active virtual switch. Use SET VSWITCH DISCONNECT to inactivate the virtual switch and then SET PORT GROUP to change the LACP mode followed by SET VSWITCH CONNECT.

SHARED may not be specified with LACP INACTIVE.

**EXClusive**

An exclusive port group is a set of OSA-E features configured so that each OSA-E feature supports only a single VSWITCH QDIO connection. In other words, no sharing of the OSA-Express adapter is permitted.

Once the port group is defined with the EXCLUSIVE option, it cannot be changed to a SHARED port group without deleting the port group.

**SHARed**

When LACP ACTIVE SHARED is specified, it defines a shared port group. A shared port group is a set of OSA-E features configured so that one or more global virtual switches and global virtual switch members share the OSA-Express adapter(s) that make up the port group. This defines a Multi-VSwitch LAG (Link Aggregation Group) configuration.

## SET PORT GROUP

A port group defined with the SHARED option can be used only with virtual switches defined with the GLOBAL option. The virtual switches can be in the same or different LPARs residing in the same CEC.

The port group has a global scope which means it provides connectivity across multiple virtual switches and multiple systems running z/VM. It is propagated to all other systems in the same IVL domain. In other words, the Control Program creates a copy of the shared port group with the same name on all other systems running z/VM that are in the domain (unless the shared port group member has already been defined with that name). A change to the shared port group on one system affects all copies of the shared port group on all other systems in the IVL domain.

A port group defined with the SHARED option provides a single point of control for all virtual switches using the shared port group. For example, a SET PORT GROUP groupname LEAVE command for a shared port group causes the specified port to be removed from **all** virtual switches on **all** IVL members using a copy of the port group with that name.

Because of the global scope, once the port group is defined with the SHARED option, it cannot be changed to an EXCLUSIVE port group without deleting the port group. In addition, the LACP mode may not be changed to INACTIVE.

See [Multi-VSwitch LAG Configuration](#) in *z/VM: Connectivity* for more information.

### **INTERVAL nnnn**

#### **INTERVAL OFF**

indicates the interval to be used by the Control Program (CP) when doing load balancing of conversations across multiple links in the group. It is specified as the number of seconds between load balancing operations across the link aggregation group. It must be a decimal number between 1 and 9990 or the keyword OFF. The interval value is rounded up to the next multiple of thirty seconds. INTERVAL OFF indicates that no load balancing is done by CP.

INTERVAL 300 is the default for a groupname until changed by a SET PORT GROUP INTERVAL command.

When the port group is configured to use the Independent Load Balance management method, the scope of the SET PORT GROUP INTERVAL setting is local to the system it is issued on.

When the port group is configured to use the Collaborative Load Balance management method, the scope of the SET PORT GROUP INTERVAL setting is global (affects all systems within the IVL).

### **LOADBALANCING INDEPENDENT**

Each VSwitch that uses a Link Aggregated Group (LAG) to provide connectivity to an external network is responsible for balancing its own bandwidth across all the OSA-Express adapters within the group. By default, exclusive port groups will use the Independent Load Balance management method.

When the port group is shared, the scope of the SET PORT GROUP LOADBALANCING setting is global (affects all systems within the IVL).

### **LOADBALANCING COLLABORATIVE**

The Collaborative Load Balance management method will consider and serialize its operation with all the sharing VSwitches. By default, a shared port group will use Collaborative Load Balance Management Method.

The Collaborative Load Balance management method can only be used when all active systems connected to the same IVL Domain have support for Collaborative Load Balance. If any z/VM System is added or already exists in the domain which doesn't have support for Collaborative Load Balance, then all Shared Port Groups within the domain will be automatically forced to use the Independent Load Balance management method.

Collaborative Load Balance is only allowed for shared port groups, and the scope of the SET PORT GROUP LOADBALANCING COLLABORATIVE setting is global (affects all systems with the IVL).

## **Usage Notes**

1. The following restrictions pertain to the OSA devices in the specified group:
  - The OSA port must support IEEE802.3ad Link Aggregation.

- To aggregate multiple OSA ports within a group, all ports in the group must connect to the same physical LAG group, run in full-duplex mode and operate at the same speed.
2. The following pertain to the OSA devices in an exclusive port group, that is, one that is configured with the EXCLUSIVE option:
    - When an OSA port is active in a link aggregated group, it can't have more than a single QDIO connection established on the adapter (CHPID). Any requests to establish a QDIO connection using another device number on the same CHPID in any logical partition will fail until the OSA port is no longer active within the group. Likewise, an OSA port with an active QDIO connection on any device number on the same CHPID will not be able to join a link aggregated group until there are no active QDIO connections on the port.
    - When the port group is configured as LACP Inactive, all ports in the group must support the network disablement function. Cards that do not support the network disablement function may be used only in a port group configured with LACP Active.
  3. The following pertain to the OSA devices in a shared port group, that is, one that is configured with the SHARED option:
    - Another shared port group with the same name defined anywhere in the IVL Domain must have a matching configuration. In fact, the Control Program propagates the shared port group to all other members of the domain if a copy of the port group does not already exist.
    - When a System Administrator specifies a device number on the SET PORT GROUP JOIN command three devices (subchannels) associated with the OSA Express adapter are reserved for system use. The Control Program chooses three devices from within the range of those associated with the OSA Express adapter, starting with the first (most significant) available device number.  
Devices reserved for system use are shown with "SYSTEM" status in the Query OSA display.
    - When a specific OSA Express adapter is configured in a shared port group, a set of three device numbers is reserved in each z/VM system that has an active IVL connection.
    - A shared port group may be shared by multiple global virtual switches that reside in the same system. Each shared port group is assigned an instance (0,1,2,3) when configured to a global virtual switch.
    - The administrator can use either port associated with a multiple-port OSA Express adapter. Once a port is activated in a shared port group, it is no longer available for guest usage -- the ATTACH command cannot be used to specify devices that are reserved for system use. Likewise, a network connection established by a guest on a specific port prevents its use in a shared port group.
    - When a shared port group is in use on a global virtual switch, an RDEV list may not be used for the virtual switch to provide back up connectivity. Instead, back up connectivity is provided by a different global virtual switch member using the shared port group.
    - A shared port group may be used by up to 64 global virtual switch members across the IVL domain. The members may be in the same or different global virtual switches.
  4. The maximum number of groups that can be defined to CP is 128.
  5. It is invalid to create a groupname of ALL.
  6. The number of devices identified by the RDEV keyword on the DEFINE or SET VSWITCH command combined with the number of devices in an associated GROUP may not exceed eight devices.
  7. When the virtual switch has been defined with the GROUP attribute, any devices identified by the RDEV keyword (on DEFINE or SET VSWITCH) are used for failover in the event of a real switch failure of the link aggregation group. Failover in this environment will be to a single OSA-Express device connected to a second real switch. The virtual switch will recognize when the port group is available again and will initiate recovery to the port group member(s). When the virtual switch has been defined with GROUP and RDEV NONE, it means that there is no link aggregation group failover in the event the real switch should fail.
  8. The port number specified by *nnnn .Pnn* will be used by the TCP/IP stack (controller) when initializing the device. If the port number is not specified, it will default to port 0. If the port number is not supported, initialization of the device will be terminated.

### Examples

To define a group named LINGROUP that contains multiple devices, specify the following:

```
set port group lingroup join B00 C00 D00
```

### Responses

Response 1:

```
Port group groupname is {created|updated|deleted}
```

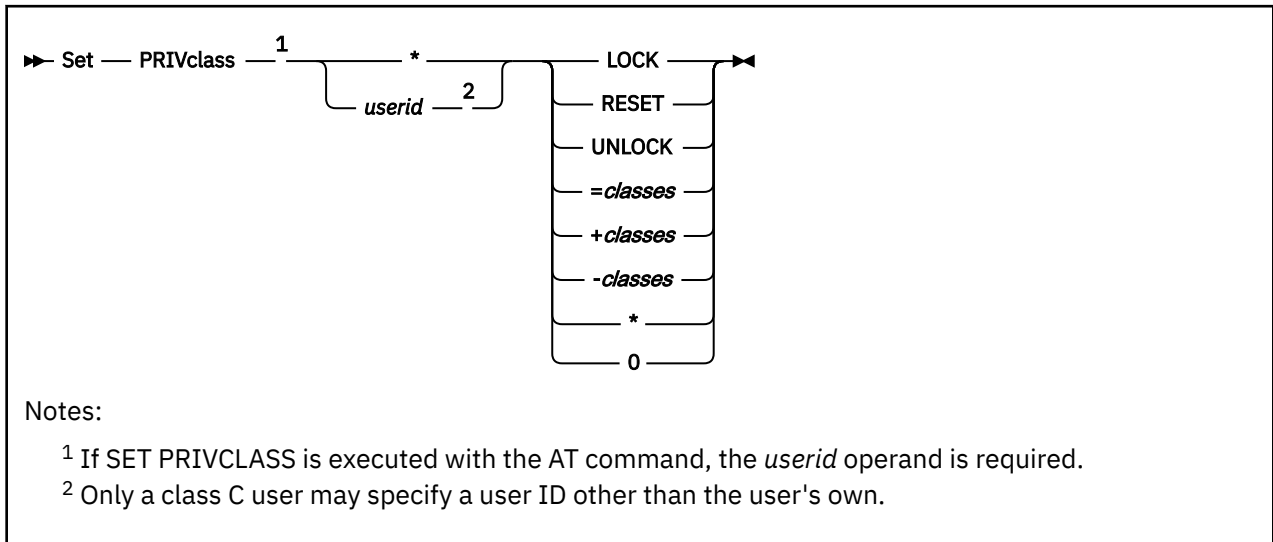

is the normal response from this command.

### Messages

- HCP6706E Invalid device address - *rdev*
- HCP6706E Invalid device address or port number - {*vdev* | *portnumber*}
- HCP6706E Invalid groupname - *groupname*

## SET PRIVCLASS

### Authorization

Privilege Class: Any, C

### Purpose

Use SET PRIVCLASS to control future SET PRIVCLASS commands or to temporarily change the set of privilege classes for a logged-on user. If you are a class C user, you can set the privilege classes for any virtual machine. If you are not a class C user, you can set the privilege classes only for your own virtual machine.

When you log on, your user ID's privilege classes are set to the privilege classes granted to you in your user directory entry. If a class C user sets the privilege classes of another user ID or selects classes beyond those defined in the user directory, CP generates an accounting record.

To use the SET PRIVCLASS command, the FEATURES ENABLE SET\_PRIVCLASS statement must be specified in the system configuration file. For more information on the [FEATURES Statement](#), see *z/VM: CP Planning and Administration*.

### Operands

**\***

#### *userid*

identifies the user whose privilege classes are to be set. An asterisk (\*) specifies that the command applies to the command issuer's user ID.

#### **LOCK**

prevents any SET PRIVCLASS commands from being issued against the target until an UNLOCK is issued, if either the issuer has class C privileges or the target user ID is the issuer's.

#### **RESET**

returns the target user ID's privilege classes to those currently specified in the CP directory if the PRIVCLASS is not locked against SET PRIVCLASS processing and either the issuer has class C privileges or the target user ID is the issuer's.

#### **UNLOCK**

allows SET PRIVCLASS commands to be issued against the target if either the:

- Issuer is not the same as the target and has class C privileges

- Target user ID is the issuer's. If the target user ID is the issuer's ID, the issuer must confirm the issuer's intentions by responding with '1' for this command to complete successfully.

A SET PRIVCLASS \* UNLOCK command issued by a disconnected virtual machine is rejected because there is no terminal to enter a response.

#### **=classes**

sets the specified privilege class or classes for the target user ID, if the user ID is not locked against SET PRIVCLASS processing and either the issuer has class C privileges or the target user ID is the issuer's and the issuer is authorized in the directory for the requested classes.

#### **+classes**

adds the specified privilege class or classes for the target user ID, if the user ID is not locked against SET PRIVCLASS processing and either the issuer has class C privileges or the target user ID is the issuer's, and the issuer is authorized in the directory for the requested classes.

#### **-classes**

removes the specified privilege class or classes from the target user ID, if the user ID is not locked against SET PRIVCLASS processing and either the issuer has class C privileges or the target user ID is the issuer's.

#### **\***

indicates all classes, A-6.

#### **0**

indicates no classes.

## Usage Notes

1. Use the SET PRIVCLASS command to change your privilege classes to a subset of those defined in your directory entry. Users with class C privilege can exceed the privilege classes in the system directory. For example, users with class C privilege may enter a SET PRIVCLASS command to change another user ID's privilege classes.

## Responses

Response 1:

If you specify the LOCK option and the command completes successfully, you see something like this:

```
DAVID's privilege classes have been locked.
```

Response 2:

If you specify the UNLOCK option and the command completes successfully, you see something like this:

```
DAVID's privilege classes have been unlocked.
```

Response 3:

When you specify other options, CP displays the new privilege classes of the target user ID in its response. For example, user ID DAVID had privilege classes ABCEG, and you entered:

```
set priv david -ab
Privilege class(es) for user DAVID
  Currently: CEG
  Directory: ABCDEFG
The privilege classes are not locked against changes.
```

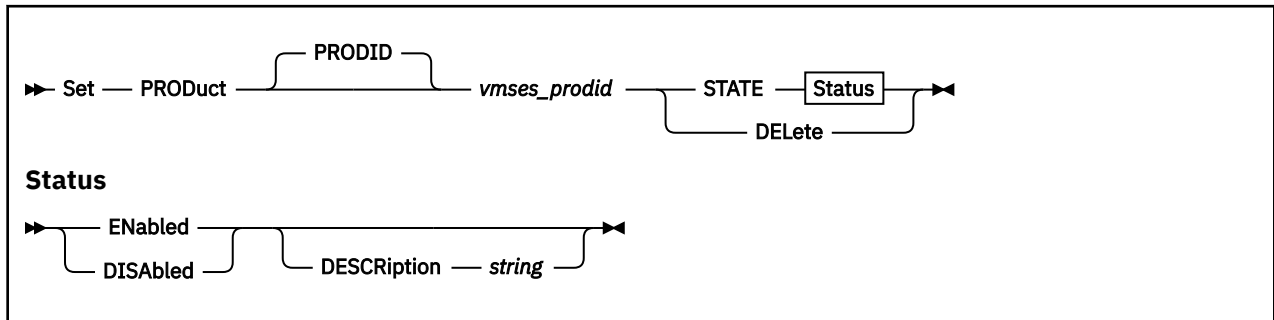

## Messages

- HCP003E Invalid option - *option*

## SET PRIVCLASS

- HCP007E Invalid userid - *userid*
- HCP020E Userid missing or invalid
- HCP028E Class missing or invalid
- HCP045E *userid* not logged on
- HCP052E Error in CP directory
- HCP053E *userid* not in CP directory
- HCP1013E An invalid operand was supplied for CLASS - *classes*
- HCP1022A Enter 1 if you wish to have your privilege classes unlocked.
- HCP1023E An error was detected while processing the user's response. Please retry the command.
- HCP6750E *userid*'s privilege classes {are|are not} locked.
- HCP6754E Command combination may not be issued by a disconnected user

## SET PRODUCT

### Authorization

Privilege Class: C, E

### Purpose

Use SET PRODUCT to define a product or feature to the z/VM system and state whether the product can run on the system.

- Allows the user to dynamically add PRODUCT statements to the running system.
- Allows the user to change the state or description of an existing PRODUCT statement.
- Enables a user to DELETE and existing PRODUCT statement.

### Operands

#### PRODIG *vmstes\_prodid*

is the identifier used by VMSES/E to install and service the given product. *vmstes\_prodid* must be 7 or 8 characters.

#### STATE ENabled

identifies this product or feature as being licensed to execute on this system.

When a product is defined with STATE ENABLED, it indicates that the product is authorized by the installation to run on this system. It does not mean that the product is installed or is being used.

#### STATE DISAbled

identifies this product or feature as not being licensed to execute on this system. The product may or may not be physically installed on the system.

#### DESCRiption *string*

is a string of data that identifies additional information regarding the product.

*string* is a 1-255 character string (including any imbedded blanks and special characters associated with the *vmstes\_prodid* entered).

#### DELeTe

removes from the system any definition information for the product ID, *vmstes\_prodid*. Description information stored with the PRODUCT statement and the current STATE information is lost.

### Usage Notes

1. Each product is identified by a unique *vmstes\_prodid*. When you issue a SET PRODUCT command, it overwrites any previous definition, including the description.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*

- HCP1003E Product *prodid* was not found.
- HCP1639E The product definition for *prodid* may not be added, altered or deleted.
- HCP2768E Missing {product|product state}
- HCP6704E Missing token at end of line
- HCP6706E Invalid {string *string*|product *string*|product state *string*}

## SET PROMPT

### Authorization

Privilege Class: B

### Purpose

Use SET PROMPT to define whether CP will prompt the operator for startup information following a CP restart after an abend or a shutdown REIPL.

### Operands

#### AFTER\_SHUTDOWN\_REIPL ON/OFF

specifies whether CP will prompt the operator for startup information on a shutdown REIPL or not.

#### AFTER\_REStart ON/OFF

specifies whether CP will prompt the operator for startup information on a CP restart after an abend or not.

### Usage Notes

1. Use the QUERY PROMPT command to display the current settings of the prompt operands.
2. Use the FEATURES ENABLE/DISABLE PROMPT configuration file statement to initialize the prompt operands at IPL time.
3. If the SET PROMPT command was not used or the FEATURES ENABLE PROMPT statement was not specified in the configuration file, the operator will not be prompted for start up information after a system restart or a shutdown REIPL.

### Responses

Response 1:

To tell CP to prompt the operator on shutdown REIPL, enter the following:

```
set prompt after_shutdown_reipl on
```

CP responds:

```
Command accepted
Ready;
```

### Messages

- HCP002E Invalid operand - *operand*

- HCP6704E Missing token at end of line
- HCP6706E Invalid string - *string*

## SET PSWTRANS

### Authorization

Privilege Class: G

### Purpose

SET PSWTRANS allows you to issue DISPLAY, DUMP, and STORE CP Commands with the PSW option (instead of the PSWG option) and get results as if you had used the PSWG option. This is valid only on z/Architecture machines.

With PSWTRANS enabled, z/Architecture mode expands 64-bit PSW display and store data into 128-bit PSWs.

### Operands

#### OFF

indicates that the PSW option is not allowed for the DISPLAY, DUMP or STORE commands when the virtual machine is in z/Architecture mode.

#### ALL

indicates that the PSW option will be accepted for the DISPLAY, DUMP and STORE commands to reference or change PSW data in the 64-bit ESA/390 format when the virtual machine is in z/Architecture mode (64-bit PSW displayed and 64-bits accepted on STORE).

#### DISPLAY

indicates that the PSW option will be accepted for the DISPLAY and DUMP commands (but not STORE) to reference PSW data in the 64-bit ESA/390 format when the virtual machine is in z/Architecture mode.

#### STORE

indicates that the PSW option will be accepted for the STORE command (but not DISPLAY or DUMP) to expand PSW data in the 64-bit ESA/390 format when the virtual machine is in z/Architecture mode.

### Usage Notes

1. The PSWTRANS option is set to OFF when a user logs on and is not changed unless the user issues a SET PSWTRANS command.
2. To obtain the setting of the PSWTRANS option, use the QUERY PSWTRANS command.

### Messages

- HCP003E Invalid option - *option*
- HCP026E Operand missing or invalid

## SET QIOASSIST

### Authorization

Privilege Class: B, G

### Purpose

Use SET QIOASSIST to control the queue-I/O assist (QDIO performance assist for V=V guests) for a virtual machine. This interpretive-execution assist applies to devices that use the Queued Direct I/O (QDIO) architecture, HiperSockets devices, and FCP devices.

On processors that support the queue-I/O assist, there is a performance benefit for I/O performed with the queued-I/O protocols. With the aid of the assist, I/O interruptions can be passed directly from the hardware to the virtual machine. In addition, certain QDIO-related instructions can be interpretively executed by the processor, without z/VM's involvement.

To use queue-I/O assist, the following are required:

- The processor must support the queue-I/O assist. See *z/VM: General Information*.
- z/VM must be running in a logical partition and not as a guest.
- The assist must be globally enabled with the CP SET QIOASSIST ON ALL command.
- The virtual machine must be enabled with the CP SET QIOASSIST ON command.
- The device must not be attached to the virtual machine with the NOQIOASSIST option of the CP ATTACH command or the system DEDICATE directory statement.
- The virtual machine must not be using the CP TRACE command.

### Operands

#### ON

#### OFF

turns the queue-I/O assist on or off for a virtual machine.

#### ALL

enables or disables eligibility for all virtual machines to use the queue-I/O assist, independent of the individual settings for each user. The individual settings are not changed. When ALL is specified by a class B user, access to the queue-I/O assist is allowed or disallowed for all virtual machines, including any new users that might log on. When this global setting is OFF, it overrides any individual user's setting to allow the assist.

#### USER *userid*

specifies an individual user of the queue-I/O assist.

## SET QIOASSIST

\*

specifies the queue-I/O assist setting is for the command issuer's virtual machine.

### Usage Notes

- If QIOASSIST is set ON for all users, an individual user can set QIOASSIST OFF without changing the setting for other users.

**Note:** The reverse is not true; setting OFF for ALL overrides individual user settings.

- Setting QIOASSIST ON or OFF for ALL users may not immediately enable or disable the assist for all users. The command will take effect as soon as possible. Use the QUERY QIOASSIST to determine when the user's virtual machine is in the desired state.
- If z/VM is not running on a configuration that supports the queue-I/O assist, the SET QIOASSIST command is not supported and an error message is issued.

### Examples

The following command will disable userid test1 from using the queue-I/O assist.

```
set qioassist off test1
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on
- HCP263E Too many operands were supplied for this command
- HCP1014E A required option is missing
- HCP2162I QIOAssist is not available

## SET QUICKDSP

### Authorization

Privilege Class: A

### Purpose

Use SET QUICKDSP to assign a user with immediate access to system resources.

**Note:** CP's virtual processor management has been improved so that no user stays in the eligible list more than an instant before being added to the dispatch list. Therefore the QUICKDSP option is now less meaningful, although it does get the virtual machine a different size elapsed time slice.

### Operands

#### *userid*

is the user ID of the virtual machine to receive the QUICKDSP designation.

#### **ON**

specifies that the user is to be added to the dispatch list immediately whenever the user has work to do, without waiting in the eligible list. Users not having this option may wait in the eligible list and be delayed for milliseconds or even seconds before running if there is a heavy load on the system. ON is the default.

#### **OFF**

specifies that the QUICKDSP option is to be taken away from this user. The user can subsequently encounter delays in the eligible list just as other users do.

### Usage Notes

1. The QUICKDSP designation is intended for selective use on virtual machines with critical response time requirements. The scheduler always moves a QUICKDSP user immediately into the dispatch list whenever it is ready to run, regardless of resource requirements and current system load. Indiscriminate use, therefore, increases response time overall and may severely affect maintenance of system storage.  
  
QUICKDSP is normally provided for use by selected service virtual machines interacting with several other users, thus having stringent response time requirements. RSCS and IUCV applications are common examples.
2. In some cases, the SET RESERVED command should be used with QUICKDSP, especially in storage-constrained environments. A user with the QUICKDSP attribute and reserved pages experiences little system overhead, further improving response time.
3. The QUICKDSP designation is given to users who are being forced or logged off from the system to expedite the logoff of those users.

### Responses

Response 1:

## SET QUICKDSP

```
USER userid: QUICKDSP={ON }  
                {OFF }
```

is returned to the command issuer.

### Messages

- HCP002E Invalid operand - *operand*
- HCP007E Invalid userid - *userid*

- HCP045E *userid* not logged on

# SET RDEVICE

---

## Authorization

Privilege Class: B

## Purpose

Use SET RDEVICE to add, change, or clear the system's definition of a set of real devices.

The following sections describe the syntax of SET RDEVICE commands for clearing real devices and for adding and changing these real devices:

- Advanced function printers
- Card punches
- Card readers
- Communication controllers
- DASDs
- Graphic display devices
- Impact printers
- Integrated communication adapters
- Special devices
- Tape units
- Unsupported devices
- 3270 displays
- 3800 printers.

## Usage Notes

1. Once you have defined a device at a certain address, you can replace that device with another device of a different class. The following are considered to be discrete device classes:
  - DASDs
  - Graphic display devices
  - Special devices (3088s, CTCAs, 37x5)
  - Special switching devices
  - Tape drives
  - Terminals
  - Unit record devices.
2. If you change the type of device for a given device address, the features previously defined for that device are returned to their defaults. When you change any feature other than device type for the device at a certain address, however, the other features remain the same. For example, assume you have an IBM 3800 Model 1 printer defined at address 0500 and CHARS GF10 and AFP YES specified and you want to replace it with an impact printer. When you use the SET RDEVICE TYPE IMPACT\_PRINTER command to tell CP the new printer is in place, CP resets all the other features to their defaults. If you leave the 3800 printer in place, however, and use SET RDEVICE to specify a flash overlay (SET RDEVICE ... FLASH *flashlib*), CP leaves all the other features unchanged.
3. You must use the VARY command to take a device offline before you can redefine it.

## SET RDEVICE

4. By default, CP issues a sense ID request to gather information about the device that you are defining or changing. If you prefer to explicitly define or change the device, you can stop CP from issuing the sense ID request by specifying the NOTSENSED operand. The only exception is the SET RDEVICE Unsupported Devices command. Because the device is unsupported, you must explicitly define that device. For information about the [DEVICES Statement](#), see *z/VM: CP Planning and Administration*.
5. The SET RDEVICE command cannot be used to change the device definition of any device that has a static device definition on an RDEVICE macro in the HCPRIO ASSEMBLE file.

### Responses

After CP has issued one of the following messages for each device address, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

### Messages

CP issues one of the following messages for each device address affected by a SET RDEVICE command. These two messages indicate that the SET RDEVICE command succeeded:

Messages:

- HCP6722I Characteristics of device *rdev* were set as requested.
- HCP6722I Created RDEV for device *rdev*.

The following messages indicate that the SET RDEVICE command failed:

- HCP1550E Device *rdev* device class does not match requested device class.
- HCP1550E Device *rdev* is not offline.
- HCP6580E Device *rdev* is active
- HCP6760E Device *rdev* is boxed.
- HCP6760E Device *rdev* is not offline.
- HCP6765E Device *rdev* cannot be changed because of an old HCPRIO definition.
- HCP6862E Device *rdev* cannot be changed or deleted because it is a base Parallel Access Volume for which an alias exists.
- HCP6870E Device *rdev* is attached to a guest
- HCP6895E RDEV *rdev* cannot be changed or deleted because it is static device definition from HCPRIO

## SET RDEVICE Advanced Function Printers

### Authorization

Privilege Class: B

### Purpose

Use this SET RDEVICE command to define advanced function printers at certain device addresses.

CP supports the following IBM advanced function printers using Advanced Function Printing licensed programs: 3825, 3828, and 3900

**Note:** Printers defined as advanced function printers that follow the CCU specifications can be used only as dedicated devices.

### Operands

#### *rdev*

#### *rdev1-rdev2*

specifies one or more real device numbers to be defined or changed. Each *rdev* specified must be a hexadecimal number between X'0000' and X'FFFF'. The maximum number of devices allowed within a range is 256.

#### **EQid** *eqid*

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters. Note that for this device class, the specified EQID must be unique across all devices on the system.

#### **NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

#### **TYpe** **AFP**

specifies an advanced function printer (AFP) that follows the CCU specification. Printers defined as TYPE AFP can only be used as dedicated devices.

#### **SENSEd**

tells CP to use the information returned from a sense ID request to determine the characteristics of this printer. If omitted, the default is SENSED.

#### **NOTSENSEd**

tells CP not to use the information returned from a sense ID request to determine the characteristics of this printer.

### Usage Notes

1. Printers defined as advanced function printers that follow the CCU specifications can be used only as dedicated devices.

## SET RDEVICE Advanced Function Printers

2. When setting an EQID for a device of this class, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCP048E and the RDEV will not be created.
3. The system cannot generate EQIDs for devices that do not support RCD CCW.

### Examples

Example 1:

To specify an advanced function printer at device number X'0110', enter the following SET RDEVICE command:

```
set rdevice 0110 type afp
```

Example 2:

To specify three advanced function printers at device numbers X'0111', X'0112', and X'0113', enter this SET RDEVICE command:

```
set rdevice 0111-0113 type afp
```

Example 3:

To specify an advanced function printer at device number X'0110' with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 0110 eqid ABCDEFGH type afp
```

Example 4:

To specify an advanced function printer at device number X'0110' and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 0110 noeqid type afp
```

### Responses

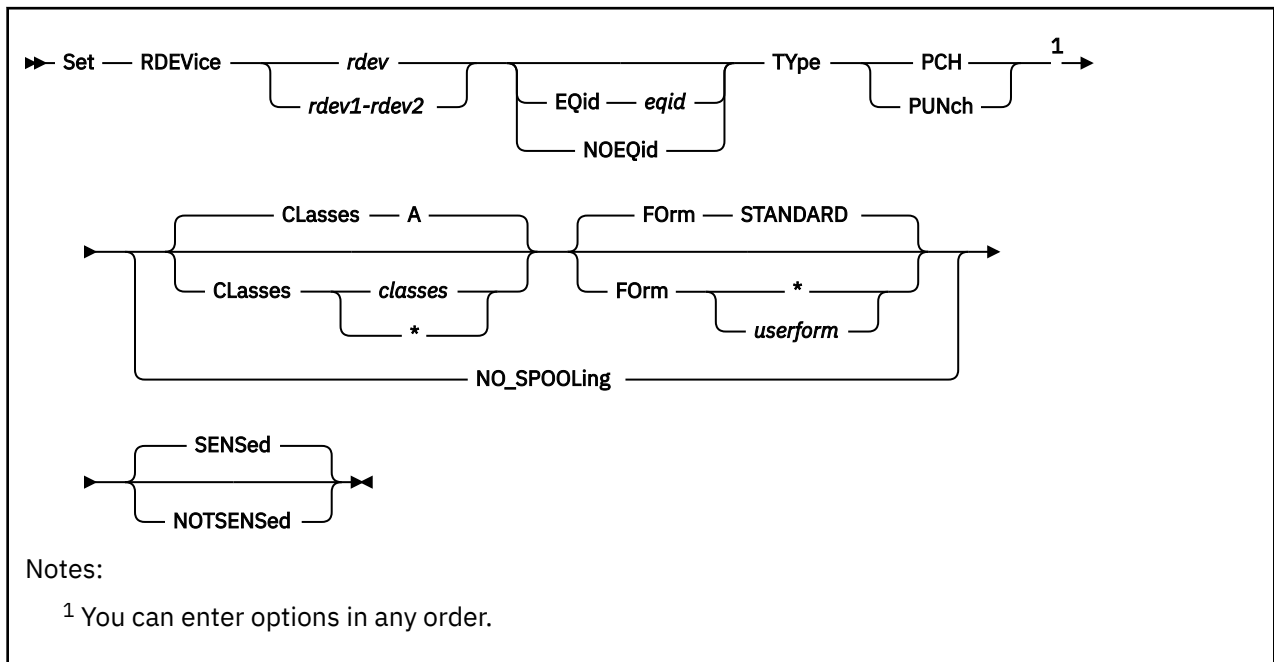

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP048E EQID must be unique for the specified device class.
- HCP048E Specified EQID already assigned to a different device.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*

## SET RDEVICE Card Punches

### Authorization

Privilege Class: B

### Purpose

Use this SET RDEVICE command to tell CP that card punches are at certain device addresses. CP supports the following card punches: 3525 and 3540

**Note:** The 3525 is supported only for punching; the printing features are not supported.

### Operands

#### *rdev*

#### *rdev1-rdev2*

specifies one or more real device numbers to be defined or changed. Each *rdev* specified must be a hexadecimal number between X'0000' and X'FFFF'. The maximum number of devices allowed within a range is 256.

#### **EQid** *eqid*

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters. Note that for this device class, the specified EQID must be unique across all devices on the system.

#### **NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

#### **TYpe** **PUNch**

specifies the type of device. The 3525 is supported only for punching; the printing features are not supported.

#### **Classes** *classes*

specifies the output spooling classes. (To change these spooling classes without having to re-IPL, use the CP START command.)

## SET RDEVICE Card Punches

You can specify CLASSES in one of the following ways:

- Do not specify the CLASSES operand for unit record devices. Class A is the default.
- Enter CLASSES *c*[*c...*] to list up to 8 output spooling classes. The spooling class, *c*, is 1 alphanumeric character. You can specify multiple classes as CLASSES ABC and a single class as CLASSES A.
- Enter CLASSES \* to have the punch process files regardless of class.

### Form *userform*

is the current spooling form number that the punch can process. This form implicitly determines the default operator form for the real punch when the operator starts the device after a cold start without specifying a form. You can specify this operand in one of the following ways:

- Enter FORM *userform*, where *userform* is a 1- to 8-character user form number for the files the punch can process.
- Enter FORM \* to specify the punch can process files regardless of form number.
- Do not specify FORM. FORM STANDARD is the default.

### NO\_SPOOLing

tells CP not to use the unit record device for spooling.

### SENSEd

tells CP to use the information returned from a sense ID request to determine the characteristics of this card punch. If omitted, the default is SENSED.

### NOTSENSEd

tells CP not to use the information returned from a sense ID request to determine the characteristics of this card punch.

## Usage Notes

1. When setting an EQID for a device of this class, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCPO48E and the RDEV will not be created.
2. The system cannot generate EQIDs for devices that do not support RCD CCW.

## Examples

Example 1:

To specify a card punch at device number X'0110', enter the following SET RDEVICE command:

```
set rdevice 0110 type punch
```

Example 2:

To specify three card punches at device numbers X'0111', X'0112', and X'0113', and indicate they can process files regardless of form number, enter this SET RDEVICE command:

```
set rdevice 0111-0113 type punch form *
```

Example 3:

To specify a card punch at device number X'0110' with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 0110 eqid ABCDEFGH type punch
```

Example 4:

To specify a card punch at device number X'0110' and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 0110 noeqid type punch
```

## Responses

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *option*
- HCP013E Conflicting option - *option*
- HCP048E EQID must be unique for the specified device class.
- HCP048E Specified EQID already assigned to a different device.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*

## SET RDEVICE Card Readers

### Authorization

Privilege Class: B

### Purpose

Use this SET RDEVICE command to tell CP that real card readers are at certain device addresses.

### Operands

**rdev**

**rdev1-rdev2**

specifies one or more real device numbers to be defined or changed. Each *rdev* specified must be a hexadecimal number between X'0000' and X'FFFF'. The maximum number of devices allowed within a range is 256.

**EQid *eqid***

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters. Note that for this device class, the specified EQID must be unique across all devices on the system.

**NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

**TYpe RDR**

**TYpe READer**

specifies the type of device (card reader).

**Class *c***

specifies the spooling class that the card reader assigns to spool files it creates. (To change the spooling class the card reader assigns without having to re-IPL, use the CP START command.)

You can specify CLASS in one of the following ways:

- If you omit the CLASS operand for unit record devices, class A is the default.
- Enter CLASS *c*

The spooling class, *c*, is one alphanumeric character.

**NO\_SPOOLing**

tells CP not to use the unit record device for spooling.

**SENSEd**

tells CP to use the information returned from a sense ID request to determine the characteristics of this card reader. If omitted, the default is SENSED.

**NOTSENSEd**

tells CP not to use the information returned from a sense ID request to determine the characteristics of this card reader.

**Usage Notes**

1. When setting an EQID for a device of this class, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCP048E and the RDEV will not be created.
2. The system cannot generate EQIDs for devices that do not support RCD CCW.

**Examples**

Example 1:

To specify a card reader at device number X'0110', enter the following SET RDEVICE command:

```
set rdevice 0110 type reader
```

Example 2:

To specify three card readers at device numbers X'0111', X'0112', and X'0113' and tell CP not to use them for spooling, enter this SET RDEVICE command:

```
set rdevice 0111-0113 type reader no_spooling
```

Example 3:

To specify a card reader at device number X'0110' with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 0110 eqid ABCDEFGH type reader
```

Example 4:

To specify a card reader at device number X'0110' and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 0110 noeqid type reader
```

**Responses**

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP048E EQID must be unique for the specified device class.
- HCP048E Specified EQID already assigned to a different device.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*

## SET RDEVICE CLEAR

### Authorization

Privilege Class: B

### Purpose

Use SET RDEVICE CLEAR to clear the information in the real device control block (RDEV) for a specific device or range of devices. After you issue this command, CP clears out all of the information in the RDEV except for the:

- Count of granted lock requests
- Count of deferred lock requests
- Device number
- Enqueued task
- Free storage RDEV indicator
- Missing Interrupt Handler control block
- Monitor flags
- RDEV lock
- Size of RDEV
- Subchannel disabled indicator
- Subchannel identifier
- Subchannel measurement block address
- Subchannel measurement block index
- Task requesting lock
- Valid device indicator

### Operands

*rdev*

*rdev1-rdev2*

specifies the real device number or a range of real device numbers that you want cleared. The variable *rdev* must be a hexadecimal number between X'0000' and X'FFFF'.

### Usage Notes

1. Only devices whose characteristics can be determined dynamically (sensed), can be directly varied online after a clear has been performed.
2. For those devices whose characteristics cannot be determined dynamically, another SET RDEVICE must be performed to define the device before it can be varied online.
3. Although the EQID and NOEQID operands are allowed, they are ignored when you specify the SET RDEVICE CLEAR command.

**Note:** To determine if the given device(s) can be dynamically sensed, see [The System Configuration File in z/VM: CP Planning and Administration](#).

## Examples

Example 1:

To clear the information in the RDEV for device 600 enter the following SET RDEVICE CLEAR command:

```
set rdevice 600 clear
```

Example 2:

To clear the information in a range of RDEVs starting at device 700 and continuing until device 710 enter the following SET RDEVICE command:

```
set rdevice 700-710 clear
```

## Responses

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*

## SET RDEVICE Communication Controllers

### Authorization

Privilege Class: B

### Purpose

Use this SET RDEVICE command to tell CP that line adapters or communication controllers are at specific device addresses.

### Operands

**rdev**

**rdev1-rdev2**

specifies one or more real device numbers to be defined or changed. Each *rdev* specified must be a hexadecimal number between X'0000' and X'FFFF'. The maximum number of devices allowed within a range is 256.

**EQid eqid**

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters. Note that for this device class, the specified EQID must be unique across all devices on the system.

**NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

**Type**

specifies the type of device.

**BSC\_ADAPTer**

specifies an IBM Binary Synchronous Terminal Control Type II for a 3745.

The BSCA adapter is supported as dedicated-only.

**IBM1\_ADAPTer**

specifies that an IBM Terminal Adapter Type I attaches a 1050 or 2741 to a 3745.

**TELE2\_ADAPTer**

specifies that a CPT-TWX (Models 33/35) Terminal, 3101, 3151, 3161, 3162, or 3163, attaches to a Line Interface Base Type I in a 3745.

**SET\_ADDRESS n**

is the set address (SAD) command to be entered for a telecommunication line attached to a control unit. The default is 4.

The values for *n* and the corresponding commands are:

- 0** SADZERO
- 1** SADONE
- 2** SADTWO
- 3** SADTHREE
- 4** (No SAD command is entered)

### 3705

defines the base address that loads the 3745 communications controller.

## Usage Notes

1. When setting an EQID for a device of this class, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCP048E and the RDEV will not be created.
2. The system cannot generate EQIDs for devices that do not support RCD CCW.

## Examples

Example 1:

To specify an IBM Terminal Adapter Type 1 at device number 01F0, enter the following SET RDEVICE command:

```
set rdevice 01F0 type ibm1_adapter
```

Example 2:

To specify three Binary Synchronous Terminal Control Type II adapters at device numbers 01F1, 01F2, and 01F3, enter this SET RDEVICE command:

```
set rdevice 01F1-01F3 type bsc_adapter
```

Example 3:

To specify Binary Synchronous Terminal Control Type II adapters at device number 01F1 with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 01F1 eqid ABCDEFGH type bsc_adapter
```

Example 4:

To specify Binary Synchronous Terminal Control Type II adapters at device number 01F1 and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 01F1 noeqid type bsc_adapter
```

## Responses

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP048E EQID must be unique for the specified device class.
- HCP048E Specified EQID already assigned to a different device.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*

## SET RDEVICE DASD

### Authorization

Privilege Class: B

### Purpose

You can enter SET RDEVICE commands for the following DASD types: 3380, 3390 and 9336.

These DASD types respond to the sense ID request instruction. You only need to enter SET RDEVICE commands for them if you want to specify one of the following operands:

- SHARED YES
- MDC DFLTOFF
- MDC OFF
- NOTSENSED.

### Operands

#### *rdev*

#### *rdev1-rdev2*

specifies one or more real device numbers to be defined or changed. A real DASD in the active configuration can be entered as a 4-digit hexadecimal device number between X'0000' and X'FFFF'. For a real DASD in the active or standby configuration, the device can be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is defined. A range of devices cannot span subchannel sets. The maximum number of devices allowed within a range is 256.

#### **EQid** *eqid*

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters. Note that for this device class, the specified EQID must be unique across all devices on the system.

#### **NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

#### **TYpe** **DASD**

tells CP the specified device or devices are DASDs.

#### **SHAREd**

tells CP to share the devices concurrently among multiple real systems.

In an SSI cluster, this setting specifies whether the devices are to be shared outside the SSI cluster.

## SET RDEVICE DASD

### **NO**

tells CP not to share the devices among multiple real systems. The default is NO.

### **YES**

tells CP to share the devices among multiple real systems.

### **MDC**

tells CP whether you want the device or devices to be cached in the minidisk cache.

### **DFLTON**

(the default if the SHARED option is not specified or the SHARED NO option is specified.) Tells CP to cache data on the real device in the minidisk cache except for minidisks for whom caching is specifically disabled via the MINIOPT NOMDC directory statement or the SET MDCACHE MDISK OFF command.

### **OFF**

(the default if the SHARED YES option is specified.) Tells CP to not cache data on the real device in the minidisk cache.

### **DFLTOFF**

tells CP to not cache data on the real device in the minidisk cache except for minidisks for whom caching is specifically enabled via the MINIOPT MDC directory statement or the SET MDCACHE MDISK ON command.

### **SENSEd**

tells CP to use the information returned from a sense ID request to determine the characteristics of this DASD. If omitted, the default is SENSED.

### **NOTSENSEd**

tells CP not to use the information returned from a sense ID request to determine the characteristics of this DASD.

## Usage Notes

1. Not all DASD types are eligible for caching in the minidisk cache. If you specify MDC DFLTON or MDC DFLTOFF for a device that is not cache eligible, data on that device will not be cached.
2. When setting an EQID for a device of this class, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCP048E and the RDEV will not be created.
3. The system cannot generate EQIDs for devices that do not support RCD CCW.
4. Specifying a 5-digit hexadecimal device number when defining an RDEV might place in into the active configuration. This would occur if there is not already a matching device number that is in the active configuration.

## Examples

### Example 1:

To specify a shared DASD with minidisk caching off at device number 0410, enter the following SET RDEVICE command:

```
set rdevice 0410 type dasd shared yes
```

### Example 2:

To define a non-shared DASD at device number 500 with minidisk caching enabled on a device only for those minidisks that have specifically enabled caching, use the following SET RDEVICE command:

```
set rdevice 500 type dasd mdc dfltoff
```

### Example 3:

To specify a shared DASD with minidisk caching off at device number 0252 with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 0252 eqid ABCDEFGH type dasd shared yes
```

Example 4:

To specify a shared DASD with minidisk caching off at device number 0252 and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 0252 noeqid type dasd shared yes
```

## Responses

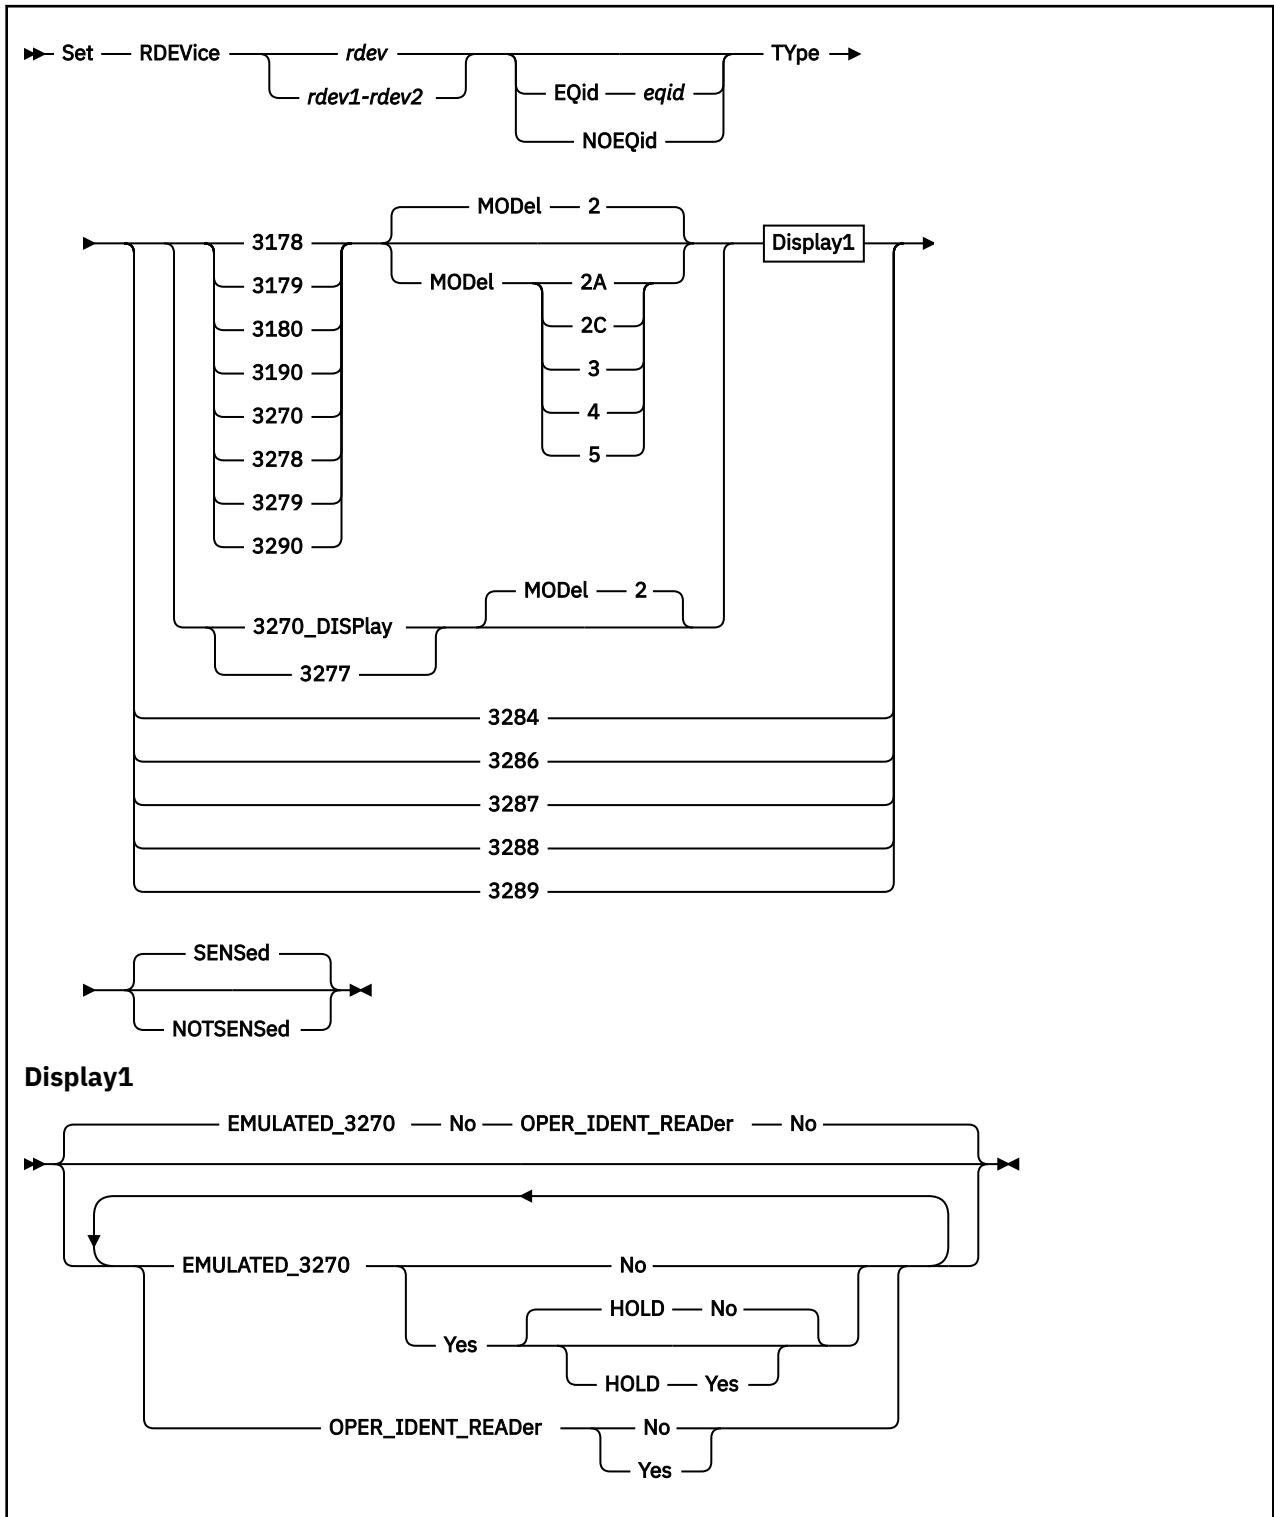

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP048E EQID must be unique for the specified device class.
- HCP048E Specified EQID already assigned to a different device.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*

## SET RDEVICE Graphic Display Devices

### Authorization

Privilege Class: B

## Purpose

Use this SET RDEVICE command to tell CP that IBM graphic display devices are at certain device addresses.

## Operands

*rdev*

*rdev1-rdev2*

specifies one or more real device numbers to be defined or changed. Each *rdev* specified must be a hexadecimal number between X'0000' and X'FFFF'. The maximum number of devices allowed within a range is 256.

**EQid** *eqid*

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters. Note that for this device class, the specified EQID must be unique across all devices on the system.

**NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

**TYpe 3178, 3179, 3180, 3190, 3270, 3278, 3279, or 3290**

tells CP that the real device (or devices) that you are defining are graphic display devices. CP can determine dynamically all of these graphic display devices during initialization or when you vary on the device. You only need to specify these graphic display devices if you want to specify the extended attributes.

**MODeL 2, 2A, 2C, 3, 4, or 5**

is the model number of the graphic display device. If omitted, the default is Model 2.

**TYpe 3270\_DISPLAY or 3277**

tells CP that the real device (or devices) that you are defining are graphic display devices. CP can determine dynamically all of the 3270 graphic display devices during initialization or when you vary on the device. You only need to specify the 3270 graphic display devices if you want to specify the extended attributes.

**Note:** The 3270-PC is supported in control-unit terminal mode and distributed-function terminal (DTF) mode when defined as a 3270.

You must specify the 3277 display because its device type cannot be determined.

**MODeL 2**

is the model number of the graphic display device. If omitted, the default is Model 2.

**TYpe 3284, 3286, 3287, 3288, or 3289**

tells CP that the real device (or devices) that you are defining are graphic printer devices. CP can determine dynamically all of the graphic printer devices during initialization or when you vary on the device; therefore, you do not need to specify them.

**Note:** CP cannot sense these devices when they are attached to either a 3174 or a 3274 control unit. If these devices are attached to a 3174 or a 3274 control unit, each device must be defined in the system configuration file using the RDEVICE statement.

**EMULATED\_3270 Yes**

**EMULATED\_3270 No**

specifies whether the device is a TTY ASCII display terminal connected to the system through a 7171 ASCII DACU or ASCII Subsystem (an emulated 3270). NO is the default.

**Note:** The 3101 must be connected to a 7171 Control Unit. You must also specify EMULATED\_3270 YES.

**HOLD Yes****HOLD No**

specifies whether the display terminal telecommunications connection to the 7171 ASCII DACU or ASCII Subsystem is to remain after logging off or disconnecting. NO is the default.

**OPER\_IDENT\_READER Yes****OPER\_IDENT\_READER No**

specifies whether there is an operator identification card reader on a 327x display. If you specify OPER\_IDENT\_READER YES, the virtual machine operator can gain access to the system (log on) only by inserting a magnetically encoded card. You may ask each user ID to use a badge reader, but it is not required. You may use a badge reader as an additional security measure after a correct password has been entered, but it cannot replace the need to enter a correct password. If you do not want to have a card reader authorize access, do not enter OPER\_IDENT\_READER YES, or enter OPER\_IDENT\_READER NO. NO is the default.

**SENSEd**

tells CP to use the information returned from a sense ID request to determine the characteristics of this graphic display device. If omitted, the default is SENSED.

**NOTSENSEd**

tells CP not to use the information returned from a sense ID request to determine the characteristics of this graphic display device.

### Usage Notes

1. *z/VM: General Information* lists all displays supported for this release.
2. Make sure the device numbers specified on the command correspond to the device numbers required for the category of display terminal in the controller.
3. Refer to *7171 Device Attachment Control Unit Reference Manual and Programming Guide* to determine which type of device (TYPE) to code for a TTY ASCII terminal attached to a 7171 DACU or ASCII Subsystem.
4. The 3178, 3179, 3180, 3190, 3278, 3279, 3290, 3284, 3486, 3287, 3288 and 3289 are defined primarily for use with second level systems. Second level, you could define a printer or display to be at a particular device number and then you could do a first level define of the device number. If the device is defined in the configuration file, the second level system would bring that device online immediately rather than the user having to define a device number first level, enter the SET RDEVICE command second level, and vary on the device second level.
5. When setting an EQID for a device of this class, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCP048E and the RDEV will not be created.
6. The system cannot generate EQIDs for devices that do not support RCD CCW.

### Examples

Example 1:

To specify a 3277 display at device number 0210, enter the following SET RDEVICE command:

```
set rdevice 0210 type 3277
```

Example 2:

To specify three 3270 displays at device numbers 0211, 0212, and 0213, and not allow users to log on to them without an operator identification card, enter this SET RDEVICE command:

```
set rdevice 0211-0213 type 3270_display oper_ident_reader yes
```

Example 3:

To define:

- 48 3270 displays at device numbers 800 through 82F
- 16 3277 displays at device numbers 830 through 83F
- 31 3278 displays at device numbers 970 through 98E
- One 3287 display at device number 98F
- One 3290 display at device number 1010
- 15 3190 displays at device numbers 1011 through 101F
- 61 3278 displays at device numbers 200 through 23C, indicate the display is a TTY ASCII display terminal connected to the system through a 7171 ASCII DACU or ASCII Subsystem (an emulated 3270), and indicate the connection between this display and the 7171 is to remain after the user logs off or disconnects

use the following SET RDEVICE commands:

```
set rdevice 800-82f type 3270_display
set rdevice 830-83f type 3277
set rdevice 970-98e type 3278
set rdevice 98f type 3287
set rdevice 1010 type 3290
set rdevice 1011-101f type 3190
set rdevice 200-23c type 3278 emulated_3270 yes hold yes
```

Example 4:

To specify a 3277 display at device number 0252 with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 0252 eqid ABCDEFGH type 3277
```

Example 5:

To specify a 3277 display at device number 0252 and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 0252 noeqid type 3277
```

## Responses

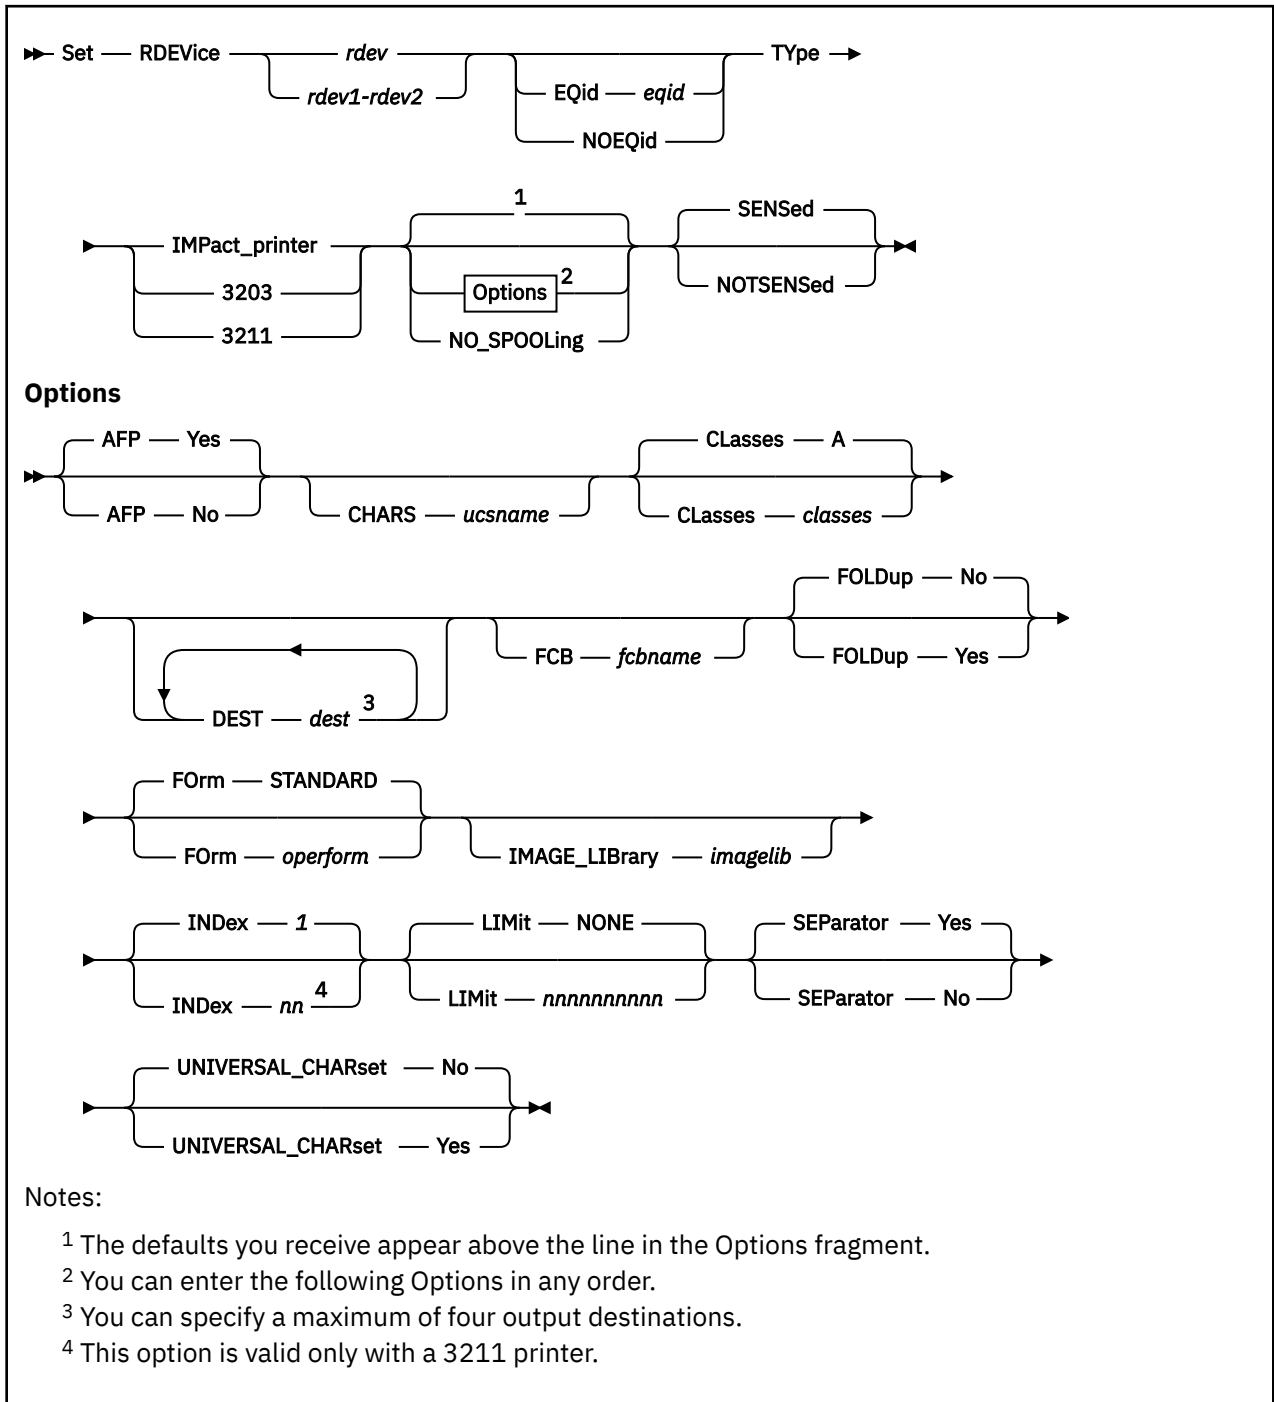

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *option*
- HCP013E Conflicting option - *option*
- HCP048E EQID must be unique for the specified device class.
- HCP048E Specified EQID already assigned to a different device.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*

## SET RDEVICE Impact Printers

### Authorization

Privilege Class: B

### Purpose

Use this SET RDEVICE command to define or change the following CP system-managed IBM impact printers: 3203, 3211, 3262, 4245, 4248, and 6262

**Note:** Only the 3203 Model 5 is supported. 3211 printers are only supported as emulated by other printers.

## Operands

### *rdev*

#### *rdev1-rdev2*

specifies one or more real device numbers to be defined or changed. Each *rdev* specified must be a hexadecimal number between X'0000' and X'FFFF'. The maximum number of devices allowed within a range is 256.

#### **EQid** *eqid*

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters. Note that for this device class, the specified EQID must be unique across all devices on the system.

#### **NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

#### **TYpe IMPact\_printer**

tells CP you are defining one of the impact printers listed above.

#### **NO\_SPOOLing**

tells CP not to use the unit record device for printing.

#### **SENSEd**

tells CP to use the information returned from a sense ID request to determine the characteristics of this printer. If omitted, the default is SENSED.

#### **NOTSENSEd**

tells CP not to use the information returned from a sense ID request to determine the characteristics of this printer.

#### **AFP Yes**

#### **AFP No**

specifies whether the printer is to process files with advanced function printer (AFP) characteristics, extended attribute buffers (XABs), or X'5A' channel command words (CCWs). The default is YES.

#### **CHARS** *ucsname*

For a printer with the UNIVERSAL\_CHARSET feature, CHARS *ucsname* specifies the 1- to 4-character suffix of the name of the default universal character set (UCS) buffer image. *ucsname* must correspond to one of the UCS images stored in the image library. For example, if you enter:

```
set rdevice 0003 type 3203 chars an
```

The image library must contain a member named 3203AN.

**Note:** If CP determines the printer is a 3262, the default for CHARS is P48. The default for 3203 is PCAN. The default for 3211 is A11.

#### **Classes**

specifies the output spooling classes the printer can print. (To change the spooling classes without having to take the printer off line, use the CP START command.)

#### **A**

is the default class.

#### **classes**

are the output spooling classes the printer can print.

You can specify CLASSES in one of the following ways:

- If you omit the CLASSES operand for unit record devices, class A is the default.

## SET RDEVICE Impact Printers

- Enter `CLASSES c[c...]` to list up to eight output spooling classes. The spooling class, *c*, is one alphanumeric character. You can specify multiple classes as `CLASSES ABC` and a single class as `CLASSES A`.
- Enter `CLASSES *` to have the printer process files regardless of class.

### **DEST** *dest*

specifies the output destination values the printer can print. (To change the spooling destination values without having to take the printer off line, use the CP START command.)

You can specify DEST in one of the following ways:

- If you omit the DEST operand, DEST OFF is the default.
- You can specify as many as four destination values by entering four different DEST operands, for example:

```
DEST PRINTER1 DEST PRINTER2 DEST PRINTER3 DEST PRINTER4
```

- Enter `DEST *` to have the printer process files regardless of destination identifiers.

### **FCB** *fcname*

specifies the 1- to 4-character suffix of the name of the default forms control buffer (FCB) to use after a cold start or force start. This must correspond to one of the FCB images added to an image library. For example, if you enter:

```
set rdevice 0003 type 3203 fcb fcb8
```

The image library must contain a member named 3203FCB8.

The number of lines to be printed on the separator page is determined by the FCB loaded on the printer. The default separator page contains 58 lines of data. If the page length defined by the FCB is less than the default separator page length, the separator page data must be customized in order to fit on a single page. This may be done using CP Exit points that are provided in separator page processing. See [z/VM: CP Exit Customization](#) for details.

### **FOLDup** Yes

### **FOLDup** No

specifies whether lowercase should be folded (translated) into uppercase. The default is NO.

### **Form** *operform*

is the current spooling form number that the printer can process. This form is the default operator form for the real printer. Specify this parameter when you are defining a new printer or when you are redefining an existing non-impact printer to be an impact printer. You can specify this parameter in one of the following ways:

- `FORM operform`

*operform* specifies a 1- to 8-character operator form number for the files the printer can process.

- `FORM *`

The asterisk indicates the printer can process files regardless of form number.

- `FORM STANDARD`

STANDARD indicates the type of paper to which the installation has assigned the name STANDARD. Each installation establishes its own set of form names, assigns those form names to types of paper, and tells the operations staff and end users the form names for the different types of paper.

FORM STANDARD is the default.

### **IMAGE\_LIBRARY** *imagelib*

specifies the image library to use after a cold start. The default for IMAGE\_LIBRARY is `IMAGnnnn`. *nnnn* is the device type number.

### **INDEX** *nn*

specifies the position at which to start printing. *nn* is a number from 1 to 31. The default is 1. If the defined printer is not a 3211, the INDEX option is ignored.

**LIMit nnnnnnnnnn****LIMit NONE**

specifies the maximum number of records of a file to be printed. You can specify up to 10 digits. NONE is the default.

**SEParator Yes****SEParator No**

specifies whether a separator is desired for output files. The default is YES.

**UNIVERSAL\_CHARset Yes****UNIVERSAL\_CHARset No**

tells CP the printer is a universal character set printer. The default is NO.

**Usage Notes**

1. When setting an EQID for a device of this class, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCP048E and the RDEV will not be created.
2. The system cannot generate EQIDs for devices that do not support RCD CCW.

**Examples**

## Example 1:

To specify a 3203 printer at device number X'0110' to print only class A spool files (the default value), enter the following SET RDEVICE command:

```
set rdevice 0110 type impact_printer
```

## Example 2:

To specify a dedicated 3262 printer at device number X'0110', enter this SET RDEVICE command:

```
set rdevice 0110 type impact_printer no_spooling
```

## Example 3:

To specify a 3203 printer at device number X'0110' with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 0110 eqid ABCDEFGH type impact_printer
```

## Example 4:

To specify a 3203 printer at device number X'0110' and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 0110 noeqid type impact_printer
```

**Responses**

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*

## SET RDEVICE Impact Printers

- HCP013E Conflicting option - *option*
- HCP048E EQID must be unique for the specified device class.
- HCP048E Specified EQID already assigned to a different device.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*
- HCP6709E Too many items specified - *token*

## SET RDEVICE Integrated Communication Adapters

### Authorization

Privilege Class: B

### Purpose

Use the SET RDEVICE command to tell CP that integrated communication adapters are at certain device addresses.

### Operands

#### *rdev*

#### *rdev1-rdev2*

specifies one or more real device numbers to be defined or changed. Each *rdev* specified must be a hexadecimal number between X'0000' and X'FFFF'. The maximum number of devices allowed within a range is 256.

#### **EQid** *eqid*

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters. Note that for this device class, the specified EQID must be unique across all devices on the system.

#### **NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

#### **TType** *ICA\_ETHERnet*

tells CP that the real device (or devices) that you are defining is a teleprocessing adapter for an 802.3 local area network.

#### **TType** *ICA\_HDLC*

tells CP that the real device (or devices) that you are defining is a teleprocessing adapter for a high level data link control.

#### **SENSEd**

tells CP to use the information returned from a sense ID request to determine the characteristics of this adapter. If omitted, the default is SENSED.

#### **NOTSENSEd**

tells CP not to use the information returned from a sense ID request to determine the characteristics of this adapter.

### Usage Notes

1. When setting an EQID for a device of this class, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCP048E and the RDEV will not be created.
2. The system cannot generate EQIDs for devices that do not support RCD CCW.

### Examples

Example 1:

To define 4 integrated communications adapters at device numbers 300 through 303 to an 802.3 Local Area Network, enter the following SET RDEVICE command:

```
set rdevice 300-303 type ica_ethernet
```

Example 2:

To specify an integrated communications adapter at device number 0252 with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 0252 eqid ABCDEFGH type ica_ethernet
```

Example 3:

To specify an integrated communications adapter at device number 0252 and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 0252 noeqid type ica_ethernet
```

### Responses

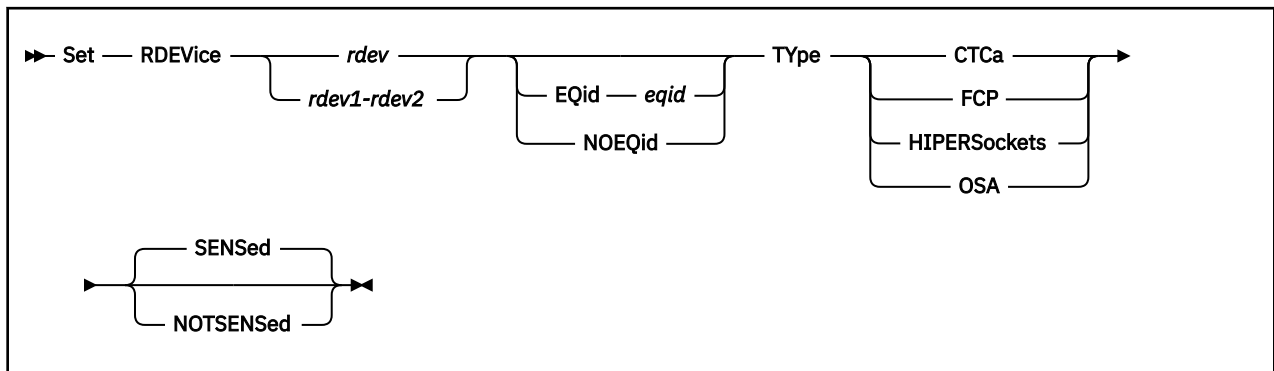

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP048E EQID must be unique for the specified device class.
- HCP048E Specified EQID already assigned to a different device.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*

## SET RDEVICE Special Devices

### Authorization

Privilege Class: B

### Purpose

Use this SET RDEVICE command to tell CP the device addresses of certain types of devices.

### Operands

*rdev*

*rdev1-rdev2*

specifies one or more real device numbers to be defined or changed. Each *rdev* specified must be a hexadecimal number between X'0000' and X'FFFF'. The maximum number of devices allowed within a range is 256.

**EQid** *eqid*

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters. Note that for CTCA, FCP, HiperSocket, and OSA devices, this EQID must be unique or be shared only by other devices of the same type.

**NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

**TYpe**

specifies the type of device.

**CTCa**

is a Channel-to-Channel device.

**Note:** Specify the 3737 Remote Channel-to-Channel Unit Model 2 as a CTCA.

**FCP**

is a Fiber-Channel-Protocol device.

**HIPERSockets**

is a HiperSockets device. To obtain status for a HiperSockets device, issue a Query OSA command.

**OSA**

is an Open-Systems-Adapter device.

**SENSEd**

tells CP to use the information returned from a sense ID device command to determine the characteristics of this device. If omitted, the default is SENSED.

### NOTSENSEd

tells CP not to use the information returned from a sense ID device command to determine the characteristics of this command.

### Usage Notes

1. Users should specify EQIDs for the following device classes in order to use them in live guest relocation:
  - a. CTCA
  - b. FCP
  - c. HiperSockets
  - d. OSA

While the system can generate EQIDs for these device classes, they are not guaranteed to extract all information necessary for equivalency, such as connection fabrics.

2. When setting an EQID for a CTCA, FCP, HiperSocket, or OSA, if one or more devices already exist with the specified EQID, they all must be of the same device type (CTCA, etc.). If the new RDEV is of a different class or type, you will receive message HCP048E and the RDEV will not be created.
3. When setting an EQID for any other Special class RDEV, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCP048E and the RDEV will not be created.
4. The system cannot generate EQIDs for devices that do not support RCD CCW.

### Examples

Example 1:

To specify a channel-to-channel adapter at device number 0250, enter the following SET RDEVICE command:

```
set rdevice 0250 type ctca
```

Example 2:

To specify an Open-Systems-Adapter device at device number 0252, enter this SET RDEVICE command:

```
set rdevice 0252 type osa
```

Example 3:

To specify an Open-Systems-Adapter device at device number 0252 with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 0252 eqid ABCDEFGH type osa
```

Example 4:

To specify an Open-Systems-Adapter device at device number 0252 and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 0252 noeqid type osa
```

### Responses

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP048E Specified EQID already assigned to a different class of devices.
- HCP048E Specified EQID already assigned to a different device.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*

## SET RDEVICE Tape Units

### Authorization

Privilege Class: B

### Purpose

Use this SET RDEVICE command to tell CP that tape units are at certain device addresses.

### Operands

*rdev*

*rdev1-rdev2*

specifies one or more real device numbers to be defined or changed. Each *rdev* specified must be a hexadecimal number between X'0000' and X'FFFF'. The maximum number of devices allowed within a range is 256.

**Note:** A device range is not valid for setting EQIDs.

**EQid** *eqid*

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters.

**Note:** For this device class, the specified EQID must be unique for each *rdev*.

**NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

**TType** 3422

specifies an IBM 3422 tape unit.

**TYpe TAPE**

specifies an IBM tape unit that can be dynamically sensed by CP (such as an IBM 3480 or 3490 tape unit).

**SENSEd**

tells CP to use the information returned from a sense ID request to determine the characteristics of this tape unit. If omitted, the default is SENSED.

**NOTSENSEd**

tells CP not to use the information returned from a sense ID request to determine the characteristics of this tape unit.

**FEATure**

tells CP about features that an online, and free, tape device is capable of.

**KEY *keyalias***

prepares CP to enable a device's hardware encryption on behalf of a guest that is not able to manage the support itself. If a *keyalias* is specified (up to two are allowed), CP will use the encoding mechanism and key label described by the alias while setting up the encryption environment. If no aliases are supplied, the external key manager's default keys will be used.

**NOKEY**

indicates that CP should no longer try to manage the encryption environment on behalf of the guest.

**Usage Notes**

1. When setting an EQID for a device of this class, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCP048E and the RDEV will not be created.
2. The system cannot generate EQIDs for devices that do not support RCD CCW.

**Examples**

Example 1:

To specify a 3422 tape unit at device number 0310, enter the following SET RDEVICE command:

```
set rdevice 0310 type 3422
```

Example 2:

To specify a tape unit that can be dynamically sensed by CP at device number 0315, enter this SET RDEVICE command:

```
set rdevice 0315 type tape
```

Example 3:

To specify a tape unit is capable of hardware encryption, but the guest will not be capable of using it itself, enter this SET RDEVICE command:

```
SET RDEVICE 07E2 FEATURE KEY
```

Example 4:

To instruct CP to stop managing the encryption settings for a tape unit, enter this SET RDEVICE command after detaching the tape from the guest:

```
SET RDEVICE 07E2 FEATURE NOKEY
```

Example 5:

## SET RDEVICE Tape Units

To specify a 3422 tape unit at device number 0252 with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 0252 eqid ABCDEFGH type 3422
```

Example 6:

To specify a 3422 tape unit at device number 0252 and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 0252 noeqid type 3422
```

## Responses

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *option*
- HCP013E Conflicting option - *option*
- HCP048E EQID must be unique for the specified device class.
- HCP048E Specified EQID already assigned to a different device.
- HCP1550E *rdev* is an invalid device class.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*
- HCP6706E Invalid model number - *number*
- HCP6721E Device *rdev* must be free and online to respond to a SET RDEVICE FEATURE command.
- HCP6721E Tape device *rdev* must be at Beginning of Tape or unloaded to a SET RDEVICE FEATURE command.

## SET RDEVICE Terminals

### Authorization

Privilege Class: B

### Purpose

Use this SET RDEVICE command to tell CP that terminals are defined at certain device addresses.

### Operands

#### *rdev*

#### *rdev1-rdev2*

specifies one or more real device numbers to be defined or changed. Each *rdev* specified must be a hexadecimal number between X'0000' and X'FFFF'. The maximum number of devices allowed within a range is 256.

#### **EQid** *eqid*

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters. Note that for this device class, the specified EQID must be unique across all devices on the system.

#### **NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

#### **TYpe 3215**

specifies a 3215 terminal.

#### **SENSEd**

tells CP to use the information returned from a sense ID device command to determine the characteristics of this device. If omitted, the default is SENSED.

#### **NOTSENSEd**

tells CP not to use the information returned from a sense ID device command to determine the characteristics of this command.

### Usage Notes

1. When setting an EQID for a device of this class, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCPO48E and the RDEV will not be created.
2. The system cannot generate EQIDs for devices that do not support RCD CCW.

### Examples

Example 1:

## SET RDEVICE Terminals

To specify a 3215 terminal at device number 0253, enter this SET RDEVICE command:

```
set rdevice 0253 type 3215
```

Example 2:

To specify a 3215 terminal at device number 0252 with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 0252 eqid ABCDEFGH type 3215
```

Example 3:

To specify a 3215 terminal at device number 0252 and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 0252 noeqid type 3215
```

## Responses

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP048E EQID must be unique for the specified device class.
- HCP048E Specified EQID already assigned to a different device.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*

## SET RDEVICE Unsupported Devices

### Authorization

Privilege Class: B

### Purpose

When you generate a device as an unsupported device, you must dedicate the device to a virtual machine. You can dedicate a device to a virtual machine by coding the DEDICATE control statement in the virtual machine's directory entry or by entering the CP ATTACH command.

### Operands

**rdev**

**rdev1-rdev2**

specifies one or more real device numbers to be defined or changed. Each *rdev* specified must be a hexadecimal number between X'0000' and X'FFFF'. The maximum number of devices allowed within a range is 256.

**EQid *eqid***

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters. Note that for this device class, the specified EQID must be unique across all devices on the system.

**NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

## SET RDEVICE Unsupported Devices

### **TType UNSUPported**

specifies an unsupported device type.

### **DEVClass**

is the device class of the unsupported device.

Valid classes for unsupported devices include the following:

<b><u>Class Value</u></b>	<b><u>Class for Unsupported Device</u></b>
DASD	Direct access storage devices
3270_DISPLAY	Graphics display devices
3270_PRINTEr	Graphics printer devices
PRINTEr	Unit record printer devices
PUNch	Unit record punch devices
READer	Unit record input devices
SWITch	Dynamic switching devices
TAPe	Tape devices
TERMinal	Terminals

### **DPS No**

### **DPS Yes**

The default is DPS YES. This indicates a DASD or TAPE device being defined supports the dynamic path selection (DPS) function.

DPS NO should only be specified for unsupported DASD and TAPE devices that do not support the DPS function.

### **RESERVE\_RELEASE No**

### **RESERVE\_RELEASE Yes**

The default is RESERVE\_RELEASE YES. This indicates the DASD being defined supports the reserve/release function.

RESERVE\_RELEASE NO should only be specified for DASD devices that do not support the reserve/release function.

## **Usage Notes**

1. The SET RDEVICE command can be used:
  - To define a device to CP for which no control blocks exist. CP will build the required control blocks to use this device.
  - To modify the control blocks for an existing device. In this case the DPS Yes parameter is not able to change the handling of the device by CP (from DPS NO to DPS YES). You must have the device defined in the SYSTEM CONFIG file with DPS YES and perform an IPL CLEAR of the entire system.
2. When setting an EQID for a device of this class, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCP048E and the RDEV will not be created.
3. The system cannot generate EQIDs for devices that do not support RCD CCW.

## **Examples**

Example 1:

To specify an unsupported DASD, enter the following SET RDEVICE command:

```
set rdevice 0fff type unsupported devclass dasd
```

**Example 2:**

To specify an unsupported DASD that supports dynamic path selection, enter this SET RDEVICE command:

```
set rdevice 0fe0 type unsupported devclass dasd dps yes
```

**Example 3:**

To specify an unsupported DASD that supports both dynamic path selection and reserve/release, enter this SET RDEVICE command:

```
set rdevice 0fd0 type unsupported devclass
dasd dps yes reserve_release yes
```

**Example 4:**

To specify an unsupported DASD at device number 0fff with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 0fff eqid ABCDEFGH unsupported devclass dasd
```

**Example 5:**

To specify an unsupported DASD at device number 0fff and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 0fff noeqid unsupported devclass dasd
```

**Responses**

After CP has issued a message for each device address affected by a SET RDEVICE command, the following summary response is displayed:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

**Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *option*
- HCP013E Conflicting option - *option*
- HCP048E EQID must be unique for the specified device class.
- HCP048E Specified EQID already assigned to a different device.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *range*

## SET RDEVICE 3800 Printers

### Authorization

Privilege Class: B

## Purpose

Use this SET RDEVICE command to define or change 3800 printers.

## Operands

### *rdev*

#### *rdev1-rdev2*

specifies one or more real device numbers to be defined or changed. Each *rdev* specified must be a hexadecimal number between X'0000' and X'FFFF'. The maximum number of devices allowed within a range is 256.

### **EQid** *eqid*

assigns the device equivalency ID (EQID) *eqid* to the RDEV. The *eqid* is a string of 1–8 alphanumeric characters. Note that for this device class, the specified EQID must be unique across all devices on the system.

### **NOEQid**

removes a previously assigned EQID from this RDEV. After the device is varied online, it reverts back to a system-generated EQID.

### **TYpe 3800**

tells CP that this is a 3800 printer.

### **MODeI**

is the model number of the 3800 that you are defining.

#### **1**

is the default.

#### **3**

is supported either in IBM 3800 Model 1 compatibility mode, defined as a Model 1, or by using the Advanced Function Printing licensed program, defined as a Model 3. If you are using an IBM 3800 Model 3 as an advanced function printer, enter AFP YES.

#### **6**

is supported either in IBM 3800 Model 1 compatibility mode, defined as a Model 1, or by using the Advanced Function Printing licensed program, defined as a Model 6. If you are using a IBM 3800 Model 6 as an advanced function printer, enter AFP YES.

#### **8**

is supported using the Advanced Function Printing licensed program.

### **NO\_SPOOLing**

tells CP not to use the unit record device for printing.

### **SENSEd**

tells CP to use the information returned from a sense ID request to determine the characteristics of this printer. If omitted, the default is SENSED.

### **NOTSENSEd**

tells CP not to use the information returned from a sense ID request to determine the characteristics of this printer.

### **AFP Yes**

### **AFP No**

tells CP whether the printer will process files with advanced function printer (AFP) characteristics, extended attribute buffers (XABs), or X'5A' channel command words (CCWs). The default is YES.

### **CHARS** *ffff*

is the name of a character arrangement table for the separator page to use after a cold start. For 3800 printers, the default values are:

- For the IBM 3800 Model 1, CHARs GF10.
- For the IBM 3800 Model 3 or Model 6, CHARs GF12.

**Classes**

are the output spooling classes that this 3800 printer can print. (To change the spooling classes without having to take the printer offline, use the CP START command.)

**A**

is the default class.

**classes**

are the output spooling classes that the printer can print.

You can specify CLASSES in one of the following ways:

- Do not specify the CLASSES operand for unit record devices. Class A is the default.
- Enter CLASSES c[c...] to list up to 8 output spooling classes. The spooling class, c, is 1 alphanumeric character. You can specify multiple classes as CLASSES ABC and a single class as CLASSES A.
- Enter CLASSES \* to have the 3800 processes files regardless of their class.

**DPMSIZE n**

is the maximum size of the delayed purge queue (see note 1) that the 3800 Model 1, Model 3, or Model 6 printer uses after a cold start. The default value for n is 1, the maximum is 9. If '0' is specified, no delayed purge queue is maintained (see note 2).

**Notes:**

1. After the 3800 prints a file, CP places the file on the delayed purge queue if a delayed purge queue is being maintained. When the queue is full, CP purges the oldest file. This delay helps to ensure the 3800:
  - Transfers the last page of the file from the page buffer in the 3800 printer to paper
  - Stacks the printed page.If the 3800 fails before CP purges a file from the delayed purge queue, CP places the file in system hold.
2. Specifying '0' for DPMSIZE will save some spool DASD space because files printed on the 3800 will be purged immediately. However, this will decrease the possibility of recovering a printer file which has failed during printing.

**FCB lpi**

is the name of the forms control buffer for the separator page to use after a cold start. You can override this value by naming a forms control buffer on the START command. The default value for lpi is 6.

The number of lines to be printed on the separator page is determined by the FCB loaded on the printer. The default separator page contains 58 lines of data. If the page length defined by the FCB is less than the default separator page length, the separator page data must be customized in order to fit on a single page. This may be done using CP Exit points that are provided in separator page processing. See CP EXIT 4402: [Separator Page Perforation Printing or 3800 Positioning in z/VM: CP Exit Customization](#) for details.

**FLASH flashlib**

is the flash overlay to use for this device.

**FOrm operform**

is the current spooling form number that the printer can process. This form is the default operator form for the real printer. Specify this operand when defining a new printer or when redefining an existing printer. You can specify this operand in one of the following ways:

- Enter FORM operform, where operform is a 1- to 8-character operator form number for the files the printer can process.
- Enter FORM \* to have the printer process files regardless of form number.
- Enter FORM STANDARD to indicate the type of paper to which the installation has assigned the name STANDARD. Each installation establishes its own set of form names, assigns those form

names to types of paper, and tells the operations staff and end users which form name to use for which type of paper.

STANDARD is the default.

### **IMAGE\_LIB**rary *imagelib*

is the name of the image library to use after a cold start. You can override this value by specifying an image library name on the START command.

The default value is IMAGE IMAG3800.

### **SE**parator Yes

### **SE**parator No

tells CP whether to insert a separator page between output files. YES is the default.

### **MARK** Yes

### **MARK** No

specifies whether a 3800 printer will mark separator trailer pages with separator bars. When 'Mark Yes' is in effect, 3 separator trailer pages are printed for each file. 'Mark No' causes only one trailer page to be printed, thus saving paper. However, using 'Mark No' could also make it more difficult to separate 3800 output, as there are no markings between files. The default is YES.

### **DEST** *dest*

is the destination that an output device can service. The variable *dest* is a 1- to 8-character alphanumeric string assigned to the printer. You may specify up to four destination values.

### **LIM**it NONE

### **LIM**it *nnnnnnnnn*

is the maximum number of records of a file to be printed. The default is NONE.

### **WCGM** 2

### **WCGM** 4

tells CP that the 3800 has either the 2-writable-character generation module feature or the 4-writable-character generation module feature.

**Note:** You can only specify this option for a IBM 3800 Model 1.

For a IBM 3800 Model 1, the default is WCGM 2. For IBM 3800 Models 3, 6, and 8, the default is WCGM 4.

## **Usage Notes**

1. When setting an EQID for a device of this class, the specified EQID must be unique across all devices in the system. If the specified EQID already exists, you will receive message HCP048E and the RDEV will not be created.
2. The system cannot generate EQIDs for devices that do not support RCD CCW.

## **Examples**

Example 1:

To specify an IBM 3800 Model 3 printer at device number 500 to be dedicated to a virtual machine, enter the following:

```
set rdevice 500 type 3800 model 3
```

Example 2:

To specify three IBM 3800 Model 8 printers at device numbers 501, 502, and 503 to be dedicated to virtual machines, enter the following:

```
set rdevice 501-503 type 3800 model 8
```

Example 3:

## SET RDEVICE 3800 Printers

To specify an IBM 3800 Model 3 printer at device number 0252 with an EQID of ABCDEFGH, enter this SET RDEVICE command:

```
set rdevice 0252 eqid ABCDEFGH type 3800 model 3
```

Example 4:

To specify an IBM 3800 Model 3 printer at device number 0252 and remove any previously defined EQID, enter this SET RDEVICE command:

```
set rdevice 0252 noeqid type 3800 model 3
```

## Responses

After CP issues a message for each device address affected by a SET RDEVICE command, CP displays the following summary response:

```
xxx RDEV(s) specified; yyy RDEV(s) changed; zzz RDEV(s) created
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP013E Conflicting option - *option*
- HCP048E EQID must be unique for the specified device class.
- HCP048E Specified EQID already assigned to a different device.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6704E Missing token at end of line
- HCP6706E Invalid address range - *rdev-rdev*

## SET RECORD

### Authorization

Privilege Class: F

### Purpose

Use SET RECORD to set the recording mode for a device.

### Operands

#### ON

#### OFF

controls the intensive recording mode for the device that you specify. You can specify intensive recording for only one device at a time.

If you do not enter SET RECORD OFF, intensive recording is automatically terminated after 10 error records have been accumulated for the device, or when you activate intensive recording for a different device.

#### *rdev*

identifies the real device involved.

#### LIMIT *nn*

specifies the value at which a recording is made. While intensive recording is active, an error record is made for the first and for every *nn*th qualifying I/O error from the specified device.

#### BYTE *nn*

#### BIT *n*

the BYTE and BIT operands define the test condition in the sense bytes. You can test two bits using an AND or OR relationship. The range for BYTE is 0 through 31; the range for BIT is 0 through 7.

#### AND

#### OR

is the logical operation that you want to perform on two bits of sense data.

### Usage Notes

1. For more information on error recording, see [Collecting Hardware Error Information](#) in *z/VM: System Operation*.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP021E A real device number was not supplied or it is invalid.
- HCP026E Operand missing or invalid
- HCP040E Device {*rdev*/*vdev*/*ldev*} does not exist

## SET REORDER

### Authorization

Privilege Class: B

### Purpose

With the introduction of z/VM memory scalability up to 1T of real memory, the reorder process is no longer supported. The SET REORDER command remains for compatibility purposes. Issuance of SET REORDER ON results in message HCP6005E.

### Operands

#### ON

#### OFF

This function is no longer supported. The default is OFF.

#### FOR

#### USER

are optional keywords to aid in readability of the command.

#### *userid*

applies the command setting to the User Frame Owned list of the specified virtual machine.

#### \*

applies the command setting to the User Frame Owned list of the command issuer's virtual machine.

#### SYSTEM

applies the command to the User Frame Owned lists for all virtual machines and also to the Shared Frame Owned list.

### Usage Notes

- 
**Attention:** This command should be used only when it has been determined that a virtual machine's periodic performance slowdown is the result of the reorder task. You should consult with IBM support personnel before using this command to ascertain whether other system characteristics may be causing the poor performance. See [z/VM Reorder Processing](#) for more information.
- You can use the COMMAND directory statement to specify a reorder setting for a specific virtual machine. The command will be executed after the virtual machine logs on. Any subsequent SET REORDER command to change the system setting will apply to all virtual machines, including those having an individual override in their directory entry who are currently logged on.
- If you issue the SET REORDER command for a specific virtual machine and subsequently issue the SET REORDER command with the SYSTEM keyword, the SYSTEM setting will override the virtual machine's setting. You can, however, change the setting for a specific virtual machine after the SYSTEM setting is as desired.
- The current value of the SYSTEM setting applies to a virtual machine at logon.

## Responses

Reorder is ON|OFF for user *userid*  
Reorder default is ON|OFF for SYSTEM

## Messages

- HCP002E Invalid operand - *operand*
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP045E User not logged on
- HCP6005E Option *option* is not supported by z/VM.

## SET RESERVED

### Authorization

Privilege Class: A

### Purpose

Use SET RESERVED to establish the amount of storage a virtual machine, named saved system (NSS), or discontinuous saved segment (DCSS) is entitled to have resident under normal system operation. The system's frame replenishment task honors the reserved setting when searching for frames to take in order to replenish the available frame lists. CP will not take frames from a virtual machine, NSS, or DCSS if doing so would reduce its resident storage footprint below its reserved storage setting unless a system outage is imminent due to a severe shortage of frames.

This command may also be used to specify a maximum reserved storage setting. The total amount of reserved storage for all virtual machines, NSSs, and DCSSs cannot be set higher than the system maximum.

You should evaluate the storage requirements of your system workload in determining when best to use this command. Overuse can limit its effectiveness and negatively affect overall performance by limiting the frames that can be stolen to satisfy system needs.

### Operands

#### USER

an optional keyword you can use when specifying a virtual machine's user ID.

#### *userid*

\*

identifies the virtual machine. To specify your own virtual machine, enter an asterisk (\*).

#### NSS *filename*

identifies a system data file containing an available NSS.

#### DCSS *filename*

identifies a system data file containing an available DCSS.

#### SPOOLID *spoolid*

identifies a system data file containing an available or pending purge NSS or DCSS. Since multiple instances of an NSS or DCSS can be pending purge, you must identify an NSS or DCSS by spool id if the NSS or DCSS is in the pending purge state.

#### SYSMAX

defines the maximum amount of storage that can be reserved for all virtual machines, NSSs, and DCSSs. If no system maximum is in effect, the total amount of storage that can be reserved is limited to the current size of the dynamic paging area (DPA) at the time the SET RESERVED command is issued. It is recommended you explicitly set a system maximum (via the STORAGE RESERVED SYSMAX statement in the SYSTEM CONFIG file or by using the SET RESERVED SYSMAX command)

rather than rely on the DPA check. The size of the DPA is a floating value that is dependent on workload and CP behavior.

There is no range checking of the system maximum. The command response shows the specified system maximum as a percentage of the DPA and of online real storage. You need to be aware that reserving storage up to or near the size of the DPA will adversely affect system performance. Even when an explicit system maximum is in effect, you will not be able to increase the total amount of reserved storage beyond the size of the DPA at the time the SET RESERVED command is issued.

If your system has reconfigurable storage, it is recommended that you explicitly set the system maximum (via the STORAGE RESERVED SYSMAX statement in the SYSTEM CONFIG file or by using the SET RESERVED SYSMAX command) to a value that is less than the size of permanent storage. This is particularly important when you are planning to reclaim all memory from reconfigurable storage, to make sure the total reserved storage on the system does not exceed the size of permanent storage.

### **frames**

### **storsize**

### **OFF**

is the amount of storage to be reserved for a virtual machine, NSS, or DCSS or to be used as the system maximum. Specify OFF to reset a reserved setting to 0. In the case of SYSMAX, a setting of OFF reverts the system maximum to the current size of the DPA.

The amount of storage to be reserved can be identified by either:

- A 1- to 8-digit decimal count of frames. A frame count of 0 removes a reserved setting and is equivalent to specifying OFF.

Specification of the reserved setting as a count of frames is maintained for compatibility with earlier releases. The SET and QUERY RESERVED command responses always show the reserved value as a storage size even when the setting was originally specified as a count of frames.

- A storage size in format *nu* where *n* is a 1- to 7-digit decimal number and *u* is the 1-character storage unit suffix (M,G,T,P,E).

A storage size of 0 removes a reserved setting and is equivalent to specifying OFF.

## **Usage Notes**

1. To avoid confusion with the CMS SET RESERVED command, you should enter the SET RESERVED command with the CP prefix (for example, `cp set reserved * 10` or you should be in CP Read mode when you enter the command).
2. Unlike the CP LOCK command, SET RESERVED does not guarantee a specific resident page will remain resident, rather it is used to protect the amount of storage a guest, NSS, or DCSS has resident to assist in performance tuning.
3. When establishing a reserved storage setting for a user, the user must be logged on.
4. The maximum amount of storage you can reserve for a user is limited by the amount of private addressable storage in all private address spaces owned by the user's virtual machine. A shared address space is not protected by a user's reserved setting.
5. The maximum number of frames you can reserve for an NSS or DCSS is limited to the number of shared pages in the NSS or DCSS definition. Exclusive pages within an NSS or DCSS are counted as private addressable storage owned by the virtual machine.
6. The DCSS must not be a member segment (filetype DCSS-M) or a segment space (filetype DCSS-S).
7. When an NSS or DCSS with reserved storage is made pending purge (class P), the reserved setting remains until the system data file is actually purged (when it is no longer loaded by any user). Any changes to the reserved setting for an NSS or DCSS in the pending purge state must be done using the SPOOLID form of the SET RESERVED command. You can use the QUERY NSS NAME command to obtain the spoolid for the NSS or DCSS.
8. If a new instance of an NSS or DCSS is created (same filename) and the previous instance had a reserved setting, the reserved setting is not automatically inherited by the new instance. A new SET

## SET RESERVED

RESERVED command must be issued to establish reserved storage for the new instance of the NSS or DCSS.

9. If you specify a value for SYSMAX that is less than the total reserved storage already established, the new SYSMAX value prevents any new reserved storage allocations, but the existing allocations are not affected. Once the total amount of reserved storage drops below the SYSMAX (for example, when a guest with reserved storage logs off), additional reserved storage allocations will be allowed.
10. Increasing the total amount of reserved storage in the system is always subject to the size of DPA at the time the SET RESERVED command is issued, even when the SYSMAX in effect exceeds the size of DPA.

When the total amount of reserved storage is decreased, the new total is compared to the current SYSMAX setting and the size of DPA. If the new total exceeds either SYSMAX or the DPA size, message HCP2548I is issued to inform you the total is set too high. In this case you should further reduce the individual reserved settings for selected virtual machines, NSSs or DCSSs.

11. The frame count specification on the SET RESERVED command is maintained for compatibility. The command response always displays the reserved setting as a storage size.
12. For readability, the storage values displayed in the command response are displayed with the same storage unit. The values for the resident and instantiated storage may be rounded to accommodate the unit specification of the reserved setting. The reserved setting will never be rounded although it may be shown in a smaller unit than entered, when the resident or instantiated storage size is less than the reserved setting, in order to maintain the same storage unit across the line.

If you want precise values for the resident and instantiated counts, you should use the INDICATE USER or INDICATE NSS commands.

13. Reserved settings are not preserved across an IPL.
14. When an NSS/DCSS is removed from storage because it is no longer in use, all of the NSS/DCSS pages are released. The reserved setting is preserved and will be reestablished as pages of the NSS/DCSS are made resident should the file be loaded again.

## Responses

Response 1:

Resource	Type	SPID	Reserved	Resident	Instantiated
userid	USER	----	rsvstorU	resstorU	instanstorU

where:

### **userid**

identifies the virtual machine.

### **USER**

identifies the type of resource as a virtual machine.

----

four dashes are displayed to indicate a spool id is not applicable when Type=USER.

### **rsvstorU**

is the reserved storage setting for this userid in storage units (K,M,G,T,P,E).

### **resstorU**

is the resident storage size for this userid in storage units (K,M,G,T,P,E) at the time the command is issued. This value may be rounded.

### **instanstorU**

is the instantiated storage size for this userid in storage units (K,M,G,T,P,E) at the time the command is issued. This value may be rounded. Since guest pages can exist in multiple levels of the storage hierarchy (for example, in real storage and in auxiliary storage), the instantiated storage may be less than the storage size calculated by summing the guest's page counts for real and auxiliary storage as shown in response to the INDICATE USER command.

Response 2:

Resource	Type	SPID	Reserved	Resident	Instantiated
filename	type	SPID	rsvstorU	resstorU	instanstorU

where:

**filename**

identifies the NSS or DCSS.

**type**

identifies the type of resource as NSS, DCSS, or DCSSG.

**spid**

is the 4-digit spool id associated with an NSS or DCSS. If the file is pending purge, the letter P is appended to the spool id.

**rsvstorU**

is the reserved storage setting for this userid in storage units (K,M,G,T,P,E).

If the reserved value was specified as count of frames on the SET RESERVED command, the value may be rounded to fit within 7-decimal digits plus a storage unit suffix.

**resstorU**

is the resident storage size for this userid in storage units (K,M,G,T,P,E) at the time the command is issued. This value may be rounded.

**instanstorU**

is the instantiated storage size for this userid in storage units (K,M,G,T,P,E) at the time the command is issued. This value may be rounded. Since guest pages can exist in multiple levels of the storage hierarchy (for example, in real storage and in auxiliary storage), the instantiated storage may be less than the storage size calculated by summing the guest's page counts for real and auxiliary storage as shown in response to the INDICATE USER command.

Response 3: Upon successful completion of the SET RESERVED SYSMAX command, the following command response is displayed:

```
SYSMAX = nU    xxx% of pageable storage    yyy% of online storage
```

where:

**nU**

identifies the total maximum allowable amount of reserved storage for all users, NSSs, and DCSSs in storage units (K,M,G,T,P,E).

**xxx%**

specifies the system maximum as an approximate percentage of the Dynamic Paging Area (DPA). The percent value is rounded to the nearest whole percent. When the value is less than .5%, it is shown as <1%.

The size of the DPA varies over time. It includes available frames and those that are pageable at the time the command is issued. A system maximum near the size of DPA can have undesirable effects on performance.

**yyy%**

specifies the system maximum as an approximate percentage of real online storage. The percent value is rounded to the nearest whole percent. When the value is less than .5%, it is shown as <1%.

Response 4: When the reserved setting is set to OFF (or to zero), the following response is displayed:

```
RESERVED is OFF for userid|filename|SYSMAX
OR
RESERVED is OFF for spoolid spoolid
```

**Messages**

## SET RESPOOL

### Authorization

Privilege Class: A

### Purpose

Use SET RESPOOL to change the CPU or storage limit setting for a resource pool. For compatibility with prior releases, CPUPOOL is accepted as a synonym for RESPOOL.

### Operands

#### *poolname*

is the name of the resource pool whose CPU or storage limit setting is to be changed.

#### **CPU LIMITHard *cpulim***

#### **LIMITHard *cpulim***

sets the enforcement of hard CPU limiting for the defined pool such that it does not receive more than *cpulim* percent of the shared logical cores of the type specified on the TYPE operand when the pool was defined. Here, "logical core" refers to a logical CPU when multithreading is not enabled, or to a set of logical processors (threads) currently dispatched on a physical processor core when multithreading is enabled. The *cpulim* value is a decimal whole number (no decimal place) from 1 to 100, followed by a percent sign (for example, 2% or 80%).

#### **CPU CAPacity *cpucap***

#### **CAPacity *cpucap***

sets the enforcement of CPU capacity limiting to the defined pool such that it does not receive an amount of processor resource greater than the equivalent of *cpucap* real cores of the type specified on the TYPE operand when the pool was defined (although the number of logical cores of that type in use simultaneously by the group can exceed *cpucap*). The *cpucap* value is a decimal number (up to two decimal places) from 0.01 to 999 (for example, 2.5 or 8).

#### **CPU NOLIMIT**

clears the enforcement of CPU capacity limiting for the defined pool.

#### **STORage NOLIMIT**

clears the enforcement of memory limiting for the defined pool.

### Usage Notes

1. The SET RESPOOL command can be issued only for a resource pool that has been created with the DEFINE RESPOOL command. For information on the types of CPUs that can be limited, see ["DEFINE RESPOOL"](#) on page 205).
2. Use the SCHEDULE command to assign users to or remove users from the resource pool.

## SET RESPOOL

3. LIMITHARD 100% is equivalent to and reported as CPU NOLIMIT.

### Responses

Response 1:

```
Resource pool poolname is changed
```

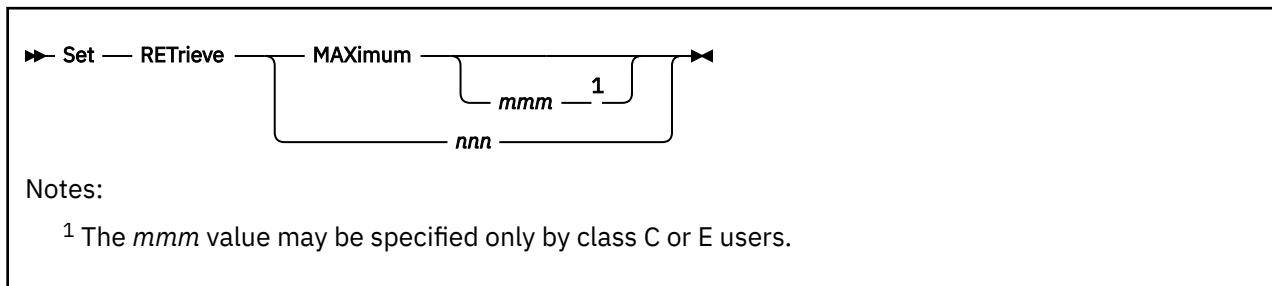

confirms that the resource pool has been changed as requested.

### Messages

## SET RETRIEVE

### Authorization

Privilege Class: C, E, G

### Purpose

Use SET RETRIEVE to allocate a specific number of program function key retrieve buffers for your virtual machine and to change the maximum number of program function key retrieve buffers that users may request.

### Operands

#### MAXimum

sets the number of program function key retrieve buffers available to your virtual machine to the maximum allowed. To set the maximum allowed, you can either use the class C and E SET RETRIEVE command or enter the information in the system configuration file using the FEATURES statement.

#### *mmm*

sets the maximum number of program function key retrieve buffers available to any virtual machine on the system to *mmm*. The value of *mmm* cannot exceed 255.

#### *nnn*

sets the number of program function key retrieve buffers available to your virtual machine to *nnn*. The value of *nnn* cannot exceed the previously defined maximum, which was set either with the FEATURES statement in the system configuration file or with the privileged version of the SET RETRIEVE command.

### Usage Notes

1. Reducing the maximum value *mmm* for program function key retrieve buffers does not affect the current program function key retrieve definitions for any user. Retrieve buffers are not deleted from users that exceed any newly established maximum.
2. After a Class C or Class E user has increased the maximum possible number of retrieve buffers, users do not have to log off to increase the number of program function key retrieve buffers available to their own virtual machines. A new SET RETRIEVE command can be used to increase the number of program function key retrieve buffers without affecting the contents of the existing buffers.
3. For more information on displaying the current number of program function key retrieve buffers available to your virtual machine and the maximum number of buffers that any user may request, see the QUERY RETRIEVE command.

### Examples

If you issue a SET PF $n$  with no parameters (for the PF key you had assigned to RETRIEVE), the number of buffers is set to zero, making your RETRIEVE ineffective.

## SET RETRIEVE

```
q pf1
PF01 RETRIEVE BACKWARD
q retrieve
7 buffers available. Maximum of 20 buffers may be selected.
Ready; T=0.01/0.01 16:06:56
set pf1
Ready; T=0.01/0.01 16:07:04
q retrieve
0 buffers available. Maximum of 20 buffers may be selected.
Ready; T=0.01/0.01 16:07:08
```

If you have two pf keys set for RETRIEVE, for example PF1 and PF12 and you set PF12 to undefined:

```
q pf1
PF01 RETRIEVE BACKWARD
Ready; T=0.01/0.01 16:18:52
q pf12
PF12 RETRIEVE BACKWARD
Ready; T=0.01/0.01 16:18:58
q retrieve
7 buffers available. Maximum of 20 buffers may be selected.
Ready; T=0.01/0.01 16:19:08
set pf12
Ready; T=0.01/0.01 16:19:15
q retrieve
7 buffers available. Maximum of 20 buffers may be selected.
Ready; T=0.01/0.01 16:19:20
```

then it does NOT set the buffer to zero.

SET RETRIEVE works to set a number of buffers for you even if you have no pf keys set to retrieve. However, if you then set your all your pf keys to null, the retrieve buffer is set to zero. Suppose you have only two pf keys set, PF3 and PF5:

```
q pf
PF01 UNDEFINED
PF02 UNDEFINED
PF03 IMMED INFOLIST
PF04 UNDEFINED
PF05 IMMED EXEC MAILBOX
PF06 UNDEFINED
.
PF24 UNDEFINED
Ready; T=0.01/0.01 17:05:03
```

and you set retrieve but then set PF3 and PF5 to null:

```
set retrieve 12
Ready; T=0.01/0.01 17:01:10
q retrieve
12 buffers available. Maximum of 20 buffers may be selected.
Ready; T=0.01/0.01 17:01:14
set pf3
Ready; T=0.01/0.01 17:01:25
set pf5
Ready; T=0.01/0.01 17:01:29
q retrieve
0 buffers available. Maximum of 20 buffers may be selected.
Ready; T=0.01/0.01 17:01:33
```

Your buffer is set to zero.

### Messages

- HCP003E Invalid option - command contains extra option(s) starting with *operand*
- HCP6704E Missing token at end of line

## SET RUN

### Authorization

Privilege Class: G

### Purpose

Use SET RUN to control whether your virtual machine runs while a CP-initiated read is outstanding at your terminal.

### Operands

#### ON

#### OFF

When RUN is set ON, the following differences in virtual machine management occur:

1. If your virtual machine is runnable, it processes instructions even if a CP-initiated read is outstanding at your terminal
2. CP does *not* automatically begin another terminal read when an outstanding read is satisfied
3. If none of your configuration virtual processors are runnable, CP does *not* automatically begin a terminal read.

Initially, RUN is set OFF for all users except the primary system operator.

RUN may not be set ON after a trace trap has been established in an active trace set unless the trace set is suspended. This ensures that the virtual machine is not running during the terminal read that may result when a trace trap springs. Similarly, RUN is automatically set OFF when a trace trap is established in a non-suspended trace set.

### Usage Notes

1. An outstanding CP-initiated read does *not* necessarily indicate that your virtual machine is not executing instructions. When RUN is set ON, your virtual machine may process even with a CP-initiated read outstanding.
2. The SET RUN command allows the operator of a second-level system operating in full-screen mode to press the break key and enter CP commands without unnecessarily delaying the instruction execution of users of that second-level system. Note that when your terminal is operating in line mode, the same effect can be achieved by entering CP commands preceded by #CP, where # represents your logical-line-end character.
3. If your virtual machine is not runnable (for example, it is in a stopped or disabled-wait state), and RUN is set OFF, CP initiates a terminal read. On locally connected terminals and logical devices, this prevents CP from writing messages sent to the user ID. In this situation, RUN can be set ON to prevent CP from initiating the read; this keeps the terminal free for incoming messages.
4. Some CP commands prevent the virtual machine from running until all terminal output associated with the command has been displayed. If the output is delayed, for example, because the screen enters "MORE..." or "HOLDING" state, then the virtual machine will not run. The SET RUN ON command does not affect this behavior.

## SET RUN

Similarly, virtual-machine I/O to the console will be queued during "MORE..." or "HOLDING" state, and the I/O completion will not be reported to the virtual machine until that state is cleared. If the virtual machine voluntarily enters wait state until its console I/O completes, then it will appear unresponsive until the "MORE..." or "HOLDING" condition is cleared.

5. In some cases, SET RUN ON may not enable a user to keep running during a CP-initiated read, or a similar situation. For example, if a console I/O error occurs, the user will not continue to run, and will eventually be FORCED off the system if a DISCONNECT\_TIMEOUT interval is set in the SYSTEM CONFIG file.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid
- HCP1031I SET RUN ON is not allowed when the trace function is active.

## SET SCMEASURE

### Authorization

Privilege Class: B, E

### Purpose

Use SET SCMEASURE to enable or disable the collecting of subchannel measurement data for a specific device or range of devices.

### Operands

#### ON

tells CP to begin collecting subchannel measurement data for the specified device or devices.

#### OFF

tells CP to stop collecting subchannel measurement data for the specified device or devices.

#### *rdev*

#### *rdev1-rdev2*

is the real device number (or numbers) of the device on which you are enabling or disabling subchannel measuring. Each *rdev* must be a hexadecimal number between X'0000' and X'FFFF'. You can specify a single device address, a range of device addresses, or any combination thereof.

**Note:** You cannot specify a device that is eligible for I/O assist.

### Usage Notes

**Format-1 measurement blocks:** When format-1 measurement blocks are being used, measurement blocks are allocated dynamically.

1. Subchannel measurement blocks (SCMBKs) are used to accumulate data about a subchannel, such as rate and utilization information. This subchannel measurement data, which CP Monitor collects in various monitor records, can be useful for analyzing the I/O performance characteristics of a real device.
2. To display whether CP is collecting subchannel measurement data for one or more devices, use the QUERY SCMEASURE command (see [“QUERY SCMEASURE”](#) on page 1149).
3. When a device is first initialized, the default is to enable it for collecting subchannel measurements. To change this default for a given device, use the SCMEASURED or NOTSCMEASURED operands of the DEVICES statement in the system configuration file. For more information about the [DEVICES Statement](#), see *z/VM: CP Planning and Administration*.
4. The SCMEASURED and NOTSCMEASURED operands of the DEVICES statement define the default to be set for a device when it is initialized. You can use the SET SCMEASURE command at any time to change the current setting for a device. That is, if you use the DEVICES statement to indicate that a device should be disabled for collecting subchannel measurements when it is initialized, CP does not prevent you from turning subchannel measuring on for that device after it is initialized.

- The SET SCMEASURE command will assign an SCMBK to a device or return an assigned SCMBK to the available pool to be reused. To obtain information on the number of SCMBKs on your system, use the QUERY SCMBKS command (see [“QUERY SCMBKS”](#) on page 1147).

Format-0 measurement blocks:

- During initialization, CP allocates 1 SCMBK for every subchannel on the system and rounds the amount of storage up to the nearest page boundary. Thus, you have enough SCMBK space for every real device on your system plus some free SCMBK space. How much free SCMBK space you have will vary, depending upon how many real devices you have on your system.
- You should plan for additional SCMBK space if you intend to dynamically add new real devices to your running system. At initialization, you can allocate more free SCMBK space than CP would normally allocate using the SCMBK operand of the STORAGE statement in the system configuration file. For more information, see the [STORAGE Statement](#) in *z/VM: CP Planning and Administration*.
- If you run out of free SCMBK space on a running system and you need to measure additional real devices, you have two choices:
  - Re-IPL and specify more free SCMBK space using the SCMBK operand mentioned in Usage Note [“2”](#) on page 1686, or
  - Stop collecting subchannel measurement data for one or more devices. When you use one of the following commands:
    - DELETE DEVICE (see [“DELETE DEVICE / IODEVICE”](#) on page 265)
    - DELETE IODEVICE (see [“DELETE DEVICE / IODEVICE”](#) on page 265)
    - DELETE RDEVICE (see [“DELETE RDEVICE”](#) on page 274)
    - SET SCMEASURE OFF (see [“SET SCMEASURE”](#) on page 1685)

CP returns the SCMBK assigned to that device (or devices) to the pool of available SCMBKs. It is then available to be used to collect subchannel measurement data for another device.

## Responses

Response 1:

To tell CP to begin collecting subchannel measurement data for devices 127 through 130, enter the following SET SCMEASURE command:

```
set scmeasure on 127-130
Subchannel measuring for device 0127 is on
Subchannel measuring for device 0128 is on
Subchannel measuring for device 0129 is already on
Subchannel measuring for device 012A is already on
Subchannel measuring for device 012B is on
Subchannel measuring for device 012C is on
Subchannel measuring for device 012D is on
Subchannel measuring for device 012E is already on
Subchannel measuring for device 012F is already on
Subchannel measuring for device 0130 is on
Ready;
```

Note that CP was already collecting subchannel measurement data for devices 129, 12A, 12E, and 12F.

Response 2:

To disable subchannel measuring for devices 399 through 402, enter the following SET SCMEASURE command:

```
set scmeasure off 399-402
Subchannel measuring for device 0399 is off
Subchannel measuring for device 039A is off
Subchannel measuring for device 039B is off
Subchannel measuring for device 039C is already off
Subchannel measuring for device 039D is already off
Subchannel measuring for device 039E is off
Subchannel measuring for device 039F is already off
```

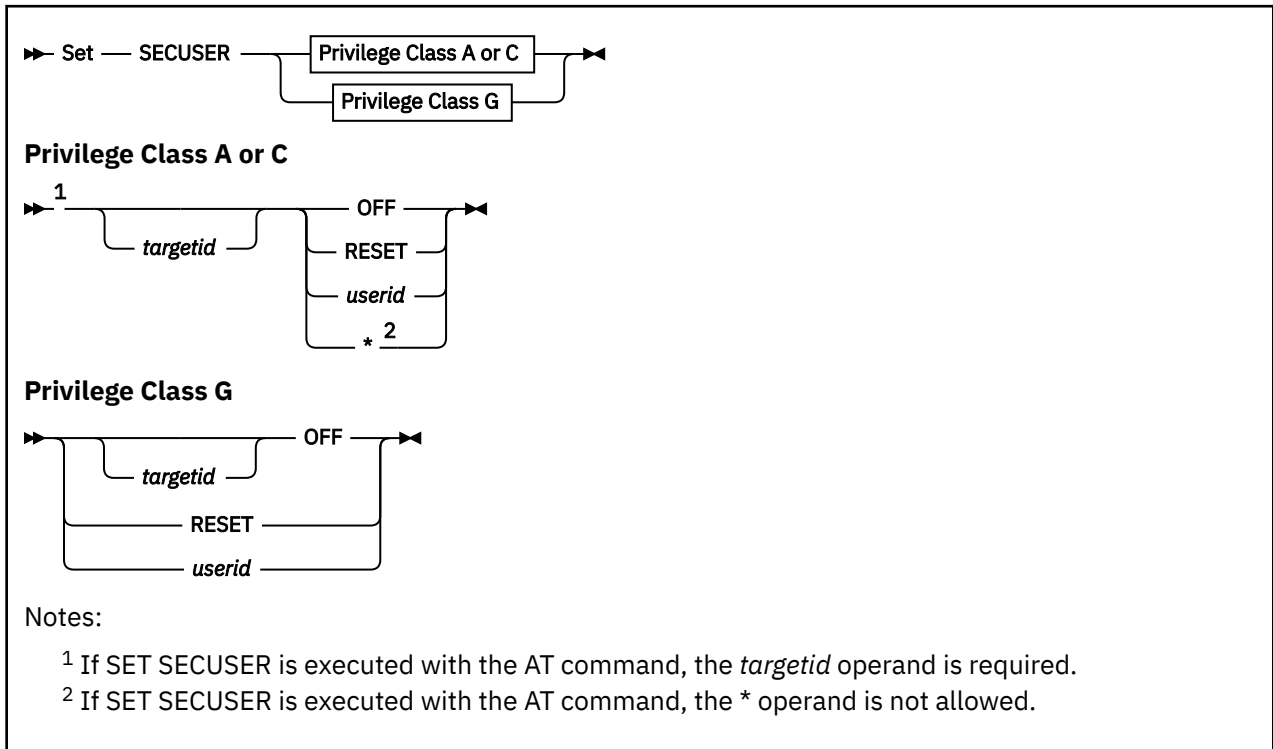

```
Subchannel measuring for device 0400 is off  
Subchannel measuring for device 0401 is already off  
Subchannel measuring for device 0402 is already off  
Ready;
```

Note that CP was not collecting subchannel measurement data for devices 39C, 39D, 39F, 401, and 402.

## SET SECUSER

### Authorization

Privilege Class: A, C, G

### Purpose

Use SET SECUSER to change the secondary user for a virtual machine. The second user is a virtual machine that receives console messages from and can enter commands to the console of a disconnected virtual machine. If you are a class G user, you can change the secondary user for your own virtual machine. If you are a class A or C user, you can change the secondary user for any virtual machine.

### Operands

#### *targetid*

is the user ID of the virtual machine whose secondary user is to be set or reset. If you are a class A or C user and you do not specify *targetid*, CP sets or resets the secondary user for your user ID. If you are a class G user, you can stop being the secondary user for *targetid* by specifying *targetid* OFF.

#### OFF

cancels the secondary user setting. OFF terminates any console sharing with an existing secondary user.

#### RESET

sets the secondary user for *targetid* or the command issuer to the user ID specified on the CONSOLE statement in the user's directory entry.

#### *userid*

is the user ID of the secondary user virtual machine.

#### \*

sets the secondary user to the virtual machine that issues the command.

## Usage Notes

1. If secondary user support is used with large console messages that are close to the free storage limit of X'1FD' doublewords, it is possible that the message could be truncated at the end in order to add the header at the beginning which indicates the user ID from which the message originated.
2. A virtual machine cannot have both a secondary user and an observer defined by any combination of the SET SECUSER and SET OBSERVER commands and the CONSOLE directory statement.
3. If the designated secondary user is currently unable to function in that capacity (for example, not logged on, or disconnected with no connection to \*MSG or \*MSGALL), the setting is nevertheless accepted by CP, and the relationship is established when the specified user ID meets the necessary criteria.
4. In an SSI cluster, the secondary user and the primary user can be logged on to different member systems.

If either user is a multiconfiguration virtual machine:

- The secondary user will function in that capacity only when it is local (logged on to the same member as the primary user). If the primary user is a multiconfiguration virtual machine, the secondary user must be logged on to the member where the SET SECUSER command was issued.
- If the secondary user is remote:
  - The secondary user can issue SEND commands to the primary user. The AT *sysname* operands are required if the primary user is a multiconfiguration virtual machine instance.
  - The secondary user will not receive responses to SEND commands or any other output from the primary user.

## Examples

Example 1:

USERA (a general user) designates USERB (another general user) as its secondary user by issuing the following command:

```
set secuser userb
```

USERB can stop being the secondary user for USERA by issuing the following command:

```
set secuser usera off
```

If USERC is the secondary user for USERD, USERD can remove its secondary user by issuing the following command:

```
set secuser off
```

Example 2:

USERC (a class A or class C user) issues the following command to assign USERD as the secondary user for USERB:

```
set secuser userb userd
```

USERD receives the following message:

```
HCP6768I SECUSER of USERB initiated for you by USERC.
```

At the same time, USERB receives one of the following messages:

```
HCP6768I Your SECUSER set to USERD by USERC.
```

-OR-

## SET SECUSER

```
HCP6769I Your SECUSER terminated by USERC.
```

Example 3:

USERC can remove the secondary user for USERB by issuing the following command:

```
set secuser userb off
```

This causes the user ID that was the secondary user (USERD) to receive the message:

```
HCP6769I SECUSER of USERB terminated for you by USERC.
```

Example 4:

If the command issuer becomes the secondary user, the message issued at initiation is:

```
HCP6768I SECUSER of primary_userid initiated.
```

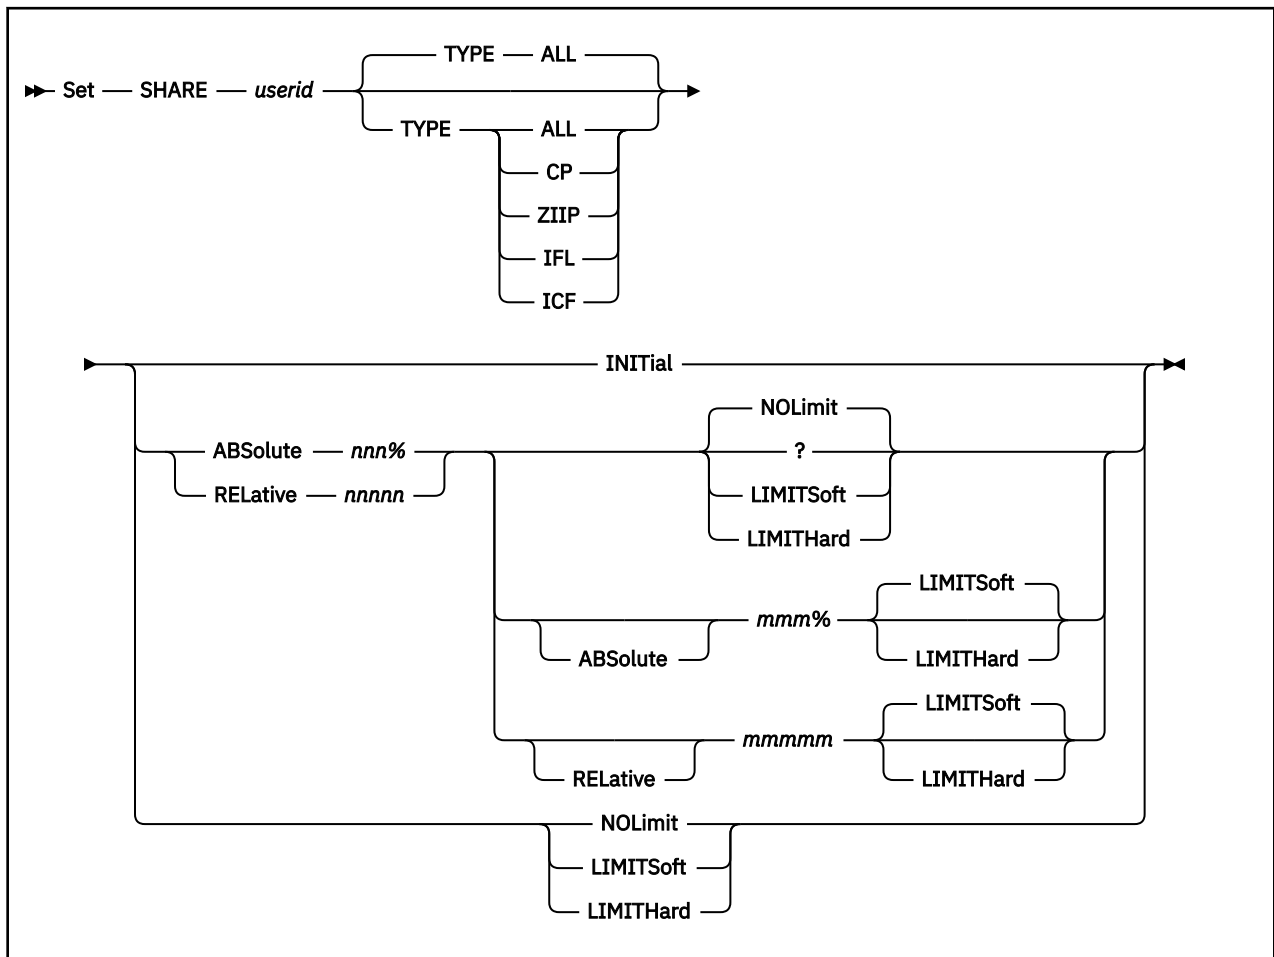

When the secondary user option is terminated, the message issued is:

```
HCP6769I SECUSER of primary_userid terminated.
```

### Messages

- HCP6768I SECUSER for *primary\_userid* of *secondary\_userid* is not functional
- HCP6768I SECUSER of *primary\_userid* initiated.
- HCP6768I SECUSER of *primary\_userid* initiated for you by *userid*.
- HCP6768I Your SECUSER set to *secondary\_userid* by *userid*.
- HCP6769I SECUSER of *primary\_userid* terminated.
- HCP6769I SECUSER of *primary\_userid* terminated for you by *userid*.
- HCP6769I Your SECUSER terminated by *userid*.

## SET SHARE

### Authorization

Privilege Class: A

### Purpose

Use SET SHARE to change the system-resource-access priority for users.

### Operands

#### *userid*

identifies the virtual machine whose share you are changing.

#### **ABSolute** *nnn%*

specifies that this user is to receive a target minimum of *nnn%* of the scheduled system resources, which include CPU, storage, and paging capacity; *nnn* is a decimal real number—no or one decimal place—from 0.1 to 100 (for example, 20.5% or 80%).

#### **RELative** *nnnnn*

specifies that this user is to receive a target minimum relative share of *nnnnn*. The amount of scheduled system resources available to relative share users is the total of resources available less the amount allocated to absolute share users. The portion that this user receives is *nnnnn* divided by the sum of the *nnnnn*'s of all relative share users. For example, if one user's relative share is 100 and another user's relative share is 200, then the second user gets twice as much access to system

## SET SHARE

resources as the first. If no share is specified in a user's directory entry, then the share defaults to a relative share of 100. The operand *nnnn* ranges from 1 to 10000.

### **INITIAL**

specifies that this user's share of the system resources is to be reset to that specified in the user's directory entry. In the rare case that this user ID no longer appears in the directory, the user's share of the system resources is set to a relative share of 100.

### **ABSolute *mmm%***

specifies that this user is to receive a target maximum of *mmm%* of the scheduled CPU resource; *mmm* is a decimal real number—no or one decimal place—from 0.1 to 100 (for example, 20.5% or 80%).

If ABSOLUTE is not specified, the maximum share has the same type as the minimum share. The *mmm%* must be specified when the minimum is an ABSOLUTE value; *mmmm* must be specified when the minimum is a RELATIVE value.

### **RELative *mmmm***

specifies that this user is to receive a target maximum relative share of *mmmm* of the scheduled CPU resource. The operand *mmmm* ranges from 1 to 10000.

If RELATIVE is not specified, the maximum share has the same type as the minimum share. The *mmm%* must be specified when the minimum is an ABSolute value; *mmmm* must be specified when the minimum is a RELATIVE value.

### **NOLimit**

specifies that a user's share of CPU resource is not limited.

### **LIMITSoft**

specifies that a user's share of CPU resource is limited. However, there are times when LIMITSOFT users will receive more than their limit. This occurs when some users are not using all of their shares (for example, they are waiting for I/O to complete), and there are no NOLIMIT users and no users who have yet to reach their limit and can use additional CPU resource.

If a maximum share value was not specified, the user's minimum share is also its maximum share of the CPU resource.

### **LIMITHard**

specifies that a user's share of CPU resource is limited. When LIMITHARD is specified, a user does not receive more than its maximum share of the CPU resource. If a maximum share is not specified, the minimum share is also the maximum.

If a maximum share value was not specified, the user's minimum share is also its maximum share of the CPU resource.

See the SET SRM LIMITHARD command for details of setting the method that the CP scheduler will use to enforce the limit on the guest's CPU usage.

### **TYPE**

specifies that this change to the user's share setting applies to the specified CPU type and that the share settings for other types are not changed. If TYPE is not specified, or if TYPE ALL is specified, this change applies to all CPU types. The determination of whether this setting has an effect on virtual CPUs depends on the CPU affinity setting for the virtual machine and whether real CPUs of the corresponding type are available in the processor configuration. See Usage Note [“8” on page 1693](#) for further details regarding setting share values by CPU type.

## **Usage Notes**

1. You can set a user's system-resource-access priority for each processor type with the SET SHARE command, but some of these processor types are not available in certain processor configurations. The share values are still displayed for the unavailable processor types, but they are not used.
2. Be aware that a user's share denotes priority access to the entire set of system resources, not just CPU. Currently, the following resources are scheduled according to the share specification:

- CPU
- Real storage
- Paging capacity.

In fact, a bottlenecked resource and a user's requirement for it determine the access priority. For example, if storage is constrained, the user receives access to real storage according to its share. Likewise, if paging is a problem, the user receives paging service according to its share.

- An absolute share user is receiving its correct service when the time it would take to complete a task if it were running alone in the system is the inverse of its share percentage. For example, if a user receives 50% (1/2) of the system, it should take no more than twice as long to complete a unit of work as it would if it were running alone. If it gets 25% (1/4) of the system, it should not take more than four times what it would running alone. The gauge of relative share delivery is slightly different. Two relative share users with similar resource requirements can be compared. If the users are limited by the same bottlenecked resource, a RELATIVE SHARE user with twice the SHARE of another should run twice as fast.
- The target maximum share is applicable only to the CPU resource.
 

If a target maximum share is specified, the user will not necessarily receive that amount of scheduled CPU resource. This is because a user will only receive more than the target minimum share for a resource when other users are not using all of their target minimum shares.
- When the limit option is specified alone (that is, without a share and without a maximum share being specified), only that option is changed. The userid retains its previous share and the maximum share is changed (if necessary) to match the new limit option. For example, if NOLIMIT is specified, then the pre-existing maximum share (if any), is reset to zero. Or, if LIMITHARD or LIMITSOFT is specified and there previously was no maximum share, then the maximum share is set equal to the user's minimum share (with the specified 'hard' or 'soft' characteristic).
- Due to the dynamics of VM systems and scheduling, the maximum share target is not always met. The actual usage should be within five percent of the system. The accuracy may be affected by the following:
  - running guest as a virtual MP
  - guest use of diagnose X'44' or X'9C'
  - running VM second level or on LPAR
  - low system utilization
- When setting SHARE RELATIVE on a userid that has multiple CPUs, the minimum share that the system will assign is one per virtual CPU. For example, if you SET SHARE MAINT RELATIVE 1 and MAINT has five virtual CPUs, the resulting SHARE will be set to five.
- When setting the SHARE of a userid that has multiple CPUs in its virtual configuration, there are special considerations. The share for the virtual machine is divided across all of the virtual processors. In the simplest case, if an absolute share of 10% is set for a virtual machine with two shared virtual CPUs, each gets a 5% share of the system's CPU resources. If one of the processors cannot use its 5% share, the other processor does not get more. Each is entitled to 5% of the system individually. If in the above case one of the virtual CPUs has been stopped and the other is started, then the entire 10% share of system resources would be given to the started virtual CPU.

The user's virtual MP configuration can include more than one type of processor, such as CP, IFL, zIIP, or ICF. In this situation, for scheduling purposes each type of processor is treated as a separate resource. There are two cases depending on whether the virtual machine has CPUAFFINITY ON or CPUAFFINITY OFF. In both cases, assume that all virtual CPUs are started.

If CPUAFFINITY is OFF, there is only one real resource pool on which these virtual CPUs can be dispatched—the primary CPU type. The virtual machine's share is distributed evenly across all of its virtual CPUs regardless of CPU type.

If CPUAFFINITY is ON, the virtual machine's share is distributed evenly across each set of virtual CPUs of the same type. As an example, consider a virtual machine with a share of absolute 24% and with two virtual CPUs—one CP and one zIIP. In this case, each virtual CPU will be given a share of

24% of its corresponding type of real processor time. If there are two real CPs and one real zIIP, the virtual CP will be entitled to a 24% share of each CP or 48% of one real CP. The virtual zIIP is entitled to 24% of the zIIP.

Now consider a virtual machine with a share setting of absolute 24% that has four virtual CPs and two virtual zIIPs, all started. In this example, each virtual CP is given a share of 6% of the real CP resources and each virtual zIIP is given a share of 12% of whatever real zIIP resources exist. However, if there are no real zIIPs, CPUAFFINITY is suppressed for the virtual zIIPs and they are dispatched on the real CPs. In that case, all six virtual CPUs are considered to be sharing the CP resources and each is given a 4% share of the real CP processors.

There are several consequences of all this which must be considered when assigning a share value to a virtual MP userid.

- a. The examples above use absolute shares as they are the easiest to visualize. However, the same concepts hold true for relative share settings.
  - b. Each type of CPU resource must be considered as a separate resource that is controlled by the SHARE setting.
  - c. The CPUAFFINITY setting for a virtual machine might have implications for the total CPU time that this virtual machine can receive. This setting can be changed with the SET CPUAFFINITY command, or by varying on a real processor if it is the first of its type, or by varying off a real processor if it is the last of its type.
  - d. Changing the number of virtual CPUs in a virtual configuration might change the actual share of real CPU resource a virtual machine is entitled to if a new type is added to the virtual configuration or the last of one type is removed from the configuration.
9. CP calculates and enforces consumption limits in a different manner than deadline limits. A virtual machine is consumption limited when the following conditions exist:
- The virtual machine is assigned an ABSOLUTE LIMITHARD share.
  - CONSUMPTION limiting (SET SRM LIMITHARD CONSUMPTION) is in effect on the system.

For consumption limits, CP always assumes that every logical CPU can run to 100% busy, regardless of the LPAR's entitlement and regardless of the availability of excess power on the CPC. For example, if the system has five shared logical IFL CPUs, CP assumes that the shared IFL CPU resource has a total capacity of 500%. If the virtual machine in this case is assigned an ABSOLUTE LIMITHARD share of 50% for TYPE IFL, the virtual machine will be allowed to consume a CPU capacity of 250% (that is, 2.5 CPUs of power). If PR/SM is limiting the LPAR's five logical IFL CPUs to 280% total capacity, CP will still allow the virtual machine to consume 250%. In that case, CP is really allowing the virtual machine to consume  $(250/280) = 89\%$  of the IFL CPU resource available to the LPAR. If DEADLINE limiting (SET SRM LIMITHARD DEADLINE) is in effect on the system, the virtual machine will be allowed to consume approximately  $(50 * 280) = 140\%$  of the IFL CPU capacity, because DEADLINE limiting considers the actual amount of CPU resource available to the LPAR.

10. When APAR VM65680 is applied and multithreading is enabled, prorated core time is used in the consumption limiting calculation for a virtual machine being consumption limited. When multithreading is not enabled or APAR VM65680 is not applied, raw CPU time is used instead. For an explanation of the different measures of CPU time, see [Simultaneous Multithreading \(SMT\) in z/VM: Performance](#).
11. Share settings control access to CPU power on a system-wide, per-processor-type basis, but they have no bearing or influence on how the power associated with a RESPOOL is distributed to its members. When the RESPOOL limit is reached, all members of the pool are put onto the limit list for a while, and then, after a delay sufficient to compensate for any excess use, they are all removed. The scheduler makes no effort to distribute the power of the RESPOOL to its members in accordance with the members' share settings.

## Responses

Response 1:

```
USER userid: CP   share_type SHARE = value
                  MAXIMUM SHARE = option share_type value
IFL  share_type SHARE = value
                  MAXIMUM SHARE = option share_type value
ICF  share_type SHARE = value
                  MAXIMUM SHARE = option share_type value
ZIIP share_type SHARE = value
                  MAXIMUM SHARE = option share_type value
```

is issued when the command completes successfully. See [“QUERY SHARE” on page 1161](#) for field descriptions.

## SET SHARED

### Authorization

Privilege Class: B

### Purpose

Use SET SHARED to control whether a full-pack minidisk is to be shared by the users of many real and virtual systems.

### Operands

**ON**

**OFF**

indicates that the device is shared or not shared among multiple real and virtual systems.

*rdev*

*rdev1-rdev2*

is the real device number or range of real device numbers of the devices to be shared.

### Usage Notes

1.  **Attention:** Use SET SHARED OFF with extreme caution and only after careful consideration.
2. You should contact the operators of the systems that are sharing the device to assure that they mark a device as unusable in their system configuration and physically disable their interfaces to that device *before* you enter the SET SHARED OFF command.
3. You may use this command to tell CP whether to issue real reserve/release CCWs to the device associated with the full-pack minidisk.
4. When you SET SHARED OFF for a full-pack minidisk, that device is *not* released by CP. If the device is currently reserved by CP for a user, it remains reserved until that user issues a release to that device.
5. You can determine the SHARED status of system DASD by issuing the class B QUERY DASD RESERVE command.
6. When you SET SHARED ON for a device, minidisk caching is turned off for the device. If minidisk caching is desired, it must specifically be set on via the SET MDCACHE command.
7. This command will be rejected for full-pack minidisks if working allegiance (SET WRKALLEG) has been turned on for one of the device's associated minidisks. Working allegiance is simulated to ensure data integrity among users sharing the same minidisk on the same VM system. Sharing real devices on the same minidisk is not allowed.

### Responses

Response 1:

```
SHARED SET {ON } FOR rdev
           {OFF }
```

is issued when the command completes successfully.

## Messages

- HCP026E Operand missing or invalid
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP2003E Shared not set for *type rdev*; not a shared device.
- HCP2004E Shared not set for *type rdev*; does not support reserve/release.
- HCP2006E Shared not set for DASD *rdev*; device not online.
- HCP2007E Shared not set for DASD *rdev*; WRKALLEG is ON for user *userid*, minidisk *vdev*.
- HCP6000E The range of device numbers cannot exceed 256.

## SET SHUTDOWNTIME

```
►► Set — SHUTDOWNtime — interval ◄◄
```

### Authorization

Privilege Class: A, C

### Purpose

Use the SET SHUTDOWNTIME command to specify the CP shutdown interval. The CP shutdown interval is the time that is reserved for CP to shut down when a SHUTDOWN command is issued or the entire z/VM system shuts down automatically as the result of receiving a hardware deactivation signal.

The SET SHUTDOWNTIME command specifies how much of the entire z/VM system-shutdown interval is reserved for CP shutdown. The entire z/VM system-shutdown interval might also include a shutdown-signal timeout interval, which provides time for guest operating systems to shut down. A shutdown-signal timeout interval occurs only if the CP shutdown interval is less than the entire z/VM system-shutdown interval.

### Operands

#### *interval*

specifies the amount of time that is reserved for a CP shutdown to be completed. The value specifies the number of seconds in the range 0 - 32767.

If the CP shutdown time is not specified in the SET SHUTDOWNTIME system configuration statement or by issuing the SET SHUTDOWNTIME command, the default is 30 seconds.

### Usage Notes

1. The CP shutdown interval is an estimation of the time that CP requires to complete an orderly CP shutdown. If CP requires more time to shut down, the actual interval can be longer.
2. The SET SHUTDOWNTIME command dynamically overrides the specified or default value of the SET SHUTDOWNTIME system configuration statement, or the value specified on a previous SET SHUTDOWNTIME command for the current system IPL.
3. The interval that is specified on this command can affect the interval that is designated for the entire z/VM system shutdown process.

If the CP SHUTDOWN command is issued without a WITHIN, BY, or IMMEDIATE operand, the start of the CP shutdown process can be delayed. The start of the CP shutdown process is delayed until the system-default shutdown-signal timeout interval elapses or until all signaled guests indicate that they shut down, whichever occurs first. The time that is designated for the entire z/VM system to shut down is the sum of the system-default shutdown-signal timeout interval and the CP shutdown interval. The entire z/VM system shutdown can take less time than the sum of the system-default shutdown-signal timeout interval and the CP shutdown interval if one or both of the following conditions occur:

- All signal-enabled guests shut down before the system-default shutdown-signal timeout interval elapses.
- The CP shutdown process finishes in less time than is reserved by the CP SET SHUTDOWNTIME specification.

Use caution when you specify the WITHIN, BY, or IMMEDIATE operand on the SHUTDOWN command. The WITHIN, BY, or IMMEDIATE operand specifies the time interval for the entire z/VM system shutdown. The actual shutdown-signal timeout interval is the difference between the entire z/VM

system shutdown interval and the CP shutdown interval. The actual shutdown-signal timeout interval might not provide guests with enough time to complete an orderly shutdown.

For examples of the interaction between the SHUTDOWN command timing operands, the CP shutdown interval, and the system-default shutdown-signal timeout interval, see [“Examples” on page 1794](#) in the SHUTDOWN command topic.

**Tip:**

- The system-default shutdown-signal timeout interval is specified by the SET SIGNAL SHUTDOWNTIME command or system configuration statement. For information about the system-default shutdown-signal timeout interval, see [“SET SIGNAL” on page 1701](#).
  - The CP shutdown interval is specified by the SET SHUTDOWNTIME command or system configuration statement.
4. When a CP shutdown occurs due to a hardware deactivation, if the SHUTDOWNTIME is more than 300 seconds (5 minutes), there is not time for guests to shut down.

## SET SHUTSIGNAL

### Authorization

Privilege Class: G

### Purpose

Use SET SHUTSIGNAL to temporarily disable and later to re-enable this user for shutdown signals.

The intended use of SET SHUTSIGNAL OFF is to allow a subset of users to be temporarily disabled from receiving shutdown signals while the remaining set of users that are enabled for shutdown signals are shut down using the SIGNAL SHUTDOWN command. Later, the disabled users can be re-enabled with the SET SHUTSIGNAL ON command, and then signaled to shut down via the SIGNAL SHUTDOWN command. This allows for an ordered shutdown of users.

The SET SHUTSIGNAL command is valid only when a guest operating system is running in the virtual machine and has enabled for shutdown signals.

### Operands

#### OFF

temporarily disables this user from receiving shutdown signals.

#### ON

ends the temporary disablement for shutdown signals imposed by the SET SHUTSIGNAL OFF command.

### Usage Notes

1. SET SHUTSIGNAL OFF should be used with extreme caution because it will prevent disabled users from receiving a shutdown signal when the z/VM system is about to shut down. These users will be stopped with no warning when the z/VM system shuts down.
2. Users that disable for shutdown signals with the SET SHUTSIGNAL OFF command will not be logged off following the timeout of a shutdown signal generated by the SIGNAL SHUTDOWN command.
3. Any shutdown signals that are not presented to a user due to being disabled by the SET SHUTSIGNAL OFF command will not be presented when the user re-enables for shutdown signals with the SET SHUTSIGNAL ON command.
4. Any action initiated by the guest operating system to modify its enablement for shutdown signals will clear any existing disablement for the user from a previously issued SET SHUTSIGNAL OFF command.
5. The QUERY SIGNALS command can be used to determine whether a user is currently enabled to receive shutdown signals.

### Messages

- HCP002E Invalid operand *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP02115E The operating system running in the virtual machine is not enabled for shutdown signals.
- HCP06704E Missing token at end of line

## SET SIGNAL

```
►► Set — SIGNAL — SHUTDOWNtime — interval ◄◄
```

### Authorization

Privilege Class: A, C

### Purpose

Use SET SIGNAL to specify the system-default shutdown-signal timeout interval.

### Operands

#### SHUTDOWNtime *interval*

specifies the duration of the system-default shutdown-signal timeout interval. The *interval* specifies a number of seconds in the range 0 - 32767. If the system-default shutdown-signal timeout interval is not specified by the SET SIGNAL SHUTDOWNTIME command or system configuration statement, the default is 0 seconds.

If a SIGNAL, FORCE, or SHUTDOWN command is issued without specifying an interval, the system-default shutdown-signal timeout interval specifies the interval for guest operating systems to complete their shutdown processing. If the interval value is greater than 0, a shutdown signal is sent to enabled users. If the interval value is 0, shutdown signals are suppressed.

### Usage Notes

1. The SET SIGNAL SHUTDOWNTIME command dynamically overrides the specified or default value of the SET SIGNAL SHUTDOWNTIME system configuration statement, or the value that was specified on a previous SET SIGNAL SHUTDOWNTIME command, for the current system IPL.
2. A user is enabled for signals only when a guest operating system is running in the virtual machine and is enabled to receive these signals.
3. The interval that is specified on this command can affect the interval that is designated for the entire z/VM system shutdown process.

If the CP SHUTDOWN command is issued without a WITHIN, BY, or IMMEDIATE operand, the start of the CP shutdown process can be delayed. The start of the CP shutdown process is delayed until the system-default shutdown-signal timeout interval elapses or until all signaled guests indicate that they shut down, whichever occurs first. The time that is designated for the entire z/VM system to shut down is the sum of the system-default shutdown-signal timeout interval and the CP shutdown interval. The entire z/VM system shutdown can take less time than the sum of the system-default shutdown-signal timeout interval and the CP shutdown interval if one or both of the following conditions occur:

- All signal-enabled guests shut down before the system-default shutdown-signal timeout interval elapses.
- The CP shutdown process finishes in less time than is reserved by the CP SET SHUTDOWNTIME specification.

Use caution when you specify the WITHIN, BY, or IMMEDIATE operand on the SHUTDOWN command. The WITHIN, BY, or IMMEDIATE operand specifies the time interval for the entire z/VM system shutdown. The actual shutdown-signal timeout interval is the difference between the entire z/VM system shutdown interval and the CP shutdown interval. The actual shutdown-signal timeout interval might not provide guests with enough time to complete an orderly shutdown.

## SET SIGNAL

For examples of the interaction between the SHUTDOWN command timing operands, the CP shutdown interval, and the system-default shutdown-signal timeout interval, see [“Examples” on page 1794](#) in the SHUTDOWN command topic.

### Tip:

- The system-default shutdown-signal timeout interval is specified by the SET SIGNAL SHUTDOWNTIME command or system configuration statement.
- The CP shutdown interval is specified by the SET SHUTDOWNTIME command or system configuration statement. For information about the CP shutdown interval, see [“SET SHUTDOWNTIME” on page 1698](#).

### Messages

- HCP002E Invalid operand - *operand*

- HCP6706E Invalid string - *string*
- HCP6706E Invalid time - *time*

## SET SMSG

### Authorization

Privilege Class: G

### Purpose

Use SET SMSG to control whether your virtual machine accepts special messages.

### Operands

#### ON

#### OFF

determines whether your virtual machine receives special messages. If you specify OFF, the virtual machine cannot receive special messages. If you specify ON, the virtual machine can receive special messages. At logon, SMSG is set to OFF.

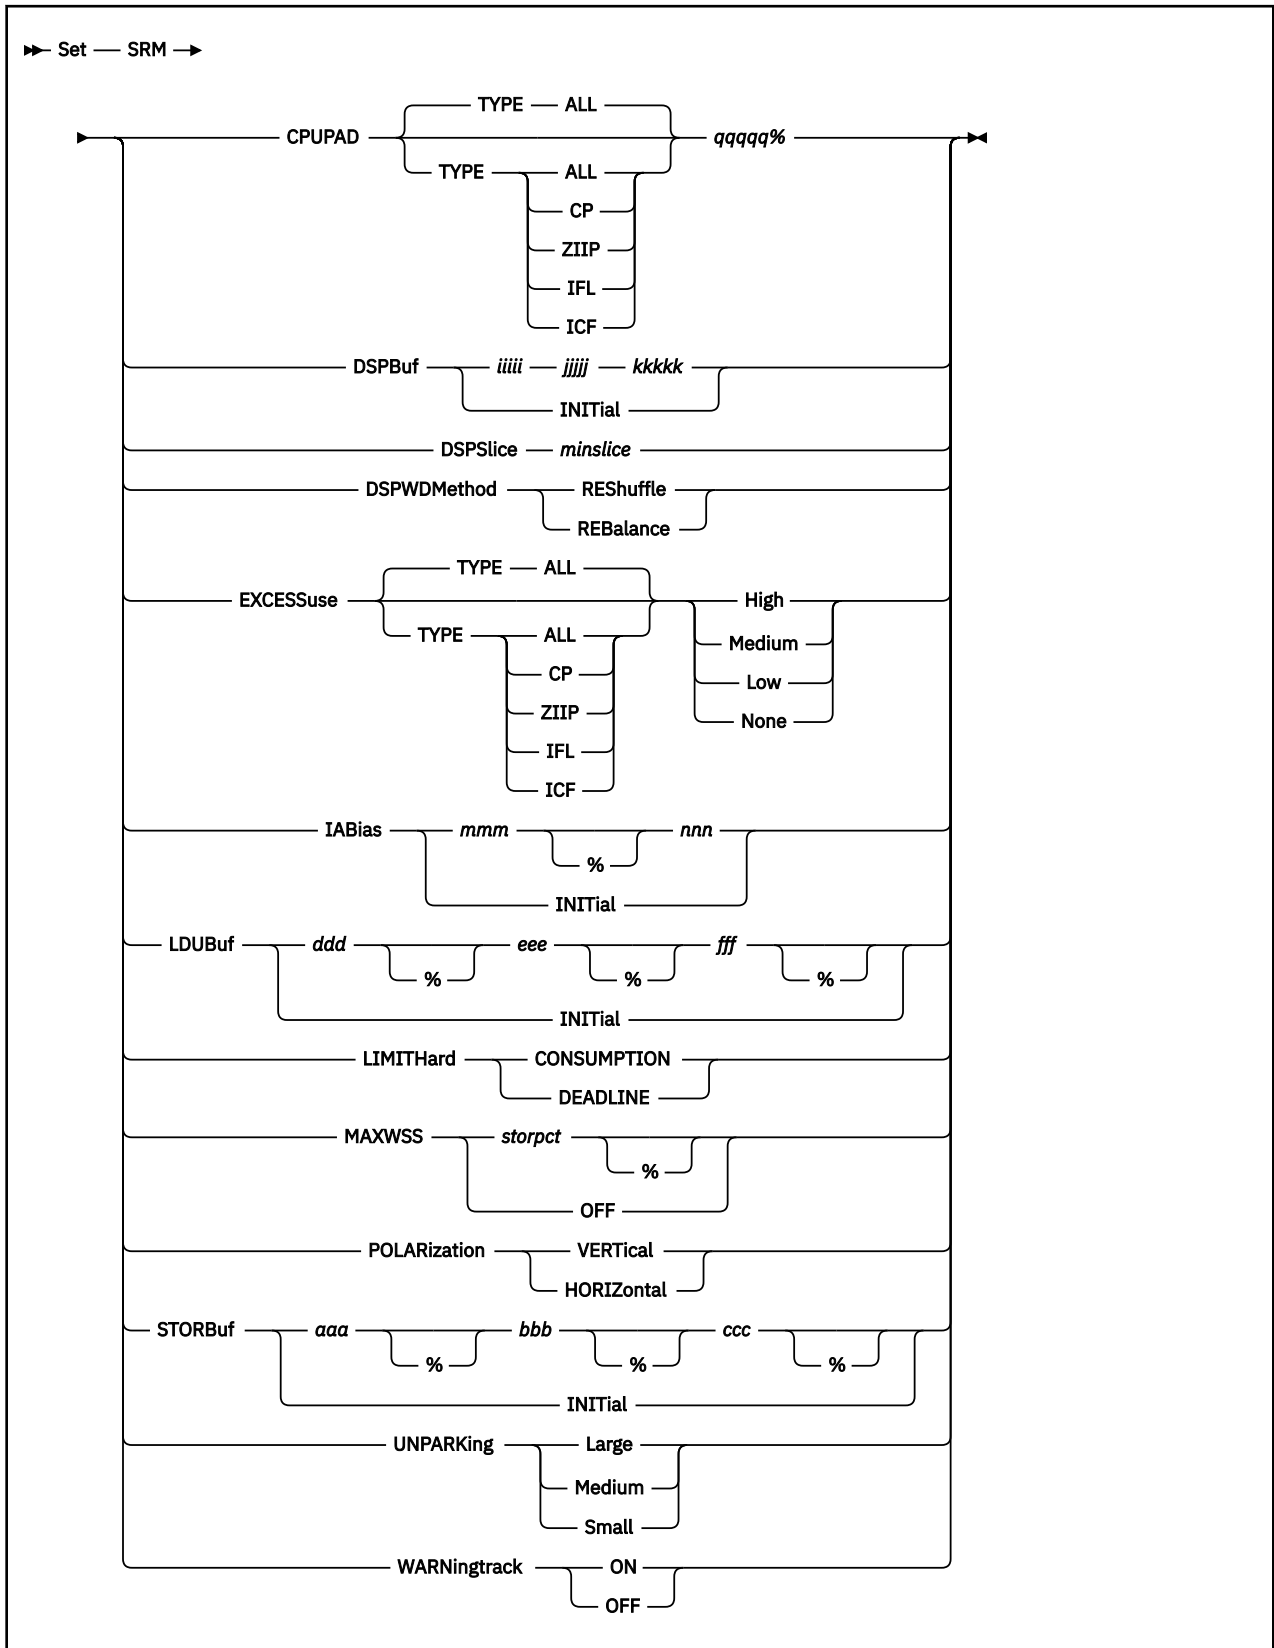

#### IUCV

specifies that special messages are to be passed to the virtual machine through IUCV if a connection to the message system service exists. If no IUCV connection exists, the message is handled as if SET SMSG ON had been issued.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid

# SET SRM

## Authorization

Privilege Class: A

## Purpose

Use SET SRM (system resource manager) to change system parameters.

## Operands

### CPUPAD TYPE

specifies the CPU type pool to which the CPUPAD setting applies.

### CPUPAD *qqqqq%*

specifies the amount of additional CPU capacity the system should be prepared to consume beyond what the system projects it will need. *qqqqq* is a value from 0 through 08000, which represents the amount of additional CPU capacity as a percentage of an entire CPU. A value of 100 represents an entire CPU. This setting applies only when the system is running in vertical polarization mode. When the system's projection plus the specified amount of additional CPU capacity exceeds the partition's entitlement, this value might not be used in determining how many CPUs are unparked. A value of 100 is the system default setting.

For additional information on CPUPAD and HiperDispatch, see the [SRM Statement](#) and [The Objective of z/VM HiperDispatch](#) in *z/VM: CP Planning and Administration*.

When multithreading is enabled, this value specifies the amount of additional core capacity the system should be prepared to consume beyond what the system projects it will need. A value of 100 represents an entire core.

### DSPBuf *{iiii jjjj kkkkk}*

gives the scheduler criteria for admitting users to the dispatch list in cases of users who are not prevented from entering by the more resource-specific barriers established by STORBUF and LDUBUF. DSPBUF stands for “dispatch buffer” and refers to the total number of users (by class) that are allowed in the dispatch list.

**Note:** CP's virtual processor management has been improved so that no user stays in the eligible list more than an instant before being added to the dispatch list. Therefore some functions intended to improve performance by managing the eligible list, such as the DSPBUF option, are now less meaningful.

The operand *iiii* refers to the number of openings in the dispatch list made available to users with short-running (E1) transactions. A subset, *jjjj*, of the *iiii* openings is also made available to users with medium-length transactions; the E1 and E2 users compete for these slots. Another subset, *kkkkk*, of the *jjjj* openings is also made available to users with long-running transactions; the E1, E2, and E3 users all compete for these slots. QUICKDSP and other E0 users are not limited by these numbers and may enter the dispatch list without limit.

The valid range of values is 1 to 32767 where  $iiii \geq jjjj \geq kkkkk$

**Example:** `dsdbuf 35 30 18`

35 openings are available to E1 users, but only 5 of them ( $5 = 35 - 30$ ) are exclusively available to E1 and are guaranteed not to be already occupied by E2 and E3 users.

30 openings are available to E2 users, but only 12 of them ( $12 = 30 - 18$ ) are guaranteed not to be already occupied by E3 users. None of the 30 openings is guaranteed against occupation by E1 users; however, E1 users generally get out of the way quickly.

18 openings are available to E3 users, but none of the openings is guaranteed against occupation by E1 and E2 users. When E1 and E2 users do occupy these openings, you can expect them to get out of the way relatively quickly compared with the time scale of an E3 transaction.

**DSPBuf INITIAL**

sets the parameters back to their initial values which, for practical purposes, are infinity.

**DSPSlice minslice**

is the new size, in milliseconds, of the dispatching minor time slice. This is the amount of CPU time a virtual machine may consume before reexamination by the scheduler. The value *minslice* must be in the range of 1 to 100.

**DSPWDMethod REShuffle**

sets the dispatcher work distribution algorithm to reshuffle. This algorithm periodically alters the home assignments of active virtual CPUs in an attempt to balance the number of virtual CPUs on all dispatch vectors. Unless a system configuration file SRM statement or a CP SET SRM command changes the work distribution algorithm, the system uses the reshuffle algorithm.

When multithreading is enabled, the only algorithm supported is reshuffle.

**DSPWDMethod REBalance**

sets the dispatcher work distribution algorithm to rebalance. This algorithm tracks virtual machine CPU utilization and periodically alters the home assignments of virtual CPUs in an attempt to balance the CPU demand on dispatch vectors. This option should be used with caution. Use this option only when specifically instructed to do so by IBM.

For additional information on DSPWDMETHOD and HiperDispatch, see the [SRM Statement and The Objective of z/VM HiperDispatch in z/VM: CP Planning and Administration](#).

When multithreading is enabled, the only algorithm supported is reshuffle.

**EXCESSuse**

specifies how aggressively the system should attempt to use unentitled CPU capacity. This setting applies only when the system is running in vertical polarization mode, and affects how aggressively vertical-low CPUs are used to consume unentitled CPU capacity.

**EXCESSuse TYPE**

specifies the CPU type pool to which the EXCESSUSE setting applies.

**EXCESSuse High**

specifies that the system should be aggressive in using unentitled CPU capacity.

**EXCESSuse Medium**

specifies that the system should be moderately aggressive in using unentitled CPU capacity. This is the system default setting.

**EXCESSuse Low**

specifies that the system should not be aggressive in using unentitled CPU capacity.

For additional information on EXCESSUSE and HiperDispatch, see the [SRM Statement and The Objective of z/VM HiperDispatch in z/VM: CP Planning and Administration](#)

**EXCESSuse None**

specifies that vertical-low logical cores should always be parked when global performance data (GPD) is available (GPD-on).

**IABias [mmm[% ] nnn]**

specifies the new "interactive bias" to take effect. An interactive bias with a nonzero *mmm* causes users doing trivial transactions to receive better service than their scheduling share would otherwise entitle them to receive. Interactive bias causes a user's share of the system to be momentarily larger than normal at the start of a new transaction. As the transaction progresses, the user's share fades back to normal. This means that transactions requiring only a small fraction of processing time get good response time.

The value *mmm* is a percentage of the distance from the user's normal dispatch-list position to the topmost user. It controls the "intensity" of the interactive bias. This value is a decimal number from 0 to 100, with initial IPL value of 90. The intensity determines where in the dispatch list the user is inserted for the first minor time slice at the start of a new transaction. The insertion point is somewhere between the normal (unbiased) insertion point and the topmost user in the list. A value of 100 gives a very strong interactive bias, and 0 eliminates the interactive bias.

The value *nnn* controls the duration of the interactive bias. This value is a decimal number from 1 to 100, with initial IPL value of 2. The duration specifies the number of minor time slices it takes for users to fade back to their normal position in the dispatch list after the initial interactive boost. For example, a setting of 3 means the boost to the user lasts for 3 minor time slices. The effect is strongest on the first time slice and fades away until on the third time slice the user receives only a small boost in the dispatch list. On the fourth and subsequent time slices the user receives no interactive boost at all.

If *mmm* is specified without *nnn*, the current interactive bias duration is not changed.

#### **IABias INITIAL**

sets the intensity (*mmm*) and duration (*nnn*) back to the initial values, 90 and 2.

#### **LDUBuf {ddd[%] eee[%] fff[%]}**

partitions the commitment of the system's paging resources when the scheduler chooses users to move from the eligible list to the dispatch list. The result is a paging capacity buffering mechanism based on the transaction class of a user. (See the description of the STORBUF parameter in this command for a definition of transaction classes.)

**Note:** CP's virtual processor management has been improved so that no user stays in the eligible list more than an instant before being added to the dispatch list. Therefore some functions intended to improve performance by managing the eligible list, such as the LDUBUF option, are now less meaningful.

During system initialization, the number of paging DASD exposures is determined. Users expected to have high paging rates in the dispatch list are termed "loading users." They are identified by recent DASD paging activity or with the knowledge that their working sets have been moved to DASD since they last ran. One loading user is regarded as keeping one paging exposure busy. The LDUBUF (loading user buffer) percentages, then, determine the number of loading users allowed in the dispatch list by transaction class.

The SET SRM LDUBUF parameters partition the paging capacity as follows:

#### **ddd[%]**

is the percentage of paging exposures the scheduler is to view when considering adding a loading E1, E2, or E3 user to the dispatch list. If the total number of loading users currently in the dispatch list plus the loading *En* user under consideration exceeds the *ddd* percentage of paging exposures, the user may not be added immediately and is delayed further.

#### **eee[%]**

is the percentage of paging exposures the scheduler is to view when considering adding a loading E2 or E3 user to the dispatch list. If the number of Q2 and Q3 loading users currently in the dispatch list plus the loading E2 or E3 user under consideration exceeds the *eee* percentage of paging exposures, the user may not be added immediately and is delayed further.

#### **fff[%]**

is the percentage of paging exposures the scheduler should view when considering adding a loading E3 user to the dispatch list. If the number of Q3 loading users currently in the dispatch list plus the loading E3 user under consideration exceeds the *fff* percentage of paging exposures, the user may not be added immediately and is delayed further.

Note that in order to enter the dispatch list, an E1 user must only pass the one barrier established by *ddd*. But an E2 user must pass the two barriers set by *ddd* and *eee*. And an E3 user must pass the three barriers set by *ddd*, *eee*, and *fff*. This is exactly analogous to the operation of STORBUF, though STORBUF was explained differently. Similarly, the differences between the values (*ddd-eee* and *eee-fff*) represent LDUBUF buffers (for Q1 and Q2 respectively), just as they do for STORBUF.

In each case, the LDUBUF values must be in the range 0 through 999, with a restriction that *ddd* ≥ *eee* ≥ *fff*. Any value greater than 100 represents an overcommitment of DASD paging capacity.

#### **LDUBuf INITIAL**

sets the percentage parameters back to their initial values, 100%, 75%, and 60%.

**LIMITHard**

sets the enforcement of hard limiting of scheduled system resources. This setting only affects users with absolute maximum shares defined with the SET SHARE command or the SHARE directory statement.

**LIMITHard CONSUMPTION**

is the method for enforcing hard limiting based on the guest's measured processor utilization. The CONSUMPTION method is generally more accurate than the DEADLINE method. CONSUMPTION is the system default that is set at initialization time and remains in effect unless the SET SRM LIMITHARD command is issued to change it.

**LIMITHard DEADLINE**

is the traditional method for enforcing hard limiting. It enforces limits based on a calculated deadline and defines the projected instant in time when a guest should complete a timeslice. In most workloads, the CONSUMPTION method will give more accurate results.

**MAXWSS storpct[%]**

sets the maximum working set that any normal user is allowed to have. It is specified as a percentage of the system's pageable real storage. (Pageable real storage is also known as the *dynamic paging area*, *DPA*, or *paging pool*.) If a user's working set size (WSS) grows and exceeds this specified percentage of the pageable real storage, the user is dropped from the dispatch list and put back in the eligible list.

When a user is put in the eligible list for exceeding the MAXWSS, that user is treated as though the user's stay in the dispatch list had run to completion. The user is advanced to the next user class (for example, Q3) and is placed well out in the eligible list so that the user does not immediately get back into the dispatch list to run again. The intent is to delay the user for a while to prevent the user from occupying any more pages than the user already does: the installation has told the scheduler (through the MAXWSS setting) that a user requires a working set size too large to be run. (For example, the installation does not want such large WSS users competing with the normal, more interactive, workload.) Still, the user travels through the eligible list and gets another chance to run, although it is likely that all of this user's page frames will, in the meantime, have been stolen and given to other users. When the user does get to run again, the scheduler again evaluates the working set size: a user with too great a working set size (WSS) requirement gets to run only briefly before the MAXWSS mechanism removes the user from the dispatch list again.

For all this to work as intended, the system must have an actual eligible list—that is, the scheduler must consider the system to be storage constrained according to the setting of the SET SRM STORBUF parameters.

If the MAXWSS percentage is set larger than the STORBUF percentages, the STORBUF percentages take precedence. A user is dropped from the dispatch list and sent to the eligible list if the user's WSS grows so large that it exceeds the STORBUF percentage for that user's class. When this happens, the user never gets a chance to grow large enough to reach the MAXWSS percentage.

Effectively, the MAXWSS control is inoperative when it is set larger than the STORBUF percentages. The value specified for MAXWSS may range up to 9999%.

Users having absolute shares are given special consideration. If a user's absolute share is larger than the MAXWSS percentage, the user is allowed to grow beyond the MAXWSS percentage and to become as large as the user's absolute share percentage. However, such users are still limited by the STORBUF percentage. Having a large absolute share allows a user to exceed the MAXWSS control but not the STORBUF control.

The MAXWSS control does not affect Q0 users, such as users with the QUICKDSP attribute.

**MAXWSS OFF**

sets the MAXWSS percentage to 9999%, effectively turning the mechanism off. (In other words, with the limit set high enough, it is in effect no longer a limit.) This is the initial setting.

**POLARization VERTical**

requests that z/VM and PR/SM operate the partition in vertical polarization mode. In vertical polarization mode, the partition's logical CPUs have differing entitlements to physical CPU resources. Some logical CPUs are entitled to an entire physical CPU, while others are entitled to only a fraction of

a physical CPU or perhaps to only the unused CPU entitlements left unconsumed by other partitions. Further, in a vertical polarization mode partition, PR/SM dispatches high entitlement logical CPUs on the same physical CPUs over and over again, thereby preserving accumulated cache contents. When z/VM runs in a vertical polarization mode partition, z/VM tends to run the system's workload on fewer logical CPUs, tends to keep MP guests' virtual CPUs together with respect to the partition's cache topology, and tends not to move virtual CPUs among logical CPUs. In aggregate, these behaviors tend to improve system performance.

When multithreading is enabled, only vertical polarization is supported.

### **POLARization HORIZontal**

requests that z/VM and PR/SM operate the partition in horizontal polarization mode. In a horizontal polarization mode partition, each online (configured) logical CPU of a particular CPU type gets an equal portion of the partition's weight for that CPU type. For instance, if a partition with 16 online logical CPUs of type CP had a PR/SM weight which entitled those logical CPUs to 8 real CPUs of type CP, then each of the 16 logical CPUs would be entitled to 50% of a real CPU; and when all other partitions consume their entitlement, these 16 will get no more than their 50% of a real CPU. Further, in a horizontal polarization mode partition, PR/SM puts less emphasis on holding logical CPUs fixed on physical CPUs, and z/VM tends to spread work evenly over the online logical CPUs and tends to let virtual CPUs move from one logical CPU to another fairly freely.

When multithreading is enabled, only vertical polarization is supported.

For additional information on POLARIZATION and HiperDispatch, see the [SRM Statement in z/VM: CP Planning and Administration](#).

### **STORBuf {aaa[%] bbb[%] ccc[%]}**

partitions the scheduler's view of real storage when it chooses users to move from the eligible list to the dispatch list. The result is a buffering mechanism based on the transaction class of a user:

#### **E1, Q1**

– users with short-running transactions

#### **E2, Q2**

– users with medium-running transactions

#### **E3, Q3**

– users with long-running transactions,

$E_n$  is the class assigned to a user in the eligible list, and  $Q_n$  is the designation after moving to the dispatch list. An E1 user in the eligible list becomes a Q1 user in the dispatch list, for example. Also, there is transaction class Q0, which is users who never wait in the eligible list to contend for resources in the dispatch list (for example, users with the QUICKDSP attribute).

**Note:** CP's virtual processor management has been improved so that no user stays in the eligible list more than an instant before being added to the dispatch list. Therefore some functions intended to improve performance by managing the eligible list, such as the STORBUF option, are now less meaningful.

The STORBUF values partition pageable storage. They are (in reverse order, for clarity):

#### **ccc[%]**

is the maximum percentage of storage that dispatch list Q3 users can occupy with their working sets.

#### **bbb[%]**

is the maximum percentage of storage that Q2+Q3 users together can occupy. The percentage of storage represented by the difference  $bbb-ccc$  represents a buffer of storage available to Q2 users that the Q3 users are not allowed to use. This buffer protects the Q2 users from delays that occur when slow-moving Q3 users take more (or all) of storage.

#### **aaa[%]**

is the maximum percentage of storage that Q1+Q2+Q3 users can occupy. The percentage of storage resulting from the difference  $aaa-bbb$  represents a buffer of storage available to Q1 users

that the Q2 and Q3 users are not allowed to use. Without this buffer Q2 and Q3 users might occupy all of storage, causing long delays to E1 users who could not enter the dispatch list until one of the slow-moving Q2 or Q3 users left. With the buffer, E1 users enter the dispatch list fairly quickly. Since the buffer is never occupied by Q2 or Q3 users, an E1 user can either enter the dispatch list immediately (if the buffer is not filled), or at worst have only to wait for some Q1 user (in the buffer) to leave.

In each case, the STORBUF values must be decimal numbers from 0 through 999, and  $aaa \geq bbb \geq ccc$ . Any value over 100 is an overcommitment of storage.

Q0 users are left out of the above discussion to keep it simple. In fact, Q0 users are allowed to crowd into storage without limit. In effect then, all of storage above the  $aaa$  percentage can be regarded as a buffer reserved for Q0 users. (Q0 users should not take too much of it, because this unspecified buffer also serves to hold the pages of active users who are temporarily “dormant” [between transactions].)

Although Q3 users may occupy the percentage of storage represented by  $ccc$ , they do not have exclusive rights to it. This storage can be occupied by Q0, Q1, Q2, and Q3 users, depending on which classes are generating a demand for it. But the Q1 and Q2 buffers tend to eliminate some of the Q1 and Q2 demand, so the  $ccc$  storage tends to be occupied mainly by Q3 users. Also, after a Q3 user gets in, the user stays there for a relatively long time, and this gives the Q3 users something of an advantage over other users when it comes to  $ccc$  storage.

Similarly the Q2 users do not have exclusive rights to the buffer represented by the difference  $bbb-ccc$ . This storage can be occupied by Q0, Q1, and Q2, depending on which classes are generating a demand for it. But for the most part it is occupied by Q2 users, just as the  $ccc$  storage is occupied mostly by Q3 users.

The Q1 users do not have exclusive rights to the buffer represented by the difference  $aaa-bbb$ . Both Q0 and Q1 users may occupy it.

#### **STORBuf INITIAL**

sets the percentage parameters back to their initial values, 300%, 250%, and 200%.

#### **UNPARKing**

specifies the unparking heuristic that is to be used when global performance data (GPD) is available.

#### **UNPARKing Large**

unparks all of the logical cores that are powered, in other words, all of the entitled cores and some of the vertical-low cores.

#### **UNPARKing Medium**

unparks all of the vertical-high logical cores, all of the vertical-medium logical cores, and whichever is fewer of the following:

1. all of the vertical-low logical cores that z/VM predicts PR/SM will power
2. all of the vertical-low logical cores that z/VM predicts will be needed to help cover the workload plus the CPUPAD setting.

#### **UNPARKing Small**

unparks only the logical cores that are needed to cover the workload plus the CPUPAD setting.

#### **WARNingtrack**

enables or disables exploitation of the warning-track-interruption facility by CP. This facility notifies CP when PR/SM is about to stop running a logical processor on a physical processor. CP can then save the context of the work being dispatched and yield the logical processor voluntarily, so that the interrupted work is eligible to run on another logical processor. Enabling warning track can improve guest response time and overall performance of workloads that are run on vertical-low or vertical-medium logical processors. When the associated machine facility is available, warning track is turned on by default.

#### **WARNingtrack ON**

enables exploitation of the warning-track-interruption facility by CP.

#### **WARNingtrack OFF**

disables exploitation of the warning-track-interruption facility by CP.

## Usage Notes

1. In using SET SRM DSPSLICE, the initial value of the dispatching minor time slice is determined by the model of the real machine that z/VM is IPLed on. Making the time slice smaller increases system overhead, but it also gives better sorting of the dispatch list and more accurate share control by the scheduler. Making the time slice larger decreases system overhead at the expense of the accuracy of the scheduler share controls. Making the time slice larger may also interfere with the scheduler's ability to quickly sort the dispatch list to get the most I/O-bound users near the top. This in turn may reduce the system's ability to drive I/O and maintain performance.

Remember that when the dispatch slice is changed, the IABIAS duration no longer represents the same amount of processing as before. If the size of the DSPLICE is changed significantly, you may want to adjust the IABIAS duration to compensate so that it still represents roughly the same amount of processing as before.

2. An installation can use the SET SRM STORBUF command to undercommit or overcommit storage. Note that Q0 users are not restricted by their storage requirement. By setting the first percentage value (*aaa*) at less than 100%, you can reserve a storage buffer for Q0 users. It is also sometimes desirable to do this to reserve a storage buffer for active users who are temporarily “dormant” (between transactions). When *aaa* is set to less than 100%, the storage above *aaa* is protected from the (non-Q0) users who are currently running. This means the running users are prevented from crowding all the pages of dormant users out of storage. This is useful when many dormant users' pages are needed sooner than the system can page them out and then in again.

By increasing or decreasing the differences in the three percentage values of STORBUF, an installation can affect the response times and expansion factors for short-running (generally interactive), medium-running, and long-running work.

3. SET SRM LDUBUF is similar to SET SRM STORBUF, except that the resource buffered is the paging configuration capacity, rather than storage. An installation may use SET SRM LDUBUF to undercommit or overcommit the access to paging, or to favor one class of transaction over another.

The values set for SET SRM LDUBUF are usually not critical. However, in most situations, the default values are too low and a better choice would be:

```
SET SRM LDUBUF 300% 200% 100%
```

This represents an overcommitment. If there is a need to do a lot of paging, an overcommitment insures that enough loading users are allowed in the dispatch list to keep the DASD paging devices running at or near their full capacity.

4. z/VM does not virtualize system topology information for its guests. Thus, when z/VM runs in a virtual machine (second level), it runs in horizontal polarization mode and the SET SRM POLARIZATION VERTICAL command produces an error message.
5. In using SET SRM EXCESSUSE:
  - The EXCESSUSE setting affects GPD-on unparking only.
  - SET SRM EXCESSUSE selects the vertical-low policy for all core types.
  - SET SRM EXCESSUSE TYPE selects the vertical-low policy for the specified core type: ALL, CP, ICF, IFL, or ZIIP.
  - When EXCESSUSE NONE is in effect for a core type and GPD is on, z/VM always parks all vertical-low logical cores of that type.
  - Invalid syntax produces message HCP026E or message HCP002E, as appropriate.
6. In using SET SRM UNPARKING:
  - The unparking heuristic can be set at any time, but the heuristic is in effect only when the LPAR is vertical and GPD is on.
  - It might take up to two seconds for the selected heuristic to take effect because z/VM makes unparking decisions only every two seconds.
  - Specifying something other than Large, Medium, or Small produces message HCP002E.

## 7. In using SET SRM WARNINGTRACK:

- z/VM does not virtualize the warning-track-interruption facility for its guests. Thus, when z/VM runs in a virtual machine (second-level), it runs with warning-track exploitation off. This cannot be changed.
- When the warning-track-interruption facility is available and the warning-track setting has not been specified using the SRM WARNINGTRACK configuration statement, the default setting is ON.
- Setting SRM WARNINGTRACK to ON is most helpful in vertically-polarized configurations that include vertical-low and vertical-medium logical processors.

**Responses**

## Response 1:

```
DSPBUF : Q1=iiii Q2=jjjj Q3=kkkk
```

is returned for the SET SRM DSPBUF command.

## Response 2:

```
DISPATCHING MINOR TIMESLICE = xxx MS
```

is returned for the SET SRM DSPSLICE command.

## Response 3:

```
IABIAS : INTENSITY=nnn; DURATION=mmm
```

is returned for the SET SRM IABIAS command.

## Response 4:

```
LDUBUF : Q1=ddd% Q2=eee% Q3=fff%
```

is returned for the SET SRM LDUBUF command.

## Response 5:

```
LIMITHARD METHOD: method
```

is returned for the SET SRM LIMITHARD command.

## Response 6:

```
MAXWSS : LIMIT=nnnn%
..... : PAGES=mmmmmmmmmm
```

is returned for the SET SRM MAXWSS command. The two-line response shows the new MAXWSS value as both a percentage of pageable real storage and the corresponding number of page frames.

## Response 7:

```
STORBUF : Q1=aaa% Q2=bbb% Q3=ccc%
```

is returned for the SET SRM STORBUF command.

## Response 8:

```
POLARIZATION: type
GLOBAL PERFORMANCE DATA: ON|OFF|NA
```

is returned for the SET SRM POLARIZATION command.

## Response 9:

```
EXCESSUSE: CP-excess IFL-excess ICF-excess ZIIP-excess
```

is returned for the SET SRM EXCESSUSE command. The response shows the EXCESSUSE setting for each CPU type.

Response 10:

```
CPUPAD: CP-qqqqq% IFL-qqqqq% ICF-qqqqq% ZIIP-qqqqq%
```

is returned for the SET SRM CPUPAD command. The response shows the CPUPAD setting for each CPU type.

Response 11:

```
DSPWMETHOD: RESHUFFLE|REBALANCE
```

is returned for the SET SRM DSPWMETHOD command.

Response 12:

```
UNPARKING: { LARGE | MEDIUM | SMALL }
```

is returned for the SET SRM UNPARKING command.

Response 13:

```
WARNING TRACK: AVAILABLE|UNAVAILABLE ON|OFF
```

is returned for the SET SRM WARNINGTRACK command.

## Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid
- HCP1050E SET SRM POLARIZATION not performed; CPU topology is not available.
- HCP1050E SET SRM POLARIZATION not performed; multithreading is enabled.
- HCP1050E SET SRM DSPWMETHOD not performed; multithreading is enabled.
- HCP1050E SET SRM WARNINGTRACK not performed; warning-track-interruption facility is not available.
- HCP1052I Global performance data is disabled. This may degrade system performance.
- HCP1054E SET SRM LIMITHARD DEADLINE cannot be issued while a resource pool exists
- HCP1401I Expanded storage is not supported.

## SET SSI

### Authorization

Privilege Class: A

### Purpose

Use SET SSI to change existing entries in the single system image (SSI) member list, to notify the SSI cluster that a non-communicating member is down, or to change the volume that holds the Persistent Data Record (PDR). The SET SSI command affects all members of the SSI cluster and is valid only if your system is in an SSI cluster. This command allows you to modify the SSI configuration that was defined by the SSI statement in the system configuration file. For more information about the [SSI Statement](#), see *z/VM: CP Planning and Administration*.

### Operands

#### SLOT *n*

specifies the number of the slot in the SSI member list that you are changing. The number *n* cannot exceed the number of slots currently defined in the SSI member list. You can use the QUERY SSI command to find the number of slots that are currently available, though all available slots might not be usable at this time. For more information, see usage note “11” on page 1716.

#### *sysname*

specifies the system name to add to the SSI member list. You cannot specify the same system name in more than one slot in the SSI member list.

#### AVAILABLE

tells CP to disassociate the slot from a specific member and make it available for allocation.

#### MEMBER *sysname* DOWN

notifies the SSI cluster that the specified member is down to enable the SSI cluster to be returned to a stable mode. The member state must be unknown and the member should be inactive in order to be declared down. The SET SSI MEMBER *sysname* DOWN command is not allowed when that member is active. A member is determined to be active if it appears to be responsive. The operator is responsible for verifying that the member is, and will, remain down.

#### FORCE DOWN *sysname*

notifies the SSI cluster that the specified members are down in order to enable the SSI cluster to be returned to a stable mode. The state of all specified members and their heartbeat activity are not checked. The operator is responsible for verifying that the specified members are, and will, remain down.

This operand is intended to be used by automated operator virtual machines that have external knowledge about the status of the members of the SSI cluster. This operand should not be used by normal system operations. Specifying members that are not truly down will cause data corruption.

This operand is only allowed if the local system is Joined or Suspended. It is not allowed if the local system is in Leaving, Isolated, or Joining state.

### **PDRVOLUME *valid***

causes the DASD volume with the specified label to become the current Persistent Data Record (PDR) device. The SET SSI PDRVOLUME command will be accepted only when the SSI cluster is in the stable mode and all joined members support this PDRVOLUME option. The new volume must be online and attached to the system on all joined members and must contain a PDR specifying the SSI cluster name. The current PDR is copied to the new device and the PDR on the old device is marked obsolete.

### **Usage Notes**

1. Unless the system configuration file has been updated, all changes applied by the SET SSI command will result in a configuration mismatch at the next system initialization. However, in the case of a successful PDR relocation by a SET SSI PDRVOLUME command, a member system attempting to join the SSI cluster after the new PDR volume is activated but before the configuration file has been updated will use the new PDR automatically. For other cases, this will most likely result in an error message and a system wait state. Always update the system configuration file promptly after each successful SET SSI command. After a successful SET SSI PDRVOLUME command, you should update the SSI configuration statement with the replacement PDR volume ID and you must ensure that the system configuration file lists the new volume in either the CP-owned list or the user volume list on all SSI members.
2. All changes applied by SET SSI command are made to all members that are joined to the SSI cluster.
3. The SET SSI command is not allowed on members that are in Isolated state or when the SSI cluster is in Influx or Safe mode with two exceptions:
  - a. If the SSI cluster is in Safe mode due to a member being in Unknown state, the SET SSI *sysname* DOWN command can be entered to mark the member that is in Unknown state DOWN.
  - b. If the SSI cluster is in Safe or Influx mode, the SET SSI FORCE DOWN command can be entered to mark any member DOWN except for the local system.
4. The SET SSI command is not allowed on a system which has been IPLed using the REPAIR IPL parameter.
5. If the local system is not a member of the SSI cluster, the SSI system configuration file statement must be used to define the local system in the SSI member list.
6. Use the QUERY SSI command to display the SSI member list, the number of available slots, and information about the current PDR volume. For more information, see [“QUERY SSI” on page 1177](#).
7. Slot definitions may be changed from AVAILABLE to a member name, or from a member name to AVAILABLE. Changes from one member name to another are not allowed.
8. A slot can not be changed to AVAILABLE status unless the member associated with the slot has been shutdown.
9. When a SNAPDUMP command is issued on a Joined member of an SSI cluster, the SNAPDUMP processing makes the member unresponsive to other Joined members in the SSI cluster. Therefore, it is possible for the SNAPDUMP processing to cause the other Joined members of the SSI cluster to become Suspended, enter SAFE mode, and change the state of the member taking the SNAPDUMP to Unknown.

If a SET SSI MEMBER *sysname* DOWN

or SET SSI FORCE DOWN command is then issued to mark the system taking the SNAPDUMP Down, the system that was marked Down will continue running once the SNAPDUMP is complete. At that point, the system will recognize that it was marked Down in the PDR and take a PLM018 abend (because data corruption could occur from a Joined member running when it is marked Down in the PDR).

10. After the successful completion of a PDR relocation to a new device, the PDR on the old device is marked obsolete. To allow an old PDR volume to be used again, initialize it using the FORMSSI utility.

Alternatively, you can switch back to the previous PDR volume with another SET SSI PDRVOLUME command if the PDR marked obsolete remains intact and still names the same SSI cluster.

- Slots 5-8 cannot be set to anything other than AVAILABLE until all joined members of the SSI cluster are using the 8-member spool ID assignment algorithm, as set on the SPOOL\_MEMBERS operand of the SSI\_CONTROLS statement in the system configuration file. To determine which members are not yet enabled, use the QUERY SSI SSI\_CONTROLS command.

If the output of the QUERY SSI command contains only four members, 8-member support is not installed on this member, so only slots 1-4 can be defined.

If the output of the QUERY SSI SSI\_CONTROLS command indicates that any joined members are using the 4-member spool ID assignment algorithm, only slots 1-4 can be defined. Slots 5-8 are displayed as AVAILABLE but cannot be defined until all joined members are using the 8-member algorithm.

If the output of the QUERY SSI SSI\_CONTROLS command indicates that all joined members are using the 8-member spool ID assignment algorithm, all 8 slots can be defined.

## Examples

- Querying the current SSI cluster displays the following information:

```
query ssi
SSI Name:  ALEAST
SSI Mode:  Stable
SSI Persistent Data Record (PDR) device: SSIVOL on 3333
SLOT SYSTEMID STATE      PDR HEARTBEAT      RECEIVED HEARTBEAT
  1 YANKEES  Joined    01/30/2010 12:03:33 01/30/2010 12:03:35
  2 REDSOX   Joined    01/30/2010 12:03:47 01/30/2010 12:03:49
  3 ----- Available
  4 ----- Available
  5 ----- Available
  6 ----- Available
  7 ----- Available
  8 ----- Available
```

To add system ORIOLES to the SSI member list in the available slot 3, enter:

```
set ssi slot 3 orioles
```

Subsequently, querying the updated SSI cluster displays the following information:

```
query ssi
SSI Name:  ALEAST
SSI Mode:  Stable
SSI Persistent Data Record (PDR) device: SSIVOL on 3333
SLOT SYSTEMID STATE      PDR HEARTBEAT      RECEIVED HEARTBEAT
  1 YANKEES  Joined    01/30/2010 12:03:33 01/30/2010 12:03:35
  2 REDSOX   Joined    01/30/2010 12:03:47 01/30/2010 12:03:49
  3 ORIOLES  Down (not IPLed)
  4 ----- Available
  5 ----- Available
  6 ----- Available
  7 ----- Available
  8 ----- Available
```

- Attempting to add a member to a slot while in REPAIR mode results in the following response:

```
set ssi slot 3 orioles
HCP1658E SET SSI command is not allowed because this system was
IPLed with the REPAIR IPL parameter.
```

- Querying the current SSI cluster displays the following information:

```
query ssi
SSI Name:  ALEAST
SSI Mode:  Stable
SSI Persistent Data Record (PDR) device: SSIVOL on 3333
SLOT SYSTEMID STATE      PDR HEARTBEAT      RECEIVED HEARTBEAT
  1 YANKEES  Joined    01/30/2015 12:03:33 01/30/2015 12:03:35
```

```

2 REDSOX   Joined    01/30/2015 12:03:47 01/30/2015 12:03:49
3 ----- Available
4 ----- Available
5 ----- Available
6 ----- Available
7 ----- Available
8 ----- Available

```

To replace the current PDR volume SSIVOL with new PDR volume NEWVOL, enter:

```
set ssi pdrvvolume NEWVOL
```

Subsequently, querying the updated SSI cluster displays the following information:

```

query ssi
SSI Name:  ALEAST
SSI Mode:  Stable
SSI Persistent Data Record (PDR) device: NEWVOL on 4444
SLOT SYSTEMID STATE      PDR HEARTBEAT      RECEIVED HEARTBEAT
  1 YANKEES   Joined    01/30/2015 12:03:33 01/30/2015 12:03:35
  2 REDSOX   Joined    01/30/2015 12:03:47 01/30/2015 12:03:49
  3 ----- Available
  4 ----- Available
  5 ----- Available
  6 ----- Available
  7 ----- Available
  8 ----- Available

```

## Messages

- HCP1640E Replacement PDR volume *valid* is not attached to the system
- HCP1640E SET SSI PDRVOLUME feature is not available on all member systems
- HCP1640E SET SSI PDRVOLUME was rejected on system *sysname*
- HCP1643E System *sysname* was specified more than once.
- HCP1645E SET SSI command did not complete because an error occurred reading the PDR
- HCP1648E SET SSI command did not complete because a higher priority SSI action is in progress.
- HCP1649E SET SSI command was rejected by another member of the SSI cluster.
- HCP1650E SET SSI command is not allowed because SSI mode is *mode*.
- HCP1651E SET SSI command is not allowed because this system's state is Isolated.
- HCP1652E SSI system slot *slot\_number* is already Available.
- HCP1653E System slot *slot\_number* cannot be marked Available because its current state is *state*.
- HCP1654E SSI system slot *slot\_number* already in use.
- HCP1655E System identifier already being used in slot *slot\_number*.
- HCP1656E System *sysname* cannot be marked Down because its current state is *state*.
- HCP1657E System *sysname* cannot be marked Down because it is currently active.
- HCP1658E SET SSI command is not allowed because this system was IPLed with the REPAIR IPL parameter
- HCP1659E SET SSI command is not allowed because the user directory is not compatible with SSI.
- HCP1664E SET SSI command is not allowed because { the specified system | system *sysname* } is not a member of the SSI cluster.
- HCP1666E This system is not a member of an SSI cluster.

## SET SSI

- HCP1668E System *sysname* cannot be forced Down because it is the local system.
- HCP1816E A relocation domain with the name *domain\_name* has already been defined
- HCP6650E Slots above *slot* cannot be defined because the cluster SPOOL\_MEMBERS setting on the SSI\_CONTROLS statement is set to *slot*.
- HCP6704E Missing token at end of line
- HCP6706E Invalid number - *number*
- HCP6706E Invalid volume label - *valid*
- HCP6706E Invalid system name - *sysname*

## SET STGEXEMPT

Notes:

<sup>1</sup> If SET STGEXEMPT is executed with the AT command, the *userid* operand is required.

### Authorization

Privilege Class: A, B, C

### Purpose

Use SET STGEXEMPT to control the state of free storage limit detection for virtual machines.

### Operands

#### *userid*

specifies the user ID for which free storage limit detection is to be disabled or enabled.

\*

specifies that free storage limit detection is to be disabled or enabled for the user issuing the command.

#### ON

specifies that the user ID is exempt from free storage limit detection.

#### OFF

specifies that the user ID is subject to free storage limit detection.

### Usage Notes

1. The SET STGEXEMPT command sets the state of free storage limit detection for the user ID. If you exempt a user ID from free storage limit detection, usage of CP storage in support of the user ID is unbounded. If you subject the user ID to free storage limit detection, CP will detect if too much CP storage is consumed in support of the user ID and if so, the user ID will be stopped or possibly forced off the system.

### Responses

Response 1:

```

Userid USERID is
{exempt from} free storage limit detection
{subject to }
  
```

is the response if the specified user ID was not previously {exempt from|subject to} free storage limit detection. There may be an additional response saying that free storage limit detection is off for the system.

Response 2:

```

Userid USERID is already
  
```

## SET STGEXEMPT

```
{exempt from} free storage limit detection  
{subject to }
```

is the response if the specified user ID was previously {exempt from|subject to} free storage limit detection. There is an additional response given if free storage limit detection is off for the system.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on

## SET STGLIMIT

### Authorization

Privilege Class: A, B, C

### Purpose

Use SET STGLIMIT to control the state of free storage limit detection for the system.

### Operands

#### ON

specifies that free storage limit detection is to be turned on for the system. CP will detect if too much CP free storage is consumed in support of userids and if so, those userids consuming excessive free storage will be stopped or possibly forced off the system.

#### OFF

specifies that free storage limit detection is to be turned off for the system. Usage of CP free storage in support of userids is unbounded.

### Responses

Response 1:

```
Free storage limit detection is now {ON }
                                   {OFF }
```

is the response if free storage limit detection was not previously {ON|OFF}.

Response 2:

```
Free storage limit detection is already {ON }
                                       {OFF }
```

is the response if free storage limit detection was previously {ON|OFF}.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP0026E Operand missing or invalid

## SET STORAGE

### Authorization

Privilege Class: A

### Purpose

Use SET STORAGE or SET STORE to dynamically increase or decrease the amount of real storage used by z/VM. No system reIPL is required. To be removable, storage must be defined as reconfigurable when it is added to the z/VM configuration. Any increase or decrease in the size of the configuration must be done in multiples of the increment size, as identified in the response to the QUERY STORAGE command.

### Operands

#### PERManent

identifies real storage that cannot be removed from the z/VM configuration.

#### RECONFigurable

identifies real storage that can be removed from the z/VM configuration.

#### size

is the new size of online real storage of the type specified: permanent or reconfigurable. The amount of reconfigurable storage cannot exceed 50% of all online storage. The *size* value has the format *nu*, where *n* is a 1- to 7-digit decimal number that is greater than 0 and *u* is the 1-character storage unit suffix (see [Table 38 on page 1723](#)). The value you specify must be a multiple of the increment size. A

value of 0, without a storage size suffix, is allowed when the memory type is RECONFIGURABLE and you want to remove all reconfigurable storage.

If your system is using SET RESERVED commands, it is recommended you explicitly set the system maximum (via the STORAGE RESERVED SYSMAX statement in the SYSTEM CONFIG file or by using the SET RESERVED SYSMAX command) to a value that is less than the size of permanent storage. This is particularly important when you are planning to reclaim all memory from reconfigurable storage, to make sure the total reserved storage on the system does not exceed the size of permanent storage.

To increase the amount of storage that is in use by z/VM, specify a new permanent or reconfigurable storage size that is greater than the current amount of storage for that type. The PERMANENT and RECONFIGURABLE operands can be specified on the same SET STORAGE command only when you are increasing the amount of each type of storage.

To decrease the amount of storage that is in use by z/VM, specify a new reconfigurable storage size that is less than the current amount of reconfigurable storage.

Table 38. Maximum Input Values for Storage Units

Storage unit (powers of 2)	Suffix ( <i>u</i> )	Maximum input value ( <i>n</i> )
Megabytes	M	9999999
Gigabytes	G	9999999
Terabytes	T	9999999
Petabytes	P	16384
Exabytes	E	16

**Note:** The maximum input value of 9999999 for the M, G, or T suffix is not a size limit; it is the physical limit of the operand (7 digits plus suffix). If the maximum input value for one of these suffixes does not allow you to define the amount of storage you want, you need to use a larger storage unit.

#### **+increase**

is the amount of permanent or reconfigurable real storage to add to the current z/VM configuration. The value by which to increase storage has the format *nu*, where *n* is a 1- to 7-digit decimal number greater than 0 and *u* is the 1-character storage unit suffix (see [Table 38 on page 1723](#)).

The value you specify must be a multiple of the increment size.

#### **-decrease**

is the amount or reconfigurable real storage to remove from the current z/VM configuration. The value by which to decrease storage has the format *nu*, where *n* is a 1- to 7-digit decimal number greater than 0 and *u* is the 1-character storage unit suffix (see [Table 38 on page 1723](#)).

The value you specify must be a multiple of the increment size.

#### **TEST**

determines the viability of a storage removal by ensuring that, if the specified amount of reconfigurable storage was removed, there are adequate amounts of real storage frames and paging slots to support the current workload. No actual removal of reconfigurable storage occurs.

#### **MAXPAGEFULL *nnn*%**

specifies the upper bound on the number of paging slots in use as a percentage of the total number of slots on all paging volumes. The *nnn* value is a decimal integer in the range of 0 to 100. This value is used in the storage reclamation viability checks performed during execution of this SET STORAGE command to make sure that the removal of storage does not cause the current workload to exceed the available space in the storage hierarchy (real storage plus paging space). The viability check is performed when the TEST operand is specified, and during a storage reclamation process (at the start and periodically throughout the reclamation).

When a MAXPAGEFULL value is not specified, the default value used is the warning percentage specified on the PAGING system configuration statement or on a previous SET PAGING command.

## SET STORAGE

Specification of the MAXPAGEFULL parameter on a SET STORAGE command does not alter the warning value established by the PAGING system configuration statement or a previous SET PAGING command.

### FORCE

indicates that no viability check should be performed prior to, or during, a storage reclamation. Use this operand only when you have determined that the storage reclamation will not cause the current workload to exceed the storage resources in your configuration. See Usage Note “10” on page 1726.

### HALT

initiates termination of a storage reconfiguration in progress. The reconfiguration operation is terminated asynchronously from the command invocation. Any portion of the reconfiguration already completed is not undone. A HALT issued during a storage reclamation only affects the vacate portion of the operation. If the storage being reclaimed is vacated and all of the removed storage has not yet been transitioned to standby, the halt will fail.

## Usage Notes

1. When you define a logical partition, two storage allocations, `Initial` and `Reserved`, are specified in the image profile for the partition. The maximum amount of storage that can be used by an operating system running in the partition is the sum of these two storage allocations. The machine uses the `Initial` and `Reserved` amounts in determining the storage increment size. The storage increment size is the unit in which storage can be added to or removed from the configuration.

For a fresh IPL (one that is not an automatic restart), the following considerations apply:

- CP uses the `PERMANENT` and `RECONFIGURABLE` specifications on the `STORAGE` statements in the system configuration file to determine how to initialize storage. There must be at least 4 GB of permanent storage online before any reconfigurable storage can be configured.
- Alternatively, you can use the IPL parameter `STORE=n` to override the storage configuration information in the system configuration file. In this case, all of the storage specified via `STORE=n` is initialized as permanent.
- If neither the `STORAGE` statement nor the IPL parameter `STORE=` was specified, all of the storage z/VM finds configured in the partition is initialized as permanent storage. If this is the first IPL after the logical partition was activated, the amount of configured storage equals the `Initial` storage allocation. If this is a subsequent IPL, the amount of storage configured at IPL depends on the configuration left by the operating system previously running in the partition.

The storage values on the `STORAGE` statement and the IPL parameter `STORE=n` are rounded up to a multiple of the storage-increment size, if necessary.

For an IPL that is the result of an automatic restart, the `AFTER_RESTART` and `AFTER_SHUTDOWN_REIPL` operands on the `STORAGE` statement in the system configuration file determine z/VM's behavior in establishing the storage configuration. The `AFTER_RESTART` operand applies to an automatic reIPL resulting from a CP abend or a PSW restart. The `AFTER_SHUTDOWN_REIPL` operand applies to an automatic reIPL resulting from the `SHUTDOWN` command with the `REIPL` operand. Parameters on these operands provide the ability for you to initialize the storage configuration as though it were a fresh IPL, or to keep the storage configuration as it was at system termination prior to the reIPL. See the [STORAGE Statement](#) in *z/VM: CP Planning and Administration* for more information.

2. After IPL, you can perform a storage reconfiguration using the SET STORAGE command to bring more permanent or reconfigurable storage online to z/VM, or to take some or all of the reconfigurable storage offline. The following fields displayed by the QUERY STORAGE command with the `RECONFIGURABLE` operand can guide you in determining the extent to which storage is reconfigurable.
  - `STORAGE=` is the amount of real storage currently online to z/VM and is the sum of the `Permanent=` and `Reconfigurable=` values. Additional permanent or reconfigurable storage can be brought online, up to the `Maximum STORAGE=` value displayed. This maximum is the sum of the `Initial`

- and Reserved settings for the logical partition in the image profile, or the maximum amount of real storage this z/VM system supports, whichever is less.
- The sum of CONFIGURED=, STANDBY=, and RESERVED equals the sum of the Initial and Reserved storage allocations in the image profile for the logical partition, or the z/VM-supported maximum, whichever is less.
  - Any storage you add or remove must be specified in multiples of the storage increment size as indicated by the INC= value.
  - Additional storage brought online to z/VM is obtained from standby storage (STANDBY=). The amount of standby storage at any time is determined by the machine, based on the amount of installed storage that is not currently claimed by other active logical partitions in the CPC, along with the Initial and Reserved storage allocations in the image profile for the partition. Although the sum of Initial and Reserved storage allocations in the image profile can exceed the z/VM-supported maximum, the STANDBY= value never allows the system to grow beyond the z/VM-supported maximum. To move storage from the RESERVED= state to the STANDBY= state, manual actions can be taken, such as deactivating another logical partition or installing more real storage.
  - Any amount of Reconfigurable= storage can be removed from the z/VM configuration. The removed storage will increase the STANDBY= value, the RESERVED= value, or both.
3. After a storage reconfiguration has begun, the QUERY STORAGE command with the RECONFIGURABLE operand can be used to display the status of the reconfiguration, including the amount of storage remaining to be added or removed, and the elapsed time of the reconfiguration.
  4. To increase the likelihood of a successful storage add operation, the following steps are recommended:
    - a. Make sure all other storage reconfigurations have completed. This includes logical partition activation or deactivation, as well as storage configuration actions by other operating systems in the central processor complex (CPC).
    - b. Issue the QUERY STORAGE command as necessary to make sure the reported STANDBY= and RESERVED= values are stable.
    - c. Make sure that available standby storage is equal to or greater than the amount of storage you want to add to the z/VM configuration.
    - d. After completing the previous steps, issue the SET STORAGE command to increase the size of the z/VM configuration.
  5. When adding storage, the final step in the storage initialization process can be performed only during nominal system activity. Therefore, all of the storage added might not appear to be available immediately. The NotInitialized= value displayed in the QUERY FRAMES command response is the count of uninitialized frames. The command issuer receives an asynchronous message when all storage is brought online and initialized. No other SET STORAGE commands are allowed until storage initialization is complete. The NotInitialized= value displayed in the QUERY FRAMES command response is the count of uninitialized frames.
  6. After increasing real storage you might want to evaluate and increase the storage settings that you specified for SET RESERVED, SET MDCACHE STORAGE, and the SET VDISK system limit.
  7. Because the SET STORAGE command can be used to remove reconfigurable storage at any time, z/VM limits allocations within reconfigurable storage to data that can be easily moved. To provide the most flexibility to z/VM in allocating memory, you should limit the amount of reconfigurable storage you define to be the amount you expect to eventually remove. When there is an insufficient amount of permanent storage available for normal system operation, z/VM converts a reconfigurable storage increment to permanent storage. When this happens, message HCP2594I is issued to the system operator.
  8. The amount of time needed to complete a reconfiguration to remove storage depends on a number of factors, including: the amount of storage to remove, the state of the guest pages within the storage, the availability of frames in which to move page content, and the paging bandwidth. You can issue the QUERY STORAGE command with the RECONFIGURATION operand to display the status of a storage

## SET STORAGE

removal in progress. The command issuer receives an asynchronous message when all storage is vacated and taken offline (unassigned).

9. Stabilizing the memory usage of your workload before removing reconfigurable storage enables z/VM to more accurately assess the storage demands on the system prior to any storage removal, and throughout the removal operation.

The reclamation viability check, as described under the MAXPAGEFULL operand, is performed prior to the removal of any reconfigurable storage and also intermittently throughout the storage removal process, unless the FORCE operand is specified. If at any time the viability check fails, the system does not remove any additional storage and message HCP2650E is issued to the user who initiated the storage removal and (if a different person) the system operator.

10. If you specify or default to AGELIST KEEPSLOT YES in the system configuration file, pageable pages can have copies in real storage and also on paging volumes. In this case, the reclamation viability check might be overly conservative, because it does not consider the number of guest pages having two copies in the storage hierarchy. If the amount of unused real storage is less than the amount of storage being removed, a storage reclamation will push pages out to DASD. The viability estimation assumes every page written to DASD is not already associated with a slot, and therefore will increase the amount of paging space in use. Depending on the amount of paging space currently in use in your configuration, this could result in a failed viability check and an unsuccessful storage reclamation.

If you have received a failed viability check and are considering using the FORCE option, you must first consider the full storage situation on your system, including real storage, paging capacity and usage, and virtual storage (for example: instantiated, resident, and DASD page counts for users, as well as writeable NSS/DCSS pages, CP pageable pages, and CP control structures). The VIR2REAL EXEC and the CHKRECLM EXEC can be helpful in assessing your storage usage and determining if the FORCE option is appropriate. The VIR2REAL EXEC gathers information about the real and virtual storage on your system as it currently appears (that is, based on the guests that are logged on and the current paging usage). The CHKRECLM EXEC accepts a storage amount as input, and uses information about your current storage configuration and usage to model how your system might look after a reclamation. It shows how the reclamation could change the virtual to real ratios, real storage, and paging. These EXECs are available here:

[VM Download Packages \(https://www.vm.ibm.com/download/packages/\)](https://www.vm.ibm.com/download/packages/)

## Responses

Response 1:

When a SET STORAGE command is issued to add storage, the command issuer and the system operator receive the following messages when the operation begins and ends:

```
HCP2580I Storage reconfiguration to add permsize of permanent and reconfsize
of reconfigurable initiated by userid.
.
HCP2582I Storage reconfiguration by userid is complete.
Permanent = permsize Reconfigurable = reconfsize
```

where:

### ***permsize***

is a storage amount represented by an integer followed by a storage unit suffix (see [Table 38 on page 1723](#)).

### ***reconfsize***

is a storage amount represented by an integer followed by a storage unit suffix (see [Table 38 on page 1723](#)).

### ***userid***

is the user ID that issued the command.

Response 2:

When a SET STORAGE command is issued to remove storage, and CP determines the reclamation will not fill paging volumes beyond the MAXPAGEFULL percentage, the command issuer receives the following message:

```
HCP2593I Storage reclamation viability test passed with MAXPAGEFULL value of
xxx%. yyy% of paging space could be required for the current workload.
```

where:

**xxx%**

is the maximum percent of paging slots in use that you will tolerate for this reclamation. This is the value of the MAXPAGEFULL operand specified on the SET STORAGE command or, if MAXPAGEFULL was not specified on the command, it is the PAGING WARNING value specified via the PAGING system configuration statement or a previous SET PAGING command.

**yyy%**

is CP's estimate for the maximum amount of paging space in use after the storage removal completes.

If the TEST operand is not specified, the storage removal process is started. The command issuer and the system operator (if a different person) receive the following messages when the storage reconfiguration remove operation begins and ends:

```
HCP2581I Storage reconfiguration to remove reconfsize of reconfigurable
initiated by userid.
:
HCP2582I Storage reconfiguration by userid is complete.
Permanent = permsize Reconfigurable = reconfsize
```

where *permsize*, *reconfsize*, and *userid* are as described in Response 1.

Response 3:

When a SET STORAGE command is issued to remove storage and CP determines that the reclamation will fill paging volumes beyond the MAXPAGEFULL percentage, no storage removal operation is initiated and the command issuer receives the following message.

```
HCP2650E Storage reclamation viability test failed with MAXPAGEFULL value of
xxx%. yyy% of paging space could be required for the current workload.
```

where *xxx%* and *yyy%* are as described in Response 2.

Response 4:

When a SET STORAGE HALT command is issued, the command issuer, the system operator, and the user who initiated the storage reconfiguration (unless they are all the same person) receive the following messages when the storage reconfiguration has been signaled to stop processing and when the storage reconfiguration ends.

```
HCP2583I Storage reconfiguration has been signaled to halt processing by
userid.
:
HCP2584I Storage reconfiguration has been halted by userid.
```

where *userid* is as described in Response 1.

- HCP2588E RECONFIGURABLE storage is not supported on this system.
- HCP2589E Storage size *storsize* is not a multiple of the storage increment size *incrsz*. The nearest increment multiples are *mult1* and *mult2*.
- HCP2590E SET STORAGE HALT cannot be processed because there is no user-initiated storage reconfiguration in progress.
- HCP2591E Storage reconfiguration failed - Processor controller response code *xxx*
- HCP2593I Storage reclamation viability test passed with MAXPAGEFULL value of *xxx%*. *yyy%* of paging space could be required for the current workload.
- HCP2598E PERMANENT storage cannot be added and RECONFIGURABLE storage removed in the same SET STORAGE command.
- HCP2599E SET STORAGE HALT cannot be processed because the storage has been vacated.
- HCP2650E Storage reclamation viability test failed with MAXPAGEFULL value of *xxx%*. *yyy%* of paging space could be required for the current workload.

## SET SVC76

### Authorization

Privilege Class: G

### Purpose

Use SET SVC76 to specify whether the control program (CP) or your virtual machine will handle the SVC76 instruction.

### Operands

#### SVC76 CP

#### SVC76 VM

controls whether SVC76 instructions issued by your virtual machine are processed by CP for recording of virtual device errors. Specify CP if guest error records are to be recorded by CP when your virtual machine is running in supervisor state. Specify VM if you do not want errors recorded and if you want all guest SVC76 operations to be processed by your virtual machine. At logon, SVC76 is set to VM if the SVC76VM parameter is specified in the OPTION control statement, or to CP if the SVC76VM parameter is not specified in the OPTION control statement.

### Usage Notes

1. If your virtual machine has SET SVC76 set to CP, then SVC76 is reflected to the user, and does one of the following:
  - Issues an SVC76 from problem state
  - Uses a not valid SVC76 interface
  - Presents an unrecognizable EREP record
  - Presents an EREP record that cannot be translated.
2. Unless you are intentionally simulating hardware errors in your virtual machine (for example, in order to test error recovery procedures), you should let CP record all errors. When CP maintains the hardware error log, your installation has the most accurate information about equipment errors.
3. Linux does not use SVC76 to record hardware errors. Therefore, if the guest has explicitly identified itself to z/VM as running Linux, then the setting of this command is ignored and it is treated as if the setting is always VM.

### Messages

- HCP003E Invalid option - {*option*|command contains extra options starting with *option*}
- HCP026E Operand missing or invalid

## SET SYSCONTROL

---

►► Set — SYSCONTROL — options ◄◄

### Authorization

Privilege Class: A

### Purpose

Use SET SYSCONTROL command to change certain system behaviors only when advised to do so by IBM support personnel. These behaviors are not related to system integrity or security policy, are subject to change without notice, and are not further documented.

## SET SYSOPER

### Authorization

Privilege Class: A

### Purpose

Use SET SYSOPER to change the user ID of the primary system operator on your system.

### Operands

#### *userid*

is the user ID that is to become the active operator. The specified user must:

- Be logged on or disconnected
- Possess at least one of the privilege classes required for system operators, which are defined on the PRIV\_CLASSES statement in the system configuration file, or must be the special operator user ID defined on the SYSTEM\_USERIDS statement.

\*

represents the user ID of the virtual machine issuing the command. The virtual machine must possess at least one of the privilege classes required for system operators, which are defined on the PRIV\_CLASSES statement in the system configuration file.

### Usage Notes

1. Use the QUERY SYSOPER command to display the user ID of the current primary system operator.  
For more information, see [“QUERY SYSOPER” on page 1202](#).
2. If the target virtual machine's user ID is specified as the system operator ID on the SYSTEM\_USERIDS statement in the system configuration file, it need not have any special privilege classes.
3. You can also change the primary system operator by logging off the current primary system operator and logging on the desired operator ID. As with the SET SYSOPER command, the new primary operator must either possess the required privilege classes or must be the special operator user ID specified on the SYSTEM\_USERIDS statement in the system configuration file.
4. An alternative to the above is to use the ALTERNATE\_OPERATORS statement in the system configuration file. The ALTERNATE\_OPERATORS statement lets you specify a list of user IDs that can become the system operator automatically when the primary system operator logs off. For more information on using the [ALTERNATE\\_OPERATORS Statement](#), see *z/VM: CP Planning and Administration*.
5. The primary system operator receives all messages sent to the OPERATOR user ID.

### Responses

Response 1:

The command issuer receives no response. CP sends the following message to the new operator user ID:

```
HCPCF06776I userid selected your userid
as the system operator ID.
```

## SET SYSOPER

CP sends the following message to the old operator user ID:

```
HCPCF06776I userid removed your userid  
as the system operator ID.
```

### Messages

- HCP020E *Userid* missing or invalid
- HCP045E *userid* not logged on
- HCP6777E *userid* in IPL, LOGOFF, or FORCE process
- HCP6778E User *userid* does not have required privilege class.

## SET TAPE

### Authorization

Privilege Class: B

### Purpose

Use SET TAPE to reencrypt (rekey) an encrypted tape with different key information without rewriting the tape.

### Operands

*rdev*

*rdev1-rdev2*

specifies a real device number, a list of real device numbers, or a range of real device numbers.

**REKEY** *keyalias1*

**REKEY** *keyalias2*

reencrypts a tape has was already encrypted using different key information so that you do not need to rewrite the tape. At least one *keyalias* must be specified.

### Usage Notes

1. The range of devices that are specified on a single CP SET TAPE command cannot span more than 256 real device numbers.
2. The REKEY function is only valid when issued against 3592 tape drives that support hardware encryption and rekeying, and when the mounted tape cartridge is encrypted and positioned at the beginning of the tape (BOT). This will take a few moments to complete as it performs the necessary key exchanges between the control unit and the key manager.

### Messages

- HCP006E Invalid device type - *rdev*
- HCP040E Device *rdev* does not exist
- HCP1130E Device *rdev* does not support a rekey operation
- HCP1131I Rekey operation succeeded for device *rdev*
- HCP1132E Rekey operation failed for device *rdev*.
- HCP1132E Rekey operation failed for device *rdev*. Tape cartridge is invalid.
- HCP6000E The range of device numbers cannot exceed 256.
- HCP9968E Key alias not found: *keyalias*.

## SET THROTTLE

### Authorization

Privilege Class: B

### Purpose

Use SET THROTTLE to control the number of I/O operations that a guest operating system can initiate to a specific real device. This prevents a guest from interfering with or dominating I/O resources.

Using the SET THROTTLE command, you can either:

- Limit the guest's I/O rate to a specific I/O device by adding that device to the I/O throttling list, or
- Give the guest and your first-level system equal control over the specified I/O device by removing that device from the I/O throttling list.

### Operands

***rdev* RATE *nnnnn***

***rdev1-rdev2* RATE *nnnnn***

adds one or more real devices to the I/O throttling list at the specified I/O rate or changes the I/O rate of one or more devices currently in the I/O throttling list. After adding devices to or changing I/O rates in the list, CP immediately begins limiting (throttling) the guest's I/O rate to the specified device or devices.

The variable *rdev* is the real device number of the device that you want to add to or change in the I/O throttling list. Each *rdev* must be a 1- to 4- digit hexadecimal number between X'0000' and X'FFFF'. You can specify a single device address, a range of device addresses, or any combination thereof.

The variable *nnnnn* is I/O throttling rate (number of I/O operations per second that this device can process from a guest operating system). It must be a decimal number between 1 and 10,000.

**ALL OFF**

tells CP to remove all the devices from the I/O throttling list.

***rdev* OFF**

***rdev1-rdev2* OFF**

tells CP to remove the specified device or devices from the I/O throttling list. The variable *rdev* is the real device number of the device that you want to stop throttling. It must be a hexadecimal number between X'0000' and X'FFFF'. You can specify a single device address, a range of device addresses, or any combination thereof.

### Usage Notes

1. CP can throttle devices that are eligible for I/O assist, but not while the device is in I/O assist. When a device is in I/O assist, the guest is controlling the device directly, not CP. CP can only throttle a device when it controls the I/O to and from that device. Thus, if you throttle a device that is currently in I/O assist, CP accepts your command, but does not actually begin throttling the device until the device is no longer in I/O assist.

2. To display which devices are on the I/O throttling list and what their rates are, use the QUERY THROTTLE command (see “[QUERY THROTTLE](#)” on page 1217).
3. You can also add devices to the I/O throttling list using the THROTTLE statement in the system configuration file. For more information about the [THROTTLE Statement](#), see *z/VM: CP Planning and Administration*.

## Responses

Response 1:

To begin throttling a range of devices, enter the following:

```
set throttle 800-804 rate 10000
23:08:36 HCPTHR040E Device 0801 does not exist
23:08:36 HCPTHR040E Device 0804 does not exist
23:08:36 3 device(s) added to I/O throttling list starting with device 0800
23:08:36 2 device(s) skipped. Rate is 10000 I/Os per second
```

Response 2:

To stop throttling all devices, enter the following:

```
set throttle all off
23:09:32 The I/O throttling list has been cleared
```

Response 3:

To stop throttling a range of devices, enter the following:

```
set throttle 800-804 off
23:10:36 HCPTHR040E Device 0801 does not exist
23:10:36 HCPTHR040E Device 0804 does not exist
23:10:36 3 device(s) deleted from the I/O throttling list starting
with device 0800
23:10:36 2 device(s) skipped
```

Response 4:

To begin throttling a device, enter the following:

```
set throttle 800 rate 10000
23:25:24 Device 0800 added to I/O throttling list. Rate 10000 I/Os
per second
```

Response 5:

To stop throttling a device, enter the following:

```
set throttle 800 off
23:25:36 Device 0800 deleted from the I/O throttling list
```

## Messages

## SET TIMEBOMB

---

### Authorization

Privilege Class: G

### Purpose

Use SET TIMEBOMB to turn on and off the dynamic virtual machine time bomb. The time bomb is a mechanism for allowing a virtual machine to cause an action to be performed if it becomes unresponsive.

### Operands

**ON**

**OFF**

ON specifies that the virtual machine time bomb facility is to operate normally. OFF specifies that the virtual machine time bomb facility is to operate normally except that the time bomb is disabled.

### Usage Notes

1. With the time bomb disabled, detection of an unresponsive condition does not cause the associated action to be performed. In all other respects, the time bomb facility appears to the virtual machine to be operating normally.
2. It may be convenient to disable the time bomb when debugging a virtual machine application, where delays caused by the debugging functions may exceed the time bomb timeout interval.
3. An application establishes a time bomb using DIAGNOSE Code X'288' - Control Virtual Machine Time Bomb, see z/VM: CP Programming Services for more information.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

## SET TIMER

### Authorization

Privilege Class: G

### Purpose

Use SET TIMER to control the interval timer for your virtual machine. SET TIMER is valid only if SET 370ACCOM is ON.

### Operands

#### ON

specifies that the virtual timer is updated only when the virtual processor is running. The initial setting when you log on is ON.

#### OFF

specifies that the timer is not updated.

#### REAL

specifies that the timer is updated during the virtual processor run time and also during virtual wait time.

### Usage Notes

1. If the 370 Accommodation facility is active the interval timer is present for XA, ESA, and XC virtual machines. Use the CP SET 370ACCOM ON command to activate the 370 Accommodation facility.

## SET TIMEZONE

```
►► Set — TIMEZONE — zoneid ◄◄
```

### Authorization

Privilege Class: A

### Purpose

Use SET TIMEZONE to change the system's active time zone ID and time zone offset.

**Note:** We strongly recommend you enter this command only when changing to standard or daylight saving time.

### Operands

#### *zoneid*

*zoneid* is the time zone ID that you want to make active, such as EST. To get a list of the defined time zones, enter a QUERY TIMEZONES command.

### Usage Notes

1. Some applications may be adversely affected by changes in time zones. IBM recommends that you stop these applications before changing the time zone and start them again after the time zone has been changed.
2. Even if the new time zone ID is the same as the current time zone ID, a privileged user may use the DEFINE TIMEZONE command to change the offset associated with the time zone ID. To put the new offset into effect, you must enter the SET TIMEZONE command. CP will issue all messages and generate all external interrupts associated with a normal time zone change. For more information on defining a new time zone or changing the existing time zone definition, see the DEFINE TIMEZONE command.
3. You can tell CP whether you want your virtual machines to receive a special external interrupt when a time zone change occurs. See the description of [DIAGNOSE Code X'274' - Set Timezone Interrupt Flag](#) in *z/VM: CP Programming Services* for details.
4. CMS levels prior to CMS level 11 do not request time zone notification using DIAGNOSE code X'274', therefore, file system time stamps do not reflect the change in time zone unless you re-IPL CMS.
5. You can check the current time zone by issuing the QUERY TIMEZONES command.
6. You can find the difference between your system's current time zone and the Coordinated Universal Time (UTC) by issuing the QUERY TIME command with the OFFSET operand.
7. Accounting records continue to contain local date and time values.
8. Queued timer interrupts are based on the Time of Day Clock, which is not changed by a SET TIMEZONE command.
9. This command is rejected when CP is deriving its time zone information from an external source (for example, when the STP\_TZ feature is enabled from the configuration file).

### Responses

Response 1:

When you enter the SET TIMEZONE command, CP issues the following response:

```
HCP6759I The time zone has changed to zone
```

CP sends the same message to each user who is logged on or disconnected from the system. Users can suppress the message by using the SET EMSG command. For more information on the SET EMSG command, see [“SET EMSG” on page 1512](#).

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP6704E Missing token at end of line
- HCP6706E Invalid time zone ID - *zone*
- HCP0987E SET TIMEZONE not valid - STP timezone in use

## SET TOKEN

### Authorization

Privilege Class: B, E

### Purpose

Use SET TOKEn to set the values of the channel subsystem configuration token description fields.

### Operands

#### DESC1 cccccccc

is the value you want assigned to the first description field of the channel subsystem configuration token. The variable *cccccccc* must be a 1- to 8-alphanumeric character string. If *cccccccc* contains blanks you must enclose the value in single quotation marks, for example, SET TOKEn DESC1 'name one'. If this operand is omitted, no change is made to the first description field.

#### DESC2 cccccccc

is the value you want assigned to the second field of the channel subsystem configuration token. The variable *cccccccc* must be a 1- to 8-alphanumeric character string. If *cccccccc* contains blanks you must enclose the value in single quotation marks, for example, SET TOKEn DESC2 'name two'. If this operand is omitted, no change is made to the second description field.

### Usage Notes

1. The SET TOKEn command is provided to allow the system programmer to set the description fields (DESC1 and DESC2) within the hardware I/O-configuration token. Setting these fields can be useful when you are running z/OS as either a guest on VM or in other LPARs on a system where VM is the controlling logical partition for dynamic-I/O configuration. z/OS uses the DESC1 field as the high-level dataset-name qualifier of the z/OS I/O-definition files (IODF). They use the DESC2 field to select which of several IODFs are to be used, with the DESC2 field taking on values in the form "IODFnn", where nn can have a value from 00 to 99.

By setting the DESC1 and DESC2 fields to the proper values for a z/OS IODF that is to be used by one or more z/OS guests, these guest operating systems will automatically select that IODF for their I/O configuration when the guests are IPLed.

VM itself makes no use of the DESC1 and DESC2 fields.

2. CP puts the machine in configuration mode to change the description fields and takes the machine out of configuration mode once the changes are made. Changing the token description fields does not affect the I/O configuration.
3. When issuing SET TOKEn, VM must not already be in configuration mode, but must be enabled for dynamic I/O configuration.
4. The Set TOKEn command changes the token for the current (i.e. the running) I/O configuration, but does not change the token that will be established from the IOCDs (I/O-configuration data set) at the next power-on reset (POR) of your machine. To make the same change to the active IOCDs (i.e. the IOCDs that will be used at the next POR), you must do the following:
  - a. Run the IOCP program, specifying all of the options you normally specify, including WRTxx (to write the newly-generated IOCDs into the machine).

- b. Issue the Set IOCDS\_active command to make the new IOCDS the "active" IOCDS (i.e. the IOCDS to be used at the next POR).

### Examples

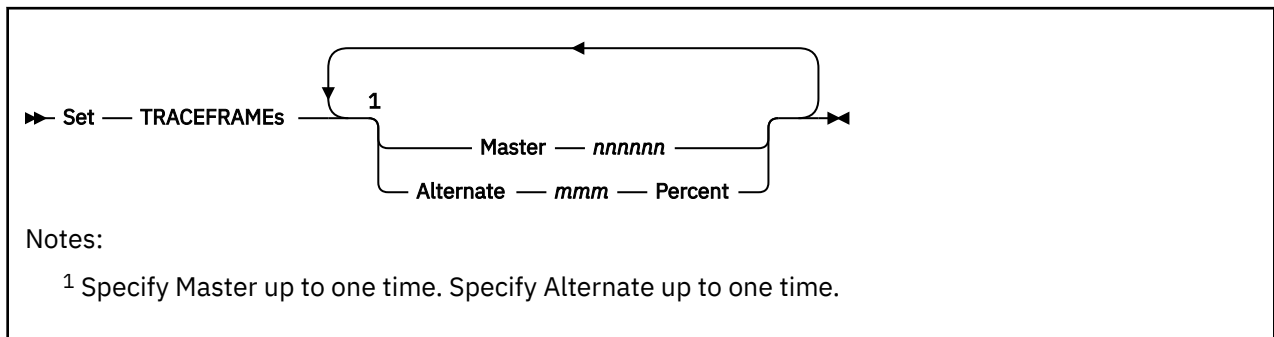

To change the first description field to 'IOCONFIG' and the second description field to 'IODF43', enter:

```
set token desc1 ioconfig desc2 iodf43
The channel subsystem configuration token was set as requested
Ready;
```

### Messages

- HCP6805E Cannot find RDEV for TYPE 1 subchannel
- HCP6806E Dynamic I/O change request failed with return code *nnnn*
- HCP6808E System disabled for dynamic I/O changes. The VM configuration token does not match the hardware configuration token.
- HCP6808E System disabled for dynamic I/O changes. The dynamic I/O support was disabled at the service console.
- HCP6809E This processor does not support dynamic I/O changes
- HCP6815E Command failed in the channel subsystem
- HCP6815E Cannot find configuration token in the system
- HCP6816E Dynamic I/O changes are not allowed on this system
- HCP6850E Cannot set system configuration token. A dynamic I/O change is in progress.
- HCP6850E Cannot set system configuration token. System is in configuration mode.
- HCP6851E I/O configuration cannot be changed because VM is not the controlling partition.

## SET TRACEFRAMES

### Authorization

Privilege Class: A

### Purpose

Use SET TRACEFRAMES to change the number of real storage frames that CP sets aside for an internal trace table for the master processor and the alternate processors in the configuration.

### Operands

#### Master *nnnnnn*

specifies the number of real storage frames for the master processor's internal trace table. The value *nnnnnn* must be equal to or greater than 3, and it cannot exceed 131072.

#### Alternate *mmm* Percent

specifies the size of each alternate processor's internal trace table, which is *mmm* percent of the master processor's internal trace table.

### Usage Notes

1. CP maintains separate internal trace tables for each processor in the configuration. You can use this command to set the size of the internal trace table for the master processor and the alternate processors, which are expressed as a percentage of the master processor's trace table.
2. Each increase in the size of the system internal trace tables should be small. You should break a large increase down into a number of smaller ones, each less than the size of the system's available frame queue. Use the QUERY FRAMES command to see how your system has allocated frames of real storage.
3. If CP processes a request to increase the internal trace table and all readily available storage has been allocated, CP returns the internal trace table to the size prior to the SET TRACEFRAMES command.
4. A TRSAVE command typically extracts data from the system internal trace table. A SET TRACEFRAMES command, therefore, will be rejected if a TRSAVE command is active. Similarly, a TRSAVE command will be rejected if a SET TRACEFRAMES command is active.
5. The number of trace frames for each processor will always be adjusted to a minimum of 3.
6. See QUERY TRACEFRAMES for information on how to display the size of the internal trace tables.
7. Trace pages associated with trace frames are in system execution space (SXS) and backed by a below-2-GB frame. This means that there is a limit on the number of trace frames due to the storage limit on SXS. An "insufficient storage" condition might occur when requesting more trace frames for each logical processor and will become more likely as the number of running logical processors in a configuration increases.

## Examples

If you issued the command:

```
SET TRACEFRAMES MASTER 100 ALTERNATE 90 PERCENT
```

and you had a four-processor CPU, the master processor would be allocated a 100-frame internal trace table, and each of the three alternate processors would be allocated a 90-frame internal trace table.

If you subsequently issued the command:

```
SET TRACEFRAMES MASTER 200
```

the master processor would be allocated a 200-frame internal trace table, and each of the three alternate processors would be allocated a 180-frame internal trace table.

## Responses

Response 1:

```
Command Complete
```

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - command contains extra option(s) starting with *operand*
- HCP013E Conflicting option - *option*
- HCP6077E TRSAVE is active.
- HCP6704E Missing token at end of line
- HCP6706E Invalid number - *operand*
- HCP6740E Insufficient storage to complete this request

## SET UNDERSCORE

### Authorization

Privilege Class: G

### Purpose

Use SET UNDERSCORE to control whether an underscore character is used to separate 16-digit output values in CP command responses for your user ID.

### Operands

#### OFF

indicates that an underscore character will not be used to separate 16-digit output.

#### ON

indicates that an underscore character will be used to separate 16-digit output into two 8-digit entities for readability.

### Usage Notes

1. UNDERSCORE is set OFF when you log on and is not changed until you issue SET UNDERSCORE ON.
2. Use QUERY UNDERSCORE to determine the current setting.
3. CP commands affected by the UNDERSCORE setting include DEFINE STORAGE, DISPLAY (Registers), DUMP (Registers), LOCATE FRAMETBL, LOCATE (Storage), LOCATE SXSTE, LOCATE VMDBK, LOCATEVM, LOCK, QUERY SXSSTORAGE, TRACE, TRACE TABLE, and VMDUMP.
4. An underscore character is always allowed on input (for the commands listed above and other CP commands), regardless of the setting of the UNDERSCORE option. When specifying an underscore on input, there must be exactly eight characters following the underscore.

### Examples

If you specify SET UNDERSCORE ON, then enter a DUMP GG12 command, the output would be formatted as follows:

```
GRG 12 = 00000000_0105E2F8
```

If UNDERSCORE OFF is in effect when you enter the DUMP GG12 command, the output would be formatted as follows:

```
GRG 12 = 000000000105E2F8
```

### Messages

- HCP003E Invalid operand - *operand*
- HCP026E Operand missing or invalid

## SET VARIABLE

### Authorization

Privilege Class: B

### Purpose

Use SET VARIABLE to define and set an environment variable that is accessible to every class G user on the system. SET VARIABLE can also be used to change the value of an environment variable or to delete it by setting it to the null string. A *null string* is a string that contains no characters. Null strings have a length of zero.

System environment variables allow automated programs to adapt to different operating environments or modes in a coordinated fashion across multiple guest virtual machines.

### Operands

#### SYSTEM

indicates that this is a system environment variable.

#### name

specifies the name of the environment variable. This name must satisfy the following rules:

- It is 1 - 63 characters in length with no blanks.
- Valid characters are 0-9, A-Z, \_ (underscore), and . (period).
- It cannot begin or end with a period.
- It cannot begin with a "CP." prefix.
- It cannot begin with a numeric digit.

#### string

is the data string that will become the value for the specified variable. This string must satisfy the following rules:

- It is 1 - 255 characters in length.
- Valid characters are the hexadecimal values x'40' - x'FE'.
- Blanks (x'40') can be embedded within the string only. Blanks are stripped from the beginning and end of the string.

If the string is omitted, the specified variable is deleted.

### Usage Notes

1. For a complete list of environment variables defined, issue the QUERY VARIABLE ALL command.
2. When SET VARIABLE is specified for an environment variable that already has a value, the new value specified replaces the previous value.
3. Variable names that start with the prefix "CP." are reserved for IBM use and cannot be defined, changed, or deleted by the SET VARIABLE command.
4. A maximum number of 1000 system environment variables can exist at a time.
5. If SET VARIABLE is issued to delete a variable that does not exist, the command completes without error.

## SET VARIABLE

6. The maximum allowable length for a Diagnose x'08' command is 240. Subtracting 13 characters for:

```
"S VAR SYSTEM "
```

and one character for the blank following the variable name leaves a total of 226 characters to be used as the sum of the lengths of both the name and value.

7. If the value contains a character that is used as a line-editing symbol, the CP TERMINAL command should be issued first to define a different line-editing symbol or to turn off the line-editing function. Issue the CP QUERY TERMINAL command to view the characters that are used as line-editing symbols.

8. A string containing lowercase characters can be defined for the environment variable value only when the command is specified through the DIAGNOSE X'08' programming interface. This includes specifying the command within a REXX EXEC, which uses the Diagnose x'08' interface. When the command is specified on the command line, CMS or CP automatically translates the input data to uppercase so it is not possible to provide lowercase input from the command line.

Here is an example of using a REXX EXEC to specify a lowercase string that includes embedded blanks:

```
(a sample REXX exec)
/* This comment format indicates the REXX interpreter is to be used */
address command "CP SET VAR SYSTEM TESTLVL4 kag 002/b 12-03 2015"
```

Note that within the command string being executed, CP SET VAR must be uppercase.

### Messages

- HCP0002E Invalid operand - *operand*
- HCP1014E A required option is missing
- HCP2147E Environment variable is not set because the maximum number of environment variables are already defined.
- HCP2149E A variable name starting with reserved prefix "CP:" cannot be set.
- HCP2768E Missing variable name
- HCP6706E Invalid variable name - *name*

## SET VCONFIG

### Authorization

Privilege Class: G

### Purpose

Use SET VCONFIG to set the virtual configuration mode for a virtual machine.

### Operands

#### MODE

indicates that the configuration mode of the virtual machine is being changed.

#### ESA390

indicates that the configuration mode of the virtual machine is ESA/390, and only virtual CPU types that are valid in an ESA/390 mode virtual machine can be defined. VCONFIG modes ESA390 and GENERAL are functionally equivalent. If ESA390 is specified while MACHINE is set to Z, the system behaves as if GENERAL was specified. See the description of GENERAL for more information. ESA390 is the default setting for virtual machines at logon when the real logical partition mode is not Linux-only and the virtual machine mode is XA, ESA, or XC.

#### GENERAL

indicates that the configuration mode of the virtual machine is GENERAL. VCONFIG modes ESA390 and GENERAL are functionally equivalent, which means that the same virtual CPU types can be defined in an ESA390 mode virtual machine and in a GENERAL mode virtual machine. For the SET VCONFIG command, ESA390 and GENERAL are synonyms and cause a configuration of the same capabilities to be defined when specified. The SET VCONFIG command, like the QUERY VCONFIG command, will display ESA390 when MACHINE is set to XA, ESA, or XC, and will display GENERAL when MACHINE is set to Z. GENERAL is the default setting for virtual machines at logon when the real logical partition mode is not Linux-only and the virtual machine mode is Z.

#### LINUX

indicates that the configuration mode of the virtual machine is LINUX. This is the default setting for virtual machines at logon and the only valid configuration mode when the real logical partition mode is Linux-only.

#### VM

indicates that the configuration mode of the virtual machine is VM and only virtual CPU types that are valid in a VM mode virtual machine can be defined.

### Usage Notes

1. The virtual configuration mode settings correspond to logical partition modes which can be set on the General page of the image profile for a logical partition.
2. Changing the virtual configuration mode setting of a virtual machine results in a System Clear operation.

3. The virtual configuration mode determines the types of virtual CPUs that can be defined for this virtual machine. Refer to the description of “[DEFINE CPU](#)” on [page 152](#) to see the possible CPU types that can be defined for each virtual configuration mode.
4. To make changes to a virtual configuration, including changing virtual CPU types and the virtual configuration mode, do the following:
  - Issue the DEFINE CPU command to change all CPU types to CP.
  - Issue the SET VCONFIG MODE command to change the virtual configuration mode.
  - Issue the DEFINE CPU command to change the CPU types to the desired types.
5. While an implicit configuration mode of CF (Coupling Facility) exists, CF cannot be specified as a mode on the SET VCONFIG command. When OPTION CFVM is specified in the user directory entry, the virtual configuration mode is set automatically to CF and cannot be changed to a different mode by the SET VCONFIG command.

### Responses

Response 1:

```
MODE = m
```

where:

**m**

identifies the configuration mode and is set to one of the following:

```
ESA390  
GENERAL  
LINUX  
VM
```

Response 2:

```
STORAGE CLEARED - SYSTEM RESET
```

is issued whenever the virtual configuration mode is changed to a different setting.

### Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *option*
- HCP1014E A required option is missing
- HCP1469E An attempt was made to define a virtual configuration mode that is not compatible with your virtual CPU configuration.
- HCP1470E The virtual configuration mode that was specified is not valid. It must be LINUX because CP is running in a Linux-Only logical partition.
- HCP1471E The virtual configuration mode that was specified is not valid. CF is the only valid virtual configuration mode for CFVM users.
- HCP5780E Adjunct does not support the *command subcommand* command

## SET VDISK

### Authorization

Privilege Class: B

### Purpose

Use SET VDISK to control the maximum amount of host real storage that is available for allocation as virtual disks in storage. Using virtual disks in storage increases the load on system paging, so you should set limits in proportion to the availability of paging space.

### Operands

#### Syslim

sets the total resource available for allocating virtual disks in storage on the system.

#### Userlim

sets the maximum resource available for virtual disks in storage created by a single user using the DEFINE command. This limit does not apply to virtual disks in storage defined by MDISK statements in the directory.

#### Default

sets the limit to the default value. If an installation default is defined in the system configuration file, that value is used. If an installation default is not defined in the system configuration file, or if the file is not found, the built-in default is used, as follows:

- The built-in default user limit is 0.
- The built-in default system limit is the minimum of:
  - The amount of virtual storage that can be represented by one-quarter of the usable dynamic paging area (DPA), based on the fact that each gigabyte of virtual disk defined requires 2050 frames of host real storage
  - The amount of storage represented by one-quarter of the paging space defined for CP use

#### Infinite

indicates all available host real storage may be allocated to virtual disks in storage up to the limit of 2147483648 512-byte blocks.

#### nnnnnnnnnn Blocks

#### nnnnnnnnnn Blks

specifies the number of 512-byte blocks of host real storage available for virtual disks in storage. If the number specified is equal to or greater than 2147483648, the limit is set to INFINITE.

#### nnnnnnnM

specifies the number of megabytes of host real storage available for virtual disks in storage. If the number specified is equal to or greater than 1048576, the limit is set to INFINITE.

### ***nnnnG***

specifies the number of gigabytes of host real storage available for virtual disks in storage. If the number specified is equal to or greater than 1024, the limit is set to INFINITE.

### **Usage Notes**

1. Virtual disks in storage are allocated in 8-block (4096-byte) pages. Therefore, the actual limit that is set may be rounded up to the nearest page.
2. If the system limit is set to a value that is less than the amount of host real storage currently allocated for virtual disks in storage, the command is accepted, but no new virtual disks in storage can be created until the total system usage drops below the limit. No currently-active virtual disks in storage are deleted. Any VDISK being created for a relocation in progress will not be subject to the new limit.
3. If the user limit is set to a value that is less than the amount of host real storage currently allocated for virtual disks in storage created by the DEFINE command by a given user, the command is accepted, but that user cannot create any new virtual disks in storage with the DEFINE command until the user's total usage of virtual disks in storage created with the DEFINE command falls below the limit. No currently-active virtual disks in storage are deleted. Any VDISK being created for a relocation in progress will not be subject to the new limit.
4. While virtual disks in storage can improve I/O performance, they may increase host real storage and paging resource requirements. Increasing the system and user limits increases the potential for end users to negatively impact system performance by using large virtual disks in storage improperly.
5. Regardless of possible USERLIM INFINITE specifications, the maximum number of USERLIM blocks is limited by the maximum number of blocks permitted by the command "CP DEFINE VFB-512". For more information, see ["DEFINE \(Virtual Disk in Storage\)"](#) on page 230.

### **Messages**

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - [command contains extra option(s) starting with] *option*
- HCP026E Operand missing or invalid

## SET VMCONIO

### Authorization

Privilege Class: G

### Purpose

Use SET VMCONIO to control the destination of the responses generated by your virtual machine. Responses include any line mode I/O between the virtual machine and the virtual machine console.

**Note:** When you log on, VMCONIO is set OFF.

### Operands

#### IUCV

specifies that responses are to be passed to the virtual machine through IUCV if a connection to the message system service exists. If no IUCV connection exists, data is handled as if SET VMCONIO OFF were issued.

#### OFF

specifies that responses are to be displayed at the terminal.

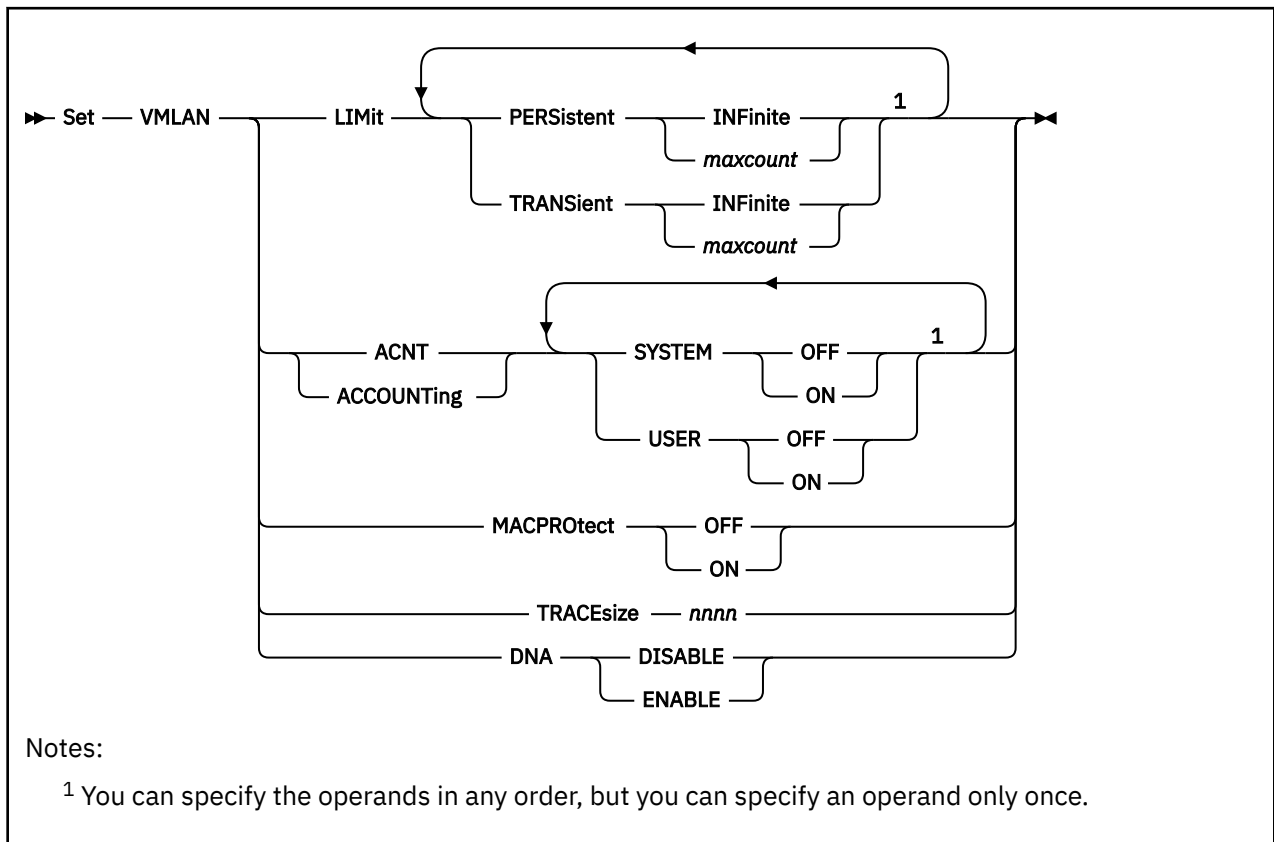

### Usage Notes

1. When full-screen CMS is on, most CMS console output is not passed to CP. In addition, applications that use the IUCV Message System Service (\*MSG) and SET VMCONIO IUCV will not trap all CMS output. Before running such applications, it is suggested that the user suspend full-screen CMS.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid

## SET VMLAN

### Authorization

Privilege Class: B

### Purpose

Use the SET VMLAN command to set system-wide attributes for virtual networking support.

### Operands

#### LIMit PERSistent INFinite|maxcount

specifies the maximum number of PERSISTENT guest LANs allowed on the z/VM system at one time. The value *maxcount* must be a decimal number in the range 0 - 1024. The default state of this attribute is INFINITE.

A persistent LAN is created when the DEFINE LAN system configuration statement is used to create a LAN during system initialization, or when a Class B user issues the DEFINE LAN command to define a SYSTEM owned LAN. A persistent virtual switch is created when the DEFINE VSWITCH system configuration statement is used to create the switch during system initialization, or when a Class B user issues the DEFINE VSWITCH command to define a virtual switch.

#### LIMit TRANSient INFinite|maxcount

specifies the maximum number of TRANSIENT guest LANs allowed on the z/VM system at one time. The value *maxcount* must be a decimal number in the range of 0 - 1024. The default state of this attribute is INFINITE.

A transient LAN is created when the DEFINE LAN command is used to define a general user LAN.

**ACNT|ACCOUNTING SYSTEM ON|OFF**

specifies the default accounting state for guest LANs owned by the SYSTEM user ID. The default state of this attribute is **OFF**. Class B users are authorized to override this setting on the DEFINE LAN and SET LAN commands.

**ACNT|ACCOUNTING USER ON|OFF**

specifies the default accounting state for guest LANs owned by individual users. The default state of this attribute is **OFF**. Class B users are authorized to override this setting on the DEFINE LAN and SET LAN commands.

**MACPROTECT**

turns MAC address protection on or off for virtual network devices on the system. Turning MAC address protection on prevents a guest from using a MAC address that is not assigned to the user's network device. MACPROTECT is valid only for ETHERNET virtual switches and guest LANs. MAC address protection is not supported for guest ports that are being bridged by this virtual switch.

There are three levels of inheritance used when determining the MAC address protection level for a MAC address assigned to a network device. The highest is the system level, followed by the virtual switch or guest LAN level. The lowest level is the protection set for a specific network data device.

The MAC address protection level assigned is determined first at the device, then virtual switch or guest LAN and lastly the system level. If MAC address protection is set at the device level using the SET NIC CP command, then its current setting is used. When the device is set to UNSPECIFIED, it will inherit the MACPROTECT setting of the virtual switch. When the virtual switch MACPROTECT setting is set to UNSPECIFIED, the SYSTEM's MAC address protection specified by this command will be used.

**OFF**

sets the MAC address protection level to off for all virtual switches, guest LANs and network devices whose MAC address protection setting are not specified (set to UNSPECIFIED). OFF is the default setting.

If MAC address protection is set to UNSPECIFIED by the SET NIC CP command for a specific device or a SET VSWITCH for virtual switch coupled devices or SET LAN for LAN coupled devices, then the device's MAC address protection will be set off.

**ON**

sets the MAC address protection level on for coupled devices defined with a MAC address protection set to UNSPECIFIED set the MAC address protection level to on for all virtual switches, guest LANs and network devices whose MAC address protection setting are not specified (set to UNSPECIFIED).

If MAC address protection is set to UNSPECIFIED by the SET NIC CP command for a specific device or a SET VSWITCH for virtual switch coupled devices or SET LAN for LAN coupled devices, then the device's MAC address protection will be set on.

**TRACEsize nnnn**

specifies the number of pages to be allocated for an internal trace table to keep track of general virtual networking events. The allowable range is 0 to 4095. The default value is 8 pages in order to increase the chance of capturing sufficient documentation in the event of a virtual networking problem. Increasing the page size allows a greater history of traces to be obtained when gathering documentation to assist IBM in diagnosing a virtual networking problem. Setting a value of 0 turns off this data capture function.

**DNA DISABLE|ENABLE**

Disable or Enable Directory Network Authorization

**DISABLE**

Turns off Directory Network Authorization management on the system. A NICDEF directory statement specified by the system administrator will not authorize the NIC defined to connect to the specified virtual network. Either a SET VSWITCH PORTNUM | GRANT CP command or a MODIFY VSWITCH System CONFIG statement must be issued on the target VSwitch to authorize the connection and to specify the NIC characteristics. Therefore, NICDEF PORTNUM, PORTTYPE, VLAN, PQUPLINKTX, PROMISCUOUS, and NOPROMISCUOUS operands will be ignored when VMLAN DNA DISABLE is specified.

### ENABLE

Turns on Directory Network Authorization management on the system (default setting). This will allow a system administrator to create and authorize a virtual NIC created by a NICDEF directory statement to connect to a virtual network. All NIC attributes and VSwitch authorization can be performed via the system directory instead of issuing either SET VSWITCH PORTNUM | GRANT CP commands or a MODIFY VSWITCH System CONFIG statement. Authorization is only granted automatically when the target VSwitch is not managed by an ESM.

### Usage Notes

1. Use the QUERY VMLAN command to find out the current attributes in effect for the running CP system.
2. The SET VMLAN statement can be used to set a limit that is lower than the current number of guest LANs. This will **not** force the elimination of any existing guest LANs. It will prevent the creation of new guest LANs until the current number drops below the stated limit.

### Examples

Set a limit of 20 TRANSIENT guest LANs:

```
set vmlan limit transient 20
command complete
```

Prevent the creation of any new TRANSIENT guest LANs:

```
et vmlan limit transient 0
command complete
```

Enable accounting for every user-owned guest LAN:

```
set vmlan acct user on
command complete
```

### Messages

- HCP3195E SET [VMLAN | VSWITCH] not performed; trace table can not be allocated.
- HCP6645E SSI cluster in safe mode; command rejected.
- HCP6706E Invalid TRACESIZE value - *value*

## SET VMRELOCATE

### Authorization

Privilege Class: A

### Purpose

Use SET VMRELOCATE to dynamically control the relocation capability of a specified user. This command can set a user's relocation domain, indicating the set of systems to which it may be relocated, or can disallow relocation of this virtual machine. The virtual architecture level of the virtual machine is the maximal common subset of the architectural features of the cluster members in the relocation domain.

### Operands

#### *user*

is the user ID whose relocation capability is being set. If "\*" is specified, the target user is the command issuer.

A relocation domain cannot be set for a user ID defined by a multiconfiguration virtual machine definition.

#### **DOMAIN** *domain\_name*

defines the domain currently associated with a user. If DOMAIN is not specified, the current domain association is not changed. If a new domain is specified, the user is assigned the new virtual architecture level immediately. This could mean a downgrade in the guest's virtual architecture level. In that case, the FORCE ARCHITECTURE option must be specified. The *domain\_name* can be specified as SSI, which is the domain that includes all members of the SSI cluster.

#### **ON**

enables relocation for the specified user. If DOMAIN is not specified, the currently associated domain is assumed. If the user is not logged on, an error is returned. If neither ON nor OFF is specified, the relocation enablement is not altered.

#### **OFF**

disables relocation for the specified user. If DOMAIN is not specified, the currently associated domain is assumed. If the user is not logged on, an error is returned. If neither ON nor OFF is specified, the relocation enablement is not altered.

#### **FORCE ARCHITECTURE**

specifies that the virtual machine should be assigned to the new domain, even if it means the guest's virtual architecture will be set to a level with less capability than it had in its original domain.

**Attention:** Extreme care should be taken when using this option. If the unavailable hardware features or CP capabilities are important to the virtual machine or its applications, it is likely that the virtual machine or its applications will fail after the domain change is complete.

## SET VMRELOCATE

The guest's architecture is never changed if the SET VMRELOCATE command assigns the guest to the same domain to which it was already assigned, even if the FORCE ARCHITECTURE option was specified.

### Usage Notes

1. Use the VMRELOCATE directory statement rather than including a SET VMRELOCATE command in the directory entry of a user.
2. For information about the virtual architecture level and [Using Relocation Domains](#), see *z/VM: CP Planning and Administration*.

### Responses

Response 1:

```
Running on member sysname  
Relocation enabled|disabled in Domain domain
```

Response 2:

```
This system is not a member of an SSI cluster
```

## SET VSWITCH

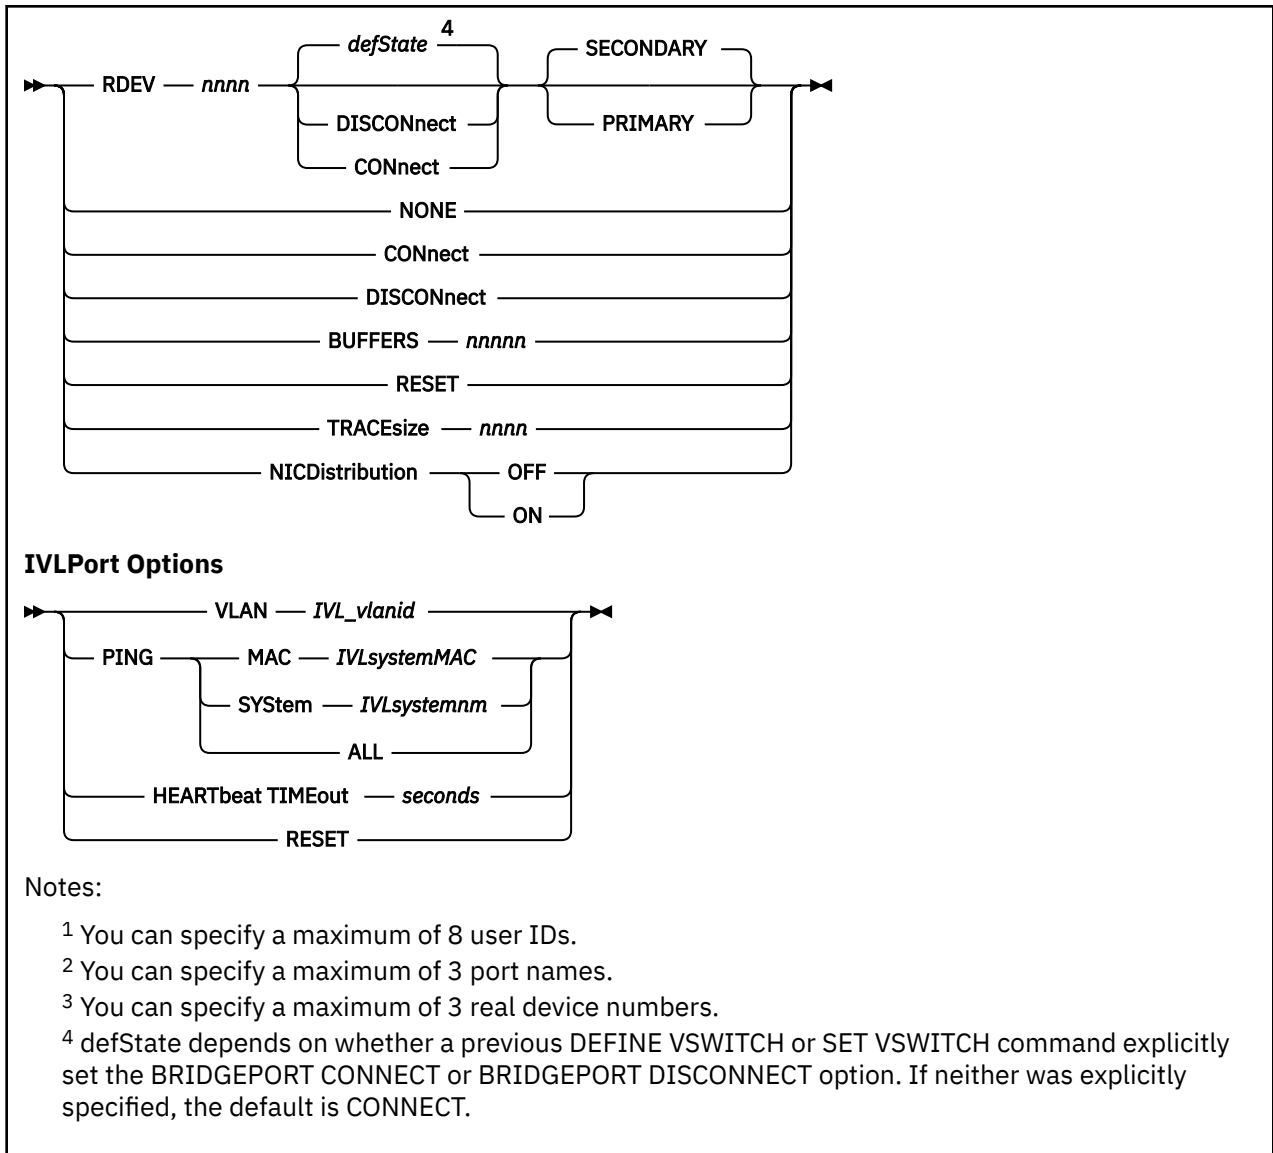

---

▶ Set VSWITCH — *switchname* ◀

## SET VSWITCH

### Authorization

Privilege Class: B

### Purpose

Use the SET VSWITCH command to set the attributes of an existing virtual switch.

### Operands

#### **switchname**

is the name of the virtual switch to be set. The *switchname* is a single token (1–8 alphanumeric characters) that identifies the virtual switch. This virtual switch was created by a DEFINE VSWITCH command or statement in the System Configuration file.

#### **GRANT userid**

specifies the *userid* to be either added or modified in the access list for this virtual switch. This allows *userid* to connect an adapter to *switchname*. If an External Security Manager (ESM) is in control of the virtual switch, it may override the CP access list.

If the *userid* is not currently in the access list, it will be added with the specified network characteristics. Any network characteristics not specified will use the defaults from the virtual switch.

If the *userid* already exists in the access list, then only the network characteristics specified on this command will be changed.

The SET VSWITCH command with GRANT creates a z/VM assigned port (in the range of 2176-4095 inclusive) representing the intended configuration if a port in this range does not already exist. The port defined by this command will persist until the VSWITCH is destroyed or the GRANT is removed by the SET VSWITCH command with the REVOKE option. If any ports are already configured for this user, update each port as specified by this new GRANT specification.

#### **PORTType**

defines the type of VSwitch connection to be used. If the GRANT or PORTNUMBER operand is being used to add a new user or port to the access list, and the virtual switch has been defined as VLAN aware and no PORTTYPE is specified on the GRANT or PORTNUMBER, the porttype assigned to the guest or port will be the default porttype as specified on the DEFINE VSWITCH command or statement.

If the GRANT or PORTNUMBER operand is issued for a user or port that has already been added to the access list, and the virtual switch has been defined as VLAN aware and no PORTTYPE is specified on the GRANT or PORTNUMBER, the current setting of porttype for the guest or port will be used. PORTTYPE TRUNK is not allowed for a TYPE IVL virtual switch.

#### **PORTType ACCESS**

defines the type of connections that are established to be an access port. The guest is unaware of VLAN IDs and sends and receives only untagged traffic.

#### **PORTType TRUNK**

defines the type of connections that are established to be a trunk port. The guest is VLAN aware and sends and receives only tagged traffic for those VLANs to which the guest is authorized. If the guest is also authorized for the *natvid*, untagged traffic sent or received by the guest is associated with the native VLAN ID of the virtual switch.

#### **VLAN vidset**

identifies the VLAN ID (or set of VLAN IDs) to which this user is restricted while connected to *switchname*. If VLAN is not specified, the default VLAN for this user is the default VLAN ID as specified on the DEFINE VSWITCH command or statement. Note that when a virtual switch is defined as VLAN AWARE, a default VLAN ID is not assigned. If a default VLAN ID is not assigned when the virtual switch is defined, then all inbound or outbound frames are discarded until a VLAN ID is assigned.

If VLAN is specified, each item in the *vidset* must be a valid VLAN number (between 1 and 4094, inclusive). The *vidset* may contain ranges:

*Table 39. vidset Ranges*

---

#### **Examples:**

---

VLAN 100-199

VLAN 100-199 1000-1099

---

VLAN 1 101-199

---

VLAN 1 101-199 4094

---

VLAN 1 2 3

---

VLAN 1 101 201 301

---

If an External Security Manager (ESM) is in control of the virtual switch, it can override the CP access list for a virtual switch.

#### **PROMiscuous**

specifies that the user ID or port is authorized for PROMISCUOUS Mode.

### **NOPROMiscuous**

specifies that the user ID or port is NOT authorized for PROMISCUOUS Mode. This is the default setting when the GRANT or PORTNUMBER operand is being used to add a new user or port to the access list.

If an External Security Manager (ESM) is in control of the virtual switch, it may override the PROMISCUOUS authority.

### **PQUPLINKTX**

specifies the priority for all packets sent from a virtual NIC's network connection to an external network. The PQUPLINKTX value will be used when priority queuing is enabled on the virtual switch (PRIQueuing ON). If PQUPLINKTX is configured for a virtual switch that does not have priority queuing enabled, the setting will be saved and used if priority queuing is enabled at a later time. If PQUPLINKTX is not specified, the default is that all outbound traffic to the external network will be sent at Normal priority. See PRIQueuing operand for additional information.

This option is not allowed for IVL virtual switches. For an IVL virtual switch, z/VM handles the priority of outbound transmissions.

Outbound traffic from the Hipersockets Bridgeport will be sent at Normal priority.

### **LOW**

specifies that outbound traffic to the external network will be sent at a low priority. This traffic will use the low priority queue which is serviced less frequently than the normal or high priority queues.

### **NORMAL**

specifies that outbound traffic to the external network will be sent at a normal priority. This traffic will use the normal priority queue which is serviced less frequently than the high priority queue but more frequently than the low priority queue.

### **HIGH**

specifies that outbound traffic to the external network will be sent at a high priority. This traffic will use the high priority queue which is serviced more frequently than the normal or low priority queues.

### **REVOKE *userid***

specifies *userid* is removed from the CP access list for this virtual switch. This prevents user *userid* from connecting an adapter to virtual switch *switchname*. If an External Security Manager (ESM) is in control of the virtual switch, it may override the CP access list.

The REVOKE option removes configured ports belonging to *userid* whether they were configured by SET VSWITCH with GRANT, PORTNUMBER, or NICDEF.

**Note:** If the connection was authorized by the ESM and it needs to be permanently removed, the ESM database must also be updated. If authorized by NICDEF, the user directory must also be updated (to permanently remove access).

### **PORTNUMBER *userportnum* USERID *userid***

The PORTNUMBER operand defines a port for a virtual switch and associates the specified user *userid* with a virtual switch port *userportnum*. This operand will also be used to specify port options including porttype, promiscuous, and VLAN ids. The *userid* will be added to the access list for this virtual switch. This allows *userid* to connect an adapter to *userportnum* on virtual switch *switchname*. If an External Security Manager (ESM) is in control of the virtual switch, the *userid* must be authorized by the ESM, and the VLANs configured with the SET VSWITCH PORTNUMBER command must be included in the VLAN list provided by the ESM. The valid range for user-defined ports is 1-2048.

This option is not allowed for a TYPE IVL virtual switch.

### **PORTNUMBER MODIFY *portnum***

This operand is used to change the port options including porttype, promiscuous, and VLAN ids. The valid range is 1-4095 because the administrator can modify user-defined ports or ports allocated by z/VM.

This option is not allowed for a TYPE IVL virtual switch.

**PORTNUMBER REMOVE *portnum***

specifies the *portnum* to be removed from the virtual switch. Connections to this port are not allowed unless the port is again added to the virtual switch. Existing connections to this port on the virtual switch will be uncoupled. If the *userid* associated with this port does not have any other ports defined on this virtual switch, this will also revoke virtual switch access for the *userid*. The valid range is 1-4095 because the administrator can remove user-defined ports or ports allocated by z/VM.

This option is not allowed for a TYPE IVL virtual switch.

**VLANID *vlanid* ADD *portset***

The ADD operand adds the port set to the specified virtual lan segment. The *vlanid* must be a valid VLAN number (between 1 and 4094, inclusive). Each item in the *portset* must be a valid port number (between 1 and 4095, inclusive). Each port must be defined with SET VSWITCH PORTNUMBER, SET VSWITCH GRANT, or NICDEF before being added to a VLAN. The *portset* may contain ranges:

Table 40. *portset* Ranges

---

**Examples:**

---

1-25

---

1 25-50

---

1 25-50 2048

---

1 2 3

---

1 101 201 301

---

Existing connections will be updated.

This option is not allowed for a TYPE IVL virtual switch.

If an External Security Manager (ESM) is in control of the virtual switch, the VLAN ids defined with VLANID command must be included in the VLAN list provided by the ESM.

**VLANID *vlanid* REMOVE *portset***

The REMOVE operand removes the ports listed from the specified virtual lan segment. The *vlanid* must be a valid VLAN number (between 1 and 4094, inclusive). Each item in the *portset* must be a valid port number (between 1 and 4095, inclusive). The *portset* may contain ranges. See [Table 40 on page 1763](#). Existing connections will be updated. When the last port number is removed from the VLAN, the VLAN is deleted.

This option is not allowed for a TYPE IVL virtual switch.

**VLANID DELETE *vlanid***

The DELETE operand deletes the VLAN *vlanid* from the specified virtual switch. The *vlanid* must be a valid VLAN number (between 1 and 4094, inclusive). The VLAN will be removed from all ports. Existing connections will be updated.

This option is not allowed for a TYPE IVL virtual switch.

**UPLINK**

enables and specifies connectivity for a virtual switch UPLINK port. The UPLINK port is a special port that typically is used to connect the virtual switch to a physical switch -- essentially bridging the virtual switch's simulated network to a physical network.

**CONNECT**

indicates that the currently configured virtual switch UPLINK port must be activated, and traffic may flow through the devices associated with the specified UPLINK ports device(s). For the case when a virtual switch has been defined with the NOUPLINK operand, the CONNECT is not performed. If an error occurs with one of the backup devices, issue the SET VSWITCH *switchname* CONNECT command to refresh the backup device once the problem is corrected.

**DISCONnect**

indicates that the currently configured virtual switch UPLINK port must not be activated, and that no traffic is to flow through the devices associated with the specified UPLINK ports device(s).

A virtual switch can be functional without a connection to a real LAN segment, and traffic flows only between virtual machines coupled to the virtual switch.

**RDEV *nnnn*****RDEV *nnnn.Pn***

is a real device number or a real device number and OSA-Express port number to be used as an UPLINK to connect the virtual switch to a OSA-Express device. The device selected must be compatible to the type of virtual switch created. Specify each real device number as a hexadecimal number between X'0001' and X'FFFD'. If specifying a real device and an OSA-Express port number, specify the real device number as a hexadecimal number between X'0001' and X'FFFD' followed by a period (.), the letter 'P' or ('p') followed by the port number as a hexadecimal number between X'0' and X'F'. For example, to specify port 1 for RDEV 300, specify "300.P1". The value of the port number depends on how many ports the OSA-Express hardware adapter supports. If the port number is not specified, it will default to port 0.

You can specify a maximum of three real device numbers. If you specify more than one device number, each must be separated from the others by at least one blank. When the virtual switch has been defined with the GROUP attribute, any devices identified by the RDEV keyword are used for failover in the event of a real switch failure of the link aggregation group. Failover in this environment will be to a single OSA-Express device connected to a second real switch.

Each real device number represents a trio of devices. For example, specifying **RDEV 111 222 333** means that the first devices, 111-113, are used to provide the connection to the real hardware LAN segment. When issuing the VSWITCH command without the GROUP attribute, if there is a problem with the connection, devices 222-224 are used next to provide the connection, and if those devices fail to connect, devices 333-335 are used. This feature provides dynamic recovery for OSA-Express device failures when issuing the VSWITCH command without the GROUP attribute or for real switch failure when issuing the VSWITCH command with the GROUP attribute. (Failure of an OSA in an aggregated group is automatically handled by the virtual switch; that is, the virtual switch will transfer the data flow to the remaining OSAs in the group.)

RDEV NONE means that the virtual switch should not be connected to the real LAN segment when defined with NOGROUP. When the virtual switch has been defined with GROUP, RDEV NONE means that there is no link aggregation group failover in the event the real switch should fail.

The number of devices identified by the RDEV keyword combined with the number of devices in an associated GROUP may not exceed eight devices.

The RDEV operand may not be used to specify device numbers when the virtual switch is configured to use a shared port group. MAC address takeover is managed by the shared port group to maintain connectivity following a failure.

**GRoup *groupname*****NOGroup**

GROUP indicates that the virtual switch is to be configured to use IEEE 802.3ad Link Aggregation. The *groupname* is a single token (1-8 alphanumeric characters) that identifies the group. Use the SET PORT GROUP command to specify the attributes of the group and the OSA-Express devices that will comprise the group. This option can be specified only when the virtual switch has been defined with the ETHERNET transport attribute. NOGROUP means that the virtual switch will not use Link Aggregation.

The GROUP or NOGROUP operands can be used only when the virtual switch is in the DISCONNECT state. If a group already has been associated with a virtual switch and you wish to change to a different group, first issue SET VSWITCH with the NOGROUP operand, followed by SET VSWITCH with a GROUP operand that specifies the new *groupname*. The port group must be defined using the SET PORT GROUP command before it can be associated with a GLOBAL virtual switch. For a LOCAL virtual switch, if the group specified has not been defined, it will be created with this command.

**NIC**

causes the UPLINK port for a virtual switch to be connected to, or disconnect from, a virtual switch guest port. The NIC operand can be specified only when a virtual switch is in the DISCONNECT state. Setting the UPLINK port to a guest port also will set RDEV NONE and NOGROUP. Changing either of the RDEV or GROUP settings causes UPLINK NIC NONE to be set.

This option is not allowed for a TYPE IVL virtual switch.

***userid2 vdev (AUTO/portnum)***

specifies that the UPLINK port is to be connected to a guest port, and that the virtual switch is not to be connected to a physical switch. In this configuration the virtual switch routes all broadcasts and destination MAC or IP Address unicast frames that cannot be resolved within the simulated LAN segment to the specified guest port. If your virtual switch is VLAN AWARE, the guest port should be configured as a TRUNK port.

- AUTO indicates that the CP determines the virtual switch port number to be used.

If a single user port was defined for this user by the SET VSWITCH command, then that port will be automatically used by COUPLE or CONNECT, and its port settings will be used. If there are multiple user ports defined, then the CONNECT or COUPLE command will fail.

- *portnum*

The guest portnum may be specified. When the uplink NIC is COUPLED or CONNECTED, it is connected to the specified *portnum* on the virtual switch. The portnumber must be a valid user-defined port number (between 1 and 2048, inclusive), and must be configured with the SET VSWITCH PORTNUMBER command. If the *portnum* is not a configured port, then the COUPLE or CONNECT command will fail.

**NONE**

disconnects the currently connected guest port from the special virtual switch UPLINK port. Until another UPLINK port is specified, all destination MAC or IP address unicast frames that cannot be resolved within the simulated LAN segment are discarded

**PATHMTUDiscovery**

indicates that CP will, by default, participate in the Path MTU Discovery process in order to minimize packet loss and to maximize the size of packets sent through a defined UPLINK RDEV port device. The Path MTU Discovery process performed by CP examines and discards any IP datagrams destined for the UPLINK port that are larger than the Path MTU Discovery value allowed by the UPLINK RDEV port device. CP also sends to the datagram source an appropriate notification in the form of an ICMP or ICMPv6 message.

The SET VSWITCH PATHMTUDISCOVERY option can be used to configure a user-defined Path MTU Discovery value, to indicate that CP should determine the Path MTU Discovery value (the default), or to indicate to CP that the Path MTU Discovery process is to be disabled.

These options are specified as follows:

**EXternal**

indicates that CP should determine the Path MTU Discovery value to assign. The value to be assigned is determined as follows:

- If the virtual switch is configured with an active UPLINK RDEV port, CP determines the Path MTU Discovery value to use from the maximum MTU value supported by the connected OSA UPLINK RDEV port device. Typically, this value is 8992 bytes.
- If the virtual switch is configured with one or more UPLINK RDEV ports but none are currently active, CP disables the Path MTU Discovery process, effectively the same as specifying the SET VSWITCH PATHMTUDISCOVERY OFF option. Later, when one of the UPLINK RDEV port devices is activated, CP determines the Path MTU Discovery value to use based on the maximum MTU value supported by the active OSA UPLINK RDEV port device. Typically, this value is 8992 bytes.
- If the virtual switch is configured without an UPLINK RDEV port device, CP disables the Path MTU Discovery process, effectively the same as specifying the SET VSWITCH

## SET VSWITCH

PATHMTUDISCOVERY OFF option. Later, when the UPLINK RDEV port device is defined and activated for the virtual switch, CP determines the Path MTU Discovery value to use based on the maximum MTU value supported by the active OSA UPLINK RDEV port device. Typically, this value is 8992 bytes.

PATHMTUDISCOVERY EXTERNAL is the default setting for the virtual switch.

### **VALue *nnnnn***

configures a user-defined value of *nnnnn* bytes to be used by CP as the Path MTU Discovery value. Specifying this option can be useful if the PATHMTUDISCOVERY value of the physical network needs to be different from the PATHMTUDISCOVERY value used by CP when SET VSWITCH PATHMTUDISCOVERY EXTERNAL is specified. To determine the recommended PATHMTUDISCOVERY value, refer to the Maximum Transmission Unit (MTU) information in the hardware documentation associated with the OSA UPLINK RDEV port device. *nnnnn* is a number from 512 to 65535.

### **OFF**

indicates that the Path MTU Discovery process for this virtual switch is to be disabled by CP. This setting is not recommended when the virtual switch is defined with a Bridge Port.

### **SWITCHOVER**

initiate a controlled port change or failover from the currently active OSA port to another configured backup port with minimal network disruption. Although the network connection is quickly terminated, it is still possible that data in transit may be lost, causing some additional network recovery actions to occur.

This command is not valid for a link aggregation or GROUP configured uplink port. To remove a port from a link aggregation group, use the SET PORT GROUP LEAVE command.

### **AVAILABLE**

Switch to one of the available configured backup uplink devices configured on the virtual switch. The first available port in which a new network connection can be established will become the active uplink port. If none of the configured backup ports can establish an active network connection, then a network connection will be established back on the original device.

### **RDEV *nnnn.Pn***

Attempt to switch to the specified configured backup device. The RDEV and OSA-Express port number specified must already be configured as a backup device with the SET VSWITCH UPLINK RDEV command. Specify the real device number as a hexadecimal number between X'0001' and X'FFFF' followed by a period (.), the letter 'P' or ('p') followed by the port number as a hexadecimal number between X'0' and X'F'. When a port number is not specified using (.Pn), then port number zero will be used.

If for any reason a network connection cannot be established on the specified RDEV, the network connection will be reestablished backed on the original uplink port.

### **PRIQueuing**

enables or disables guest priority queuing support on all outbound data transmissions from the virtual switch uplink port to an external network. Priority queuing is a capability of the OSA-Express feature where multiple output queues are defined for a single network connection with each queue weighed by a priority on how often it gets serviced by the OSA-Express feature. The highest priority queue is serviced first and more often followed by the next highest priority and so on. No queue is starved and all will get serviced at some point by the OSA-Express feature. See [Virtual Switch Priority Queuing Function](#) in *z/VM: Connectivity* for more information on virtual switch exploitation of priority queuing.

If PRIQueuing is to be enabled on a virtual switch, then the OSA-Express features configured to the virtual switch's uplink port must be configured by IOCP to enable the feature within the adapter (PQ\_ON). (See "[DEFINE CHPID / PATH](#)" on page 132 for more information.

### **OFF**

The virtual switch will not exploit priority queuing. A single input queue is established for inbound transmissions from the external network and a single output queue is established for outbound

transmissions. All outbound data to the external network is transmitted with equal priority. This is the default for TYPE QDIO virtual switches.

The OFF option is not allowed for a TYPE IVL virtual switch.

## ON

The virtual switch will exploit priority queuing. If the customer configured the OSA-Express features used by a virtual switch uplink port for priority queuing via IOCP (PQ\_ON), then z/VM will establish one input queue and four output queues when activating its network connection. This will allow z/VM to transmit data to the external network at four different priorities. CP will use the highest priority queue for control and management traffic. The other three queues (low, normal and high) can be used for virtual NIC's network connections. This is the default for TYPE IVL virtual switches.

For an IVL virtual switch, z/VM will attempt to establish an active network connection with the first OSA device specified. For migration reasons, if the OSA-Express features (used by the IVL virtual switch uplink port) are configured without priority queuing (PQ\_OFF), z/VM will establish an active network connection, and force priority queuing off. A warning message will be displayed to inform the customer to configure priority queuing via IOCP.

If the OSA-Express features used by a non-IVL virtual switch uplink port are configured without priority queuing (PQ\_OFF), z/VM will NOT establish an active network connection, and an error message will be displayed.

The policy used to select which priority a specific datagram is transmitted to the external network is determined by the type of virtual switch.

For an IVL virtual switch, the priority of outbound transmissions is handled by z/VM. IVL management traffic will be queued and transmitted on a high priority queue, and encapsulated production data failover traffic will be sent on a lower priority queue. The default for TYPE IVL virtual switches is PRIQUEUING ON, given priority queuing of both management and encapsulated production data is required to maintain a viable IVL network. Only an OSA-Express feature configured for priority queuing should be used on an IVL virtual switch's uplink port.

For all other virtual switch types, the priority can be set to low, normal or high for all packets sent from a guest NIC's network connection to an external network via the SET VSWITCH command. See the PQUPLINKTX operand on [“SET VSWITCH” on page 1757](#) for more information.

The PRIQueuing operand can be specified only when virtual switch's uplink port is in the DISCONNECT state.

## TRACEsize *nnnn*

specifies the number of pages to be allocated for an internal trace table to keep track of trace events pertaining to this UPLINK port. The allowable range is 0 to 4095. The default value is 8 pages in order to increase the chance of capturing sufficient documentation in the event of a virtual switch problem. Increasing the page size allows a greater history of traces to be obtained when gathering documentation to assist IBM in diagnosing an UPLINK related problem. Setting a value of 0 turns off this data capture function.

## BRIDGEport

enables and specifies connectivity for a virtual switch Bridge Port. The Bridge Port is a special port that is used to connect the virtual switch to a HiperSockets CHPID, essentially bridging the HiperSockets CHPID to the virtual switch's simulated and physical networks.

Configuring a virtual switch Bridge Port is only supported when the Bridge facility is supported by the processor, the virtual switch transport type is ETHERNET, the virtual switch TYPE is QDIO and the ISOLATION and VEPA modes are OFF.

Only guest operating systems running in a virtual machine under z/VM and exploiting QDIO Enhanced Buffer State Management (QEBSM) are eligible to be bridged from the HiperSockets CHPID to the virtual switch's simulated and physical networks.

**RDEV *nnnn***

is a real device to be used as a Bridge Port to connect the virtual switch to a HiperSockets CHPID. Only devices that have been configured with the HiperSockets CHPID parameters EXTERNAL\_BRIDGED, can be specified. The RDEV operand can be specified only when the Bridge Port is in the DISCONNECT state.

The device selected must be compatible to the type of virtual switch created; that is, EXTERNAL\_BRIDGED for a QDIO type virtual switch. Connectivity to the HiperSockets CHPID will be prevented when the specified device does not match the virtual switch's type.

Specify a single real device number as a hexadecimal number between X'0001' and X'FFFD'. The real device number specified represents a trio of devices. For example, specifying BRIDGEPORT RDEV 508 means the devices 508-50A are used to provide the connection to the HiperSockets CHPID.

**NONE**

specifies that the virtual switch does not have a Bridge Port. If a Bridge Port was previously defined, it must be in the DISCONNECT state in order to be removed.

**CONnect**

indicates that the device identified by the RDEV keyword will be immediately activated, allowing the connection to be used as the active or standby Bridge Port.

**DISCONnect**

indicates that the device identified by the RDEV keyword will be placed in the inactive state. If this connection is the active Bridge Port connection, another virtual switch with a Bridge Port on the same CHPID in standby state will take over the active Bridge Port connection.

**SECONDARY**

indicates that this virtual switch should be assigned a role as a SECONDARY Bridge Port for the HiperSockets CHPID. The SECONDARY operand can be specified only when the Bridge Port is in the DISCONNECT state. See the DEFINE VSWITCH usage note [“17” on page 242](#) for more information about the SECONDARY Bridge Port role.

**PRIMARY**

indicates that this virtual switch must be assigned the role as the PRIMARY Bridge Port for the HiperSockets CHPID. The PRIMARY operand can be specified only when the Bridge Port is in the DISCONNECT state. See the DEFINE VSWITCH usage note [“17” on page 242](#) for more information about the PRIMARY Bridge Port role.

**BUFFERS *nnnnn***

indicates the maximum number of asynchronous requests that are allowed to be outstanding on the Bridge Port. The allowable range is 0 to 65535. The default value is 2048.

**RESET**

is intended for diagnostic purposes when directed by IBM to synchronize the virtual switch and HiperSockets bridge communications. This RESET operand can be specified only when the Bridge Port is in CONNECT state and is the active Bridge Port connection.

**TRACEsize *nnnn***

specifies the number of pages to be allocated for an internal trace table to keep track of trace events pertaining to this Bridge Port. The allowable range is 0 to 4095. The default value is 8 pages in order to increase the chance of capturing sufficient documentation in the event of a virtual switch problem. Increasing the page size allows a greater history of traces to be obtained when gathering documentation to assist IBM in diagnosing a Bridge Port related problem. Setting a value of 0 turns off this data capture function.

**NICDistribution**

specifies how Ethernet frames flow from HiperSockets bridge capable ports on the HiperSockets CHPID into the virtual switch uplink or other simulated guests that are coupled to the virtual switch.

**OFF**

The virtual switch does not examine each Ethernet frame to identify the HiperSockets guest port that sent the frame. The virtual switch distributes all Ethernet frames from the

HiperSockets CHPID as a single source. OFF is the default setting if you do not specify the NICDISTRIBUTION parameter.

**ON**

The virtual switch examines each Ethernet frame to identify the HiperSockets guest port that sent the frame. The virtual switch uses the HiperSockets guest port information to distribute the frames among the virtual switch uplinks or other simulated guests that are coupled to the virtual switch. The information is used to balance the load, especially when links are in a link-aggregation port group configuration and when most guests are on the HiperSockets CHPID.

When NICDISTRIBUTION is ON, additional information that is related to the HiperSockets guest ports is displayed by the QUERY VSWITCH command, in monitor records, and by Diagnose x'26C'. For example, packet counters and IP addresses of the guests are displayed. For more information, see [QUERY VSWITCH](#) in *z/VM: CP Commands and Utilities Reference*.

**CONTROLLER \* | userid1**

identifies the z/VMz/VM user ID that controls the OSA-Express device connected to the virtual switch. You can specify a maximum of eight user IDs. If you specify more than one user ID, each must be separated from the others by a least one blank. CONTROLLER \* means CP selects from any of the eligible z/VM TCP/IP stacks. See usage note [“1”](#) on page 1773 for more information about the function of a controller.

If you specify multiple real devices on the RDEV keyword or through the GROUP keyword, then specify CONTROLLER \* or allow it to default or specify a list of user IDs. The controller functions are then spread across multiple z/VM TCP/IP stacks, providing more flexibility in case of a failure. You can also specify a pool of specific controllers to be chosen from by specifying a list of user IDs after the CONTROLLER keyword with the SET VSWITCH command or the MODIFY VSWITCH statement.

**MACProtect**

turn on or off MAC address protection for devices coupled to this virtual switch. Turning MAC address protection on prevents a guest from using a MAC address that is not assigned to the user's network device. MACPROTECT is valid only for an ETHERNET virtual switch. MAC address protection is not supported for guest ports that are being bridged by this virtual switch.

There are three levels of inheritance used when determining the MAC address protection level for a MAC address assigned to a network device. The highest is the system level, followed by the virtual switch (or guest LAN) level. The lowest level is the protection set for a specific network data device.

The MAC address protection level assigned is determined first at the device, then virtual switch and lastly the system level. If MAC address protection is set at the device level using the SET NIC CP Command, then its current setting is used. When the device is set to UNSPECIFIED, it will inherit the MACPROTECT setting of the virtual switch. When the virtual switch MACPROTECT setting is set to UNSPECIFIED, the SYSTEM's MAC address protection specified by the SET VMLAN CP command or VMLAN configuration statement is assigned.

**UNSPECified**

allow the MAC address protection to be determined by the SYSTEM level setting. UNSPECIFIED is the default setting for a virtual switch.

If MAC address protection is set to UNSPECIFIED by the SET NIC CP command for a specific device, then the device's MAC address protection will be set to the SYSTEM level defined by the SET VMLAN CP command or the VMLAN configuration statement.

**OFF**

set the MAC address protection level off for coupled devices defined with a MAC address protection set to UNSPECIFIED.

If MAC address protection is set to UNSPECIFIED by the SET NIC CP command for a specific device, then the device's MAC address protection will be set off.

**ON**

set the MAC address protection level on for coupled devices defined with a MAC address protection set to UNSPECIFIED.

## SET VSWITCH

If MAC address protection is set to UNSPECIFIED by the SET NIC CP command for a specific device, then the device's MAC address protection will be set on.

### **MACID** *macid*

is a unique identifier (up to six hexadecimal digits) used as part of the virtual switch MAC address. This MACID (three bytes) is appended to the system MACPREFIX (three bytes) or USERPREFIX (three bytes) to form a unique MAC address for this virtual switch. If a specified MACID is already in use, the virtual switch is not changed. You must eliminate the conflict or select a different MACID. If no MACID is set for the virtual switch, CP generates a unique identifier for this virtual switch. Also, specifying SET VSWITCH MACID without *macid* changes the MACID from the user-specified value to a system-generated value.

**Note:** The MAC address is used in LACP (Link Aggregation Control Protocol). It is necessary for proper operation of a virtual switch defined with the GROUP operand. The MAC address is also used when a z/VM TCP/IP stack is providing management services for a virtual switch, such as acting as an SNMP agent reporting bridge MIB information.

### **VEPA**

determines the operational mode of the virtual switch with regard to forwarding guest-to-guest and guest-to-external destination communications.

#### **OFF**

allows guest ports to communicate with each other and with any hosts and/or LPARs that share the same OSA port. VEPA OFF is the default setting for a QDIO virtual switch.

#### **ON**

prohibits guests from sending traffic to other guests on the same virtual switch without going through an external entity by forwarding all traffic from the guest through the OSA uplink to an adjacent switch. In addition, no direct LPAR communications sharing the same OSA port is permitted with the guest ports of the virtual switch. All traffic from the virtual switch destined for any sharing hosts/LPARs on the same OSA port will be forwarded as well. Any traffic destined for the virtual switch guest ports from hosts/LPARs sharing the same OSA port will also be forwarded to the adjacent switch. VEPA ON requires an ETHERNET virtual switch (without a Bridge Port) with OSA uplink(s) that supports VEPA as well as the partner switch must support Reflective Relay.

VEPA ON may not be specified if ISOLATION is ON.

VEPA ON may not be specified for a GLOBAL virtual switch.

### **ISOLation**

determines if guests on the virtual switch can communicate between themselves and other hosts and/or LPARs that share the same OSA-Express port with the virtual switch. ISOLATION OFF is set by default for all other virtual switch types to allow unrestricted network communications. ISOLATION is not supported for a virtual switch that has a Bridge Port.

#### **OFF**

allows guest ports to communicate with each other and with any hosts and/or LPARs that share the same OSA port.

#### **ON**

prohibits guests from sending traffic to other guests on the same virtual switch by discarding traffic that is destined for another guest port on the virtual switch. In addition, no direct LPAR communications sharing the same OSA port is permitted with the guest ports of the virtual switch. All traffic from the virtual switch destined for any sharing hosts/LPARs on the same OSA port will be dropped. Any traffic destined for the virtual switch guest ports from hosts/LPARs sharing the same OSA port will also be dropped.

ISOLATION ON may not be specified if VEPA is ON.

ISOLATION ON may not be specified for a GLOBAL virtual switch.

### **IPTimeout** *nnn*

indicates the length of time in minutes that a remote IP address table entry remains in the IP address table for the virtual switch.

*nnn* is a number from 1 to 240.

### **VLAN\_counters**

indicates the level of detail that should be maintained for the virtual switch network activity.

#### **OFF**

indicates that the detailed VLAN counters are not needed. That is, the system should stop keeping counters at the VLAN level, and begin keeping transmission counters only at the port level. Packet counters are kept for each port to show the number of frames received, transmitted or discarded. VLAN\_counters OFF is the default.

#### **ON**

indicates that the system should begin keeping transmission counters at the VLAN level. That is, for each port, packet counters are maintained to show the number of frames received, transmitted or discarded for each VLAN. See [Virtual Switch Configuration Strategy with VLAN in z/VM: Connectivity](#) for guidance on selecting VLAN IDs to maximize performance.

### **COUNTERS CLEAR [UPLINK|BRIDGEport] [ALL|DATA|DISCARDed|ERRORs]**

resets counts for the virtual switch.

#### **UPLINK**

resets counts for the uplink port.

#### **BRIDGEport**

resets counts for the bridge port.

#### **ALL**

resets discarded, error and data counts for the specified port.

#### **DATA**

resets data counts for the specified port. Data counts include transmitted packets, transmitted bytes, received packets and received bytes.

#### **DISCARDed**

resets discarded counts for the specified port.

#### **ERRORs**

resets error counts for the specified port.

### **QUEuestorage *numberM***

indicates the upper limit of the amount of fixed storage CP and Queued Direct I/O Hardware Facility will use for buffers for each OSA-Express data device.

*number* defines the maximum number of megabytes of storage that can be consumed for QDIO queues on a single OSA port. When multiple OSA devices are defined in a link aggregation group, then each OSA port within the group will use the specified amount of storage. Fixed storage is allocated as needed based on network traffic, until the maximum of *numberM* are allocated.

*number* is a number from 1 to 8. 8M is the default value.

### **GVRP**

specifies that the VLAN IDs in use on the virtual switch should be registered with GVRP-aware switches on the LAN. This allows offloading of VLAN filtering to the switch from the z/VM Control Program (CP).

### **NOGVRP**

Do not register VLAN IDs with GVRP-aware switches on the LAN.

### **NONrouter**

indicates that the OSA-Express device identified by the RDEV keyword will not act as a router to the virtual switch. If a datagram is received at this device for an unknown IP address, the datagram will be discarded. This is the default.

NONrouter is valid only for an IP virtual switch.

### **PRIrouter**

indicates that the OA Express device identified by the RDEV keyword will act as a primary router to the virtual switch. If a datagram is received at this device for an unknown IP address, the datagram will be passed to the virtual switch.

PRIrouter is valid only for an IP virtual switch.

### **PORTname portname**

is a 1- to 8-character name that identifies the OSA-Express adapter. You can specify a maximum of three port names. Multiple port names are used when different port names are needed for the multiple *rdevs* specified on the RDEV operand. See usage note “5” on page 1774 for more information.

**Note:** The PORTNAME operand is ignored when the GROUP operand is used.

### **IVLPORT**

specifies operations that are allowed only for an IVL-type virtual switch. An IVL virtual switch is a special type of virtual switch that provides communication infrastructure to exchange control information and data necessary to manage global networking objects that can span multiple systems running z/VM.

### **VLAN IVL\_vlanid**

provides the system administrator with a way to change the VLAN ID associated with the IVL port on an IVL virtual switch that is VLAN AWARE. This changes the default VLAN ID assigned when the IVL virtual switch was created. It is a number between 1 and 4094.

### **PING [MAC | SYSTEM | ALL]**

tests connectivity with another system running z/VM, to determine if it is a member of the same IVL domain.

#### **SYSTEM IVLsystemnm**

*IVLsystemnm* is the 8 byte EBCDIC z/VM system identifier of the remote system running z/VM as specified in the system configuration file.

#### **MAC IVLsystemMAC**

*IVLsystemMAC* can be a unicast or multicast MAC address. A MAC address can be entered using any one of the following MAC notations:

- Twelve contiguous hex character: 02A000123456
- Greater than twelve but no more than eighteen hex characters delineated by any non-space character. This permits both standard and even nonstandard MAC address notations to be entered as shown.
  - 02-A0-00-12-34-56
  - 02:A0:00:12:34:56
  - 02A000-123456

#### **ALL**

use ALL to send a ping to the IVL domain multicast MAC address which will check connectivity with all members of the IVL domain.

Use QUERY VMLAN to display the members of the IVL domain along with the *IVLsystemMAC* for each.

### **HEARTbeat TIMEout seconds**

changes the length of time that is allowed to expire before the local system declares a communication problem with another system in the IVL domain if heartbeat signals are missing. Every 5 seconds, each system in the IVL domain broadcasts a signal to confirm current communication with all IVL domain members.

The default HEARTBEAT TIMEOUT is 30 seconds.

The allowable range is 10 to 3600 seconds.

**RESET**

is intended to be used for diagnostic purposes when directed by IBM. The RESET operand:

- terminates and then recreates the IVL virtual switch's connection, forcing the system to serialize itself with all other members of the IVL domain.
- disconnects and immediately reconnects the IVL virtual switch UPLINK port.

**Usage Notes**

1. A virtual switch's connection to a real hardware LAN segment is not operational until an eligible z/VM TCP/IP stack is selected to be the controller for the OSA-Express device. CP selects an eligible z/VM TCP/IP stack to be the controller by either:

- It is recommended that the VSWITCH controller be at the same release level as CP, although all supported releases are allowed.
- If CONTROLLER *userid1* is specified on the DEFINE or SET VSWITCH commands or the DEFINE or MODIFY VSWITCH system configuration statements, with either a single user ID or a list of user IDs, only those user IDs are selected.
- If CONTROLLER \* is specified or allowed to default, CP selects from any eligible z/VM TCP/IP stacks.

A z/VM TCP/IP stack becomes eligible when:

- The TCP/IP MODULE running in the controller is at a release level that supports the function required for the virtual switch.
- An IUCV \*VSWITCH statement is included in its CP directory entry.
- The TCP/IP VSWITCH CONTROLLER statement is coded, and has defaulted to be ON or is explicitly set to ON in the TCP/IP configuration file or through an OBEYFILE command.
- The stack has completed initialization.
- The stack has virtual device numbers available for CP to attach the control device.

The virtual device range used by CP is specified in the VSWITCH CONTROLLER TCP/IP configuration statement. If no VDEV range is specified, CP uses the virtual device number (*vdev*) that matches the *rdev* number specified on the DEFINE VSWITCH or SET VSWITCH command. See *z/VM: TCP/IP Planning and Customization* for more information about the [VSWITCH CONTROLLER Statement](#).

**Note:** Do not code DEVICE and LINK TCP/IP configuration statements for the device. Do not attach the device to a TCP/IP controller virtual machine. These steps are handled by DEFINE VSWITCH processing when a controller is selected.

If an eligible stack is not found, or none of the *rdevs* are operational, you receive a message, and the virtual switch operates in a local LAN environment.

2. Use the QUERY CONTROLLER command output to find the z/VM TCP/IP stacks that are the virtual switch controllers. Use the QUERY VSWITCH command to display information about virtual switch.
3. CP manages the devices used to control a virtual switch's connection to a real LAN segment through an OSA-Express device. CP attaches the devices to the z/VM TCP/IP virtual machine. CP also defines a device of type VSWITCH-OSD to the z/VM TCP/IP stack, concatenating *switchname* with *vdev* and "DEV" to form the device name and *switchname* with *vdev* and "LINK" to form the link names. These names appear in the TCP/IP query and trace information. The status of a link that represents the active connection to a real LAN segment is **Status: Ready**. **Status: Inactive** is shown for any links defined for backup devices.

DEVICE and LINK statements must not be included in the TCP/IP configuration file for these devices. Use the CONNECT and DISCONNECT operands to control whether the traffic flows through the OSA-Express Adapter to a real LAN segment.

If the OSA-Express Adapter has been initialized, you must issue SET VSWITCH with the DISCONNECT option before the PORTNAME, CONTROLLER, NONROUTER, PRIROUTER, GVRP, VEPA, PRIQUEUING,

or the currently active UPLINK port values can be changed. However, you can add or remove backup RDEVs while the virtual switch is connected.

4. Multiple real devices and portnames can be specified on the RDEV and PORTNAME parameters. If your OSA-Express device requires a portname, specify one portname for each real device number. This feature allows failover to an alternate real device in the event of a failure with the current OSA-Express device or link aggregation group. All real devices specified must be active and connected in order to dynamically failover to an alternate device. In addition, the alternate devices must be defined on separate CHPIDs.
5. When the real device identified by one of the *rdevs* is started on a VSWITCH command with the NOGROUP attribute, TCP/IP assigns the port name as the hardware adapter name. If an adapter name was already assigned by a previous connection, then the port name must be the same as assigned by any other connection in order to share the adapter. This includes sharing the OSA-Express adapter with this logical partition or all other partitions.

The PORTNAME operand is optional. However, some levels of the OSA-Express adapters require that the PORTNAME operand is specified. When such an adapter is in use and the PORTNAME operand is omitted, an error message is displayed during switch initialization.

If the device is already started, you must stop it by issuing the SET VSWITCH *switchname* DISCONNECT command before changing the port name.

6. VLAN configuration information can be found in [Planning for Guest LANs and Virtual Switches in z/VM: Connectivity](#).
7. PRIROUTER is required only when IP forwarding (routing) nodes will be coupled to the switch. Router nodes provide connectivity for their LAN segments (remote nodes) through their switch connection. When Router nodes are deployed, their switch connection must be configured as PRIROUTER. In addition to this, the switch itself must also be configured as PRIROUTER to the OSA-E adapter. This will insure delivery of datagrams destined for LAN segments that are connected through routers coupled to a switch. Only one connection on each OSA-Express card can be designated as PRIROUTER. If the switch is successful in establishing PRIROUTER on the OSA-Express card, no other node (or switch) sharing the same OSA-Express<sup>®</sup> card will be able to act as PRIROUTER. If another connection has already been established as PRIROUTER, the switch will be left with NONROUTER status (which is reflected in the QUERY VSWITCH response).
8. NONROUTER is the default mode for the switch. Every node is directly coupled to the switch and the associated IP destinations are registered with the OSA-Express connection. This is the most efficient way to use the virtual switch. In this mode, packets with an unrecognized IP destination are automatically sent out through the switch connection.
9. If the virtual switch has a guest port for the UPLINK port (UPLINK NIC *userid2 vdev*), the PRIROUTER and NONROUTER options are ignored.
10. If the virtual switch has been defined as VLAN UNAWARE, the following are not allowed:
  - the PORTTYPE and VLAN option on GRANT
  - the PORTTYPE and VLAN option on PORTNUMBER
  - the VLANID option
11. If a virtual switch is defined as VLAN aware and no VLAN membership is given with the GRANT, PORTNUMBER, NICDEF or the VLANID (or provided by an external security manager), a guest is a member of the virtual switch's default VLAN ID (*defvid*) only if a *defvid* was assigned as part of the virtual switch definition.
12. The MACID may not be changed while a z/VM TCP/IP stack is providing management (SNMP) services for the virtual switch. That is, when a HOME TCP/IP configuration statement has established a management IP address for the virtual switch using the VSWITCH *switchname* keyword. Use the QUERY VSWITCH command to find the name of the stack providing management services and contact the administrator of the stack to remove the management IP address using the OBEYFILE command for the HOME configuration statement. This disables management services (including SNMP) for the virtual switch. When the MACID has been changed successfully notify SNMP clients

of the MACID change and issue the OBEYFILE command to reassign the IP address and reactivate SNMP services.

13. The MACID may not be changed while the virtual switch connection to the hardware LAN is active. Use the SET VSWITCH *switchname* DISCONNECT command before changing the MACID.
14. Changing the RDEV list with SET VSWITCH RDEV can affect SNMP data, specifically the port number that represents the OSA-E connection to the real network. This is the Bridge MIB *dot1dBasePort* variable (1.3.6.1.2.1.17.1.4.1).
15. Using the VLAN\_counters ON option on SET VSWITCH can significantly degrade throughput and increase system utilization for a virtual switch. Use this option only if there is a need to understand traffic patterns at the level of VLAN IDs. One example of when you might want VLAN\_counters ON is when you are using a network management tool to analyze VLAN network traffic.
16. Detailed transmission counters are available only for a VLAN AWARE Virtual Switch with the VLAN\_counters option set to ON. These values can be obtained by using the Diagnose x'26C' interface.
17. If the virtual switch is VLAN aware, the VLANs need to be configured with the GRANT, VLANID or PORTNUMBER command or via the NICDEF statement in the user directory. If an External Security Manager (ESM) is in control of the virtual switch, the VLANs configured (with GRANT, VLANID, PORTNUMBER or NICDEF) must be included in the VLAN list provided by the ESM.
18. When SET VSWITCH commands are used in conjunction with NICDEF statements to configure the network attributes, the following rules apply:
  - No SET VSWITCH configuration is required if the NICDEF statement provides all necessary network configuration.
  - NICDEF attributes override any prior SET VSWITCH configuration (and this is reflected in subsequent QUERY VSWITCH output).
  - After a device is connected to the virtual switch, subsequent SET VSWITCH commands change the active configuration (but do not alter NICDEF statements in the USER DIRECT source).
  - Each time the virtual NIC is created (or coupled) to the network, network attributes from the NICDEF statement are refreshed (replacing any dynamic changes made using the SET VSWITCH command).
19. The following notes are related to the SET VSWITCH PATHMTUDISCOVERY option:
  - When a PORT GROUP is defined using the SET PORT command, the PATHMTUDISCOVERY option applies to all members of the group.
  - If a virtual switch is configured with an UPLINK NIC, the SET VSWITCH PATHMTUDISCOVERY option is not applicable. However, it can be set for use later when an UPLINK RDEV port device is defined.
  - If a virtual switch is configured with the NOUPLINK option, the SET VSWITCH PATHMTUDISCOVERY option is not allowed.
20. A Global virtual switch is a collection of virtual switches that share the same networking characteristics. This collection of virtual switches spans multiple systems running z/VM but logically operates as a single switch.

Virtual switches defined with the same name and the GLOBAL option are said to be members of the same global virtual switch when they reside in systems running z/VM that belong to the same IVL domain. (Definition and activation of an IVL virtual switch allows a system running z/VM to join an IVL domain. See usage note [“19” on page 243](#) for more information about the IVL virtual switch.)

The following conditions must be fulfilled in order to create or change a global virtual switch member:

- The system's IVL virtual switch must be defined and its UPLINK port connected. In other words, the system must be an active member of an IVL domain.

Creation of Global virtual switches specified in the SYSTEM CONFIG file will be deferred until the IVL virtual switch UPLINK port connects the system to the IVL domain. Message HCP3178I will be displayed for each deferred Global virtual switch.

## SET VSWITCH

- If any other virtual switch exists in the IVL domain with the same name the following attributes must match or the DEFINE VSWITCH or SET VSWITCH will fail with message HCP3170E.
  - IP or ETHERNET
  - ISOLATION
  - VEPA
  - VLAN AWARE or UNAWARE
  - NATIVE *natvid*
  - USERBASED or PORTBASED
- The following additional restrictions exist if a global virtual switch is configured to use a shared port group:
  - RDEV *device\_addr* is not allowed

21. SET VSWITCH COUNTERS CLEAR only affects the data displayed via the QUERY VSWITCH and QUERY NIC commands. It does not affect other data such as Virtual Switch monitor records, Diagnose x'26C' data, or SNMP BRIDGE-MIBs for a virtual switch.

### Examples

The following examples apply when CP, not an ESM, is protecting the guest LAN:

1. To allow user VMTCPIP to connect to virtual switch BIGANG and filter any incoming traffic using VLAN 9, specify the following:

```
set vswitch bigang grant vmtcpip vlan 9
```

2. To remove the authority of LINUX1 to connect to virtual switch BIGANG, specify the following:

```
set vswitch bigang revoke linux1
```

3. To connect virtual switch BIGANG to a real LAN using device FD00, specify the following:

```
set vswitch bigang rdev fd00
```

4. To disconnect virtual switch BIGANG from device FD00 and reconnect it to a real LAN using device FE00 and portname ableport, specify the following:

```
set vswitch bigang disconnect
set vswitch bigang portname ableport
set vswitch bigang rdev fe00
set vswitch bigang connect
```

5. To define a port based virtual switch VSWITCH1 with multiple access ports 10 and 20 for user1, specify the following. Port 10 will be added to VLAN 11 and port 20 will be added to VLAN 21.

```
define vswitch vswitch1 portbased vlan aware
set vswitch vswitch1 portnumber 10 userid user1
set vswitch vswitch1 portnumber 20 userid user1
set vswitch vswitch1 vlanid 11 add 10
set vswitch vswitch1 vlanid 21 add 20
```

6. Given VSWITCH1 (a VLAN AWARE network), individual device connections can be configured in the user directory with no need for SET VSWITCH commands:

```
USER USER1 ...
//
NICDEF 2100 TYPE QDIO LAN SYSTEM VSWITCH1 VLAN 11 PORTTYPE ACCESS
NICDEF 2200 TYPE QDIO LAN SYSTEM VSWITCH1 VLAN 21 PORTTYPE ACCESS
```

### Responses

Response 1:

```
command complete
```

is the normal response from this command.

## Messages

- HCP002E Invalid operand - *operand*.
- HCP003E Invalid option - *option*
- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP007E Invalid userid - *userid*
- HCP025E Storage missing or invalid
- HCP2768E Missing switchname
- HCP2783E VSWITCH SYSTEM *switchname* does not exist
- HCP2798I User *userid* is already authorized
- HCP2799E VSWITCH change is not allowed.
- HCP2838I Device *device* specified for VSWITCH *switchname* BRIDGEPORT is not a bridge-capable HiperSockets device.
- HCP2838I Device *device* specified for VSWITCH *switchname* does not exist.
- HCP2838I Device *device* specified for VSWITCH *switchname* is already attached to user *username*.
- HCP2838I Device *device* specified for VSWITCH *switchname* is not compatible with the VSWITCH type.
- HCP2838I Device *device* specified for VSWITCH *switchname* is offline.
- HCP2838I Port *portnumber* specified for device *device* is invalid; maximum port number is *maxportnumber*.
- HCP2838I Device *device* specified for VSWITCH *switchname* is not configured for priority queuing.
- HCP2839E Invalid operand for specified VSWITCH: *operand*
- HCP2846E The [VLAN | PORTTYPE | GVRP | NATIVE | VLAN\_COUNTERS | VLANID | IVLPORT VLAN] option is not allowed for a VLAN UNAWARE virtual switch.
- HCP2847E PORTTYPE ACCESS is not allowed when the user is authorized for more than one VLAN
- HCP2850E MACID is not set for *switchname*. SSI cluster mode not stable.
- HCP2850E MACID is not set for VSWITCH *vswname*. [ Stack *userid* is providing management services | MAC address *macaddr* is already in use [ by *user ID* ] | Suffix for MAC address *macaddr* is not within USER MACIDRANGE | No MACID is available ].
- HCP2853E SET VSWITCH not performed; device limit exceeded.
- HCP2856E SET VSWITCH not performed; port group already assigned to VSWITCH SYSTEM *switchname*.
- HCP2856E SET VSWITCH not performed; port group *groupname* is already in use.
- HCP2858I Guest *userid* is authorized for too many VLAN IDs on SYSTEM *switchname*. VLAN-specific ARP processing is disabled.
- HCP2858I *userid* connection to *lanowner lanname* has been [revoked | updated] by *userid1*.
- HCP2858I *userid* connection to *lanowner lanname* is not affected by this update.
- HCP3001E Device *device* is defined for both port group *groupname* and VSWITCH SYSTEM *switchname*.
- HCP3002E Unable to establish ISOLATION mode at this time; VSWITCH SYSTEM *switchname* configuration in transition.
- HCP3003E Controller *controllername* for VSWITCH SYSTEM *switchname* does not support OSA QDIO Connection Isolation.
- HCP3004E Device *device* for VSWITCH SYSTEM *switchname* does not support OSA QDIO Connection Isolation.

## SET VSWITCH

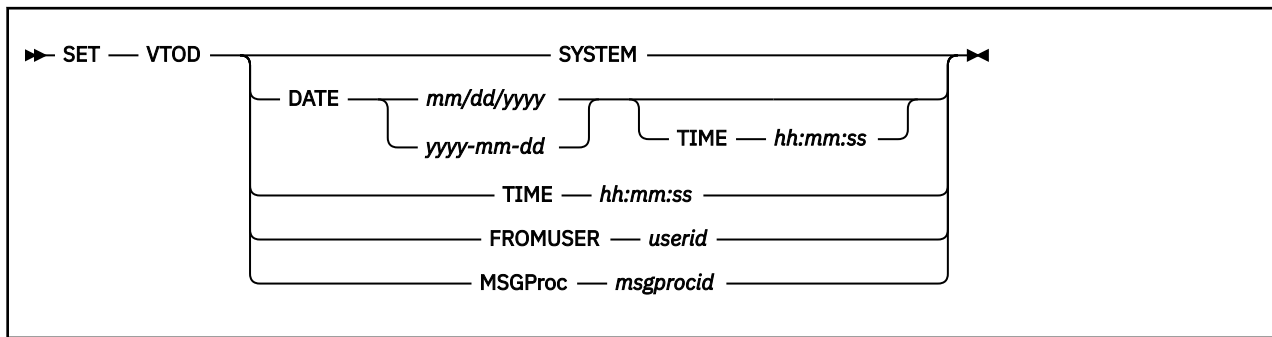

- HCP3022E SET VSWITCH not performed; virtual switch *switchname* is defined with NOUPLINK.
- HCP3022E SET VSWITCH not performed; user *userid* not logged on.
- HCP3022E SET VSWITCH not performed; device *vdev* does not exist.
- HCP3022E SET VSWITCH not performed; NIC type *nictype* does not match VSWITCH type *switchname*.
- HCP3022E SET VSWITCH not performed; NIC *vdev* is already attached to *owner switchname*.
- HCP3022E SET VSWITCH not performed; CONNECT or DISCONNECT is already in progress on the {UPLINK | BRIDGE} port.
- HCP3022E SET VSWITCH not performed; *userid* is not authorized to COUPLE to VSWITCH *switchname*.
- HCP3022E SET VSWITCH not performed; VLAN configuration error.
- HCP3022E SET VSWITCH not performed; NIC transport type *transport1* does not match VSWITCH transport type *transport2*.
- HCP3022E SET VSWITCH not performed; internal logic error code *code*.
- HCP3022E SET VSWITCH not performed; *vdev* is not the correct device type.
- HCP3022E SET VSWITCH not performed; VSWITCH does not exist.
- HCP3022E SET VSWITCH not performed; ESM error.
- HCP3022E SET VSWITCH not performed; Uplink port error.
- HCP3022E SET VSWITCH not performed; ESM VLAN configuration error.
- HCP3022E SET VSWITCH not performed; MACPROTECT is not valid for the IP transport type.
- HCP3022E SET VSWITCH not performed; [BRIDGEPORT | VEPA] is not valid when the transport type is IP.
- HCP3022E SET VSWITCH not performed; [BRIDGEPORT | VEPA] is not valid when the ISOLATION setting is ON.
- HCP3022E SET VSWITCH not performed; ISOLATION is not valid when a Bridge Port is defined.
- HCP3022E SET VSWITCH not performed; BRIDGEPORT RESET requires the virtual switch to be the active Bridge Port connection.
- HCP3022E SET VSWITCH not performed; PATHMTUDISCOVERY is not valid when the virtual switch is defined with the NOUPLINK option.
- HCP3022E SET VSWITCH not performed; [VEPA | ISOLATION] is not valid when [ISOLATION | VEPA] is on.
- HCP3022E SET VSWITCH not performed; SWITCHOVER is not valid when the virtual switch is disconnected.
- HCP3022E SET VSWITCH not performed; SWITCHOVER is not valid when the uplink port is a NIC.
- HCP3022E SET VSWITCH not performed; SWITCHOVER is allowed only when there is an eligible backup device in the uplink RDEV list.
- HCP3022E SET VSWITCH not performed; SWITCHOVER is allowed only when the active device is in the uplink RDEV list.
- HCP3022E SET VSWITCH not performed; SWITCHOVER is allowed only when the virtual switch is not configured for link aggregation.
- HCP3022E SET VSWITCH not performed; UPLINK NIC is not valid when the VEPA setting is ON.
- HCP3022E SET VSWITCH not performed; VEPA is not valid when an Uplink NIC is defined.
- HCP3022E SET VSWITCH not performed; [VEPA | ISOLATION] ON is not valid for a GLOBAL virtual switch.
- HCP3022E SET VSWITCH not performed; UPLINK NIC is not valid for an IVL virtual switch.
- HCP3022E SET VSWITCH not performed; No port is available.
- HCP3022E SET VSWITCH not performed; PRIQUEUING OFF is not valid for an IVL virtual switch.
- HCP3022E SET VSWITCH not performed; PQUPLINKTX is not valid for an IVL virtual switch.

- HCP3031I Port *portnum* cannot join VLAN *vlanid*. The port is not defined.
- HCP3031I Port *portnum* cannot join VLAN *vlanid*. Access ports cannot join more than one VLAN.
- HCP3032I Port *portnum* cannot be removed from VLAN *vlanid*. The port is not defined.
- HCP3032I Port *portnum* cannot be removed from VLAN *vlanid*. The port has not joined that VLAN.
- HCP3033E SET VSWITCH not performed; Port *portnum* is already defined.
- HCP3033E SET VSWITCH not performed; Port *portnum* is not defined.
- HCP3033E SET VSWITCH not performed; VLAN *vlanid* is not defined.
- HCP3033E SET VSWITCH not performed; Port definition conflicts with Uplink NIC port definition.
- HCP3033E SET VSWITCH not performed; Uplink NIC port conflicts with existing port definition.
- HCP3039I Port *portnum* has joined VLAN *vlanid*.
- HCP3039I Port *portnum* has been removed from VLAN *vlanid*.
- HCP3040I SET VSWITCH completed with messages.
- HCP3045E The Bridge facility is not supported by this processor.
- HCP3046E Port number conflicts with configured port *portnum*.
- HCP3049E An internal error occurred; the state of the virtual switch *switchname* may be unstable.
- HCP3160E Virtual switch *switchnm* cannot be configured with the RDEV operand specifying back up devices.
- HCP3160E Virtual switch *switchnm* cannot be configured with a shared port group.
- HCP3161E [DEFINE VSWITCH | SET VSWITCH] is not performed; a port group defined with the SHARED option can be used only with a virtual switch defined with the GLOBAL option.
- HCP3163E SET VSWITCH is not performed; IVLPORT is valid only for an IVL virtual switch.
- HCP3163E SET VSWITCH is not performed; system *sysname* is isolated from IVL Domain *domain* due to a configuration problem.
- HCP3163E SET VSWITCH is not performed; the IVL virtual switch does not exist or its IVL port is not connected.
- HCP3166E [DETACH VSWITCH | SET VSWITCH DISCONNECT] for IVL VSWITCH *ivlswitchnm* failed. Virtual switch *switchname* is defined on *systemnm* with the GLOBAL attribute.
- HCP3167E [DEFINE VSWITCH *switchnm* | SET VSWITCH *switchnm* | SET PORT GROUP *groupname*] failed. The IVL virtual switch does not exist or its UPLINK port is not connected.
- HCP3170E VSWITCH *systemname.switchname* [is not created | is not changed]. The virtual switch defined on *systemname* [ conflicts with the [ IP | ETHERNET | ISOLATION | VEPA | VLAN AWARE | VLAN UNAWARE | NATIVE VLAN | USERBASED | PORTBASED ] attribute ].
- HCP3170E VSWITCH *systemname.switchname* [is not created | is not changed]. An internal error occurred.
- HCP3170E VSWITCH *systemname.switchname* [is not created | is not changed]. The virtual switch defined on *systemname* [ is currently not responding | is currently in synchronization ].
- HCP3173E Device *device* is reserved for system use.
- HCP3174I System *systemname* is not a member of the local system's IVL Domain.
- HCP3186E [DEFINE VSWITCH GROUP | SET PORT GROUP | SET VSWITCH GROUP] for shared port group *groupname* not performed; devices on OSA PCHID *pchid* do not exist or are not available.
- HCP3195E SET [VMLAN | VSWITCH] not performed; trace table can not be allocated.
- HCP3196E SET VSWITCH not performed; the port group must be defined before associating it with a GLOBAL vswitch.
- HCP3199E SET VSWITCH not performed; uplink port group *groupname* on this system is not equivalent to other IVL members sharing the same port group.
- HCP3221E SET VSWITCH GROUP not performed; usage of shared port group *groupname* would exceed the maximum number of virtual switches allowed by a single system sharing the same port group.

## SET VSWITCH

- HCP6704E Missing token at end of line.
- HCP6706E Invalid BUFFER value - *value*
- HCP6706E Invalid device address - *vdev*
- HCP6706E Invalid device address or port number - *{vdev | portnumber}*
- HCP6706E Invalid groupname - *groupname*
- HCP6706E Invalid HEARTBEAT value - *value*
- HCP6706E Invalid MACID - *id*
- HCP6706E Invalid number - *number*
- HCP6706E Invalid PATHMTUDISCOVERY value - *value*
- HCP6706E Invalid PING value - *value*
- HCP6706E Invalid portname - *portname*
- HCP6706E Invalid port number - *portnumber*
- HCP6706E Invalid switchname - *switchname*
- HCP6706E Invalid TRACESIZE value - *value*
- HCP6706E Invalid VLAN id - *vlanid*

## SET VTOD

### Authorization

Privilege Class: A, B, G

### Purpose

Use the SET VTOD command to set a virtual machine's Time-of-Day (TOD) clock. By default, the virtual machine's TOD clock is set and synchronized to the system TOD clock at LOGON. This command:

- enables a user to set their virtual TOD clock to a different date and time,
- enables a user to synchronize the virtual TOD clock of a message processor user to the issuing user's virtual TOD clock,
- enables a user to synchronize their virtual TOD clock with the virtual TOD clock of another user ID,
- resets the user's virtual TOD clock to the system TOD clock.

Use of this command requires authorization which is provided by the OPTION directory statement. Refer to the individual operand description below and the [OPTION Directory Statement](#) in *z/VM: CP Planning and Administration*.

### Operands

#### SYSTEM

the user's virtual machine TOD clock will be set to the current system value. This is the default value that is set at LOGON.

#### DATE *mm/dd/yyyy*

#### DATE *yyyy-mm-dd*

specifies the new date to be used for this virtual machine's TOD clock. If the TIME operand is not specified, the date is changed and the time remains unchanged. The date entered must be in a range from 01/01/1942 to 12/31/2041.

#### TIME *hh:mm:ss*

specifies the new time to be used for this virtual machine's TOD clock. If the DATE operand is not specified, the time is changed and the date remains unchanged.

#### FROMUSER *userid*

the user's virtual machine TOD clock will be set exactly to the specified user ID's TOD clock.

The user must be authorized to use this operand via the TODENABLE operand of the OPTION directory statement. Without authorization, the virtual machine's TOD clock will not be changed and an error message is presented.

#### MSGPROC *msgprocid*

the virtual TOD clock of the specified message processor user will be set exactly to the issuer's virtual TOD clock.

## SET VTOD

If you have Class G privilege only, the message processor that you specify must be currently in your I/O configuration. A message processor may be defined in your I/O configuration by either the DEFINE MSGPROC command or the SPECIAL directory statement.

If you have Class A or Class B privilege, the specified message processor user must have the CFVM operand of the OPTION directory statement.

Regardless of privilege class, the specified message processor user must have the TODENABLE operand of the OPTION directory statement.

**CAUTION:** Setting the TOD clock of the message processor will cause a RESTART MSGPROC command to be executed on the specified message processor. The RESTART MSGPROC command will cause the message processor to be re-IPLed, thus causing all structures within the Coupling Facility to be lost and will affect all coupled guests connected to the message processor. See the RESTART MSGPROC command for more information.

### Usage Notes

1. A system reset will occur for the virtual machine whose virtual TOD clock value has changed. If the virtual TOD clock of a message processor is changed, the message processor's virtual machine is restarted.
2. The virtual TOD clock will be changed for all virtual CPUs of the affected configuration.
3. This command does not affect the time and date information that is returned from DIAG X'000C', DIAG X'270', REXX DATE(), REXX TIME(), or PIPE TIMESTAMP functions. The EXEC2 &TIME and &DATE functions are affected. This command is NOT intended to allow an ordinary CMS user to run their virtual machine with a date and time that is different than the system date and time. This command is to allow guest operating systems running on VM to synchronize their virtual TOD clocks in order to participate in a parallel sysplex environment.

### Responses

Response 1:

To modify the date of your virtual machine's TOD clock, enter the following:

```
set vtod date 12/31/1999
Storage cleared - system reset.
```

Response 2:

To set the TOD clock of the message processor CFCC2 to your virtual machine's TOD clock, enter the following:

```
set vtod msgp cfcc2
HCPMFM2809I Restart of message processor CFCC2 by SHARE1 initiated.
```

Message processor CFCC2 will automatically be restarted. HCP2809I will be displayed to both the message processor and the user who issued the SET VTOD MSGP CFCC2 command.

### Messages

- HCP002E Invalid operand – *operand*
- HCP003E Invalid option – command contains extra option(s) starting with *option*
- HCP020E Userid missing or invalid
- HCP045E *userid* not logged on
- HCP1014E A required option is missing.
- HCP2805E Message processor *msgprocid* does not exist in your I/O configuration.
- HCP2809I Restart of message processor *msgprocid* by *userid* initiated.

- HCP2812E User *userid* does not have *operand* authorization on *statement* directory statement
- HCP6704E Missing token at end of line
- HCP6706E Invalid string – *string*
- HCP6706E Invalid time – *time*
- HCP6706E Invalid date – *date*

## SET WNG

---

### Authorization

Privilege Class: G

### Purpose

Use SET WNG to control the display of WARNING command messages. The initial setting for WARNING is installation dependent and is defined in the system configuration file.

### Operands

#### ON

#### OFF

determines whether warning messages are shown on your display screen. If you specify ON, all messages sent using the WARNING command are displayed. If you specify OFF, no warning messages are received.

#### IUCV

specifies that warnings are to be passed to the virtual machine through IUCV if a connection to the message system service exists. If no IUCV connection exists, the message is handled as if SET WNG ON had been issued.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid

## SET WRKALLEG

### Authorization

Privilege Class: G

### Purpose

Use SET WRKALLEG to turn virtual working allegiance simulation on or off for one or more minidisks. Working allegiance guarantees that if multiple guests (or one guest using multiple virtual devices) start I/O to the same device, one channel program will run to completion or be terminated before another channel program is allowed to begin. When WRKALLEG is off, CP may interleave execution of guest channel programs to the same minidisk.

**Note:** You must have a write link to the specified minidisks to issue this command.

### Operands

#### ON

indicates that virtual working allegiance will be activated for the minidisks specified.

#### OFF

indicates that virtual working allegiance will be ended for the minidisks specified.

#### vdev

#### vdev1-vdev2

is the virtual device number or a range of virtual device numbers of the minidisks.

### Usage Notes

1. This command must be used when running two or more z/OS guests as part of a Sysplex configuration using the cross-system coupling facility (XCF) component of z/OS. SET WRKALLEG ON must be used for any minidisk containing the XCF couple dataset to maintain cross-system lock integrity (and thereby, data integrity) within the sysplex.
2. VM supports a z/OS guest's participation in a Sysplex configuration only if all participating z/OS systems are guests of the same VM host. Environments which include a z/OS system running natively in a separate processor partition, or as a guest of a different VM system are not supported.
3. This command is rejected for full-pack minidisks on a shared real volume. Virtual working allegiance is incompatible with sharing real DASD. SET WRKALLEG is only for sharing virtual devices.
4. This command is rejected for dedicated DASD. Working allegiance is only necessary for shared minidisks. Virtual working allegiance is incompatible with sharing real DASD. SET WRKALLEG is only for sharing virtual devices.
5. Working allegiance applies only to users with write access to the minidisk. This command is rejected if the issuer has read-only access. Furthermore, working allegiance is simulated only when a guest with write access initiates I/O. Only one guest of the sysplex configuration needs to issue SET WRKALLEG ON to activate the function.
6. Working allegiance is always simulated for virtual disks in storage. SET WRKALLEG is rejected if the vdev is a virtual disk in storage.

## SET WRKALLEG

7. The WRKALLEG setting applies to the minidisk, not to an individual virtual device. If two users have links to the same minidisk and one issues SET WRKALLEG, the setting will apply to both users' access to the minidisk.
8. If WRKALLEG is turned on and I/O is already in progress at the minidisk, the first working allegiance I/O to the minidisk may be interleaved with the previous I/O.
9. Caution must be used when WRKALLEG is turned off. If WRKALLEG is turned off while an I/O is already in progress, unpredictable results may occur. The issuer should determine that all users to the minidisk no longer need working allegiance before terminating the function.
10. For more information on working allegiance, see the Principles of Operation for your processor.
11. For information about the WRKALLEG rules when linking, see [“LINK” on page 578](#).

## Responses

Response 1:

```
DASD <vdev> working allegiance is being
simulated among same system guests.
```

is returned for each virtual device specified where WRKALLEG=ON.

Response 2:

```
DASD <vdev> working allegiance is turned off.
```

is returned for each virtual device specified where WRKALLEG=OFF.

## Messages

- HCP003E Invalid option - *option*
- HCP006E Invalid device type - *vdev*
- HCP026E Operand missing or invalid
- HCP040E Device *vdev* does not exist
- HCP2010E DASD *vdev* is dedicated, WRKALLEG is rejected.
- HCP2010E DASD *vdev* is read only, WRKALLEG is rejected.
- HCP2010E DASD *vdev* is a full-pack mini on a shared real volume, WRKALLEG is rejected.
- HCP2010E DASD *vdev* is a VDISK, WRKALLEG is rejected.
- HCP6645E SSI cluster is in safe mode; command rejected.
- HCP6706E Invalid address range - *string*

## SET 370ACCOM

### Authorization

Privilege Class: G

### Purpose

Use SET 370ACCOM to allow System/370 CMS applications to run in an ESA/390 or ESA/XC virtual machine.

### Operands

#### ON

indicates that 370-only applications can run in an ESA/390 or ESA/XC virtual machine.

#### OFF

indicates that 370-only applications cannot run in an ESA/390 or ESA/XC virtual machine. This is the initial setting.

### Usage Notes

1. When 370ACCOM is set ON, it remains on until it is either set OFF or until the virtual machine experiences a subsystem-reset operation. A subsystem-reset operation occurs during the execution of commands such as the following:
  - IPL
  - DEFINE STORAGE
  - SET MACHINE
  - SYSTEM RESET
  - SYSTEM CLEAR
  - DETACH CPU
2. A guest in z/Architecture or z/XC mode can not have 370ACCOM ON.
  - If a MACHINE ESA guest with 370ACCOM ON switches into z/Architecture mode, 370ACCOM will be turned OFF as part of the transition.
  - If a MACHINE XC guest with 370ACCOM on switches to z/XC mode, 370ACCOM will be turned off as part of the transition.
  - If a MACHINE Z guest issues the SET 370ACCOM ON command, the command will be rejected with error message HCP2632E.
3. For information on running your 370-only CMS applications in an ESA/390 or ESA/XC virtual machine, see the following topics in *z/VM: CP Programming Services*:
  - [370 Accommodation Facility Overview](#)
  - [370 Accommodation Facility Definition](#)
  - [DIAGNOSE Code X'58' – 3270 Virtual Console Interface](#)

**Messages**

- HCP2632E When a virtual machine is in z/Architecture or z/XC mode, you cannot set 370ACCOM ON.

# SHUTDOWN

## Authorization

Privilege Class: A

## Purpose

Use SHUTDOWN to complete the following tasks:

- Systematically end all system function.
- Checkpoint the system for an eventual warm start.

Optionally, SHUTDOWN does an automatic warm start of the current or specified CP module.

## Operands

### SYSTEM *sysname*

specifies the name of the system that is to be shut down. The *sysname* must be the name of the system on which the command is issued.

## SHUTDOWN

The SHUTDOWN command shuts down only the system on which the command is issued. Specifying the system name serves as a check to verify that the intended system is being shut down (you cannot shut down system B from system A).

The system configuration file can be defined to require the SYSTEM to be specified on the SHUTDOWN command (see the [FEATURES Statement](#) in *z/VM: CP Planning and Administration*). This might be preferred in large data centers with multiple operator consoles to help prevent accidentally shutting down the wrong system.

### **WITHIN interval**

specifies a time interval for the entire z/VM system shutdown.

The *interval* specifies a number of seconds in the range 1 - 65535.

If the interval is greater than the CP shutdown interval, CP immediately sends a shutdown signal to enabled guests and delays the start of the CP shutdown. The start of the CP shutdown is delayed until either of the following events occurs:

- All signaled guests indicate that they shut down.
- The shutdown-signal timeout interval elapses.

See usage notes [“10” on page 1792](#), [“11” on page 1792](#), and [“12” on page 1793](#).

### **BY time**

specifies a time-of-day target for the entire z/VM system shutdown.

The *time* can be specified as *hh:mm* or *hh:mm:ss*. The interval from the time of day that the command is entered until the specified time-of-day must be in the range 1 - 65535 seconds.

The start of the CP shutdown is delayed until one of the following events occurs:

- All signaled guests indicate that they shut down.
- The shutdown-signal timeout interval elapses.
- The specified time of day (minus the amount of time that is reserved for a CP shutdown) is reached.

See usage notes [“10” on page 1792](#), [“11” on page 1792](#), and [“12” on page 1793](#).

### **IMMEDIATE**

shuts down the entire z/VM system immediately without sending shutdown signals to enabled users, even if a previous SHUTDOWN command is pending. If a previous SHUTDOWN command is pending, its operands are not used and must be specified with IMMEDIATE on the new command if they are required. See usage note [“10” on page 1792](#).

### **REIPL**

specifies that the system is to be restarted immediately after the SHUTDOWN command completes.

#### **rdev**

identifies the real device to be IPLed when the system is restarted. If *rdev* is not specified, the system will REIPL from the *rdev* that was used for the last IPL or SHUTDOWN REIPL.

**Note:** If you specify *rdev*, you cannot specify MDISK.

### **WAIT code**

causes a disabled wait state PSW to be loaded after shutdown. The code in the PSW is a hexadecimal number between 1 and FFFF.

### **NOCKPT**

will suppress taking a checkpoint and load a disabled PSW of 9027 after the following message is displayed:

```
HCP9027W  SYSTEM TERMINATION COMPLETE WITHOUT CHECKPOINT
```

### **CANCEL**

causes a scheduled shutdown to be terminated. Any guests that received termination signals when the original SHUTDOWN command was issued continue to process those signals.

## Options

### **MDisk *userid vdev***

specifies the owning user ID and virtual device number of the minidisk that contains the CP module.

### **EXTent *n***

specifies which minidisk extent on a CP-formatted volume contains the module to be loaded. The variable *n* is a single decimal number in the range 1 - 9. 1 refers to the first extent formatted as "PARM", while 9 refers to the ninth such extent.

### **MOdule *filename***

specifies the file name of the module that SHUTDOWN is to load. The file type of the module must be MODULE.

### **OFFset *nnnnnnnn***

specifies the offset from the beginning of the disk (identified by *rdev*) at which the CMS-formatted minidisk that contains the module resides. You can specify up to 8 digits for OFFSET. For CKD and ECKD DASD, the offset is specified as the number of cylinders from the beginning of the disk. For FBA DASD, the offset is specified as the number of blocks from the beginning of the disk.

### **ORigin *hexloc***

specifies the address at which SHUTDOWN loads the module. This option is ignored by SHUTDOWN if the module that is being loaded was not generated with the RLDSAVE option. In this case, the module is loaded into storage at the location at which the module was generated.

When loading CP, the ORIGIN option is accepted, but CP relocates itself to location X'2000'.

### **Iplparms**

specifies information that is to be passed to the loaded program by SHUTDOWN.

#### ***text/?***

specifies information that is to be passed to the loaded program by SHUTDOWN. The information replaces all currently specified IPL parameters.

**Note:** When you enter *text* on the command line, IPLPARMS must be the last option that you specify. The format of the IPL parameters depends entirely on the options that are supported by the loaded program. For a list of IPL parameters supported by CP, see [Passing IPL Parameters in z/VM: System Operation](#).

#### **?**

causes SHUTDOWN to prompt the operator for up to three lines of data to be read from the console. A null entry can be used to signify that all parameters are entered.

SHUTDOWN command processing accepts a "?" or a "? " (a "?" followed by a blank) as valid arguments to initiate the prompting sequence for the IPL parameters. All other arguments are assumed to be IPL parameters and do not initiate the prompting sequence.

## Usage Notes

1. Because SHUTDOWN stops all virtual machine operations, consider warning all users of an impending shutdown as early as possible so that they can quiesce their systems in an orderly manner.

You can use the SET LOGMSG, MESSAGE, and WARNING commands to inform the affected users.

**Note:** CMS file pool servers shut down automatically without operator intervention unless a server is explicitly disabled from receiving a shutdown signal from CP. For more information, see [Startup Parameter Descriptions in z/VM: CMS File Pool Planning, Administration, and Operation](#).

2. Specifying SHUTDOWN with no operands causes the system to come to an orderly termination. When the termination completes, CP enters a disabled wait state.
3. SHUTDOWN terminates all outstanding Concurrent Copy (CONCOPY) sessions, and disbands the path groups of all DASD if CP is running in a native machine.
4. If REIPL is specified but *rdev* is omitted, the current system residence device is re-IPLed.

## SHUTDOWN

5. When REIPL is specified, CP attempts to do an automatic warm start. If the automatic warm start is to succeed:
  - a. It must have its warm start cylinders and checkpoint cylinders defined in the same location that the current system does.
  - b. The new CP module must contain the same versions of control blocks that are used by the checkpoint or warm start process, such as HCPCKIBK, HCPCKPBK, HCPPFXPG, HCPSYSCM, HCPSPBKB, HCPSPFBK, and HCPSPMBK.
  - c. The new CP module must contain the same version of the checkpoint (HCPCKP or HCPCKS) and warm start (HCPWRM or HCPWRS) modules.
  - d. Any CP system volumes that are shared between the old and the new system must have the same position in the CP\_Owned statement in the system configuration file.

Otherwise, the automatic warm start might fail and a hardware IPL with a FORCE start must be completed.

6. When REIPL is specified, CP uses the parm disk location from the previous IPL. If the parm disk was moved by using CPFMTXA or ICKDSF, CP might fail to find the CPLOAD module and issue message HCP6739E. Or CP might find the old CPLOAD module on the previous parm disk. Use the EXTENT option of the SHUTDOWN command to force CP to find the parm disk at its new location, or use the OFFSET option to specify the new location of the parm disk. It is recommended to move the parm disk only shortly before a planned REIPL.
7. When a SHUTDOWN is issued, the trace data for all active DEFERIO traces are not written.
8. All IPL parameters that are used with the IPLPARMS option remain in effect until they are changed with a subsequent SHUTDOWN REIPL command that specifies the IPLPARMS parameter, or the CP nucleus is shut down, or a SET IPLPARMS is issued.
9. If the REIPL option is used, some I/O subsystem features might not be available if the system that is brought up on the re-IPL supports a superset of the features that are supported by the system that was shut down. A full I/O reset is necessary to support all the features. A full I/O reset can be completed only by using the Load function on the processor's hardware console. For example, the Parallel Access Volumes feature of an IBM DASD Subsystem might not be available on re-IPL if the system that was shut down did not support that feature.
10. A user is enabled for signals only when a guest operating system is running in the virtual machine and is enabled to receive these signals.
11. If the WITHIN, BY, or IMMEDIATE operand is not specified on the SHUTDOWN command, and the system-default shutdown-signal timeout interval is greater than 0, the following occurs:
  - CP sends a shutdown signal to enabled users.
  - The start of the CP shutdown is delayed. The delay gives guest systems an opportunity to do their own shutdown processing. The CP shutdown is delayed until the shutdown-signal timeout interval elapses or all signaled guests shut down, whichever occurs first.

If the WITHIN, BY, or IMMEDIATE operand is not specified on the SHUTDOWN command and the system-default shutdown-signal timeout interval is 0, shutdown signals are suppressed and the CP shutdown begins immediately.

Use caution when you specify the WITHIN, BY, or IMMEDIATE operand on the SHUTDOWN command. The resulting interval might not provide guests with enough time to complete an orderly shutdown.

The WITHIN, BY, and IMMEDIATE operands specify the time interval for the entire z/VM system shutdown. The shutdown-signal timeout interval, which provides time for guests to shut down, is the difference between the entire z/VM system shutdown interval and the CP shutdown interval. When you specify the WITHIN or BY operand, the shutdown-signal timeout interval might not provide guests with enough time to complete an orderly shutdown. When you specify the IMMEDIATE operand, the shutdown-signal timeout interval does not provide guests with enough time to complete an orderly shutdown.

If the interval that you specify with the WITHIN or BY operand is equal to the CP shutdown interval, shutdown signals are suppressed and the CP shutdown begins immediately.

For examples of the interaction between the SHUTDOWN command timing operands, the CP shutdown interval, and the system-default shutdown-signal timeout interval, see [“Examples” on page 1794](#).

**Tip:**

- The system-default shutdown-signal timeout interval is specified by the SET SIGNAL SHUTDOWNTIME system configuration statement or command. For more information, see [“SET SIGNAL” on page 1701](#).
  - The CP shutdown interval is specified by the SET SHUTDOWNTIME system configuration statement or command. For more information, see [“SET SHUTDOWNTIME” on page 1698](#).
12. A user might issue the SET SHUTSIGNAL OFF command to temporarily make shutdown signals unavailable. The QUERY SIGNALS command can be used to display the signal status of a specified user or all users.
  13. After the SHUTDOWN command is initiated successfully, this message is sent to the primary system operator:

```
HCP2116I SHUTDOWN initiated at yyyy-mm-dd hh:mm:ss by userid
```

14. After the SHUTDOWN CANCEL command is issued, this message is sent to the primary system operator:

```
HCP2117I SHUTDOWN CANCEL issued at yyyy-mm-dd hh:mm:ss by userid
```

15. Users who receive the shutdown signal and need more information about the system shutdown can issue QUERY SHUTDOWN STATUS to get information about the current shutdown.

## Responses

### Response 1:

```
System shutdown may be delayed for up to interval seconds
```

is displayed when the command is accepted and some guests require time to shut down. If a user other than the primary system operator issues the SHUTDOWN command, this response is sent to both the command issuer and the primary system operator.

### Response 2:

```
SYSTEM SHUTDOWN STARTED
```

is displayed when the command is accepted and termination processing is in progress. If a Class A user other than the primary system operator issues the SHUTDOWN command, this response is sent to both the command issuer and the primary system operator.

### Response 3:

```
STARTING SYSTEM SHUTDOWN STEP name - description
```

is displayed for each step of the shutdown process as it proceeds. Each message identifies the *name* of the step and a *description* of its function. On a 3270 terminal, these messages are displayed on the first line of the screen, always showing the last step that was initiated. On the system console (SYSC) device, the messages are displayed one after another in line mode.

## Examples

1. In the following example, a guest is not provided their time to process signals because the duration is not long enough.

```
SET SHUTDOWNTIME 70
SET SIGNAL SHUTDOWNtime 30
SHUTDOWN WITHIN 90
```

Guests get only 20 seconds to respond to shutdown signals because CP requires 70 of the 90 seconds for CP shutdown.

2. In this example, assume that the time is exactly 11:58. The SHUTDOWN command's BY operand specifies a time of 12:00, which provides 120 seconds to process a shutdown.

```
SET SHUTDOWNTIME 70
SET SIGNAL SHUTDOWNtime 30
SHUTDOWN BY 12:00
```

Guests get 50 seconds to respond to shutdown signals because CP needs only 70 of the 120 seconds for the CP shutdown.

## SIGNAL

### Authorization

Privilege Class: A, C, G

### Purpose

Use `SIGNAL` to send a signal to a user or to all users who are enabled to receive signals.

A class A or C user can send a signal to a specific user or to all users who are enabled to receive signals, and log the users off after they have processed the signal.

A class G user can send a signal to the user's own virtual machine, if the virtual machine is enabled for signals.

### Operands

#### SHUTDOWN

indicates that a termination signal is to be sent.

#### userid

identifies the user to be signaled. Use the keyword `USER` when you specify a user ID of "all".

#### ALL

indicates that all users who are enabled to receive termination signals should be signaled.

#### WITHIN interval

sends the user a shutdown signal that times out when the specified interval elapses. The *interval* specified is a number of seconds in the range 1 - 32767.

#### BY time

sends the user a shutdown signal that times out when the designated time is reached. The *time* can be specified as *hh:mm* or *hh:mm:ss*. The equivalent interval in seconds must be in the range 1 - 32767 seconds.

## Usage Notes

1. A user is enabled for signals only when a guest operating system is running in the virtual machine and has enabled to receive these signals.
2. When the signal times out or the user machine indicates that it has terminated operation, whichever occurs first, the virtual machine is logged off if it has been disconnected.
3. If the WITHIN or BY operand is not specified, and the system default shutdown signal timeout interval is set to a value greater than 0 (by the SET SIGNAL SHUTDOWNTIME system configuration statement or command), that value is used as the signal timeout interval. If the system default value is 0, you must specify an interval on the SIGNAL command. For additional information about this behavior, see [“SET SIGNAL” on page 1701](#).
4. A user might have issued the SET SHUTSIGNAL OFF command to temporarily disable for receiving shutdown signals. The QUERY SIGNALS command can be used to display the signal status of a specified user or all users.
5. When the SIGNAL SHUTDOWN \* command or the class G SIGNAL SHUTDOWN command is issued, no message is sent to the primary system operator. When a SIGNAL SHUTDOWN is initiated successfully by a class A or C user with the SIGNAL SHUTDOWN ALL command or the SIGNAL SHUTDOWN *user* command, this message is sent to the primary system operator:

```
HCP2118I SIGNAL SHUTDOWN {ALL | user} issued at yyyy-mm-dd hh:mm:ss by userid
```

## Messages

## SILENTLY

---

```
►► SILENTly — command_string ◄◄
```

### Authorization

Privilege Class: Any (See usage note “1” on page 1798).

### Purpose

Use SILENTLY to execute another CP command, suppressing its responses if that command is so enabled. A command is enabled for response suppression by specifying the SILENT option on the DEFINE COMMAND / CMD or MODIFY COMMAND / CMD command or system configuration statement.

**Note:** Response suppression is supported only for the ATTACH, DETACH, and GIVE commands.

### Operands

#### *command\_string*

is the full text of the CP command to be executed. If the command is enabled for response suppression, command responses are suppressed. Warning, error, and informational messages produced by the command are not affected. If the command is not enabled for response suppression, it executes as if it was issued directly.

### Usage Notes

1. You must have the proper privilege class for the CP command to be executed.

### Examples

1. To attach device 1234 to user MVS and suppress the messages sent to the issuer, to the user who is the object of the ATTACH, and to the system operator:
  - a. Enable the ATTACH command for response suppression:

```
modify command attach silent
```

- b. Issue the SILENTLY command for ATTACH:

```
silently attach 1234 to mvs as 1234
```

# SLEEP

## Authorization

Privilege Class: Any

## Purpose

Use SLEEP to stop your virtual machine for a specified period of time. When the specified period elapses, your virtual machine automatically resumes processing.

## Operands

***nn* SEC**

***nn* MIN**

***nn* HRs**

identifies the number of seconds, minutes, or hours, measured by the time-of-day clock, that your virtual machine is to remain stopped. The value *nn* can be any decimal number from 00 through 99. If you specify no time unit, CP assumes that *nn* indicates minutes.

### ATTN

specifies that if the SLEEP command with a time interval is issued through a DIAGNOSE X'08' instruction, the return code indicates whether the virtual machine restarted because the time interval expired (RC=0), or because an attention was signaled (RC=1457).

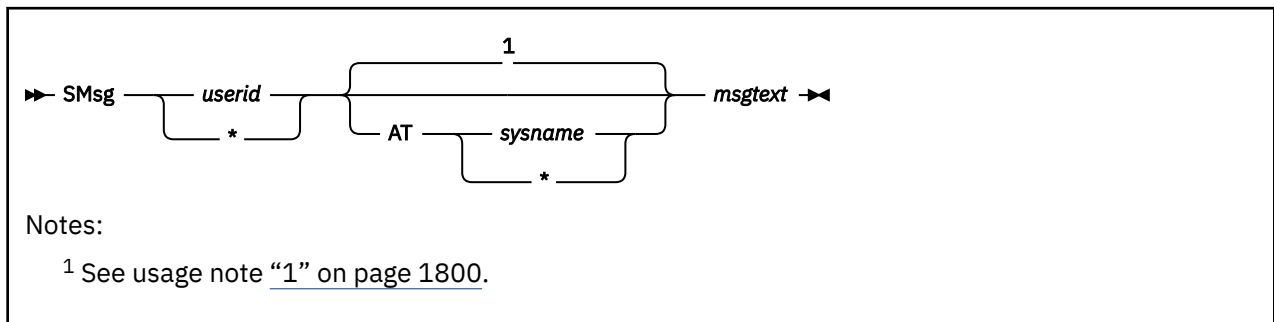

## Usage Notes

1. During the dormant period, the virtual machine does not run, but connection time is still counted.
2. Messages continue to be displayed even though your virtual machine is in the dormant state.
3. You can start your virtual machine at any time by pressing the ENTER key. If you specify a sleep interval in the command line, your virtual machine awakens automatically when the specified interval has elapsed.
4. If you do not specify an interval, your virtual machine remains dormant until you press the ENTER key.
5. If you enter the SLEEP command from a CP environment, you will return to the CP environment when the time interval has elapsed, or when you press the ENTER key.
6. If you enter the SLEEP command while in virtual machine environment, the end of the time interval or pressing ENTER returns your display to virtual machine mode without entering the CP environment.
7. The SLEEP command, with the time interval, is a convenient way to delay or schedule the execution of certain jobs that could be run more efficiently at a later time (for example, second shift).

## Messages

- HCP002E Invalid operand - *operand*

## SMSG

### Authorization

Privilege Class: G

### Purpose

Use SMSG to send a special message to a virtual machine programmed to accept and process the message.

### Operands

#### *userid*

\*

is the virtual machine to which the special message is to be sent. To send the message to yourself, specify an asterisk (\*).

#### **AT** *sysname*

sends the special message to a specific system in the SSI cluster to which this system belongs. The return code is sent to the command issuer.

#### **AT** \*

sends the special message only to the system where the command is issued. This is the default if the system is not a member of an SSI cluster.

#### *msgtext*

is the text of the message you are sending. The length of the message is limited by the number of characters remaining on the input line after the command and the appropriate operand are entered. Mixed DBCS data may be used as input message text.

### Usage Notes

- If the AT operand is not specified:
  - If the sender's system is not a member of an SSI cluster, the default is AT \*.
  - If the sender's system is a member of an SSI cluster, the message is sent to all members of the cluster, except in the following cases, when it is sent only to the local system:
    - If the specified user ID is OPERATOR.
    - If the specified user ID is logged on to the same system as the sender.
    - If the specified user ID or the sender is defined by a multiconfiguration virtual machine definition.
- Special messages do not appear on the receiving user's console because the messages are expected to be instructions or commands that are processed by the receiving virtual machine.
- Virtual machines can receive special messages only under the following conditions:

- The receiving virtual machine has issued the SET SMSG ON command, or set the VMCP SMSG flag at authorization time.
- The user wishing to receive special messages has issued an AUTHORIZE with the Virtual Machine Communication Facility (VMCF).

You can also receive special messages through IUCV by issuing the SET SMSG IUCV command.

4. If an external security manager (ESM) is installed on your system, you might not be authorized to enter this command. However, messages sent to or from the system operator are not subject to authorization checking by the ESM. For additional information, contact your security administrator.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid
- HCP045E *userid* not logged on
- HCP057I *userid* not receiving; *text*
- HCP2970E The SSI cluster member name is missing or invalid.
- HCP2971I Specified SSI cluster member is not joined.
- HCP6600E An error was detected by installation-wide {*CP module name*|exit point 1210} - return code *nnnn*

## SNAPDUMP

### Authorization

Privilege Class: A

### Purpose

Use SNAPDUMP to generate a system dump without terminating and restarting the system. The dump that is created is identical to a hard abend dump, except that it will not contain PGMBKs unless they were requested.

### Operands

#### FRMTBL NO

#### FRMTBL YES

specifies whether the full CP frame table is included in the dump. If you specify NO, the default, the frame table is not included and the dump includes a correlation table describing only the frames whose contents were dumped. YES forces inclusion of the frame table. IBM recommends using the default unless IBM support personnel instruct you to do otherwise in order to diagnose a specific problem.

#### PGMBKS NONE

#### PGMBKS ALL

specifies whether user PGMBKs are included in the dump. If you specify NONE, the default, no user PGMBKs are included. ALL forces inclusion of all PGMBKs that aren't paged out. IBM recommends using the default unless IBM support personnel instruct you to do otherwise in order to diagnose a specific problem.

### Usage Notes

1. This command is particularly useful when diagnosing a hung user situation. The settings specified by the SET DUMP command determine where the output will go.
2. The frame table and PGMBKs together constitute the vast majority of CP-owned frames, because they contain entries describing each 4K unit of real and virtual memory, respectively. The CP frame table is 1/128th the size of configured memory (8 GB per TB). PGMBKs take up 8K for each 1MB of virtual memory; though they are pageable, a PGMBK must remain resident as long as any page of that megabyte is resident. Omitting these structures from dumps when they are not likely to be needed for diagnosis dramatically reduces dump size and dumping time. When debugging problems using a snap dump, it is very rare to need information from the frame table or any of the PGMBKs. You will be directed by IBM support personnel to include these items if this will aid in problem determination.
3. Because SNAPDUMP command operands can influence the size of the dump, CP allocates dump space corresponding to the maximum possible size of the dump. Make sure you have enough DASD space available to support another dump after this one is taken.
4. Although this command will generate a dump without taking your system down, all activity in the system is stopped. If you specify FRMTBL YES or PGMBLKS ALL, the amount of time necessary to

dump the system could be sufficient to cause your communication lines to drop, which could adversely affect your system.

Consider this before using this command:

- You may want to send a message to all logged-on users warning them of the impending quiesce (similar to what an operator might do before issuing SHUTDOWN). Although the system should not go into a shutdown, it will appear to the users that the system has stopped while the dump is being taken.

In a Multi-VSwitch LAG environment, if the LPAR issuing the SNAPDUMP is also the controlling LPAR for all the LAG ports, this can also cause network outages on the other LPARs in that LAG group.

5. The abend code in a dump created from use of the SNAPDUMP command will be SNP001.

## Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid
- HCP9265I The SNAPDUMP command has been entered causing the non-destructive dump function to be called. The system will be quiesced until the dump is complete.
- HCP9662I The SNAPDUMP command has been issued, however the current dump setting is OFF. No dump will be generated.
- HCP9267E The system is unable to determine the dump device settings following a non-destructive dump. The dump device is now set to OFF. To assign a different device, enter the SET DUMP command.
- HCP1858I The non-destructive dump function has completed.

## SPACE

►► SPACe — rdev ◄◄

### Authorization

Privilege Class: D

### Purpose

Use SPACE to override real printer file carriage control commands and force single-spaced output.

### Operands

#### *rdev*

identifies the printer whose output file is to be single spaced.

### Responses

Response 1:

```
PRT rdev SPACING   userid   FILE spoolid RECS {nnnn} COPY [*] nnn
                               {nnnK}
                               {nnnM}
SEQ sss CL c typ
```

#### *rdev*

identifies the printer.

#### *userid*

identifies the user whose file was active and single spaced.

#### FILE *spoolid*

identifies file currently being processed.

#### RECS *nnnn*

#### RECS *nnnK*

#### RECS *nnnM*

identifies the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines rounded to the nearest 1000. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines rounded to the nearest million.

#### COPY [\*] *nnn*

identifies the remaining number of copies of the file to be created. The asterisk (\*) indicates that the 3800 printer is to copy each page *nnn* times before going on to the next page.

#### SEQ *sss*

identifies the sequence number for the file on the printer.

#### CL *c*

is the spool file class.

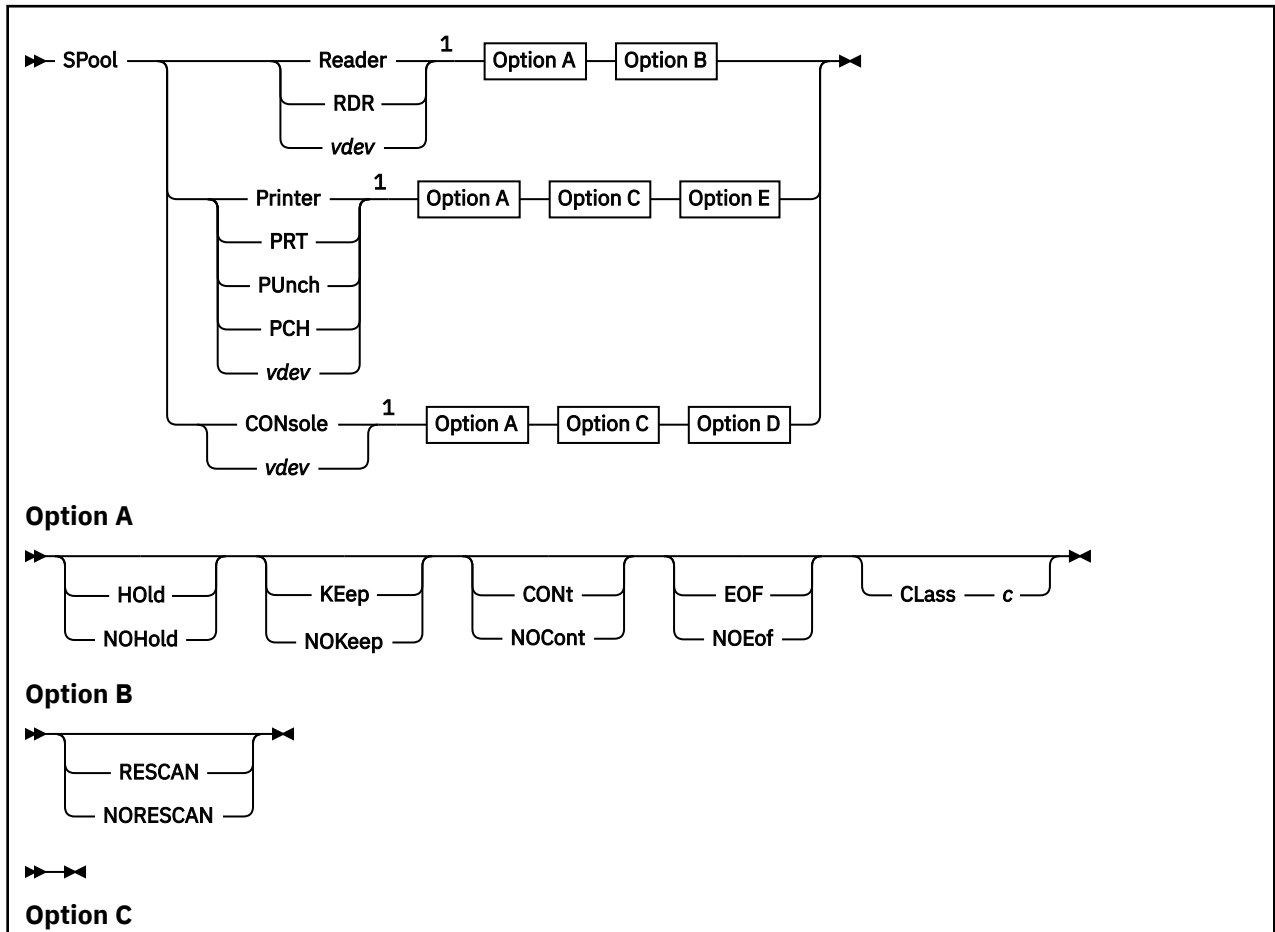

#### *typ*

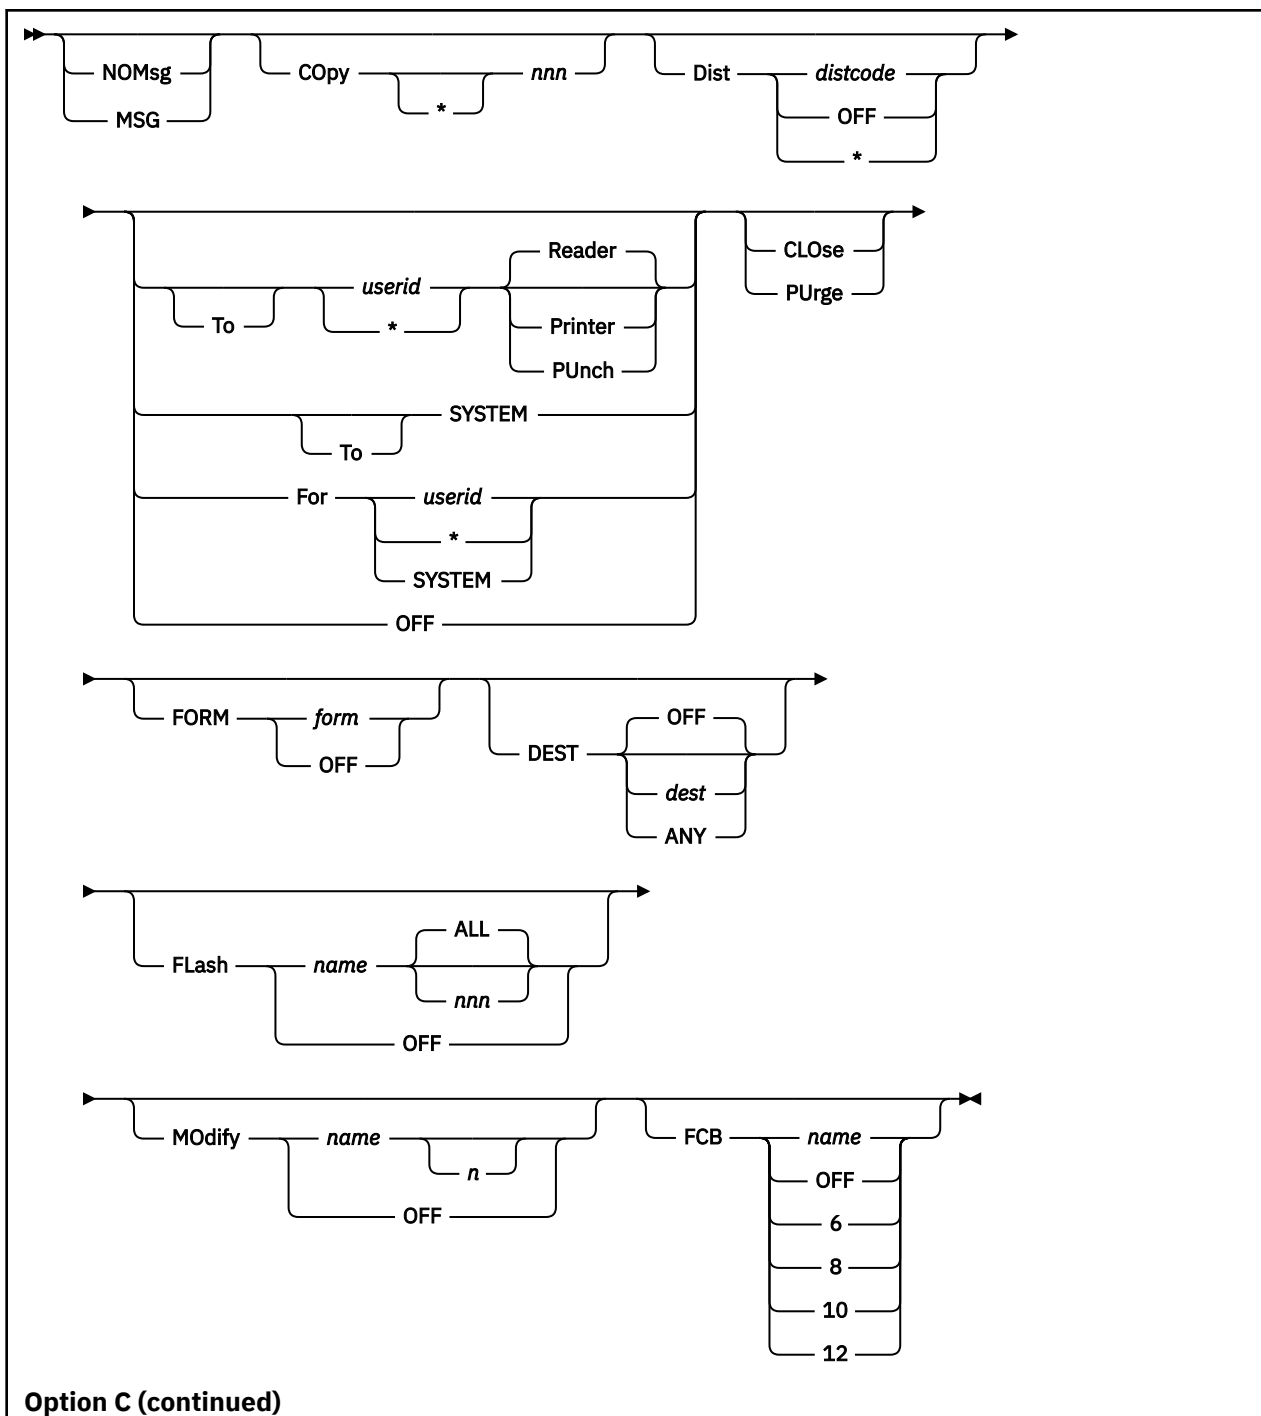

shows device type that originally produced the spool file. The type can be RDR, PRT, PUN, CON, DMP, or SYS.

## Messages

- HCP418E *{rdev/vdev}* is not a spooled device.
- HCP419E *{rdev/vdev}* is not a spooled printer.

# SPOOL

Option C (continued)

# SPOOL

## Authorization

Privilege Class: G

## Purpose

Use SPOOL to set control options for one or more of your virtual spool devices. The options you select modify operational functions associated with your virtual reader, printer, punch, or console. These options also control the disposition of files after they have been processed.

## Operands

### Reader

**RDR**

### Printer

**PRT**

### PUnch

**PCH**

### CONsole

*vdev*

modifies the options for all of your virtual readers, printers, punches, or console spooling devices, including the starting or stopping of spooling operations. Alternatively, you can enter the virtual device number *vdev* of the virtual spooling device whose options you want to modify.

## Options

### HOLD

#### NOHOLD

indicates whether you want to HOLD files.

If you specify HOLD for an output device, all the files created by the device are placed in user hold status. When a spool file is in user hold status, it is not processed at its destination device (the real printer, punch, or virtual reader) until you remove the hold status by issuing the CHANGE command with the NOHOLD option.

If you specify HOLD for an input device, files are retained after they have been read. Unless you specify the KEEP operand for the file or for the device, the file remains in the reader queue and is the next file eligible for processing. This is in contrast to the hold status on a spool file, which makes the file ineligible for processing.

A reader may not be spooled with the string CONT/RESCAN/HOLD/NOKEEP, as this would cause the same file to be processed repeatedly. If a SPOOL command is issued which would result in the reader being spooled with this combination, the reader will be spooled KEEP to remove the conflict.

Specify NOHOLD to allow files to be purged after processing.

### KEep

#### NOKeep

indicates whether you want to retain a spool file after it has been processed. Specify KEEP if you want to retain files after they have been processed.

For a virtual printer or punch directed to a real device, after the file has been printed or punched, it is placed in user, hold status, while retaining its keep status.

For a reader, KEEP also places your spool file in user, hold status after it has been read, but keep status is not set on the file. Note that the reader DEVICE hold option does not affect file hold status.

A reader may not be spooled with the string CONT/RESCAN/HOLD/NOKEEP, as this would cause the same file to be processed repeatedly. If a SPOOL command is issued which would result in the reader being spooled with this combination, the reader will be spooled KEEP to remove the conflict.

Specify NOKEEP to reset the keep status so that files are not retained in the system after processing has been completed.

### CONT

#### NOCont

controls the continuous spooling option.

For output devices, CONT causes all CLOSE requests to be ignored unless specified with EOF override option. NOCONT resets the option.

For readers, CONT specifies that reading will continue without end-of-file indications at the end of each virtual spool file. Reading continues until the virtual reader queue has been scanned once from

beginning to end. After each spool file is read, scanning is continued at the next logical file (unless RESCAN is specified).

NOCONT specifies that end-of-file is signaled after each spool file is read. The reader resets at the next logical file.

**RESCAN****NORESCAN**

When a reader is spooled CONT, RESCAN causes the first logical file in the virtual reader queue to always be the next file read. This allows files which have been ordered or changed during continuous processing to become eligible for processing.

A reader may not be spooled with the string CONT/RESCAN/HOLD/NOKEEP, as this would cause the same file to be processed repeatedly. If a SPOOL command is issued which would result in the reader being spooled with this combination, the reader will be spooled KEEP to remove the conflict.

NORESCAN causes scanning to resume at the next logical file in the virtual reader queue.

**EOF****NOEOF**

For a printer or punch, EOF causes the device to be closed automatically when 50000 records are placed into the active spool file. Punches are closed immediately at 50000 records. If page controls are found in a print file within the next 100 records, the file is closed at the end of the page. If no page controls are found by then, it is presumed there are none, and the file is closed after 50100 records.

For a reader, the EOF/NOEOF option specifies whether end-of-file is reached (as defined by the CONT/NOCONT option). EOF specifies that a unit exception is reflected on the first read past the end of the file. Further reads result in a normal read of the next file, if any, or with a unit check if the device is empty. NOEOF specifies that unit check is reflected on the first read past end-of-file, or any subsequent read to an empty reader.

**Class c**

specifies the spool class of the device. The operand *c* is a 1-character alphanumeric field whose values can be A through Z, 0 through 9, or asterisk (\*). The CLASS option determines which destination devices can process the spool file. If you print or punch a file from one of your virtual devices, the file is assigned the class that is associated with the device. The file is then printed or punched on a real device that also has this class associated with it. The operator sets this class.

The class associated with a virtual reader determines which files it recognizes for processing. If you specify a specific class, the reader processes only files of the same class. If you specify asterisk (\*), the reader processes all files, regardless of class.

**NOMsg****MSG**

indicates whether you want to be informed about file printing and punching. If you specify MSG, you are informed of file printing and punching if the file is printed or punched on the same system as your user ID. The message is sent to you when the file begins printing or punching on a real device. Specify NOMSG if you do not want messages sent to you when the file begins printing or punching on a real device.

**Copy [\*] nnn**

identifies the number of copies to be printed or punched when the file is spooled to the real unit record device. Note that regardless of what number you specify for COPY, only one spool file is actually created. However, z/VM continues to associate the COPY number with the spool file until the spool file is processed by a real printer or punch. At that time, z/VM produces the specified number of real printed or punched copies. If the real printer is a 3800 device, an asterisk (\*) indicates that the printer is to print each page *nnn* times before going on to the next page, where *nnn* is a decimal number from 1 to 255.

**Dist *distcode*****Dist OFF****Dist \***

specifies the distribution code to be assigned to spool files created on this virtual device. The operand *distcode* is one to eight characters long. You can override *distcode* using the DIST option on the CLOSE or CHANGE commands.

DIST OFF and DIST \* reset the distribution code of the spool files to the DIST code in the system directory at the time you logged on and will not reset to an updated value until logoff.

**TO *userid*****TO \*****TO SYSTEM**

sends the output of the virtual device to the virtual reader, virtual printer, or virtual punch of the specified user ID. The distribution code on the spool files retains the distribution code specified for the originator in the system directory.

When you specify the keyword TO, you retain control of the spool file. For example, you can use the TRANSFER command to retrieve the file from the specified user ID.

TO SYSTEM is equivalent to specifying OFF and resets the transferred spool option.

**Reader****Printer****PUnch**

identifies the spool file queue to which your file is directed. If you do not specify a queue, the file is transferred to the other user's reader queue.

**CLOse**

closes the spool file on the specified device regardless of the CONT setting for the device. CLOSE is equivalent to entering CLOSE with the EOF option. If PURGE is specified, CLOSE is not necessary.

**PURge**

closes and purges the spool file on the specified device, regardless of the CONT setting for the device. If PURGE is specified, the CLOSE option is not necessary. PURGE is equivalent to entering CLOSE with the PURGE option.

**FOR *userid*****FOR \*****FOR SYSTEM**

except for console output, the user ID option transfers the spool file from the virtual device to the corresponding virtual device of the specified user ID. z/VM transfers console output to the receiver's virtual printer. The distribution code on the spool files becomes the distribution code specified for *userid* in the system directory.

You can specify FOR \* to change the spool file ownership and destination code to those of your own virtual machine. Specifying FOR \* is equivalent to specifying the OFF operand for the device.

FOR SYSTEM is equivalent to specifying OFF and resets the transferred spool option. If you specify FOR *userid*, you cannot specify either the TO or the OFF operand.

**OFF**

resets the TO or FOR option from the previous spooling command.

**FORM *form***

specifies the form name for the resulting spool file or files. The operand *form* is one to eight characters long. The FORM option determines which destination devices can process the spool file. If you print or punch a file from one of your virtual devices, the file is assigned the form associated with the device. The file is then printed or punched on a real device that also has this form associated with it. The operator sets this form.

**FORM OFF**

resets the form to the system default as specified by the installation.

**DEST *dest***

specifies the destination value for the resulting spool file or files. The operand *dest* is a 1- to 8-character value. The DEST option determines which destination devices can process the spool file. If you print or punch a file from one of your virtual devices, the file is assigned the destination associated with the device. The file is then printed or punched on a real device that also has this destination associated with it. The operator sets this destination.

**DEST ANY**

indicates that the resulting spool file or files can be processed on any CP output device that meets other selection criteria, regardless of the device's DEST setting.

**DEST OFF**

indicates that the resulting spool files are processed by a device specifically started, or they are defaulted to OFF. OFF is the initial setting of the destination value for virtual devices.

**Flash ALL****Flash *nnn***

signifies that a form overlay contained in the 3800 printer is to be superimposed (or flashed) onto the specified number of copies of the output. The operand *name*, 1- to 4-characters long, identifies the forms overlay to be used in the projection. The operand *nnn* must be in the range from 0 to 255. The number specifies that the first *nnn* copies of output are to be flashed.

For example, if you specify COPY 4 and FLASH *name* 2, the first two copies of your file are flashed, while the last two copies remain unflashed. If ALL is specified, the flash count matches the copy count. ALL is the default.

**Flash OFF**

resets the flash parameters. Blanks are inserted into the flash name field of the specified spool file or files, and the count is set to 0.

**MODify *name n***

assigns a copy modification module to be used when printing the spool file or files on the 3800. This function makes it possible to alter text by either preventing the printing of certain information or adding labels to output. The name must be one to four characters long.

The operand *n* selects one of the character sets specified by the CHARS operand, to be used for the copy modification text. The values 0, 1, 2, and 3 correspond to the order in which the table names have been specified. If no *n* is specified, the first character set (0) is assumed.

**MODify OFF**

resets the modify parameters. Blanks are inserted into the modify name field of the spool file or files and, when printed, no modification occurs. The modify number *n* is set to 0.

**FCB *name*****FCB 6****FCB 8****FCB 10****FCB 12**

specifies the forms control buffer to be used when printing the spool file or files on the 3800 printer. The operand *name* is the 1- to 4-character name of an FCB image or the number 6, 8, 10, or 12. This number tells the 3800 to print the entire spool file at 6, 8, 10, or 12 lines per inch, regardless of the size of the paper that is currently loaded. An FCB specified at 10 will print only on a 3800 model 3 printer.

**FCB OFF**

resets the FCB parameter. Blanks are inserted into the FCB name field of the spool file or files and, when printed, a default FCB will control the vertical spacing of the output text.

**CHars *name0 name1...*****CHars *name0 CHars name1...***

specifies the name of the character set or sets used when printing the spool file or files on the 3800 printer. Each name must be from one to four characters long, with a maximum of four names specified. The multiple use of CHARS need only be used if *namen* would conflict with an option name

(for example, FORM) or with a user ID. If more than one name is specified, along with modification, the order in which the names appear determines which table is used for copy modification text.

### **CHars OFF**

resets the CHARS parameters. Blanks are inserted into the name fields of character sets used for output generation. The resulting spool file or files, therefore, uses a default character set when actually printed on a 3800 printer.

### **LPP *nnn***

### **LPP OFF**

### **LPP RESET**

sets the lines per page value for a virtual printer or a virtual console. '*nnn*' must be a decimal number with a range of 30 to 255.

If 'OFF' is specified, internal default values will be used for lines per page. The defaults are the same as those which have been used on prior releases of VM.

'RESET' will reset the lines per page value for the virtual printer or console to the global system value. This is also the default lines per page setting for virtual printers and consoles when they are defined.

The global system value for LPP may be defined in the system configuration file. If it is not defined, the default global value for the system is 'OFF'. This causes all virtual printers and consoles to be defined with a default LPP value of 'OFF'. See the *z/VM: CP Planning and Administration* for information about the [USER\\_DEFAULTS Statement](#).

The lines per page value is used by VM functions which generate virtual printer and console output. For CP, these include console spooling, CP dump and trace output, DDR, load maps generated by HCPLDR, and SPXTAPE log files. CMS functions which use the lines per page value for virtual printer output include the PRINT, ASSEMBLE, UPDATE, GENMSG, TAPE, FILEPOOL FORMAT AUDIT, and SET DOSLNCNT commands.

The lines per page value for a virtual printer is displayed in the response for QUERY VIRTUAL PRT command (as well as other QUERY commands which display virtual printer status).

The lines per page value for a virtual console is displayed in the response for QUERY VIRTUAL CONS command (as well as other QUERY commands which display virtual console status).

The lines per page value for a virtual printer or console may be obtained by application programs by issuing DIAGNOSE X'260' subcode 08.

### **NAME *fname ftype***

### **NAME *dsname***

specifies the file name and optional file type, or the data set name that will be given to each spool file the virtual device creates. The *fname* and *ftype* values must be eight characters or fewer. The data set name may be up to 24 characters; however, if the name has more than 16 characters, it is truncated to 16 characters.

### **NOName**

resets the NAME option. Blanks are inserted into the name field for spool files the virtual device creates.

### **STArt**

begins placing input and output from your display station into a spool file. Full-screen data output operations are not placed in the spool file. After the console is closed, the file becomes a printer spool file. START applies only to consoles.

### **STOp**

terminates the spooling of display station input and output. STOP does not close the console spool file. STOP applies only to consoles.

### **TErm**

displays the display station input and output on your display screen and places it in a spool file. The TERM operand has no effect unless the START function is also in effect. TERM applies only to consoles.

## NOTerm

suppresses the display of input and output on your display screen while placing it in a spool file. The display of console input and output is not suppressed if:

- It is the result of CP commands entered from CP mode
- The output line immediately precedes a virtual machine read to the console.

The NOTERM operand has no effect unless the START function is in effect. NOTERM applies only to consoles.

Full screen mode applications such as XEDIT and full screen CMS are not supported when the console is spooled NOTERM.

## ASYNChronous

indicates you want to process other commands while the SPOOL command completes.

## SYNChronous

prevents you from executing other commands until the SPOOL command completes.

## Usage Notes

1. When specifying [TO] *userid*, if you omit the keyword TO, *userid* cannot be T or TO. If you are transferring your output to your own virtual machine, you may specify *userid* as an asterisk (\*). If you specify TO *userid*, you cannot specify either the OFF or FOR operand.
2. Full screen functions may hang a user whose console is spooled NOTERM. For example, if a user is in XEDIT and tries to QUIT, the keyboard remains locked.
3. SET IMSG OFF suppresses informational messages for this command.
4. A spool file is created when the first record for a printer or punch is processed by the virtual unit record simulation routines in CP. CP associates this spool file with the virtual unit record device and assigns it a number called the *spoolid* (spool file identification). You can use *spoolid* to identify the file that you have produced, and to manipulate the file using the z/VM CP spooling commands, such as ORDER, CHANGE, and PURGE.

When you print or punch a file, CP displays its *spoolid*. You can use the *spoolid* to find out various kinds of information about the file using the QUERY command.

5. It is important to remember that the SPOOL command controls both operational characteristics of your virtual spooling devices and the disposition of files after they have been processed.

For example, you use the SPOOL command to select the files you want to process on your virtual readers. The SPOOL READER command does not change any of the characteristics associated with the files in your reader queue, but simply indicates whether a file is purged or retained after being read, and if it is retained, whether the file remains eligible for immediate reprocessing.

The files in your reader queue are controlled through a combination of file characteristics and the options in effect for the virtual reader on which they are processed. Input files do not derive their characteristics from the reader, except for hold status, which is set as a function of the KEEP option. [Table 41 on page 1815](#) summarizes the disposition of a reader file after it has been processed, depending on the hold/keep settings specified for the reader, and the keep setting of the file.

For output devices (virtual printers, punches, and consoles) use the SPOOL command to define the characteristics of the spool files you are creating. You can use the SPOOL command to indicate whether files are to be held from further processing, and whether they are to be retained after they have been processed. This information is associated with the spool file itself, regardless of the characteristics of the device on which the file is to be processed. In addition, use SPOOL to direct the output files that you are creating to unit record devices (readers, printers, and punches) associated with other virtual machines.

Table 41. Disposition of Reader Files Depending upon HOLD/KEEP Settings

<b>File Status</b>	<b>Device Options</b>	<b>Disposition</b>
NOKEEP	NOHOLD/NOKEEP	The file is purged.
NOKEEP	NOHOLD/KEEP	The file is retained in user hold status. KEEP is not set on the file.
NOKEEP	HOLD/NOKEEP	The file is retained and remains eligible for processing on your virtual reader.
NOKEEP	HOLD/KEEP	The file is retained in user hold status. KEEP is not set on the file.
KEEP	Any setting	The file is retained in user hold status. KEEP status remains on the file.

All of your output files derive their characteristics from the virtual device on which they were created. If the output device is spooled with the KEEP and NOHOLD options, the file is printed or punched, and then placed in HOLD status, retaining its KEEP characteristics. If you change the file status to NOHOLD, the file is processed at the real device one more time and once again is placed in HOLD status. If you do not want to retain the file, you must change both its NOHOLD status and NOKEEP characteristic, or purge it using the PURGE command.

6. Unless you reset these values, the following options are the default values for your spool files:

<b>Device</b>	<b>Default Options</b>
Reader	NOHOLD NOKEEP NOCONT NORESCAN EOF CLASS A <sup>1</sup>
Punch	NOHOLD NOKEEP NOCONT CLASS A <sup>1</sup> OFF COPY 001 NOMSG NONAME NOEOF DEST OFF
Printer	NOHOLD NOKEEP NOCONT CLASS A <sup>1</sup> OFF COPY 001 NOMSG NONAME NOEOF DEST OFF
Console	NOHOLD NOKEEP NOCONT CLASS T <sup>1</sup> OFF COPY 001 TERM TO * PRINTER NOMSG STOP NONAME NOEOF DEST OFF

<sup>1</sup>These are default classes only if a specific class is not part of your entry in the system directory.

7. You can transfer a spool file to another z/VM user by issuing the SPOOL, CHANGE, CLOSE, or TRANSFER commands. Use the CHANGE and TRANSFER commands to transfer already existing files. Use the SPOOL or CLOSE commands to transfer files that you are in the process of creating, or files you plan to create. For example, if you want to transfer the printer or punch files you are creating to another user's virtual reader, enter **spool vdev to userid rdr**, where *vdev* identifies by number or type your virtual machine output device, and *userid* identifies the virtual machine of the receiving user. Designating a reader, a printer, or a punch is optional; the default designation is reader. The command defines the user queue to which you are directing the file.

If you want to print or punch a file for someone else, enter **spool vdev for userid**, where *vdev* identifies by number or type your virtual machine output device, and *userid* identifies the virtual machine of the receiving user.

8. When a file changes ownership, as when it is changed to or from another user, the *spoolid* number changes also; the new number is obtained from a pool of numbers available to the file recipient.

Thus, if user SAM transfers his file number 3 to user HARRY, he gets the response:

```
RDR 0003 SENT TO HARRY RDR AS 0018
```

Harry now has the file as file number 18.

9. If you specify options that apply to a 3800 printer, such as COPY(\*), FLASH, MODIFY, FCB, or CHARS, the 3800 printer must be controlled by CP rather than the print server.

10. If DEST is not specified on a command that sets a DEST value, the current value is unchanged.
11. If an external security manager is installed on your system, you may not be authorized to transfer spool files using the *TO* and *FOR* options. For additional information, contact your security administrator.
12. The SPOOL command may not be used to direct files to the RDR queue of a user with a password of NOLOG. SPOOL may be used to direct files to the PRT and PUN queues of a user with a password of NOLOG.

## Responses

Response 1:

```
{RDR} FILE spd1 SENT {TO } userid {RDR } AS spd2 RECS {nnnn}
{PRT}                {FROM}      {PRT }
{PUN}                {PUN }      {nnnK}
{CON}                {CON }      {nnnM}
```

Continued:

```
COPY [*]nnn c {HOLD } {KEEP }
              {NOHOLD} {NOKEEP}
```

### RDR PRT PUN CON

identifies the spool file queue. If you are transferring a file to another user's virtual machine, this field indicates the queue from which the file originated. If you are receiving a file from another user, this field indicates the file queue to which the file has been added.

### *spd1*

identifies the spool file at the time the command is issued.

### *TO userid* *FROM*

*TO* indicates the user to whom the file has been sent. *FROM* indicates the user sending the file.

### RDR PRT PUN

identifies the spool file queue. If you are transferring a file to another user's virtual machine, this field indicates the queue to which the file has been added. If you are receiving a file from another user, this field indicates the file queue in which the file originated.

### *spd2*

identifies the file after the command is complete.

### RECS *nnnn* RECS *nnnK* RECS *nnnM*

identifies the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines rounded to the nearest 1000 records. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines rounded to the nearest million.

### COPY [\*] *nnn*

identifies the number of copies of the file you want printed or punched when the file is produced. The asterisk (\*) indicates that the 3800 printer is to copy each page *nnn* times before going on to the next page, where *nnn* is a decimal number from 1 to 255. If a file is not spooled to the 3800 printer, the function performed by specifying the asterisk (\*) is ignored and duplication occurs normally.

### *c*

identifies the spool file class assigned to the file.

**HOLD**  
**NOHOLD**

identifies the user hold status associated with the file.

**KEEP**  
**NOKEEP**

identifies the keep status associated with the file.

**Messages**

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP007E Invalid userid - *userid*
- HCP020E Userid missing or invalid
- HCP022E A virtual device number was not supplied or it was invalid.
- HCP026E Operand missing or invalid
- HCP030E Copies missing or invalid
- HCP035E Device type missing or invalid
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP052E Error in CP directory
- HCP053E *userid/value* not in CP directory
- HCP088E An invalid number was supplied for {COPY|FLASH} - *operand*.
- HCP418E {*rdev/vdev*} is not a spooled device.
- HCP422E The same option was specified twice.
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP424I The requested option(s) would result in incompatible settings for reader *vdev*. The reader has been spooled KEEP to remove this conflict.
- HCP429E *type vdev* spool error; file {held|purged}
- HCP439E {User *userid*|\*NSS|\*IMG|\*UCR|\*NLS} spool fileid limit exceeded
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP1001E An operand is missing for *option*.
- HCP1013E An invalid operand was supplied for *option* - *operand*.
- HCP1551E *value* is an invalid number for MODIFY.
- HCP1552E More than {4|8} operands were specified for the {CHARS|CLASS} option.
- HCP1559E The DSNAME is truncated to 16 characters.

## SPXTAPE

---

### Authorization

Privilege Class: D, E, G

### Purpose

Use SPXTAPE to:

- Save standard spool files and system data files on tape
- Restore SPXTAPE-format files from tape to the spooling system.

Standard spool files are:

- Printer spool files
- Punch spool files
- Reader spool files.

System data files are:

- Image libraries
- National language support files, such as message repository files
- Named saved systems
- Saved segments
- System trace files
- User class restructure files.

SPXTAPE provides the following major functions:

#### **CANCEL**

Immediately cancels an SPXTAPE DUMP, LOAD, or SCAN operation. See [“SPXTAPE CANCEL” on page 1834.](#)

#### **DUMP**

Reads files from the spooling system and writes them on tape. See [“SPXTAPE DUMP” on page 1836.](#)

#### **END**

Ends an SPXTAPE DUMP, LOAD, or SCAN operation at the completion of the current file. See [“SPXTAPE END” on page 1844.](#)

#### **LOAD**

Reads SPXTAPE-format files from tape and writes them into the spooling system. See [“SPXTAPE LOAD” on page 1846.](#)

#### **SCAN**

Determines what files exist on tape in SPXTAPE format. See [“SPXTAPE SCAN” on page 1857.](#)

The spooling operator can use SPXTAPE to selectively store on tape and retrieve standard spool files and system data files. The scan and selective-read-in functions allow the operator to avoid an overload in the spooling system. Should an overload occur, SPXTAPE allows the operator to quickly store the files temporarily on tape.

The general user can use SPXTAPE to save on tape and retrieve the standard spool files and system trace files that belong to that user ID.

**Note:** The status of an outstanding SPXTAPE operation can be determined using the QUERY VIRTUAL command. See the description of QUERY VIRTUAL TAPES for more details.

Log Files

The activities of each SPXTAPE command are recorded in at least two spool files: a command summary log and one or more volume logs. These logs are created by the SPXTAPE DUMP, LOAD, and SCAN commands.

Both logs have the same routing and disposition as the virtual console of the user who enters the SPXTAPE command (or causes the SPXTAPE operation to begin). If you enter the command `spool cons *` before you enter the SPXTAPE command, all logs are sent to your virtual reader. If you want to change the spooling of your console, you should do it before you enter the SPXTAPE command, or the logs may be sent to different destinations.

#### *Command Summary Log:*

The command summary log records the progress and status of an SPXTAPE DUMP, LOAD, or SCAN operation. Most command responses, as well as any error messages, are recorded in this log. A new command summary log is created for each SPXTAPE DUMP, LOAD, or SCAN command, unless the command is appended to a previous SPXTAPE command.

Each command summary log has a unique name. The file name and file type have the following format:

```
aabbcccc hhmmss
```

#### **aa**

is the month the SPXTAPE command is issued.

#### **bb**

is the day the SPXTAPE command is issued.

#### **cccc**

is the SPXTAPE operation: DUMP, LOAD, or SCAN.

#### **hh**

is the hour the SPXTAPE command is issued.

#### **mm**

is the minute the SPXTAPE command is issued.

#### **ss**

is the second the SPXTAPE command is issued.

The command summary log contains a header (response 1) for the command that creates the log. If the command that creates the log is issued with the APPEND operand, a header is also written in the log for each appended command.

#### *Volume Log:*

The volume log records information about the files processed by an SPXTAPE DUMP, LOAD, or SCAN command that are associated with a particular tape volume. There is one volume log for each tape volume for each SPXTAPE command. For example, if you use the SPXTAPE DUMP command with the LEAVE operand 10 times to save files on a single tape volume, 10 volume logs are created. If you use a single SPXTAPE DUMP command to dump files to 10 different tape volumes (and all 10 are actually used), 10 volume logs are created.

The volume log is a record of what is dumped to, loaded from, or scanned on a tape volume. For an SPXTAPE LOAD operation, the volume log may record more than what is actually loaded from the tape. A failure or operator action that occurs after a file has been read from the tape and logged (such as spool space being exhausted, or the SPXTAPE CANCEL command being used against the tape drive) may prevent the file from being stored in the spooling system. The files that are not loaded successfully are reported with messages sent to the SPXTAPE user and recorded in the command summary log.

Each volume log has a unique name. The file name and file type have the following format:

```
aabbccvvv hhmmssstt
```

#### **aa**

is the month the SPXTAPE command is issued.

**bb**

is the day the SPXTAPE command is issued.

**c**

is the first letter of the SPXTAPE operation: D = DUMP, L = LOAD, S = SCAN.

**vvv**

are the three least significant digits of the virtual device number of the tape drive.

**hh**

is the hour the SPXTAPE command is issued.

**mm**

is the minute the SPXTAPE command is issued.

**ss**

is the second the SPXTAPE command is issued.

**tt**

are the two least significant digits of the volume sequence number, which is the number of this volume in the sequence of volumes processed so far on this device for this command.

The volume log contains a header (response 1) for the command that creates the log. If the command that creates the log is issued with the APPEND operand, a header is also written in the log for each appended command. Each header is followed by the file information (response 2 entries) for the files selected by the command identified in the header.

## Usage Notes

1. SPXTAPE cannot load or scan files dumped by the SPTAPE command, which is no longer supported. See *z/VM: Migration Guide*.
2. SPXTAPE supports all tape drives fully supported by z/VM. For a list of supported devices, see *z/VM: General Information*.
3. On tapes that have standard tape labels, SPXTAPE skips over the header label group. If the header label group was written on a drive with a format that is incompatible with the drive where the tape is currently mounted, SPXTAPE DUMP cannot read the label and will write over it.
4. SET IMSG OFF suppresses the display of SPXTAPE informational messages, error message HCP1909E, and response 9. However, SET IMSG OFF does not suppress the request to mount a new tape when the current one is full. Message HCP1916I is written in the command summary log only and not displayed, even if IMSG is set ON.
5. Specifying a range of one virtual device number on an SPXTAPE command is the same as specifying just one device. For example, `spxtape dump 181-181` is the same as `spxtape dump 181`.
6. When an SPXTAPE command is issued with a device number range, the command begins processing if a supported tape drive is attached to at least one device number in the range. Unsupported devices and device numbers where no device is attached are ignored and are reported only if there is no valid device in the range. On SPXTAPE DUMP, tape devices attached read-only are ignored and are reported only if no device is attached write-enabled.  
  
If the range includes any device already active for a matching SPXTAPE DUMP, LOAD, or SCAN command, the active command range is expanded to include the drives covered by the expanded range. This capability can be used to add drives at any time for performance or to recover from tape drive errors. However, if the previous command was not entered with the APPEND operand, the command to expand the range cannot include any file selection criteria.
7. If all the tape drives on an active SPXTAPE command are reset (using RESET, DETACH, GIVE, or some other command), or if the issuer of the SPXTAPE command logs off or is forced off, the effect is the same as issuing the SPXTAPE CANCEL command for each tape drive.
8. You may specify selection criteria operands in any order. All selection criteria specified on a command must be met for a file to be selected.
9. A user with only class E command privileges cannot process reader, printer, or punch files.

A class G user can process only files on the user's own reader, printer, punch, and system trace file queues, or files on tape that were dumped from these queues.

A class G user should not be given access to tapes containing files that belong to other users. Although SPXTAPE does not permit the class G user to load or scan a file that belongs to another user, there are other commands and programs the user could use to read the contents of the tape.

10. **Attention:** Using multiple SPXTAPE commands to load and dump files simultaneously is not recommended. Simultaneous SPXTAPE operations may overlap. For example, if a DUMP PURGE request matches the selection criteria of a file that was just loaded by a LOAD request, the file might be dumped and purged from the system before it can be used.

If multiple SPXTAPE DUMP commands are issued simultaneously for the same files, some files might not be dumped as many times as specified in the commands. This is because SPXTAPE DUMP opens a file to be dumped, but a file already open (except a named saved system or saved segment file) cannot be dumped.

11. SPXTAPE attempts to dump or load the selected files in the minimum amount of time by overlapping and optimizing the DASD and tape I/O activity. To maximize performance in a DUMP operation, unless you know the files being dumped will occupy less than one volume, it is recommended that you use at least one tape drive for every 4-6 spool DASD volumes, with a minimum of two (to allow overlapping volume mounting).
12. Tape-handling options (disposition operands) of LEAVE, REWIND, and RUN (rewind and unload) are provided for the DUMP, LOAD, and SCAN operations. The disposition is processed when the command is complete (or when the operation is ended by an SPXTAPE END command) to position the tape for subsequent commands. For LOAD and SCAN, the disposition also determines what conditions cause completion of the command.

SPXTAPE rewinds and unloads the current tape and waits for another tape to be mounted when:

- DUMP encounters either the physical end-of-tape or a permanent tape I/O error.
- LOAD or SCAN with the RUN disposition encounters either the logical end-of-tape (the end of the tape file written by SPXTAPE DUMP) or a permanent I/O error.

If SPXTAPE END is issued for a tape drive that is currently active for an SPXTAPE command with the APPEND disposition, the disposition is changed to RUN; that is, the tape is rewound and unloaded.

If SPXTAPE CANCEL is issued for a tape drive, no disposition is processed. After the cancel has been performed (and response 8 issued), SPXTAPE does not perform any further I/O operations (including RUN or REWIND) to the canceled drive.

13. SPXTAPE supports the dumping of files that are too large to fit on a single tape reel or cartridge. A file whose size exceeds the capacity of a single tape volume is split across as many volumes as are required to contain it.

To load such a multivolume file, all volumes that contain parts of the file must be read by a single SPXTAPE command. The order in which the volumes are read does not matter as long as all the parts are included. SPXTAPE puts the parts together in the proper sequence.

14. While SPXTAPE is processing a file in the spooling system (except a named saved system or saved segment), the file can be queried but not manipulated in any way.
15. While an SPXTAPE operation is running on a virtual tape device, no other virtual I/O is permitted to that device. If other virtual I/O is attempted, it is rejected.
16. Almost all of the processor time used by an SPXTAPE command is scheduled and accounted for on the command issuer's user ID.

## Responses

Response 1:

When SPXTAPE DUMP, LOAD, or SCAN processes any files to or from a tape volume, or SPXTAPE with the APPEND disposition appends any files to be processed, the following header is written in the command summary log and the volume log:

```
date time userid command
```

**date**

is the date the command is issued.

**time**

is the time the command is issued.

**userid**

is the user ID of the user who enters the command.

**command**

is a string containing the first 132 characters of the SPXTAPE command.

Response 1 may include an additional line with the following format if the tape was positioned at the beginning of the volume and contained a standard tape label.

```
Tape Volume ID: valid
```

where *valid* is the 1 to 6 character tape volume identifier from the standard tape label.

Response 1 may also include the following line if encryption keys are specified on the ATTACH or SET RDEVICE commands.

```
Tape Volume Encryption: Key manager defaults are being used
```

Response 2:

When SPXTAPE DUMP, LOAD, or SCAN processes a file to or from a tape volume, the file is identified by the following entry in the volume log:

```
USERID FILE QUEUE FILENAME FILETYPE OPENDATE OPENTIME ORIGINID
userid file queue filename filetype opendate opentime originid

SIZE SEG_STAT HOLDSTAT RECCOUNT C FORM DEST LASTPAGE
size seg_stat holdstat reccount c form dest lastpage
```

**Note:** The heading is included before the first response 2 entry for that command in the log. It is repeated each time the flow of response 2 entries for the command is interrupted by some other response or message.

**userid**

is the user ID of the owner of the file. On LOAD, if the owner's user ID does not exist on the system or has reached the maximum number of spool IDs allowed for that virtual machine, this is the user ID that entered the command.

**file**

is the spool ID that identifies the file. On LOAD, this is the new spool ID assigned to the file on the system. If the file could not be loaded because no spool IDs are available, this field contains the spool ID of the file when it was dumped.

On LOAD or SCAN, if the file to be loaded or scanned is a duplicate of a file on the system (the SEG\_STAT field of this response contains the entry DUP\_FILE), this is the spool ID of the file on the system.

**queue**

is the source or destination queue (PRT, PUN, RDR, IMG, NLS, NSS, TRF, or UCR) that identifies the type of file being processed.

**filename**

is the file name of the file.

**filetype**

is the file type of the file.

**opendate**

is the date the file was created, in the format *mm/dd/yy*.

**opentime**

is the file creation timestamp, in the format *hh:mm:ss*.

**originid**

is the user ID of the creator of the file. On LOAD, if the file owner's user ID does not exist on the system or has reached the maximum number of spool IDs allowed for that virtual machine, the file owner's user ID is placed in this field.

**size**

is the number of spool data pages the file occupies.

**seg\_stat**

is the status of the file:

**PARTIAL**

indicates the volume contains only a part of the file, which is continued on one or more other volumes, and this part is *not* the one that completes the processing of the file.

**Note:** If a tape read error occurs on LOAD or SCAN, SPXTAPE cannot determine if the file is complete on this volume and puts PARTIAL in this field.

**COMPLETE**

indicates the dump, load, or scan of the file has been completed on this volume. Either the entire file is contained on this volume, or the part of the file on this volume is the one that completes the processing of the file.

**DUP\_FILE**

indicates the NODUP operand was specified on a LOAD or SCAN and the file on the tape duplicates a file already on the system:

- For a standard spool file or system trace file, this means all the attributes of the two files are identical.
- For a system data file other than a system trace file, this means the file name, file type, and class of the two files are identical. For a named saved system or saved segment, class A (active) and class R (restricted active) files with the same file name and file type are also considered to be duplicates.

The FILE field of this response contains the spool ID of the file on the system. The file on the tape is not loaded or scanned.

**NO\_LOAD**

indicates the file has not been loaded because:

- If the file is a standard spool file or a system trace file, one of the following conditions exists:
  - Both the user who owned the file when it was dumped and the user who entered the SPXTAPE LOAD command have run out of available spool IDs.
  - The user who owned the file when it was dumped does not exist on the system, and the user who entered the SPXTAPE LOAD command has run out of available spool IDs.
- If the file is a type IMG, NLS, NSS, or UCR system data file, the system has run out of available spool IDs.

**holdstat**

is the hold status of the file:

**USER**

indicates the file is user-held.

**SYS**

indicates the file is system-held.

**USYS**

indicates the file is both user-held and system-held.

**NONE**

indicates the file is not held. This is the entry for a system data file.

**reccount**

is the number of records in the file.

**c**

is the class of the file.

**form**

is the operator form name associated with the file. For a system data file, this field is blank.

**dest**

is the destination value of the file. For a system data file, this field is blank.

**lastpage**

is the highest relative page processed to or from the file.

Response 3:

When SPXTAPE DUMP, LOAD, or SCAN finishes processing, the following response is written in the command summary log and displayed on the screen.

```

SPXTAPE {DUMP} COMMAND {COMPLETED } ON VDEV {vdev } [WITH ERRORS]
        {LOAD}          {ENDED           } {vdev1-vdev2}
        {SCAN}          {CANCELED        }
                          {TERMINATED}

TIME STARTED:           hh:mm:ss
TIME ENDED:             hh:mm:ss

TAPE COUNT:            nnn
FILES PROCESSED:      nnn,nnn,nnn
SPOOL PAGES:          nnn,nnn,nnn

```

**Note:** If the number of Files or Spool Pages processed is larger than 999,999,999, it will continue to display as 999,999,999.

**DUMP****LOAD****SCAN**

is the SPXTAPE operation that has finished.

**COMPLETED**

indicates the operation completed on its own accord.

**ENDED**

indicates the user ended the operation with the SPXTAPE END command.

**CANCELED**

indicates the user canceled the operation with the SPXTAPE CANCEL command or by resetting the last tape drive.

**TERMINATED**

indicates the system terminated the operation. One or more messages are issued to identify the reason.

**VDEV vdev****VDEV vdev1-vdev2**

indicates the virtual device number, or the range of virtual device numbers, on which the SPXTAPE operation was active.

**WITH ERRORS**

indicates there was a problem processing at least one file. The specific files and problems are reported in messages and recorded in the logs.

**TIME STARTED: hh:mm:ss**

indicates the time the SPXTAPE command started.

**TIME ENDED: hh:mm:ss**

indicates the time the SPXTAPE command ended.

**TAPE COUNT: nnn**

indicates the number of tape volumes processed by the operation.

**FILES PROCESSED: *nnn,nnn,nnn***

indicates the number of files processed by the operation. A file that is split between two or more volumes is counted only once.

**SPOOL PAGES: *nnn,nnn,nnn***

indicates the number of spool pages processed by the operation. This includes XAB data pages and map pages. For SCAN, this is the number of pages that would be required to hold the files if they were loaded.

Response 4:

The following response is written in the command summary log and the volume log and displayed on the screen when:

- A user enters the SPXTAPE command with the END or CANCEL disposition selecting an active tape device
- SPXTAPE DUMP with the APPEND disposition has completed the processing of the selected files
- SPXTAPE processing is complete on a tape.

**Notes:**

1. For DUMP, this response is written at the beginning of the volume log; for LOAD or SCAN, it is written at the end.
2. If only one tape drive and one tape volume are being processed, this response is written only in the volume log and not displayed.

```

SPXTAPE {DUMP} {COMPLETED} } ON VDEV vdev [WITH ERRORS]
        {LOAD} {ENDED}       }
        {SCAN} {CANCELED}    }
                {WAITING}    }
                {TERMINATED} }

TAPE NUMBER:      vdev-nnn
FILES PROCESSED:  nnn,nnn,nnn
SPOOL PAGES:     nnn,nnn,nnn

```

**Note:** If the number of Files or Spool Pages processed is larger than 999,999,999, it will continue to display as 999,999,999.

**DUMP****LOAD****SCAN**

is the SPXTAPE operation that was active.

**COMPLETED**

indicates the operation completed on its own accord.

**ENDED**

indicates the user ended the operation with the SPXTAPE END command.

**CANCELED**

indicates the user canceled the operation by using the SPXTAPE CANCEL command or by resetting the last tape drive.

**WAITING**

indicates the tape drive is being processed by DUMP with the APPEND disposition and is waiting for another DUMP command selecting more files. When in this state, the tape is still "open" (incomplete, tape marks not written). To complete the tape, enter another SPXTAPE DUMP command with a disposition other than APPEND, or enter the SPXTAPE END command.

**TERMINATED**

indicates the system terminated the operation. One or more messages are issued to identify the reason.

**VDEV *vdev***

identifies the virtual device number of the tape drive on which the SPXTAPE operation is processing.

**WITH ERRORS**

indicates there was a problem processing at least one file. The specific files and problems are reported in messages and recorded in the logs.

**TAPE NUMBER: *vdev-*nnn****

identifies the virtual device number of the tape drive followed by the volume sequence number for this command (the number of tape volumes processed so far on this device for this command). The three least significant digits of the device number correspond to the last three characters of the file name of the volume log that records the processing done by this command on this tape volume on this device. The two least significant digits of the sequence number correspond to the last two characters of the file type of the volume log.

**FILES PROCESSED: *nnn,nnn,nnn***

indicates the number of files processed by the operation for this volume. If a file is split between two or more volumes, only the part that completes the processing of the file is counted (the one for which response 2 is issued with COMPLETE in the SEG\_STAT field).

**SPOOL PAGES: *nnn,nnn,nnn***

indicates the number of spool pages processed by the operation for this volume. This includes XAB data pages and map pages. For SCAN, this is the number of pages that would be required to hold the files if they were loaded.

**Note:** This number may differ from the actual pages contained on the volume if there are any partial files on the volume. For DUMP, XAB data pages and map pages are reported with the first volume that contains part of the file. For LOAD or SCAN, XAB data pages and map pages are reported with the volume that completes the file (the one for which response 2 is issued with COMPLETE in the SEG\_STAT field).

Response 5:

The following response is written in the command summary log and the volume log and displayed on the screen when the end of the tape is reached during:

- DUMP processing
- LOAD or SCAN processing with the RUN disposition.

```
SPXTAPE {DUMP} END-OF-TAPE ON VDEV vdev [WITH ERRORS];
        {LOAD}
        {SCAN}

MOUNT NEXT TAPE

TAPE NUMBER:      vdev-nnn
FILES PROCESSED:  nnn,nnn,nnn
SPOOL PAGES:      nnn,nnn,nnn
```

**Note:** If the number of Files or Spool Pages processed is larger than 999,999,999, it will continue to display as 999,999,999.

**DUMP**  
**LOAD**  
**SCAN**

is the SPXTAPE operation that was active.

**VDEV *vdev***

identifies the virtual device number of the tape drive on which the SPXTAPE operation is processing.

**WITH ERRORS**

indicates there was a problem processing at least one file. The specific files and problems are reported in messages and recorded in the logs.

**TAPE NUMBER: *vdev-*nnn****

identifies the virtual device number of the tape drive followed by the volume sequence number for this command (the number of tape volumes processed so far on this device for this command). The three least significant digits of the device number correspond to the last three characters of the file name of the volume log that records the processing done by this command on this tape volume on this

device. The two least significant digits of the sequence number correspond to the last two characters of the file type of the volume log.

**FILES PROCESSED: *nnn,nnn,nnn***

indicates the number of files processed by the operation for this volume. If a file is split between two or more volumes, only the part that completes the processing of the file is counted (the one for which response 2 is issued with COMPLETE in the SEG\_STAT field).

**SPOOL PAGES: *nnn,nnn,nnn***

indicates the number of spool pages processed by the operation for this volume. This includes XAB data pages and map pages. For SCAN, this is the number of pages that would be required to hold the files if they were loaded.

**Note:** This number may differ from the actual pages contained on the volume if there are any partial files on the volume. For DUMP, XAB data pages and map pages are reported with the first volume that contains part of the file. For LOAD or SCAN, XAB data pages and map pages are reported with the volume that completes the file (the one for which response 2 is issued with COMPLETE in the SEG\_STAT field).

When you receive this response, the tape drive enters the mount-pending state. The drive remains in this state until you mount and ready another tape. If this is a DUMP operation and there are other drives active that you believe will hold the rest of the files, do nothing. The mount-pending condition is removed when the command completes.

For the SPXTAPE operation to complete, you must mount enough volumes to complete any files in the process of being dumped, loaded, or scanned that span volumes. If a file takes more than one additional volume, you receive this response at the end of each volume until you reach the last volume.

If you do not want to continue the operation on this drive, do one of the following:

- Enter the SPXTAPE END command to remove the drive from the active drives or, if this is the last active drive, to end the operation.
- Enter the SPXTAPE CANCEL command for the device. However, if this was a DUMP operation, and if the device specified in the response is the last or only tape drive in the operation, using CANCEL could cause a file that was started on a previous tape volume to be not completed on this volume. You should use CANCEL only if you want to immediately halt the operation on the device regardless of the status of the files.

If all drives enter the mount-pending state and you take no action, the command remains dormant.

Response 6:

When SPXTAPE DUMP is dumping files to tape, it reports its progress at the interval requested with the PROGRESS\_interval option (or about every 15 seconds by default) by displaying the following response on the screen.

```
SPXTAPE DUMPING {vdev          }; nnn,nnn,nnn FILES, PAGES nnn,nnn,nnn
                 {vdev1-vdev2}
nn% COMPLETE
```

**Note:** If the number of Files or Spool Pages processed is larger than 999,999,999, it will continue to display as 999,999,999.

**DUMPING**

identifies the SPXTAPE operation that was active.

***vdev***

***vdev1-vdev2***

is the virtual device number or range on which the SPXTAPE operation is processing.

***nnn,nnn,nnn* FILES**

indicates the number of files processed to date by the operation. The rate at which this number changes is an inverse function of the size of the files being processed.

**PAGES *nnn,nnn,nnn***

indicates the number of spool pages processed to date by the operation. The rate at which this number changes is the rate at which data is being transferred to tape. Usually this is less than the transfer rate of the tape drives because in most cases performance is governed by the DASD read rates.

***nn%* COMPLETE**

indicates the percentage of the selected pages that have been dumped. If you are using the APPEND disposition and selecting additional files, this number can *decrease* as SPXTAPE includes the additional files in its processing.

If you do not receive this response during a DUMP operation, then SPXTAPE is not dumping any files. Possible reasons are:

- One or more tape drives are in "WAITING" state (identified by response 4 or 10), waiting for another SPXTAPE DUMP command.
- One or more tape drives are in mount-pending state (identified by response 5), waiting for additional tapes to be mounted.
- One or more tapes are in intervention-required state.
- You placed your virtual machine in CP READ state.

Response 7:

When SPXTAPE LOAD or SCAN is loading or scanning files, it reports its progress at the interval requested with the PROGRESS\_interval option (or about every 15 seconds by default) by displaying the following response on the screen.

```
SPXTAPE {LOADING } {vdev      }; nnn,nnn,nnn FILES, PAGES nnn,nnn,nnn
        {SCANNING} {vdev1-vdev2}
```

**Note:** If the number of Files or Spool Pages processed is larger than 999,999,999, it will continue to display as 999,999,999.

**LOADING  
SCANNING**

identifies the SPXTAPE operation that is active.

***vdev***

***vdev1-vdev2***

is the virtual device number or range on which the SPXTAPE operation is processing.

***nnn,nnn,nnn* FILES**

indicates the number of files processed to date by the operation. The rate at which this number changes is a direct function of the number of files selected and an inverse function of their size.

**PAGES *nnn,nnn,nnn***

indicates the number of spool pages processed to date by the operation. The rate at which this number changes is the rate at which data is being read from tape. It is a direct function of the percentage of files that are selected and their distribution on the tape. For LOAD, it may be less than the transfer rate of the tape drives because the load rate can be governed by the speed of the spooling system DASD.

If you do not receive this response during a LOAD or SCAN operation, then SPXTAPE is not reading the tape. Possible reasons are:

- One or more tape drives are in "WAITING" state (identified by response 4 or 10), waiting for another SPXTAPE LOAD or SCAN command.
- One or more tape drives are in mount-pending state (identified by response 5), waiting for additional tapes to be mounted.
- One or more tapes are in intervention-required state.
- You placed your virtual machine in CP READ state.

Response 8:

Each tape drive on which an SPXTAPE operation is initiated is reported with the following response written in the command summary log and displayed on the screen.

```
SPXTAPE {DUMP } INITIATED ON VDEV vdev
        {LOAD }
        {SCAN }
        {CANCEL}
        {END }

```

**DUMP**  
**LOAD**  
**SCAN**  
**CANCEL**  
**END**

is the SPXTAPE operation that was started.

***vdev***

is the virtual device number of the tape drive on which the SPXTAPE operation is running.

Response 9:

When a file is dumped with the PURGE operand, or when a file is loaded, the following response is sent to the file owner, if currently logged on. For DUMP, the response is issued after the tape is "closed" (trailers and tape marks have been successfully written), because files are purged in groups that correspond to a tape volume that has been successfully completed. For LOAD, the response is issued after each individual file has been placed on the queue.

```
{RDR} FILE spd1 SENT {TO } userid {RDR} AS spd2 RECS {nnnn}
{PRT}                {FROM} {PRT} {nnnK}
{PUN}                {PUN} {nnnM}
                    {**** PURGED **** }

CPY [*]nnn c {HOLD } {KEEP }
              {NOHOLD} {NOKEEP}

```

**RDR**  
**PRT**  
**PUN**

identifies the virtual device on which the file is being created or read.

***spd1***

is the spool ID of the file associated with the command user.

***userid***

is the user receiving the file.

**RDR**  
**PRT**  
**PUN**

identifies the spool file queue that now contains the file.

***spd2***

is the spool ID of the file associated with the user ID in the response.

**RECS *nnnn***

**RECS *nnnK***

**RECS *nnnM***

indicates the number of logical records in the file. If the number is greater than 9999, it is rounded to the nearest thousand and shown as *nnnK*, where *nnn* is the number of thousands. If the number is greater than 999499, it is rounded to the nearest million and shown as *nnnM*, where *nnn* is the number of millions.

**CPY [\*]*nnn***

indicates the number of file copies to be printed or punched when the file is produced. If the number is preceded by an asterisk (\*), the 3800 printer prints each page from the spooled output files *nnn* times before going on to the next page.

**c**

is the spool class assigned to the file.

**HOLD****NOHOLD**

is the user hold status associated with the file.

**KEEP****NOKEEP**

is the keep status associated with the file.

Response 10:

A tape drive specified on an SPXTAPE DUMP, LOAD, or SCAN command with a disposition of APPEND may be placed in a "WAITING" state:

- For DUMP, this occurs if the command with APPEND finishes processing before the next command is entered. The drive remains in this state until it is selected by another SPXTAPE DUMP command, or the operation is canceled or ended.
- For LOAD or SCAN, this occurs between the entry of the first command with APPEND and the command that completes the append sequence. The drive remains in this state until it is selected by a corresponding SPXTAPE LOAD or SCAN command with a disposition other than APPEND, or the operation is canceled or ended.

The following response is written in the command summary log and the volume log and displayed on the screen.

```
SPXTAPE {DUMP} WAITING ON VDEV vdev
        {LOAD}
        {SCAN}
```

**DUMP****LOAD****SCAN**

is the SPXTAPE operation.

***vdev***

is the virtual device number of the tape drive on which the SPXTAPE function is now waiting.

Action Taken on Tape Overflow or RUN (Rewind and Unload)

If either of the following conditions occurs, the tape drive enters the mount-pending state and response 5 is issued:

- On SPXTAPE DUMP, if the output tape fills before all the files selected on the command are written
- On SPXTAPE LOAD or SCAN with the RUN disposition, when SPXTAPE rewinds and unloads the tape after reading all the selected data.

You can either continue or end the SPXTAPE operation. See Response 5.

If all drives enter the mount-pending state and you take no action, the command remains dormant.

Action Taken on Error Conditions

The following sections summarize the action taken by SPXTAPE when various error conditions are encountered. Error messages are written in the command summary log.

*I/O Error during DUMP while Reading a File:* If an I/O error occurs during an SPXTAPE DUMP operation while reading a file from the spooling system:

1. The file is placed in system hold status.
2. The command continues with other selected files.

*I/O Error during DUMP while Writing a File:* If an I/O error occurs during an SPXTAPE DUMP operation while writing a file to tape:

1. The tape is rewound and unloaded.

2. The tape drive is placed in the mount-pending state.
3. The command continues by reprocessing all the files that were dumped to the volume that has the error. The files are dumped again, either to other active drives for this command (if any) or to this drive when a new tape is mounted.

*I/O Error during LOAD or SCAN while Reading a File:* If an I/O error occurs during an SPXTAPE LOAD or SCAN operation while reading a file from tape:

1. SPXTAPE tries to find the beginning of the next file on the tape by reading blocks until either a block is read without error or 10 consecutive bad blocks have been skipped.
2. If SPXTAPE finds a good block, the command continues. If SPXTAPE encounters 10 consecutive bad blocks, the tape is positioned according to the disposition specified on the command:
  - For LEAVE, the tape remains positioned after the last bad block. Response 4 is issued. The volume log indicates which files were successfully loaded or scanned. If this is the last or only active tape drive, the command completes with response 3. If the tape is a multiple dump tape (created by SPXTAPE DUMP with the LEAVE disposition), you can position it with the CMS TAPE command if you want to try loading or scanning the remaining files on the tape.
  - For REW, the tape rewinds but does not unload. Response 4 is issued. The volume log indicates which files were successfully loaded or scanned. If this is the last or only active tape drive, the command completes with response 3.
  - For RUN, the tape rewinds and unloads. Response 5 is issued. The volume log indicates which files were successfully loaded or scanned. You can mount another tape on this drive; if one or more other drives are active, you can do nothing; or you can enter the `spxtape end vdev` command to end processing on the device and complete the operation.

For recovery procedures for LOAD, see the section on recovering from an I/O error, cancel, or reset in the description of “[SPXTAPE LOAD](#)” on page 1846.

*I/O Error during LOAD while Writing a File:* If an I/O error occurs during an SPXTAPE LOAD operation while writing a file into the spooling system, SPXTAPE keeps trying to write the file until successful, or until spool space is exhausted.

*Spool Space Full:* If spool space becomes full during an SPXTAPE LOAD operation:

1. Partially loaded files are purged. The files that were successfully loaded are recorded in the volume log.
2. SPXTAPE LOAD terminates with responses 3 and 4.
3. The tape is positioned according to the disposition specified on the command.

Because of the spool space full condition, it is possible that the last part of the volume log and the command summary log may be lost.

If there is any doubt that there is insufficient spool space to do the SPXTAPE LOAD, it is highly recommended that you first enter the CP QUERY ALLOC SPOOL command and compare the results to the SPOOL PAGES field in response 3 in the command summary log created when the files were dumped. If that log is not available, use the SPXTAPE SCAN command to scan the volume, and use the information in response 3 from the scan.

*Spool File Limit Exceeded:* If the maximum spool file limit is reached during an SPXTAPE LOAD operation:

- If the owner of the file has reached the maximum number of spool IDs allowed for that virtual machine, SPXTAPE assigns the file to the user who entered the command, issues an error message, and continues processing.

If the issuer of the command has also reached the maximum spool ID limit, SPXTAPE continues processing the files without loading them, marking each file with NO\_LOAD in the SEG\_STAT field of the entry in the volume log.

- If the system maximum spool file limit has been reached, SPXTAPE issues an error message and terminates with responses 3 and 4. The tape is positioned according to the disposition specified on the command.

*System Failure:* If the system fails (stops) during an SPXTAPE DUMP, LOAD, or SCAN operation, the command summary log and volume logs are possibly incomplete. If the operation was SPXTAPE LOAD, files in the process of being loaded are purged by system restart.

Recovery of a DUMP or LOAD operation that was in progress can be accomplished as follows (after attaching new drives, if necessary):

- For DUMP with PURGE, discard the tape volumes not already rewound and unloaded prior to the failure, and reenter the SPXTAPE DUMP command with the same file selection criteria.
- For DUMP without PURGE, discard all the tape volumes already dumped and repeat the total process by reentering the SPXTAPE DUMP command.
- For LOAD, see the section on recovering from an I/O error, cancel, or reset in the description of the SPXTAPE LOAD command. Enter HELP SPXTAPE LOAD.
- For SCAN, discard the volume logs for the volumes actively being scanned at the time of the failure (the ones without response 4 at the end). Reenter the SPXTAPE SCAN command for these volumes.

- HCP1914E Virtual device *vdev1[-vdev2]* not write-enabled
- HCP1915E Operands beginning with *operand* conflict with an active SPXTAPE command
- HCP1916I File *userid queue spoolid* matches the SPXTAPE selection criteria but could not be dumped
- HCP1917E Tape device(s) {*rdev[-rdev]*|*vdev[-vdev]*} attached MULTIUSER.
- HCP6525E External Security Manager is unavailable.

## SPXTAPE CANCEL

### Authorization

Privilege Class: D, E, G

### Purpose

Use SPXTAPE CANCEL to cancel an SPXTAPE DUMP, LOAD, or SCAN operation on one or more tape drives.

### Operands

**vdev**

**vdev1-vdev2**

is the virtual device number of the tape drive, or the range of virtual device numbers, on which the SPXTAPE operation is canceled. If you specify a range, and all active tape drives in the range are operating for a single SPXTAPE command, they are canceled.

### Usage Notes

1. Use SPXTAPE CANCEL only when you want to *immediately* cancel the SPXTAPE operation on the specified tape drive or drives, even in the middle of a file. For example, use this command if a tape drive malfunctions in such a way as to be totally unavailable to you, or if you accidentally select a huge file that is going to take several tapes to dump. In contrast, SPXTAPE END allows processing to continue until the end of the current file.

2. When you receive response 8:

```
SPXTAPE CANCEL vdev initiated
```

SPXTAPE halts the I/O operation that was in progress. There are no further I/O operations to the canceled device by the SPXTAPE command currently processing.

3. No tape disposition is processed for a canceled tape drive. The tape drive and tape are left in the state that results from halting the I/O operation.
4. Only the user who entered the SPXTAPE DUMP, LOAD, or SCAN command can enter SPXTAPE CANCEL to cancel it.
5. If the specified range of virtual device numbers does not include all the tape drives associated with a single SPXTAPE command, only the selected drives are canceled. The original command continues to operate on the remaining drives.

If the range includes tape drives that are active for different SPXTAPE commands, none of the tapes are canceled. You must use separate SPXTAPE CANCEL commands. For example, if device 181 is active for one command and device 182 is active for another command, you cannot use a range of 181-182 to cancel them both at the same time.

6. If a canceled tape drive was being used by SPXTAPE DUMP, the files already dumped are discarded. Information about the files or pages processed on the canceled tape are not included in the command summaries. However, if there are other tape drives active for that SPXTAPE DUMP command, the files dumped to the canceled tape are dumped again to one of the other tapes.

7. If a canceled tape drive was being used by SPXTAPE LOAD, the files already loaded are not affected. If a file is in the process of being loaded when the tape drive is canceled, the file is purged from the system.
8. For additional usage information, see SPXTAPE [“Usage Notes”](#) on page 1820.

## Responses

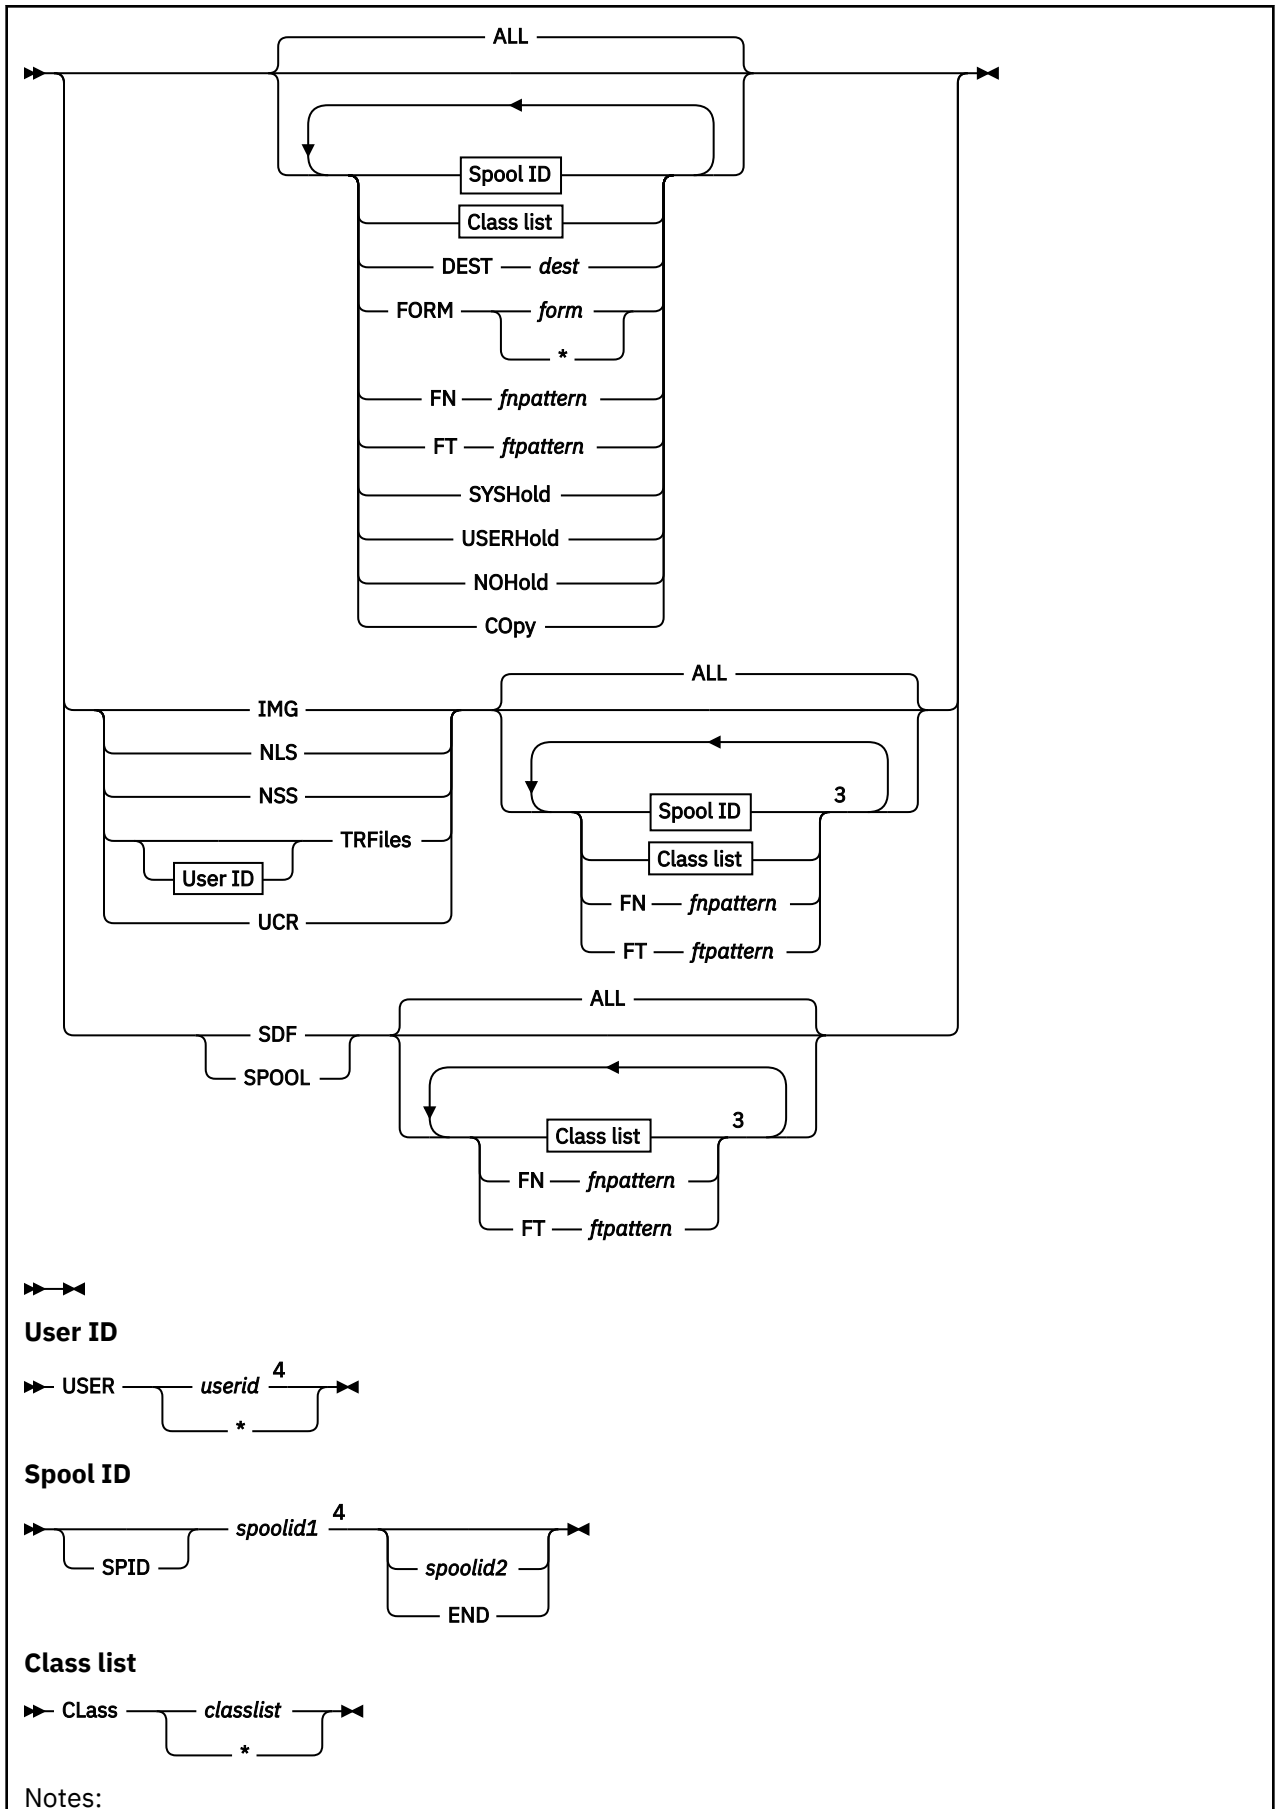

For response information, see SPXTAPE [“Responses”](#) on page 1821.

## Messages

For message information, see SPXTAPE [“Messages”](#) on page 1832.

# SPXTAPE DUMP

- <sup>1</sup> The status of an outstanding SPXTAPE operation can be determined using the QUERY VIRTUAL command. See the description of QUERY VIRTUAL TAPES for more details.
- <sup>2</sup> An abbreviated syntax is permitted for adding devices to a previous command.
- <sup>3</sup> You can specify file attribute selection operands in any order but you can specify each operand only once.
- <sup>4</sup> For a class D or E user, USER *userid* is required if you specify *spoolid1* with PRINTER, PRT, PUNCH, PCH, READER, RDR, STD, or TRFILES.

## Authorization

Privilege Class: D, E, G

## Purpose

Use SPXTAPE DUMP to read standard spool files and system data files from the spooling system and write them on tape.

## Operands

### **vdev**

#### **vdev1-vdev2**

is the virtual device number of the tape drive, or the range of virtual device numbers, where files are to be dumped. If you specify a range, any real supported tape drives attached as virtual device numbers in the range are used to contain the files being dumped.

Queue Selection Operands:

### **Printer**

#### **PRT**

selects printer spool files. Class D or G users can use this operand. (If you have only class G authority, only files owned by your user ID are dumped.)

### **Punch**

#### **PCH**

selects punch spool files. Class D or G users can use this operand. (If you have only class G authority, only files owned by your user ID are dumped.)

### **Reader**

#### **RDR**

selects reader spool files. Class D or G users can use this operand. (If you have only class G authority, only files owned by your user ID are dumped.)

### **STD**

selects all types of standard spool files (printer, punch, and reader). Class D or G users can use this operand. (If you have only class G authority, only files owned by your user ID are dumped.)

### **IMG**

selects image libraries. Class D or E users can use this operand.

### **NLS**

selects national language support files, such as message repository files. Class D or E users can use this operand.

### **NSS**

selects named saved systems and saved segments. Class D or E users can use this operand.

### **TRFiles**

selects system trace files. Class D, E, or G users can use this operand. (If you have only class G authority, only files owned by your user ID are dumped.)

### **UCR**

selects user class restructure files. Class D or E users can use this operand.

**SDF**

selects all types of system data files (IMG, NLS, NSS, TRFILES, and UCR). Class D or E users can use this operand.

**SPOOL**

selects all types of standard spool files and system data files. Because this includes all spooling system queues, only class D users can use this operand.

File Attribute Selection Operands:

**USER *userid*****USER \***

selects files owned by the specified user ID. An asterisk (\*) indicates your own user ID. (If you are a class G user, you cannot specify any entry except your own user ID or \*.)

If you are a class D or class E user, you must specify this operand if you are selecting standard spool files or system trace files by spool ID.

If you omit this operand, files are dumped regardless of user ID. (If you have only class G authority, only files owned by your user ID are dumped.)

**ALL**

selects files regardless of file attributes other than user ID. This is the default.

**SPID**

indicates the following value is a spool ID.

***spoolid1***

is the spool ID of a single file to be dumped or the start of a range of spool IDs. If you omit this operand, files are dumped regardless of spool ID.

If you are a class D or class E user, you must also specify the USER *userid* operand when selecting standard spool files or system trace files by spool ID.

***spoolid2***

is the end of the spool ID range.

**END**

indicates the spool ID range includes all spool IDs equal to or greater than *spoolid1*.

**Class *classlist*****Class \***

selects files with any of the specified classes. You can specify from one to eight classes (single alphanumeric characters with no intervening blanks).

For system data files, only certain classes are valid for each type of file. For information about system data file classes, see [z/VM: CP Planning and Administration](#).

If you specify an asterisk (\*) for the class list, or if you omit this entire operand, files are dumped regardless of class.

**DEST *dest***

selects files with the specified destination value, which may be from one to eight characters. If you omit this operand, files are dumped regardless of destination value.

**FORM *form*****FORM \***

selects files with the specified operator form name, which may be from one to eight characters. If you specify an asterisk (\*) for the name, or if you omit this entire operand, files are dumped regardless of form name.

**FN *fnpattern***

selects files that match the specified file name search pattern. The pattern may be a complete file name or a character string containing wild cards. For information about using wild cards, see usage note "6" on page 1841. You cannot use this operand to select *only* files that have *no* file name (whose file name field contains only blanks). If you omit this operand, files are dumped regardless of file name (including those with no file name).

**FT *ftpattern***

selects files that match the specified file type search pattern. The pattern may be a complete file type or a character string containing wild cards. For information about using wild cards, see usage note “6” on page 1841. You cannot use this operand to select *only* files that have *no* file type (whose file type field contains only blanks). If you omit this operand, files are dumped regardless of file type (including those with no file type).

**SYSHold**

selects system-held files. If you specify SYSHOLD but not USERHOLD or NOHOLD, only system-held files and files that are both system-held and user-held are dumped. If you do not specify SYSHOLD, USERHOLD, or NOHOLD, files are dumped regardless of hold status.

**USERHold**

selects user-held files. If you specify USERHOLD but not SYSHOLD or NOHOLD, only user-held files and files that are both user-held and system-held are dumped. If you do not specify USERHOLD, SYSHOLD, or NOHOLD, files are dumped regardless of hold status.

**NOHold**

selects files that are not held. If you specify NOHOLD but not SYSHOLD or USERHOLD, only files that are not held are dumped. If you do not specify NOHOLD, SYSHOLD, or USERHOLD, files are dumped regardless of hold status.

**COPY**

includes SSI cluster cross-system spool copy files in the dump. If COPY is not specified, only original files are dumped.

Tape Disposition Operands:

**RUN**

rewinds and unloads the tape after the dump completes. This is the default.

**LEAVE**

leaves the tape positioned to do another SPXTAPE operation.

**REWIND**

rewinds the tape after the dump completes but does not unload.

**APPEND**

appends the selection criteria specified on this command to the selection criteria specified on one or more *successive* SPXTAPE DUMP commands within one logical SPXTAPE DUMP operation. All commands in the append sequence must address the same tape devices and all except the last must be specified with the APPEND disposition. For additional information, see usage note “7” on page 1841.

Control Operands:

**MODE NOCOMP**

does not use the hardware compaction feature. This is the default. The density used is whatever the hardware defaults to.

**MODE COMP**

uses the hardware compaction feature. All tape drives within the virtual device number range specified on the command must have the hardware compaction feature. The density used is whatever the hardware defaults to.

**PURGE**

deletes files from the spooling system after they are successfully dumped. Only standard spool files are eligible for purging; system data files are not eligible. You can specify PURGE only on the SPXTAPE DUMP command that initiates a dump operation, not on any subsequent appends. For additional information, see usage note “9” on page 1842.

**PROGress\_interval 15 SEC****PROGress\_interval *progrint* SEC****PROGress\_interval *progrint* MIN**

allows the time interval between the progress reports to be changed from the default of 15 seconds. (See [Response 6](#).) The interval can be specified as a decimal number from 0 to 9999. Requesting an interval of 0 causes the progress reports to be suppressed.

If a logical SPXTAPE command is being created through the use of the APPEND option, the last explicitly requested interval will be used.

**Usage Notes**

1. Open and in-use files, with the exception of named saved systems and saved segments, cannot be dumped.
2. SPXTAPE does not dump class P named saved systems and saved segments or class W system trace files.
3. In an SSI cluster shared spool environment, printer and punch files locked on another system are not dumped.
4. A reader file being dumped is marked "in-use" and is therefore not available to the owner during the dump. Reader files are dumped even if they are locked on another system in an SSI cluster shared spool environment. However, if the owner of a reader file being dumped is logged on to another system in the SSI cluster (not where the file is being dumped), there is no indication to the owner that the file is not available.
5. Using SPXTAPE DUMP at off-peak hours on the system will have less impact on users due to I/O contention to the spool DASD. Also, with fewer users logged on, the availability of closed spool files for dumping is increased.
6. When using the FN or FT file attribute selection operand, you can use two special characters, \* (asterisk) and % (percent), as wild cards in the file name or file type pattern. These special characters have the following meaning:

**\***

is a placeholder character that represents any number of characters from zero to eight, depending on how many other characters are specified in the pattern. You can use as many asterisks as necessary anywhere in the pattern as long as the total number of characters, including the asterisks, does not exceed eight. For example, a pattern of *d\** means any string that begins with the character "D". However, a pattern of *\*d\** means any string that contains a "D", whether it is at the beginning, in the middle, or at the end. A pattern containing a single asterisk and no other characters means all strings regardless of length or character content (including the string that contains only blanks).

**%**

is a placeholder character that represents a single character. You can use as many percents as necessary anywhere in the pattern as long as the total number of characters, including the percents, does not exceed eight. For example, a pattern of *%%%* means any string that is three characters in length. A pattern of *%%%s* means any string that is four characters in length and ends with the character "S".

Wild cards can also be combined. For example, a pattern of *vm%%\** means any string four characters in length *or longer* that begins with the characters "VM".

7. Using the APPEND operand prevents the SPXTAPE DUMP operation from completing when all the files selected on the command have been processed. SPXTAPE waits for another DUMP command, addressing the same tape devices, either selecting more files or specifying a disposition other than APPEND. At that point, the files selected on this command might not have been written to tape yet, but might reside in a partially filled buffer.

SPXTAPE DUMP processing begun with the APPEND disposition completes only when you enter an SPXTAPE DUMP command, addressing the same tape devices, with a disposition operand of RUN, LEAVE, or REWIND (or no disposition, which results in a default of RUN).

A sequence of appended SPXTAPE DUMP commands are processed as one logical SPXTAPE DUMP command. This allows you (or an exec) to specify different sets of selection criteria for individual files or groups of files to be dumped on the same set of tapes in a single SPXTAPE DUMP processing run, as shown in the following sequence:

```
spxtape dump 300-399 selection_criteria_1 append
spxtape dump 300-399 selection_criteria_2 append
:
spxtape dump 300-399 selection_criteria_n run
```

It is not necessary to wait for the response to the first SPXTAPE DUMP command (response 4) before entering the next SPXTAPE DUMP command in the sequence.

8. In a sequence of appended SPXTAPE DUMP commands, if the file selection criteria specified on a new append overlap the file selection criteria specified on a previous append, duplicate files may be dumped. When looking for a file to dump, SPXTAPE does not check to see if the file has already been dumped.
9. When you use the PURGE operand, a file is purged only after all data has been successfully written to the tape volume (or volumes) that contain the file, and the file information has been recorded in the log. The log records for all the files on the volume are written after the trailer record is successfully written and the SPXTAPE disposition is performed. Therefore, the file is actually purged only after the volume that contains the end of the file is complete. Except in the case of a system failure, the log reflects what has been purged.  
  
In the system failure case (when the system stops while SPXTAPE DUMP is running), if the specified SPXTAPE disposition is RUN and any log data exists for the volume after warmstart, then all the data on the tape is good. However, all the corresponding purges may not have been done. You can use SPXTAPE SCAN to recover a log of what is actually on the tape. To determine what spool files you have to purge, you can use the logs obtained from scanning the dumped tapes (this is the most conservative method) or you can use the logs of the dump (this is a little less conservative).
10. If you specify PURGE on the first SPXTAPE DUMP command in an APPEND sequence, and you select system data files on that command or any subsequent commands in the sequence, the system data files are dumped but not purged.
11. If a dump is initiated to more than one tape drive and only a few files are being dumped, it is possible for an intervention-required condition on one of the drives to hold up the dumping of all the files. For example, if only two files are being dumped, the end of the first file and the beginning of the second file may fall in the same data block that SPXTAPE is writing to the first drive. If that drive goes into intervention-required status during the dumping of the first file, SPXTAPE waits for the intervention-required condition to be cleared. So the dumping of the second file cannot begin, even though another drive is available. No further dumping occurs until the first drive is taken out of the intervention-required state. No periodic progress report (response 6) is issued under these circumstances.
12. A logical SPXTAPE DUMP command, which may be a single command or a sequence of appended commands, dumps the selected files on the tape as a single tape file and writes a double tape mark at the end. SPXTAPE DUMP does not write tape marks between individual files.  
  
If an SPXTAPE DUMP command is entered with the LEAVE disposition, SPXTAPE backspaces over the second tape mark after dumping the files. Therefore, the result of using multiple SPXTAPE DUMP commands with the LEAVE disposition to dump files to a single tape is that the tape files are separated by single tape marks and the last tape file ends with a double tape mark. To load these tape files back into the spooling system, you must use multiple SPXTAPE LOAD commands.
13. For additional usage information, see [“Usage Notes” on page 1820](#).

#### Expanding the Device Range

You can add one or more tape drives to the device or range of devices specified on a previous SPXTAPE DUMP command that is still active. Enter another SPXTAPE DUMP command with an expanded range that includes all of the devices specified on the previous command plus the device or devices you want to add.

If the previous SPXTAPE DUMP command was entered with a disposition of LEAVE, REWIND, or RUN (or no disposition, which defaults to RUN), the command that you enter to expand the range is an abbreviated form that omits the selection criteria, disposition, and control operands:

```
spxtape dump vdev1-vdev2
```

If the previous SPXTAPE DUMP command was entered with the APPEND disposition, the command you enter to expand the range can include additional selection criteria. If you intend to append additional commands to the sequence, you must also specify APPEND on the command that expands the range. Otherwise, SPXTAPE interprets the command as the final one in the sequence.

For example, suppose the previous command was:

```
spxtape dump 300-349 std class a syshold append
```

If you want to add device 352 and also add class D system trace files to the selection criteria, enter:

```
spxtape dump 300-352 trfiles class d append
```

If you only want to add device 352, enter:

```
spxtape dump 300-352 append
```

Note that the range now also includes devices 350 and 351, if such devices are attached to you and are active. You cannot skip any active tape devices in the range. If you do not want to use devices 350 and 351, you must redefine or detach them before entering the SPXTAPE command.

## Responses

For response information, see SPXTAPE [“Responses”](#) on page 1821.

## Messages

For message information, see SPXTAPE [“Messages”](#) on page 1832.

## SPXTAPE END

### Authorization

Privilege Class: D, E, G

### Purpose

Use SPXTAPE END to end SPXTAPE DUMP, LOAD, or SCAN processing at the completion of the current file.

### Operands

**vdev**

**vdev1-vdev2**

is the virtual device number of the tape drive, or the range of virtual device numbers, on which the SPXTAPE operation is ended. If you specify a range, and all active tape drives in the range are operating for a single SPXTAPE command, they are ended.

### Usage Notes

1. Only the user who entered the SPXTAPE DUMP, LOAD, or SCAN command can enter SPXTAPE END to end the operation.
2. If the specified range of virtual device numbers does not include all the tape drives associated with a single SPXTAPE command, only the selected drives are ended. The original command continues to operate on the remaining drives.  
  
If the range includes tape drives that are active for different SPXTAPE commands, none of the tapes are ended. You must use separate SPXTAPE END commands. For example, if device 181 is active for one command and device 182 is active for another command, you cannot use a range of 181-182 to end them both at the same time.
3. You can use either SPXTAPE END or SPXTAPE CANCEL to remove failing drives or to make drives available for other work. END does it gracefully, at the completion of the current file; CANCEL does it immediately, even in the middle of a file.
4. The tape is positioned as specified by the disposition operand on the SPXTAPE command that initiated the activity being ended.

For LOAD or SCAN with the LEAVE disposition, the tape is positioned at an indeterminate record on the volume. To process another tape file on the same tape, enter TAPE FSF.

For DUMP with the APPEND disposition, if no other drives are active, the dump of the current file is completed and the DUMP command completes. This could leave many selected files not dumped. Therefore, you should not select all drives with SPXTAPE END unless the drives are in the "WAITING" status. If your intent is to have all the appended files complete, use SPXTAPE DUMP with REWIND, RUN, or LEAVE. This causes the command to complete when all the appended files have been dumped.

For LOAD or SCAN with the APPEND disposition, if the drive is in the "WAITING" status, no files are processed.

For LOAD, DUMP, or SCAN with the APPEND disposition, if the drive is active, SPXTAPE END changes the disposition to RUN; that is, the tape is rewound and unloaded.

Entering SPXTAPE END between tape reel mounts during a multiple reel load or scan of a single file is the way to bring an SPXTAPE LOAD or SCAN operation with the RUN disposition to completion.

5. For additional usage information, see [“Usage Notes” on page 1820](#).

## **Responses**

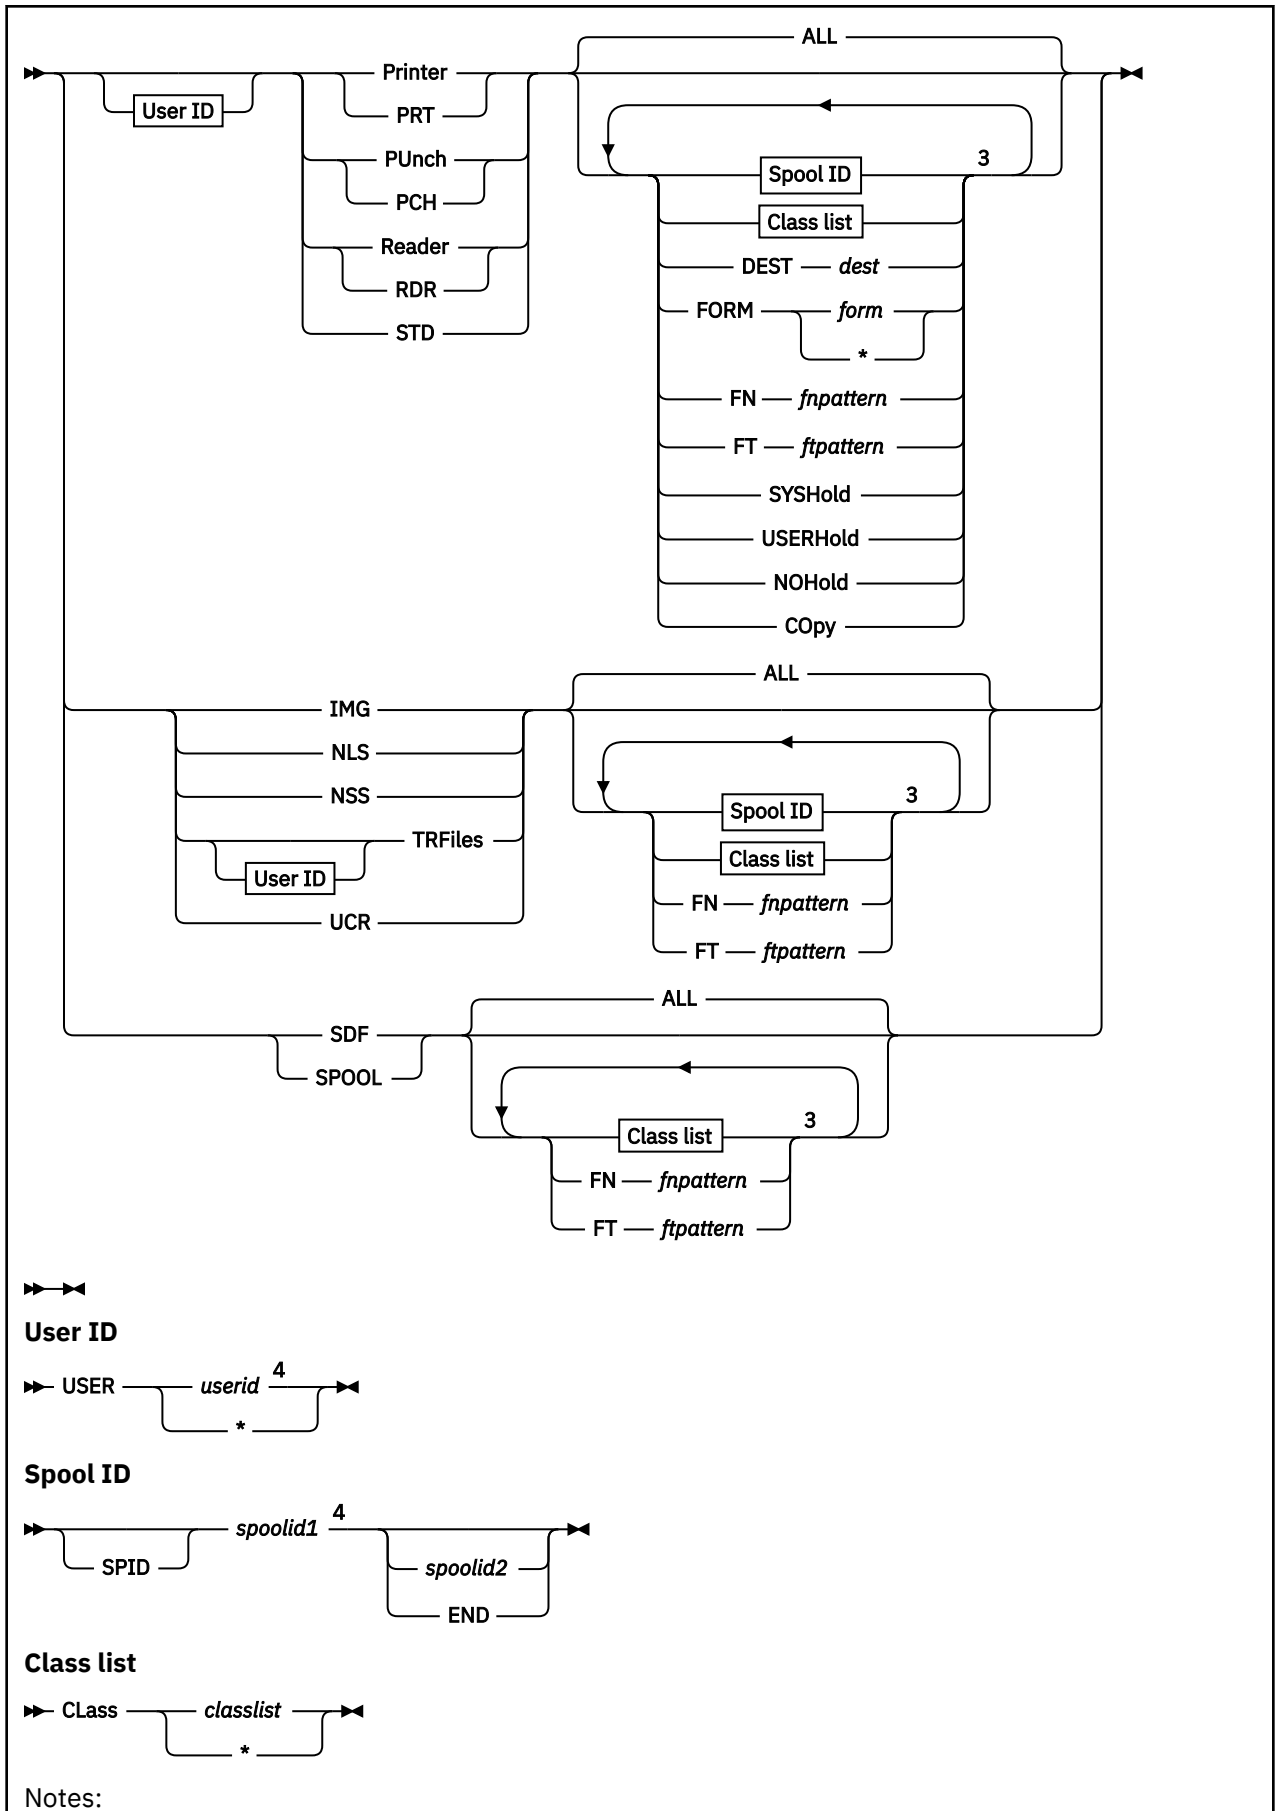

For response information, see SPXTAPE [“Responses” on page 1821](#).

## **Messages**

For message information, see SPXTAPE [“Messages” on page 1832](#).

## SPXTAPE LOAD

<sup>1</sup> The status of an outstanding SPXTAPE operation can be determined using the QUERY VIRTUAL command. See the description of QUERY VIRTUAL TAPES for more details.

<sup>2</sup> An abbreviated syntax is permitted for adding devices to a previous command.

<sup>3</sup> You can specify file attribute selection operands in any order but you can specify each operand only once.

<sup>4</sup> For a class D or E user, USER *userid* is required if you specify *spoolid1* with PRINTER, PRT, PUNCH, PCH, READER, RDR, STD, or TRFILES.

### Authorization

Privilege Class: D, E, G

### Purpose

Use SPXTAPE LOAD to read standard spool files and system data files from tape (that were written to tape by SPXTAPE DUMP) and write them into the spooling system.

### Operands

#### **vdev**

#### **vdev1-vdev2**

is the virtual device number of the tape drive, or the range of virtual device numbers, from which files are to be loaded. If you specify a range, any real supported tape drives attached as virtual device numbers in the range are used as the source for the files being loaded.

Queue Selection Operands:

#### **Printer**

#### **PRT**

selects printer spool files. Class D or G users can use this operand. (If you have only class G authority, only files owned by your user ID are loaded.)

#### **Punch**

#### **PCH**

selects punch spool files. Class D or G users can use this operand. (If you have only class G authority, only files owned by your user ID are loaded.)

#### **Reader**

#### **RDR**

selects reader spool files. Class D or G users can use this operand. (If you have only class G authority, only files owned by your user ID are loaded.)

#### **STD**

selects all types of standard spool files (printer, punch, and reader). Class D or G users can use this operand. (If you have only class G authority, only files owned by your user ID are loaded.)

#### **IMG**

selects image libraries. Class D or E users can use this operand.

#### **NLS**

selects national language support files, such as message repository files. Class D or E users can use this operand.

#### **NSS**

selects named saved systems and saved segments. Class D or E users can use this operand.

#### **TRFiles**

selects system trace files. Class D, E, or G users can use this operand. (If you have only class G authority, only files owned by your user ID are loaded.)

#### **UCR**

selects user class restructure files. Class D or E users can use this operand.

**SDF**

selects all types of system data files (IMG, NLS, NSS, TRFILES, and UCR). Class D or E users can use this operand.

**SPOOL**

selects all types of standard spool files and system data files. Because this includes all spooling system queues, only class D users can use this operand.

File Attribute Selection Operands:

**USER *userid*****USER \***

selects files owned by the specified user ID. An asterisk (\*) indicates your own user ID. (If you are a class G user, you cannot specify any entry except your own user ID or \*.)

If you are a class D or class E user, you must specify this operand if you are selecting standard spool files or system trace files by spool ID.

If you omit this operand, files are loaded regardless of user ID. (If you have only class G authority, only files owned by your user ID are loaded.)

The USER operand is checked for validity and will be rejected if the *userid* specified is not a user in the directory for the system that SPXTAPE LOAD is running on, and the *userid* does not have any SPOOL files on the system.

**ALL**

selects files regardless of file attributes other than user ID. This is the default.

**SPID**

indicates the following value is a spool ID.

***spoolid1***

is the spool ID of a single file to be loaded or the start of a range of spool IDs. If you omit this operand, files are loaded regardless of spool ID.

If you are a class D or class E user, you must also specify the USER *userid* operand when selecting standard spool files or system trace files by spool ID.

***spoolid2***

is the end of the spool ID range.

**END**

indicates the spool ID range includes all spool IDs equal to or greater than *spoolid1*.

**Class *classlist*****Class \***

selects files with any of the specified classes. You can specify from one to eight classes (single alphanumeric characters with no intervening blanks).

For system data files, only certain classes are valid for each type of file. For information about system data file classes, see [z/VM: CP Planning and Administration](#).

If you specify an asterisk (\*) for the class list, or if you omit this entire operand, files are loaded regardless of class.

**DEST *dest***

selects files with the specified destination value, which may be from one to eight characters. If you omit this operand, files are loaded regardless of destination value.

**FORM *form*****FORM \***

selects files with the specified operator form name, which may be from one to eight characters. If you specify an asterisk (\*) for the name, or if you omit this entire operand, files are loaded regardless of form name.

**FN *fnpattern***

selects files that match the specified file name search pattern. The pattern may be a complete file name or a character string containing wild cards. For information about using wild cards, see usage note [“2” on page 1851](#). You cannot use this operand to select *only* files that have *no* file name (whose file name field contains only blanks). If you omit this operand, files are loaded regardless of file name (including those with no file name).

**FT *ftpattern***

selects files that match the specified file type search pattern. The pattern may be a complete file type or a character string containing wild cards. For information about using wild cards, see usage note [“2” on page 1851](#). You cannot use this operand to select *only* files that have *no* file type (whose file type field contains only blanks). If you omit this operand, files are loaded regardless of file type (including those with no file type).

**SYSHold**

selects system-held files. If you specify SYSHOLD but not USERHOLD or NOHOLD, only system-held files and files that are both system-held and user-held are loaded. If you do not specify SYSHOLD, USERHOLD, or NOHOLD, files are loaded regardless of hold status.

**USERHold**

selects user-held files. If you specify USERHOLD but not SYSHOLD or NOHOLD, only user-held files and files that are both user-held and system-held are loaded. If you do not specify USERHOLD, SYSHOLD, or NOHOLD, files are loaded regardless of hold status.

**NOHold**

selects files that are not held. If you specify NOHOLD but not SYSHOLD or USERHOLD, only files that are not held are loaded. If you do not specify NOHOLD, SYSHOLD, or USERHOLD, files are loaded regardless of hold status.

Tape Disposition Operands:

**RUN**

rewinds and unloads the tape after the load completes. This is the default.

Upon detecting the logical end-of-tape (the end of the tape file written by SPXTAPE DUMP on that volume), SPXTAPE LOAD issues response 5, rewinds and unloads the tape, and waits for another volume to be mounted (the drive becomes "mount pending"). You must use the SPXTAPE END or SPXTAPE CANCEL command to cause SPXTAPE LOAD with the RUN disposition to complete.

**LEAVE**

leaves the tape positioned to do another SPXTAPE operation.

**REWind**

rewinds the tape after the load completes but does not unload.

**APPEND**

appends the selection criteria specified on this command to the criteria specified on one or more *successive* SPXTAPE LOAD commands within one logical SPXTAPE LOAD operation. All commands in the append sequence must address the same tape devices and all except the last must be specified with the APPEND disposition. For additional information, see usage note [“3” on page 1851](#).

Control Operands:

**NODUP**

prevents the loading of any file that would duplicate a file that already exists on the target spooling system queue. For additional information, see usage note [“4” on page 1851](#).

**PROGress\_interval 15 SEC****PROGress\_interval *progint* SEC****PROGress\_interval *progint* MIN**

allows the time interval between the progress reports to be changed from the default of 15 seconds. (See [Response 7](#).) The interval can be specified as a decimal number from 0 to 9999. Requesting an interval of 0 causes the progress reports to be suppressed.

If a logical SPXTAPE command is being created through the use of the APPEND option, the last explicitly requested interval will be used.

## Usage Notes

1. Using SPXTAPE LOAD at off-peak hours on the system will have less impact on users due to I/O contention to the spool DASD.
2. When using the FN or FT file attribute selection operand, you can use two special characters, \* (asterisk) and % (percent), as wild cards in the file name or file type pattern. These special characters have the following meaning:

**\***

is a placeholder character that represents any number of characters from zero to eight, depending on how many other characters are specified in the pattern. You can use as many asterisks as necessary anywhere in the pattern as long as the total number of characters, including the asterisks, does not exceed eight. For example, a pattern of d\* means any string that begins with the character "D". However, a pattern of \*d\* means any string that contains a "D", whether it is at the beginning, in the middle, or at the end. A pattern containing a single asterisk and no other characters means all strings regardless of length or character content (including the string that contains only blanks).

**%**

is a placeholder character that represents a single character. You can use as many percents as necessary anywhere in the pattern as long as the total number of characters, including the percents, does not exceed eight. For example, a pattern of %%% means any string that is three characters in length. A pattern of %%%s means any string that is four characters in length and ends with the character "S".

Wild cards can also be combined. For example, a pattern of vm%%\* means any string four characters in length *or longer* that begins with the characters "VM".

3. When using the APPEND operand, if there is no SPXTAPE LOAD command currently active on the addressed tape devices, the devices are placed in the append waiting state (response 10 is issued).

Actual loading from the tape devices does not commence until you enter an SPXTAPE LOAD command with a disposition of RUN, LEAVE, or REWIND (or no disposition, which results in a default of RUN).

A sequence of appended SPXTAPE LOAD commands are processed as one logical SPXTAPE LOAD command. This allows you (or an exec) to specify different sets of selection criteria for individual files or groups of files to be loaded from the same set of tapes in a single SPXTAPE LOAD processing run, as shown in the following sequence:

```
spxtape load 300-399 selection_criteria_1 append
spxtape load 300-399 selection_criteria_2 append
:
spxtape load 300-399 selection_criteria_n run
```

4. When using the NODUP operand, the definition of "duplicate" depends on the type of file.

For standard spool files and system trace files, "duplicate" means that all the file attributes of the file on the tape are identical to a file on the queue. This includes the time stamp for when the file was opened. An identical time stamp indicates that they are identical files. (If some files on the system have been imported from other systems, it is possible that files could have been created on both systems at exactly the same microsecond with all the same file attributes, but contain different data. However, this is not very probable.)

For system data files other than system trace files, "duplicate" means that the file name, file type, and class of the file on the tape are identical to the file on the queue. In addition, for named saved system and saved segment files, class A (active) and class R (restricted) files of the same file name and file type are considered duplicate because they cannot exist on the system at the same time.

A file that is found to be a duplicate is identified in the resulting volume log with DUP\_FILE in the SEG\_STAT field. The FILE field of this entry in the log contains the file ID of the file already on the

system. If the file on the system is moved to a different queue or user ID, or its file attributes are changed (for example, its spool class), the file is no longer identified as a duplicate.

The NODUP operand helps you recover if a system failure occurs while you are loading files from tape. If you add the NODUP operand to your selection criteria and reprocess all the tapes that have already been processed, all the files that loaded correctly before the system failure are skipped. However, even with NODUP specified, you may still receive duplicate files if you are loading the same file concurrently from more than one tape.

Keep in mind when using the NODUP operand that as the number of files in the queue where the files are being loaded increases, the amount of processing required to load the files from the tape increases dramatically. Each file to be loaded is compared to every file in the queue. For example, if the queue contains 1000 files and 1000 files are to be loaded, the result is over one million comparisons.

The consequence of loading duplicate files is more serious for system data files than for standard spool files. If the NODUP operand is not used when loading system data files (or all files) from a tape for which no dump log is available, you should check to make sure that duplicate files were not loaded. If this happens, check the files to determine which should be kept and purge the unnecessary files.

5. A logical SPXTAPE LOAD command, which may be a single command or a sequence of appended commands, loads one tape file. A tape file (which ends with one or more tape marks) contains one or more files dumped by one logical SPXTAPE DUMP command. If multiple tape files exist on the tape (written by multiple logical SPXTAPE DUMP commands), you must enter separate SPXTAPE LOAD commands to load each tape file.
6. Do not load the same tape more than once during processing of the same SPXTAPE command. Unpredictable results may occur, such as incomplete files, duplicate files, or loss of spool DASD space. However, there may be times when you need to reload the same volume. For example, if you encounter an I/O error while reading a tape, you might want to retry the operation. For more information, see the Recovering from an I/O Error, Cancel, Reset, or System Failure section in this command.
7. A file being loaded retains the same characteristics as the original file but is assigned a new spool ID in the spooling system. The new spool ID is obtained from the pool of IDs available to the recipient of the file.
8. If the file owner's user ID does not exist on the system to which the file is being loaded, or if the file owner runs out of spool IDs, the file is assigned to the user who issued the SPXTAPE LOAD command. If that user also runs out of spool IDs, the file is not loaded, and NO\_LOAD is recorded in the SEG\_STAT field of the entry in the volume log.
9. During SPXTAPE LOAD processing, response 5 is issued when all data has been read from a tape. Response 7, which is issued periodically to indicate the command is processing, may continue to be received even after response 5 has been issued for all the tapes being processed because the files are still being written into the spooling system. However, the command can no longer be ended or canceled at this point.
10. If you entered SPXTAPE LOAD with the RUN option (or no disposition, which results in a default of RUN), there is no way for SPXTAPE to know how many tape volumes are involved in the LOAD operation. Therefore, each time logical end-of-tape is reached, SPXTAPE issues Response 5 asking for the next volume to be mounted. Logical end-of-tape means the end of the tape file written by SPXTAPE DUMP on that volume.

If there are other tapes to be processed, mount the next tape. If you are using more than one tape drive, CP continues reading on the other drives. When you mount and ready the new tape, CP starts reading on that drive again.

If there are no other tapes to be mounted, and all tapes currently mounted have finished processing (you have received the mount next tape response for each drive), use the SPXTAPE END command to end the operation. A CANCEL command can be used in abnormal circumstances.

For more information, see the previous section on "Tape Disposition Operands" for SPXTAPE LOAD.

11. For additional usage information, see [“Usage Notes” on page 1820](#).
12. User Class Restructure (UCR) files that are loaded using SPXTAPE are no longer supported, and they will not be activated at the next IPL. Use the MODIFY statement or command to change command privilege classes. For information about MODIFY, see [Modifying a Command and Diagnose Code in z/VM: CP Exit Customization](#).

### Expanding the Device Range

You can add one or more tape drives to the device or range of devices specified on a previous SPXTAPE LOAD command that is still active. Enter another SPXTAPE LOAD command with an expanded range that includes all of the devices specified on the previous command plus the device or devices you want to add.

If the previous SPXTAPE LOAD command was entered with a disposition of LEAVE, REWIND, or RUN (or no disposition, which defaults to RUN), the command that you enter to expand the range is an abbreviated form that omits the selection criteria, disposition, and control operands:

```
spxtape load vdev1-vdev2
```

If the previous SPXTAPE LOAD command was entered with the APPEND disposition (in other words, you are in a sequence of SPXTAPE LOAD commands to be bundled into one logical command), the new command that you enter to expand the range can include additional selection criteria. If you do not also specify the APPEND disposition on the new command, SPXTAPE interprets the new command as the final command in the sequence.

For example, suppose the previous command was:

```
spxtape load 300-349 std class a syshold append
```

If you want to add device 352 and also add class D system trace files to the selection criteria, enter:

```
spxtape load 300-352 trfiles class d append
```

If you only want to add device 352, enter:

```
spxtape load 300-352 append
```

Note that the range now also includes devices 350 and 351, if such devices are attached to you and are active. You cannot skip any active tape devices in the range. If you do not want to use devices 350 and 351, you must redefine or detach them before entering the SPXTAPE command.

### Recovering from an I/O Error, Cancel, Reset, or System Failure

A file may be only partially loaded from a tape if:

- SPXTAPE LOAD encounters an I/O error while trying to read the file
- You cancel the SPXTAPE LOAD operation on the device where SPXTAPE is reading the file
- You reset the device (using RESET, DETACH, GIVE, or a similar CP command) where SPXTAPE LOAD is reading the file
- The system fails (stops) while SPXTAPE LOAD is reading the file.

Other files that follow on the tape volume may not be loaded at all.

Before attempting to recover any files from that volume, allow the load to continue on the other devices (if any) until the command completes, to load as many files as possible.

There are two ways to recover files from the volume:

- You can compare the volume log for the load to the volume log for the dump to see if files are missing or partially loaded. Then use the SPXTAPE LOAD command to load the files individually. If you are recovering from an I/O error, you must mount the tape on a different drive. Check all the volume logs for the dump to see if any file in question was dumped to more than one volume. You may also have to purge an incomplete version of the file that currently exists on the system in system hold status. This happens to a standard spool file if:

## SPXTAPE LOAD

- The file is partially loaded (the load is interrupted)
- The command ends on this volume before the file is read, but other parts of the file are loaded from other volumes.

If a system data file is incomplete, SPXTAPE purges it. When reloading a file, make sure you include all the volumes that contain parts of the file.

- You can reprocess the entire tape. If you are recovering from an I/O error, you must mount the tape on a different drive. Enter the SPXTAPE LOAD command for that drive, using your original selection criteria *plus* the NODUP operand.

If the reload completes without error, examine the volume log for the reload. Look for response 2 entries in which the SEG\_STAT field contains either PARTIAL or DUP\_FILE. If you find such an entry, check how the same file is recorded in the first volume log. (In some cases, there may be no entry in the first volume log.) All the possible combinations are shown in [Table 42 on page 1854](#), which also indicates if any additional actions are required. Additional actions are described following the table.

If you are using either of these methods to recover from an I/O error and the error is repeated, the tape has a bad spot. If you are reprocessing the entire tape, and SPXTAPE processing ends without loading any additional files after encountering the I/O error, either the bad spot extends to the end of the tape file or the spot is too large (10 consecutive bad records) for SPXTAPE to skip. Files in the bad records cannot be retrieved from the tape and must be recovered from some other source. However, all the files after the bad spot, either within the same tape file or in other tape files contained on the tape may be loaded. Physically position the tape past the damaged spot with the CMS command TAPE FSR or FSF, and enter the SPXTAPE LOAD command again. You may need to do this more than once to skip past the entire bad area. You may receive message HCP1911W as SPXTAPE skips to the start of where the next file was backed up, and resumes normal operation.

Type of File	First Load		Reload (NODUP)		Additional Actions Required?
	Load Results	Volume Log Entry	Load Results	Volume Log Entry	
Standard spool file, complete on this volume	Loaded	COMPLETE	Not loaded	DUP_FILE	No
	Partially loaded and placed in SYSHOLD	PARTIAL	If file on tape is <i>not</i> SYSHOLD, then loaded	COMPLETE	No, but you may want to purge the partially loaded file
			If file on tape is SYSHOLD, then not loaded	DUP_FILE	Yes
	Not loaded (not read)	No entry	Loaded	COMPLETE	No
System data file, complete on this volume	Loaded	COMPLETE	Not loaded	DUP_FILE	No
	Partially loaded and then purged	PARTIAL	Loaded	COMPLETE	No
	Not loaded (not read)	No entry	Loaded	COMPLETE	No

Type of File	First Load		Reload (NODUP)		Additional Actions Required?
	Load Results	Volume Log Entry	Load Results	Volume Log Entry	
Standard spool file, continued on one or more other volumes	Loaded	PARTIAL	Not loaded	DUP_FILE	Yes, if file on tape is SYSHOLD
	Partially loaded; when other parts of file on other volumes are loaded, incomplete file is placed in SYSHOLD	PARTIAL	If file on tape is <i>not</i> SYSHOLD, then loaded	PARTIAL	Yes
			If file on tape is SYSHOLD, then not loaded	DUP_FILE	Yes
	Not loaded (not read); when other parts of file on other volumes are loaded, incomplete file is placed in SYSHOLD	No entry	If file on tape is <i>not</i> SYSHOLD, then loaded	PARTIAL	Yes
			If file on tape is SYSHOLD, then not loaded	DUP_FILE	Yes
	System data file, continued on one or more other volumes	Loaded	PARTIAL	Not loaded	DUP_FILE
Partially loaded; when other parts of file on other volumes are loaded, incomplete file is purged		PARTIAL	Loaded and then purged	PARTIAL	Yes
Not loaded (not read); when other parts of file on other volumes are loaded, incomplete file is purged		No entry	Loaded and then purged	PARTIAL	Yes

*Additional Actions to Recover a File:* Follow these steps if [Table 42 on page 1854](#) indicates additional actions are required to recover a file.

1. Check the other volume logs (if any) for the same load to see if those volumes contain parts of the file.
2. If you find an entry in any log in which the file is recorded as COMPLETE, the file has been completely loaded. No further action is required.
3. If the file is recorded only as PARTIAL in other logs (or if this is the only volume log for the load), and the file is a standard spool file, purge the partially loaded file that exists on the system in system hold status. If the file is a system data file, SPXTAPE has already purged the partially loaded file.
4. Reload the file from all the volumes on which parts are located.

## SPXTAPE LOAD

*Recovering Multiple Files:* Instead of recovering each file separately, you can combine the loading of many individual files from various tape volumes into a single SPXTAPE LOAD operation, as long as all the files you want to load were dumped by one logical SPXTAPE DUMP command. Enter each SPXTAPE LOAD command (except the last) with the APPEND disposition operand. If you are using more than one tape drive, make sure you specify the complete device number range on each command. The load does not begin until you enter a command with a disposition other than APPEND. The order in which you mount the tapes does not matter.

### Responses

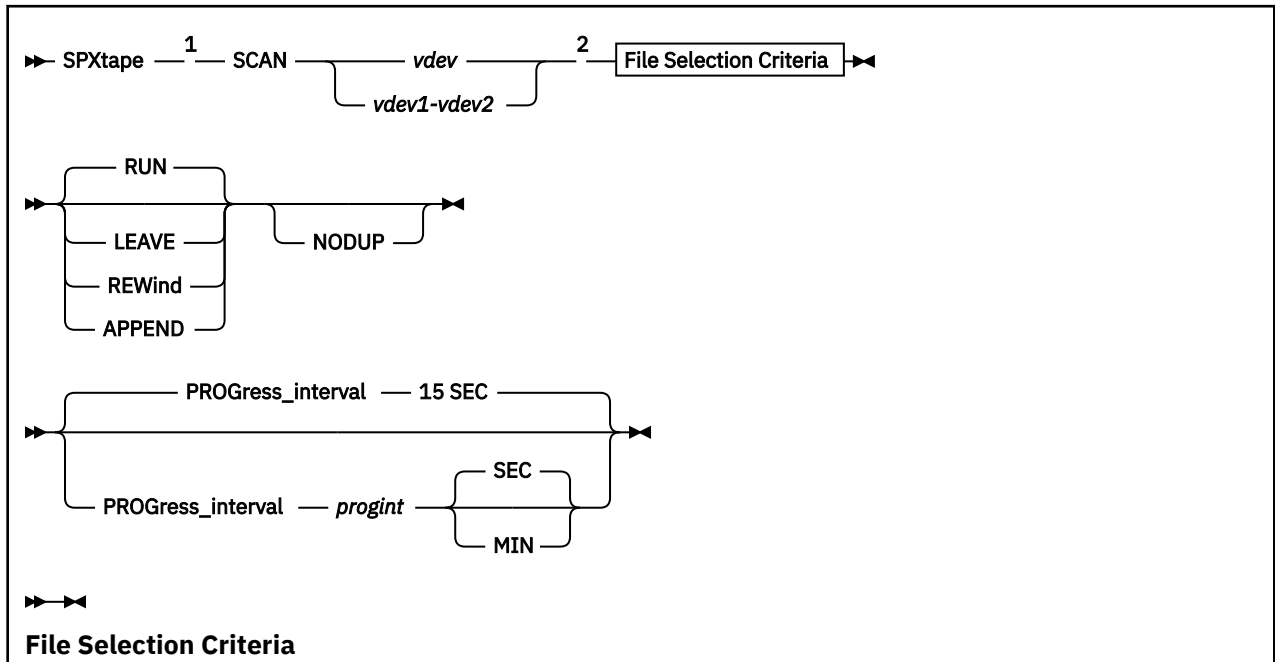

For response information, see SPXTAPE [“Responses”](#) on page 1821.

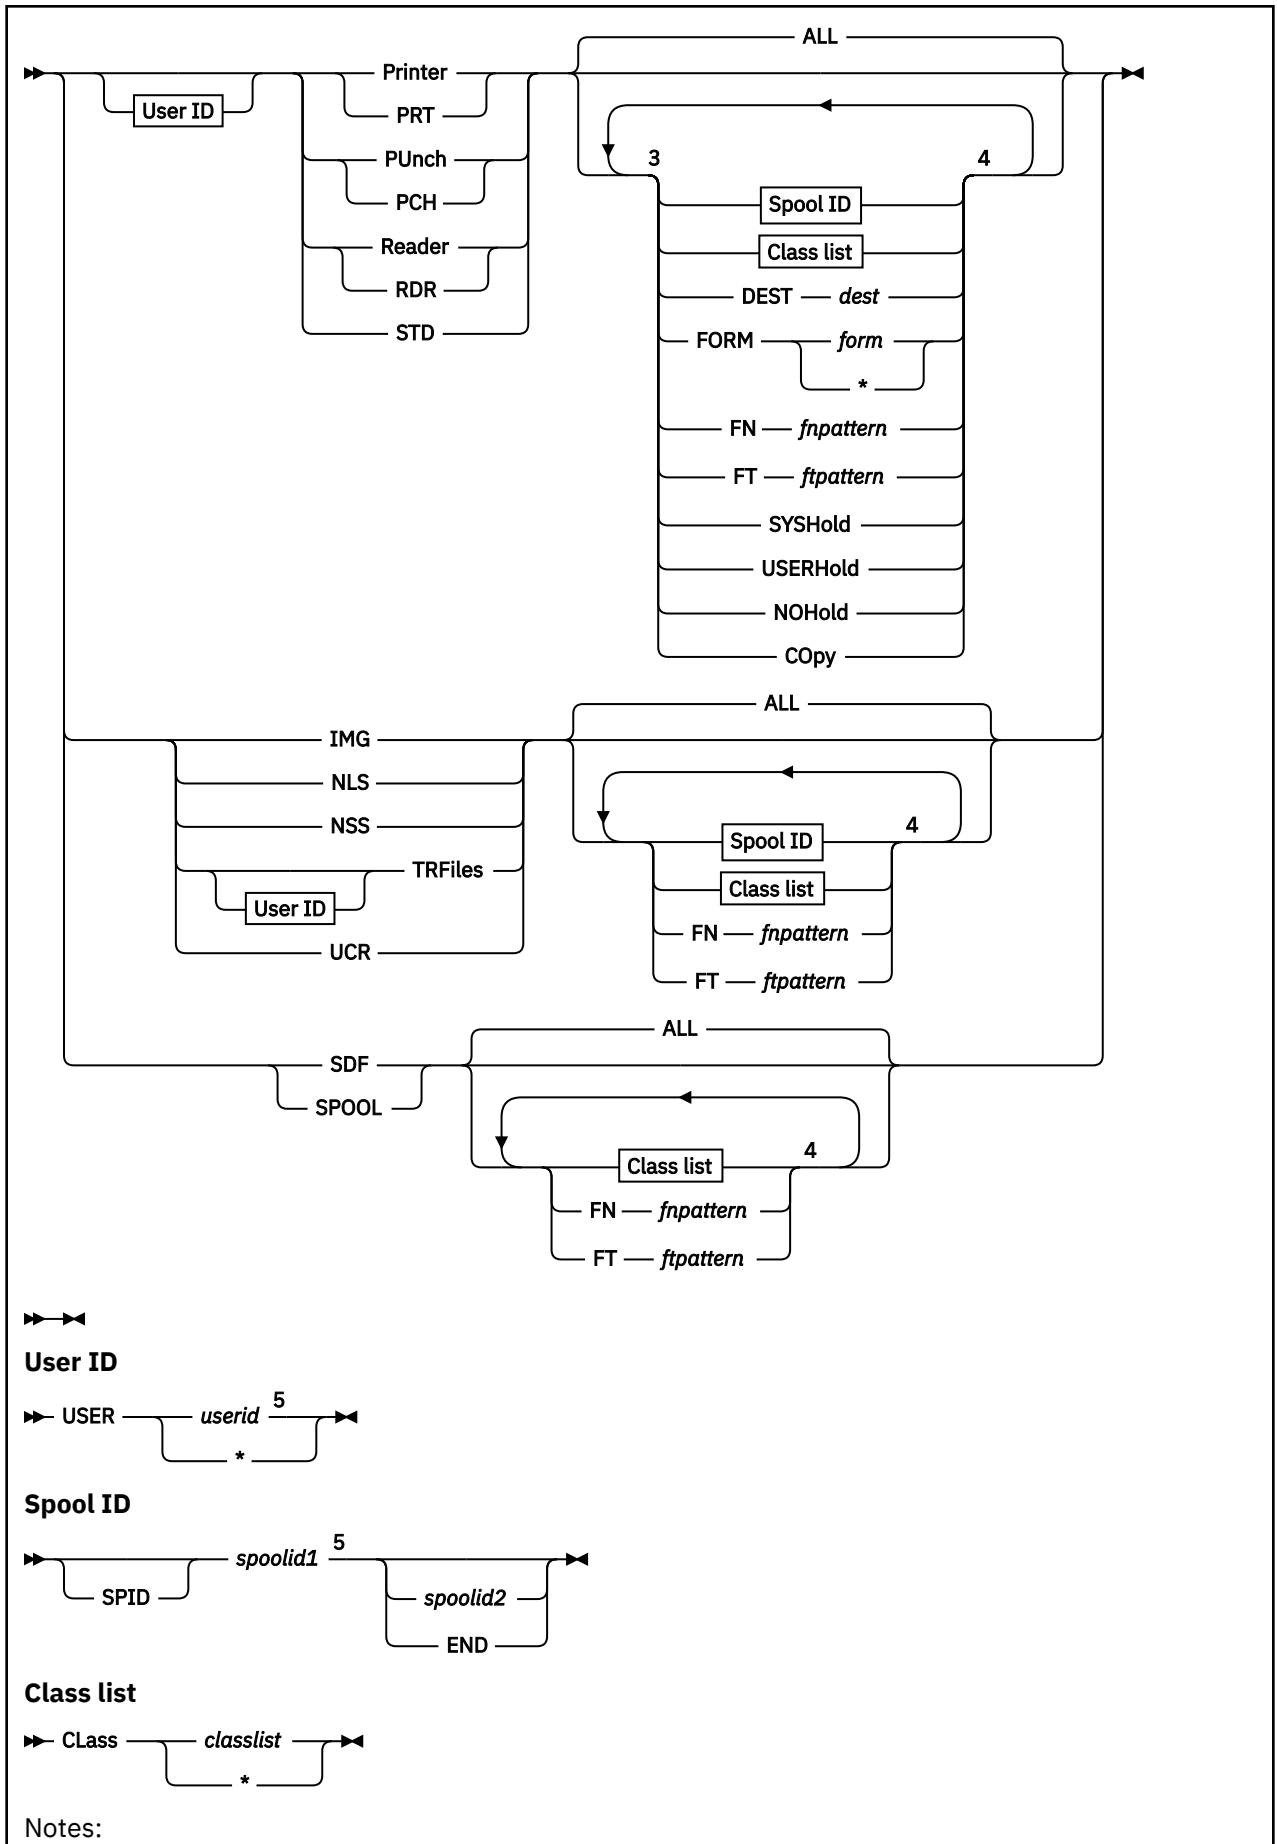

### Messages

For message information, see SPXTAPE [“Messages”](#) on page 1832.

# SPXTAPE SCAN

<sup>1</sup> The status of an outstanding SPXTAPE operation can be determined using the QUERY VIRTUAL command. See the description of QUERY VIRTUAL TAPES for more details.

<sup>2</sup> An abbreviated syntax is permitted for adding devices to a previous command.

<sup>3</sup> The status of an outstanding SPXTAPE operation can be determined using the QUERY VIRTUAL command. See the description of QUERY VIRTUAL TAPES for more details.

<sup>4</sup> You can specify file attribute selection operands in any order but you can specify each operand only once.

<sup>5</sup> For a class D or E user, USER *userid* is required if you specify *spoolid1* with PRINTER, PRT, PUNCH, PCH, READER, RDR, STD, or TRFILES.

## Authorization

Privilege Class: D, E, G

## Purpose

Use SPXTAPE SCAN to determine what standard spool files and system data files exist on tape (that were written to tape by SPXTAPE DUMP).

## Operands

**vdev**

**vdev1-vdev2**

is the virtual device number of the tape drive, or the range of virtual device numbers, where files are to be scanned. If you specify a range, any real supported tape drives attached as virtual device numbers in the range are used as the source for the files being scanned.

Queue Selection Operands:

**Printer**

**PRT**

selects printer spool files. Class D or G users can use this operand. (If you have only class G authority, only files owned by your user ID are scanned.)

**PUnch**

**PCH**

selects punch spool files. Class D or G users can use this operand. (If you have only class G authority, only files owned by your user ID are scanned.)

**Reader**

**RDR**

selects reader spool files. Class D or G users can use this operand. (If you have only class G authority, only files owned by your user ID are scanned.)

**STD**

selects all types of standard spool files (printer, punch, and reader). Class D or G users can use this operand. (If you have only class G authority, only files owned by your user ID are scanned.)

**IMG**

selects image libraries. Class D or E users can use this operand.

**NLS**

selects national language support files, such as message repository files. Class D or E users can use this operand.

**NSS**

selects named saved systems and saved segments. Class D or E users can use this operand.

**TRFiles**

selects system trace files. Class D, E, or G users can use this operand. (If you have only class G authority, only files owned by your user ID are scanned.)

**UCR**

selects user class restructure files. Class D or E users can use this operand.

**SDF**

selects all types of system data files (IMG, NLS, NSS, TRFILES, and UCR). Class D or E users can use this operand.

**SPOOL**

selects all types of standard spool files and system data files. Because this includes all spooling system queues, only class D users can use this operand.

File Attribute Selection Operands:

**USER *userid*****USER \***

selects files owned by the specified user ID. An asterisk (\*) indicates your own user ID. (If you are a class G user, you cannot specify any entry except your own user ID or \*.)

If you are a class D or class E user, you must specify this operand if you are selecting standard spool files or system trace files by spool ID.

If you omit this operand, files are scanned regardless of user ID. (If you have only class G authority, only files owned by your user ID are scanned.)

**ALL**

selects files regardless of file attributes other than user ID. This is the default.

**SPID**

indicates the following value is a spool ID.

***spoolid1***

is the spool ID of a single file to be scanned or the start of a range of spool IDs. If you omit this operand, files are scanned regardless of spool ID.

If you are a class D or class E user, you must also specify the **USER *userid*** operand when selecting standard spool files or system trace files by spool ID.

***spoolid2***

is the end of the spool ID range.

**END**

indicates the spool ID range includes all spool IDs equal to or greater than *spoolid1*.

**Class *classlist*****Class \***

selects files with any of the specified classes. You can specify from one to eight classes (single alphanumeric characters with no intervening blanks).

For system data files, only certain classes are valid for each type of file. For information about system data file classes, see [Performing Data Management Services](#) in *z/VM: System Operation*.

If you specify an asterisk (\*) for the class list, or if you omit this entire operand, files are scanned regardless of class.

**DEST *dest***

selects files with the specified destination value, which may be from one to eight characters. If you omit this operand, files are scanned regardless of destination value.

**FORM *form*****FORM \***

selects files with the specified operator form name, which may be from one to eight characters. If you specify an asterisk (\*) for the name, or if you omit this entire operand, files are scanned regardless of form name.

**FN *fnpattern***

selects files that match the specified file name search pattern. The pattern may be a complete file name or a character string containing wild cards. For information about using wild cards, see Usage

Note “1” on page 1862. You cannot use this operand to select *only* files that have *no* file name (whose file name field contains only blanks). If you omit this operand, files are scanned regardless of file name (including those with no file name).

#### **FT *ftpattern***

selects files that match the specified file type search pattern. The pattern may be a complete file type or a character string containing wild cards. For information about using wild cards, see Usage Note “1” on page 1862. You cannot use this operand to select *only* files that have *no* file type (whose file type field contains only blanks). If you omit this operand, files are scanned regardless of file type (including those with no file type).

#### **SYSHold**

selects system-held files. If you specify SYSHOLD but not USERHOLD or NOHOLD, only system-held files are scanned (which includes any file that is both system-held and user-held). If you do not specify SYSHOLD, USERHOLD, or NOHOLD, files are scanned regardless of hold status.

#### **USERHold**

selects user-held files. If you specify USERHOLD but not SYSHOLD or NOHOLD, only user-held files are scanned (which includes any file that is both user-held and system-held). If you do not specify USERHOLD, SYSHOLD, or NOHOLD, files are scanned regardless of hold status.

#### **NOHold**

selects files that are not held. If you specify NOHOLD but not SYSHOLD or USERHOLD, only files that are not held are scanned. If you do not specify NOHOLD, SYSHOLD, or USERHOLD, files are scanned regardless of hold status.

Tape Disposition Operands:

#### **RUN**

rewinds and unloads the tape after the scan completes. This is the default.

Upon detecting the logical end-of-tape (the end of the tape file written by SPXTAPE DUMP on that volume), SPXTAPE SCAN issues response 5, rewinds and unloads the tape, and waits for another volume to be mounted (the drive becomes "mount pending"). You must use the SPXTAPE END or SPXTAPE CANCEL command to cause SPXTAPE SCAN with the RUN disposition to complete.

#### **LEAVE**

leaves the tape positioned to do another SPXTAPE operation.

#### **REWind**

rewinds the tape after the scan completes but does not unload.

#### **APPEND**

appends the selection criteria specified on this command to the criteria specified on one or more *successive* SPXTAPE SCAN commands within one logical SPXTAPE SCAN operation. All commands in the append sequence must address the same tape devices and all except the last must be specified with the APPEND disposition. For more information, see Usage Note “2” on page 1862.

Control Operands:

#### **NODUP**

prevents the scanning of any file that would duplicate a file that already exists on the spooling system queue where the file would be loaded. For more information, see Usage Note “3” on page 1862.

#### **PROGress\_interval 15 SEC**

#### **PROGress\_interval *progint* SEC**

#### **PROGress\_interval *progint* MIN**

allows the time interval between the progress reports to be changed from the default of 15 seconds. (See [Response 7](#).) The interval can be specified as a decimal number from 0 to 9999. Requesting an interval of 0 causes the progress reports to be suppressed.

If a logical SPXTAPE command is being created through the use of the APPEND option, the last explicitly requested interval will be used.

## Usage Notes

1. When using the FN or FT file attribute selection operand, you can use two special characters, \* (asterisk) and % (percent), as wild cards in the file name or file type pattern. These special characters have the following meaning:

**\***

is a placeholder character that represents any number of characters from zero to eight, depending on how many other characters are specified in the pattern. You can use as many asterisks as necessary anywhere in the pattern as long as the total number of characters, including the asterisks, does not exceed eight. For example, a pattern of d\* means any string that begins with the character "D". However, a pattern of \*d\* means any string that contains a "D", whether it is at the beginning, in the middle, or at the end. A pattern containing a single asterisk and no other characters means all strings regardless of length or character content (including the string that contains only blanks).

**%**

is a placeholder character that represents a single character. You can use as many percents as necessary anywhere in the pattern as long as the total number of characters, including the percents, does not exceed eight. For example, a pattern of %%% means any string that is three characters in length. A pattern of %%%s means any string that is four characters in length and ends with the character "S".

Wild cards can also be combined. For example, a pattern of vm%\* means any string four characters in length *or longer* that begins with the characters "VM".

2. When using the APPEND operand, if there is no SPXTAPE SCAN command currently active on the addressed tape devices, the devices are placed in the append waiting state (response 10 is issued).

Actual scanning on the tape devices does not commence until you enter an SPXTAPE SCAN command with a disposition of RUN, LEAVE, or REWIND (or no disposition, which results in a default of RUN).

A sequence of appended SPXTAPE SCAN commands are processed as one logical SPXTAPE SCAN command. This allows you (or an exec) to specify different sets of selection criteria for individual files or groups of files to be scanned on the same set of tapes in a single SPXTAPE SCAN processing run, as shown in the following sequence:

```
spxtape scan 300-399 selection_criteria_1 append
spxtape scan 300-399 selection_criteria_2 append
:
spxtape scan 300-399 selection_criteria_n run
```

3. When using the NODUP operand, the definition of "duplicate" depends on the type of file.

For standard spool files and system trace files, "duplicate" means that all the file attributes of the file on the tape are identical to a file on the queue. This includes the time stamp for when the file was opened. An identical time stamp indicates that they are identical files. (If some files on the system have been imported from other systems, it is possible that files could have been created on both systems at exactly the same microsecond with all the same file attributes, but contain different data. However, this is not very probable.)

For system data files other than system trace files, "duplicate" means that the file name, file type, and class of the file on the tape are identical to the file on the queue. In addition, for named saved system and saved segment files, class A (active) and class R (restricted) files of the same file name and file type are considered duplicate because they cannot exist on the system at the same time.

A file that is found to be a duplicate is identified in the resulting Volume Log with DUP\_FILE in the SEG\_STAT field. The FILE field of this entry in the log contains the file ID of the file already on the system. If the file on the system is moved to a different queue or user ID, or its file attributes are changed (for example, its spool class), the file is no longer identified as a duplicate.

Keep in mind when using the NODUP operand that as the number of files in the queue where the files would be loaded increases, the amount of processing required to scan the files on the tape increases dramatically. Each file being scanned is compared to every file in the queue. For example, if the queue contains 1000 files and 1000 files are scanned on the tape, the result is over one million comparisons.

4. A logical SPXTAPE SCAN command, which may be a single command or a sequence of appended commands, scans one tape file. A tape file (which ends with one or more tape marks) contains one or more files dumped by one logical SPXTAPE DUMP command. A logical SPXTAPE DUMP command may be a single command or a sequence of appended commands. If multiple tape files exist on the tape (written by multiple logical SPXTAPE DUMP commands), you must enter separate SPXTAPE SCAN commands to scan each tape file.
5. If you entered the SPXTAPE SCAN command with the RUN disposition (or no disposition, which results in a default of RUN), CP sends you a response when processing of a tape volume is complete that:
  - Asks you to mount the next tape on that device
  - Indicates the number of files and spool pages processed so far

If there are other tapes to be processed, mount the next tape. If you are using more than one tape drive, CP continues reading on the other drives. When you mount and ready the new tape, CP starts reading on that drive again. If there are no other tapes to be mounted, and all tapes currently mounted have finished processing (you have received the mount next tape response for each drive), use the SPXTAPE END command to end the operation.
6. For additional usage information, see [“Usage Notes” on page 1820](#).

### Expanding the Device Range

You can add one or more tape drives to the device or range of devices specified on a previous SPXTAPE SCAN command that is still active. Enter another SPXTAPE SCAN command with an expanded range that includes all of the devices specified on the previous command plus the device or devices you want to add.

If the previous SPXTAPE SCAN command was entered with a disposition of LEAVE, REWIND, or RUN (or no disposition, which defaults to RUN), the command that you enter to expand the range is an abbreviated form that omits the selection criteria, disposition, and control operands:

```
spxtape scan vdev1-vdev2
```

If the previous SPXTAPE SCAN command was entered with the APPEND disposition (in other words, you are in the middle of entering a sequence of SPXTAPE SCAN commands to be bundled into a single logical command), the command that you enter to expand the range can include additional selection criteria. However, you must also specify the APPEND disposition on your command. Otherwise, SPXTAPE interprets your command as the final command in the sequence.

For example, suppose the previous command was:

```
spxtape scan 300-349 std class a syshold append
```

If you want to add device 352 and also add class D system trace files to the selection criteria, enter:

```
spxtape scan 300-352 trfiles class d append
```

If you only want to add device 352, enter:

```
spxtape scan 300-352 append
```

Note that the range now also includes devices 350 and 351, if such devices are attached to you and are active. You cannot skip any active tape devices in the range. If you do not want to use devices 350 and 351, you must redefine or detach them before entering the SPXTAPE command.

## Responses

For response information, see SPXTAPE [“Responses” on page 1821](#).

## Messages

For message information, see SPXTAPE [“Messages” on page 1832](#).

## START (Disk)

### Authorization

Privilege Class: B

### Purpose

Use START to restart (allow new allocations for) a device after it has been drained. You can also use it to change the processing options currently in effect for the device.

### Operands

#### DASd *rdev*

is the real device address of a particular device (or a range of DASD) you want to start. You can specify more than one real device.

#### VOLid *valid*

indicates you want to start a real DASD device by supplying its real volume serial number (*valid*).

### Options

#### ALL

means all of the following:

#### LInks

tells CP to allow users to link to minidisks on this device.

#### PAge

tells CP to write pages to this device during page-out operations.

#### SPol

#### SPool

tells CP to allocate space on this device for new spool records.

**TDisk****TDsk****TEmpdisk**

tells CP to allocate temporary minidisk space on this device.

**Responses**

Response 1:

```
Command Complete
```

- or -

```
nnnnnnnn device(s) specified; nnnnnnnn device(s)
successfully processed by START
```

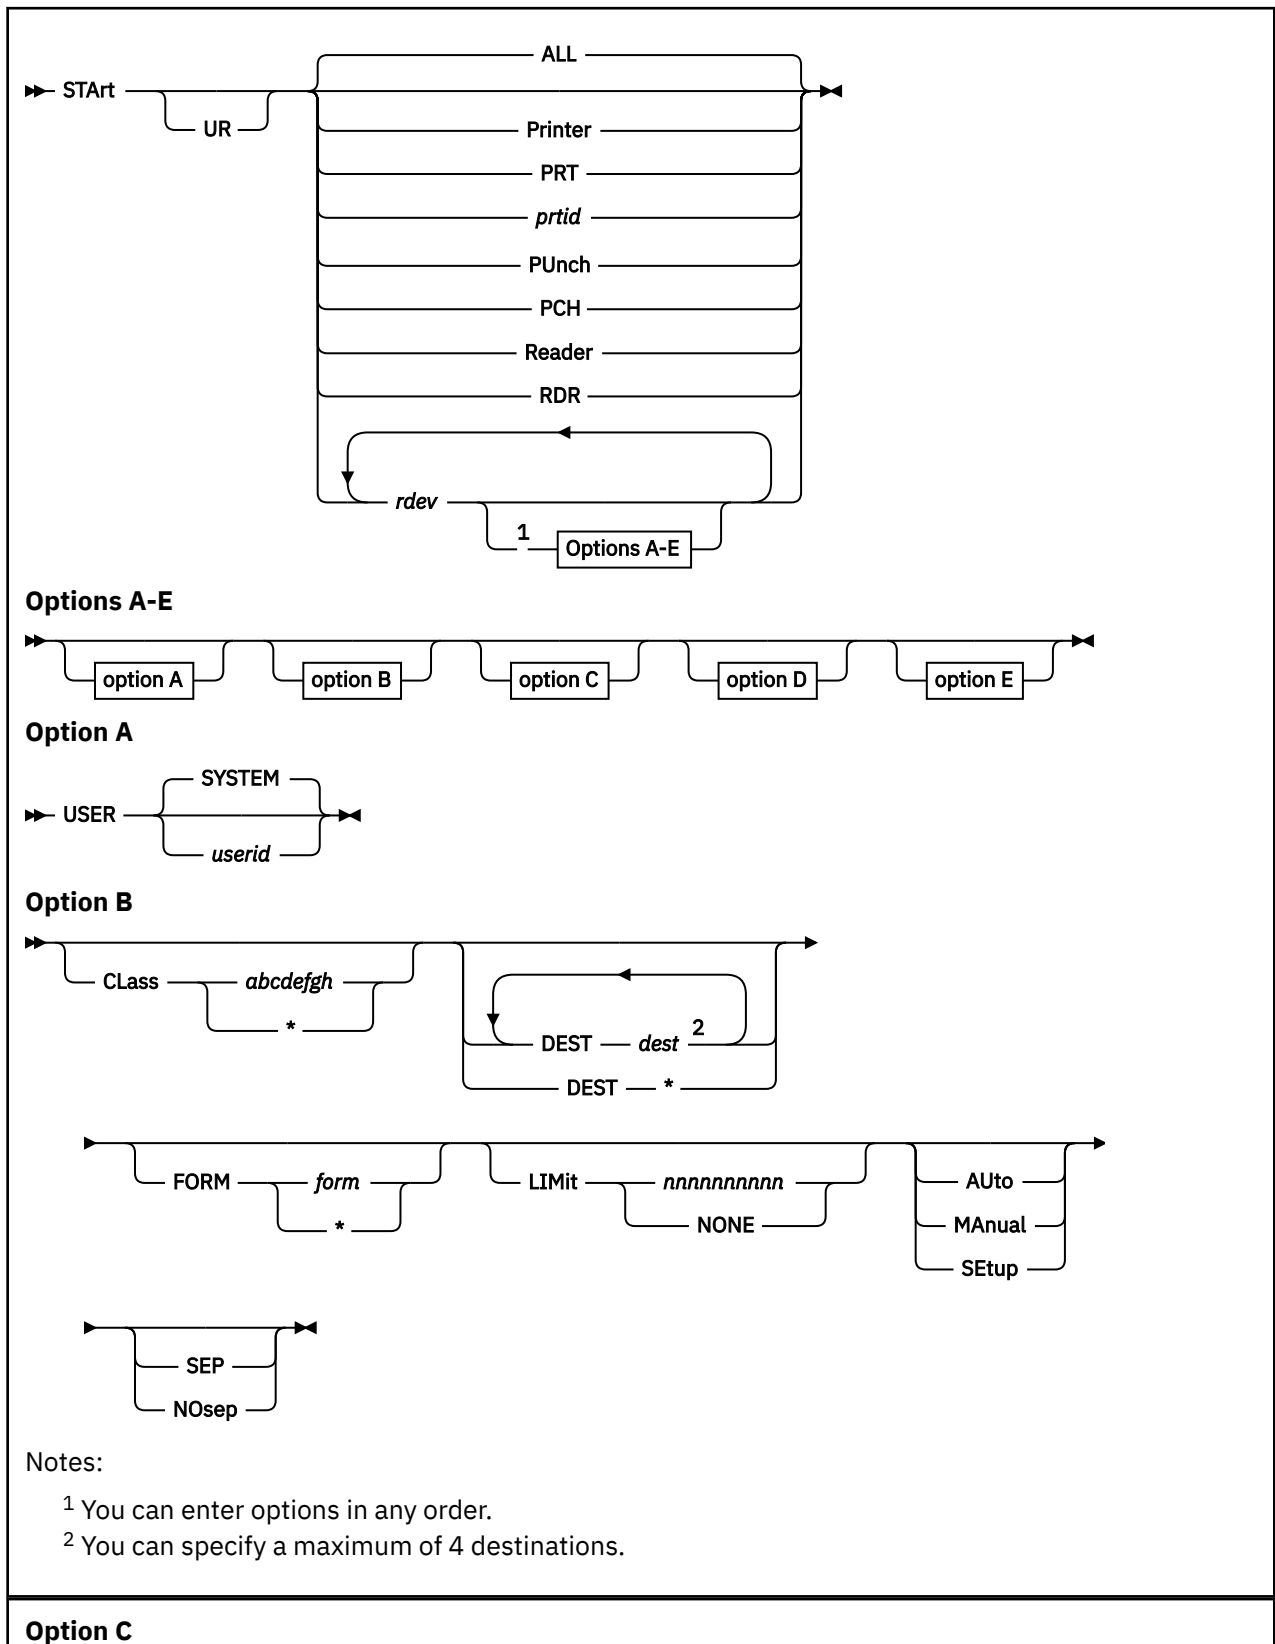

The following response may be sent to the system operator:

```
userid issued START command for volume volid on
device rdev for alloctype1 [alloctype2] [...]
```

**Messages**

- HCP002E Invalid operand - *operand*
- HCP021E A real device number was not specified or it is invalid.
- HCP023E VOLID missing or invalid
- HCP026E Operand missing or invalid
- HCP040E Device *rdev* does not exist
- HCP009E Invalid range - *range*
- HCP1004E *rdev* is not a DASD volume or is an invalid DASD type.
- HCP1127E {*rdev|volid*} is permanently drained.

## START UR (Unit Record)

## Authorization

Privilege Class: D

## Purpose

Use START to restart a drained spool device or to change the processing options in effect for the device.

## Operands

### UR

tells CP that you want to start a real unit record device.

### ALL

starts all of your readers, printers, and punches. ALL is the default.

### Printer

#### PRT

starts your printers.

#### *prt*id

tells CP to pass the entire command to the specified print server virtual machine (*prt*id) for processing. The *prt*id is provided by the print server virtual machine that issues the START command to an AFP. The variable *prt*id is 1 to 8 alphanumeric characters long. If you specify a *prt*id of 4 or fewer characters, *prt*id cannot contain all hexadecimal characters, because CP then interprets *prt*id as *rdev*.

### Punch

#### PUN

starts your punches.

#### *rdev* ...

is the real device number of the spooling device that you want to start. You can specify more than 1 real device, each with its own set of options.

### Reader

#### RDR

starts your readers.

### Options

Whenever a START command is issued with options, only the device settings that correspond to those options are changed. The other device settings remain unchanged from the previous START command. Device settings are saved across system warm starts. Cold, force, and clean start defaults are indicated under each option.

#### Option A

is valid for all real spooling devices.

#### Option B

is valid for printer and punch devices only, except for SETUP, which is valid only for impact printers.

#### Option C

is valid for both impact and 3800 printers.

**Note:** CHARS is not valid for 1403 printers without the UCS feature installed on 4245 or 4248 printers. FCB is not valid for a 1403 type printer.

#### Option D

is valid for impact printers only. DEFFCB and FILEFCB are valid for non-1403 impact printers.

#### Option E

is valid for 3800 printers only.

### USER *userid*

#### USER SYSTEM

specifies which virtual machines this device may service. If you specify *userid*, the spooling device prints or punches only that user's files. If the device is a printer or punch, the class designation must still match the class of the spool files that it services. If the device is a reader, no ID card is required.

If you specify SYSTEM, the spooling device is available to service spool files belonging to any user, which is the normal operation.

If no START command with the USER option has been issued since the last cold, force, or clean start, SYSTEM is the default.

### Class *abcdefgh*

#### Class \*

specifies the output classes the device can service. You can specify from 1 to 8 classes (each a single character, with no intervening blanks). If you are specifying multiple classes for your device, your files are serviced in the same order as the classes that you have specified. For example, if for your printer, you enter:

```
class ad1
```

all class A files are processed before class D files, and all class D files before class 1 files.

**Note:** The CLASS operand is not valid for a reader.

Specify a class of asterisk (\*) for printers or punches so that they can service any spool file class.

If no START command with the CLASS option has been issued since the last cold, force, or clean start, the default classes specified on the RDEVICE statement in the system configuration file.

### DEST *dest*

#### DEST \*

specifies the destinations that an output device can service. The operand *dest* is a 1- to 8-character value assigned to the printer. As many as 4 destination values can be specified.

Specify a DEST of asterisk (\*) to indicate that files are to be selected for processing regardless of the file's DEST setting.

If no START command with the DEST option has been issued since the last cold, force, or clean start, the default destinations specified on the RDEVICE statement in the system configuration file.

**FORM *form*****FORM \***

specifies the form that an output device can service. The operand *form* is a 1- to 8-character operator form number.

Specify asterisk (\*) for printers or punches so that files can be printed or punched regardless of form.

If no START command with the FORM option has been issued since the last cold, force, or clean start, the default form specified on the FORM\_DEFAULT statement in the system configuration file is used. If a default form was not specified, the default is STANDARD.

**LIMit *nnnnnnnnnn*****LIMit NONE**

specifies the number of records of a file to be printed or punched. The variable *nnnnnnnnnn* indicates the maximum number of records of a file to be printed or punched. You can specify up to 10 digits. NONE indicates there is no limit to the size of the file that can be printed or punched.

**AUto**

indicates that the operator wants CP to schedule forms output. The currently active form is processed first. When all files with the current form have been printed or punched, CP automatically selects a new form for the device. The operator receives a message to change forms, and the output device is idle. The operator can then put in the new form and press the START button (or enter the START UR command) to print files with the new form.

**MAnual**

indicates that the operator schedules output forms. Only spool files with the form currently active on the device are processed. When the last spool file with the current form is printed or punched, the output device stops. The operator can then schedule a new form by issuing START with the FORM option.

If FORM (asterisk) \* is specified, spool files are printed or punched, regardless of the form, and the output device does not stop between spool files with different forms.

**SEtup**

indicates that the operator wants CP to print a page so that forms alignment can be verified. (This option is only valid for impact printers). The operator gets a message indicating that the form should be set up. When the form has been set up, the operator should press the STOP button, then the START button. An alignment page is then printed. The alignment page is the first nonblank page of the file, with letters replaced with Xs and numbers replaced by 9s. Each time the operator presses the STOP, START buttons after a full alignment page has been printed, another alignment page is printed. When the forms are aligned, issue the START command for the device. The printer returns to its previous mode (AUTO or MANUAL), and the file prints in its entirety.

If neither AUTO, MANUAL, nor SETUP is specified and the printer is currently in SETUP mode, it returns to the previous mode, AUTO or MANUAL. If no START command has been issued with the AUTO, MANUAL, or SETUP options since the last cold, force, or clean start, the default is MANUAL.

**SEP****NOsep**

indicates whether you want a file separator for output files. This option is not valid for readers.

If you *do not* want separator pages to be printed, you must always specify NOSEP.

If no START command with the SEP or NOSEP option has been issued since the last cold, force, or clean start, the default specified on the RDEVICE statement in the system configuration file.

**Note:** If an external security manager is installed and security label checking is enabled, the NOSEP option is not valid. For more information, see your security administrator.

### **AFP NOAfp**

specifies whether the printer is to process files with advanced function printer (AFP) characteristics. This option is valid for CP printers only. If a CP printer is started with the NOAFP option, that CP printer does not choose a file having an associated XAB or containing the special X'5A' CCWs. If a CP printer is started with the AFP option, that CP printer can select files having an associated XAB or containing the special X'5A' CCWs, but CP discards these attributes because they have no meaning for a CP printer.

If no START command with the AFP/NOAFP option has been issued since the last cold, force, or clean start, the default setting specified on the RDEVICE statement in the system configuration file.

### **ANY3800**

places no restrictions on the presence or absence of 3800 load CCWs within spool files. This option can potentially cause a slower output queue, depending on the number of 3800 load CCWs issued by the selected spool files.

### **BEG3800**

specifies that only spool files without 3800 load CCWs, or that contain 3800 load CCWs only at the beginning of the file, be printed on this device. This allows the user an initial setup with which the entire file is to be printed.

### **NO3800**

specifies that no spool files containing 3800 load CCWs be printed. Since load CCWs issued to 3800 printers can take a great deal of time, this option insures a fast output queue.

If no START command with the ANY3800, BEG3800, or NO3800 options has been issued since the last cold, force, or clean start, the default is NO3800.

### **CHars *name***

specifies the character set to be used by the printer when printing both the separator pages and the file. For 3800 printers, the character set specified is used for the separator pages and only those spool files that do not request a specific character set. The variable *name* is 1 to 4 characters long. This character set name must reside in the image library specified for the device.

For impact printers that support a character set, the CHARS specified is used for the entire file.

If no START command with the CHARS option has been issued since the last cold, force, or clean start, the default CHARS specified on the RDEVICE statement in the system configuration file.

**Note:** CHARS is not valid for 1403 printers without the UCS feature installed on 4245 or 4248 printers.

### **FCB *name***

#### **FCB 6, 8, 10, or 12**

specifies the forms control buffer used by the printer when printing both the separator pages and the file. For 3800 printers, the FCB specified is used for separator pages, and only those spool files that do not request a specific FCB.

For impact printers (except the 1403 which does not support the FCB), the FCB specified is used for the entire file.

The variable *name* is either a 1- to 4-character name of an FCB image in the image library specified for this device, or the number 6, 8, 10, or 12. This number tells the 3800 to print the entire spool file at 6, 8, 10, or 12 lines per inch, regardless of the size of the paper that is currently loaded.

**Note:** The number 10 is only supplied for 3800 Model 3 printers.

FCB values of 6, 8, 10, or 12 are only special cases on 3800 printers. If an FCB of 6, 8, 10, or 12 is specified for an impact printer, the START UR command tries to find an image library member with the corresponding name (for example, 32036 if FCB 6 is specified for a 3203 printer).

The number of lines to be printed on the separator page is determined by the FCB loaded on the printer. The default separator page contains 58 lines of data. If the page length defined by the FCB is less than the default separator page length, the separator page data must be customized in order

to fit on a single page. This may be done using CP Exit points that are provided in separator page processing. See *z/VM: CP Exit Customization* for details.

If no START command with an FCB option has been issued since the last cold, force, or clean start, the default FCB specified on the RDEVICE statement in the system configuration file.

### **IMage *imagelib***

specifies the name of the system image library file that contains the load images (character sets, FCBs, graphic character modifications, or copy modifications) to be used for printing files and separators. The variable *imagelib* is 1 to 8 characters long, and must be an existing image library file.

If no START command with the IMAGE option has been issued since the last cold, force, or clean start, the default image library file specified on the RDEVICE statement in the system configuration file.

### **SEClabel *sssssss***

specifies the security label of files to be printed on the printer. The variable *sssssss* is 1 to 8 alphanumeric characters that identify the SECLABEL of files that may be printed on the printer. The SECLABEL option is valid only when an external security manager (ESM) is installed and security label checking is enabled on your system.

### **DEFFCB**

uses the default FCB that was loaded in the printer. CP does not send imbedded LOAD FCB CCWs to the printer. The LOADBUF command specifies the default FCB. (DEFFCB is valid only for non-1403 impact printers.)

### **FILEFCB**

sends file FCBs to the real printer. File FCBs are LOAD FCB CCWs imbedded in the spool file. This is the default when you start the printer following a cold, force, or clean start. (FILEFCB is valid only for non-1403 impact printers.)

### **FOLD**

#### **NOFOLD**

specifies the loading of the universal character set (UCS) buffer with an operation code that permits printing of uppercase and lowercase bit configurations. If FOLD is specified, all characters are printed in uppercase. This is used when lowercase is specified in a file, but no lowercase exists in the UCS specified. If NOFOLD is specified, the characters are not translated into uppercase.

**Note:** If you specify the FOLD option, the control unit ignores bit positions 0 and 1 of the EBCDIC code when comparing the character codes from the UCS buffer and the print line buffer. Only uppercase characters are printed from either uppercase or lowercase data codes.

**Attention:** Misuse of the FOLD option can cause multiple characters to be printed for the same EBCDIC bit configuration.

### **INDEX *nn***

starts printing the output in print position *nn*. The variable *nn* is a decimal number from 0 to 31; a leading zero need not be specified. If you do not specify INDEX, the current setting of the indexing value is retained.

If you specify an INDEX of 0 then indexing is turned off and no indexing is performed. If you specify an indexing value from 1 to 31, then that value is used as the indexing value.

If you specify the INDEX keyword without a value, message HCP036E is issued. The LOADBUF command must be used to set the indexing value if you want to use the default indexing value coded in the FCB.

**Note:** INDEX is valid only for a device emulating a 3211 printer.

### **Flash *name***

#### **Flash OFF**

specifies the forms overlay negative loaded into the device. Spool files designated to be flashed with *name*, and spool files with no flash name associated with them, are selected for printing. The variable *name* is 1 to 4 alphanumeric characters long.

If OFF is specified, it indicates that no flash is to be used.

## START UR (Unit Record)

If no START command with the FLASH option has been issued since the last cold, force, or clean start, the default FLASH *name* specified on the RDEVICE statement in the system configuration file.

### **HOLD** **PURge**

specifies the system action to be taken on files with 3800 load errors. If HOLD is specified, all files with load errors are placed in system hold status. If PURGE is specified, all files with load errors are purged.

If no START command with the HOLD or PURGE option has been issued since the last cold, force, or clean start, the default is HOLD.

### **MARK** **NOMARK**

specifies whether a 3800 printer will mark 3800 separator trailer pages with separator bars.

If no START command with the MARK or NOMARK option has been issued since the last cold, force, or clean start, the default MARK setting specified on the RDEVICE statement in the system configuration file.

## Usage Notes

1. If a device is busy when you issue the START command, the changes that you specify take effect after the current file is complete.
2. If you specify the NOSEP operand for a punch, separator cards are not punched. Instead, for each file the operator receives the message:

```
PUN rdev START FOR OUTPUT
```

The punch can be started for the next file by pressing the START/STOP key on the device.

3. If a real spooling printer that is not a 3800 is started with the BEG3800 or ANY3800 options, all 3800 load CCWs contained in selected spool files are removed, and the file is printed with the available setup.
4. IBM does not recommend that you use spool file class to determine the output form (paper) for 3800 operation. If you change the paper on the 3800 printer without specifying a new form name with the FORM operand of the START command, 3800 errors result.  
  
Accordingly, when you change the paper on a 3800 printer, IBM recommends that you start the printer with the FORM operand and a new form name. If you prefer, you may instead drain the printer (with the DRAIN command) and enter the START command without the FORM operand.
5. If you are working within CMS and you want to enter a CP START command, use #CP START.
6. Throughout the START command operation, the 3800 printer specified refers to a CP-driven 3800 printer.
7. For printer IDs, the virtual machine associated with the printer ID processes the START command. Therefore, the options given on the START command must be valid for the virtual machine processing it.

When you enter either the START, START PRINTER, or START ALL commands, it causes all virtual machines associated with all print IDs to be started.

8. The keyword DEST is required to precede any destination value that is four or fewer hexadecimal characters or that matches the minimum truncation of an option on the START command.
9. If DEST is not specified on a command that sets a DEST value, the current value is unchanged.
10. A printer with DEST set to OFF only processes files with DEST specifically set to, or defaulted to, OFF.
11. If the START command is issued with the NOAFP option for a CP printer, the printer does not select files with advanced function printer (AFP) characteristics—that is, files that contain X'5A' CCWs or an extended attributes buffer (XAB). These files are not selected, even if other selection criteria are satisfied (for example, CLASS, FORM, DEST).

12. If you issue the START command for an output device that has been drained, or for an output device with a different FORM than the one previously started, you receive CP Message 0405. You should ensure that the correct form is mounted on the device; then, press the start button on the device or issue START from the console. Message HCP405 does not appear for an output device started with FORM asterisk (\*) or for one that was genned with FORM asterisk (\*) and started without using a different FORM.
13. If an error is detected loading an FCB or UCS to an impact printer, an error message is not issued until after the second START command. The first START command completes and the user is prompted to mount FORM.  
  
Also, if the printer is not ready, an error message is not issued until the printer is made ready.
14. CP prints the first nonblank page of the spool file as the alignment page when the printer is in SETUP mode. Pages of blanks that exist before the nonblank page will be processed. In this case, you will receive blank pages before the alignment page is printed.
15. When in SETUP mode, if all of the data in the spool file that is selected for printing is blanks, or if the first nonblank page contains only unprintable characters, then the alignment page results are unpredictable.
16. If the START command is issued with the FCB option, the LPP value will not change until the new FCB is actually loaded on the printer. The FCB is loaded, and the LPP value is changed, when the next file begins printing.

## Responses

Response for a Real Reader:

```
RDR  rdev STARTED {SYSTEM}
                    {userid}
```

Responses for a Real Printer:

When a printer is started, the first two lines of the response are:

```
PRT  rdev STARTED {SYSTEM} CLASS abcdefgh [SECLABEL ssssssss]
                    {userid}

PRT  rdev FORM operform {MANUAL} {SEP } { NO3800} [DEFFCB]
                        {AUTO } {NOSEP} {BEG3800} [FILEFCB]
                        {SETUP }      {ANY3800}
```

For 3800 printers, the third line is:

```
PRT  rdev FLASH name IMAGE imagelib CHARS name FCB {name} {HOLD } LPP nnn
                                                { 6 } {PURGE}
                                                { 8 }
                                                {10 }
                                                {12 }
```

For impact printers, the third line is:

```
PRT  rdev {NOFOLD} IMAGE imagelib CHARS chars [FCB name] [INDEX nn] LPP nnn
        {FOLD }
```

The fourth line of the response for all printers is:

```
PRT  rdev DEST {dest1} DEST {dest2 } DEST {dest3 } DEST {dest4 }
              {OFF }      {- NONE -} {- NONE -} {- NONE -}
```

The last line of the response for 3800 printers is:

```
PRT  rdev {AFP } {MARK }
          {NOAFP} {NOMARK}
```

The last line of the response for impact printers is:

```
PRT rdev {AFP }
        {NOAFP}
```

**rdev**

is the real device number of the device.

**SYSTEM****userid**

indicates which virtual machine's files the device can service.

**CLASS abcdefgh**

indicates which output classes the device can service.

**SECLABEL ssssssss**

indicates the SECLABEL of files to be printed on the printer. This is shown only when an ESM is installed and security label checking is enabled.

**FORM operform**

is the current form number processed on the device.

**MANUAL****AUTO****SETUP**

indicates the mode of forms processing for the printer or the punch.

**SEP****NOSEP**

indicates if file separators are to be produced between output files.

**NO3800****BEG3800****ANY3800**

specifies the restriction placed on 3800 load CCWs for spool files processed on a real printer. NO3800 means there are no load CCWs in the file. BEG3800 means only spool files without 3800 load CCWs, or with the CCWs at the beginning of the spool file are processed. ANY3800 means CP is to process any spool file, regardless of the occurrence of 3800 load CCWs.

**DEFFCB****FILEFCB**

specifies the FCB that is currently in use. DEFFCB means that the default FCB that was loaded in the printer is used. FILEFCB means that file FCBs are sent to the real printer.

**Note:** This only appears for non-1403 impact printers.

**FLASH name**

specifies the name of the forms overlay within the 3800 device.

**IMAGE imagelib**

indicates the image library containing load images (character sets, FCBs, graphic character modifications, or copy modifications) to be used for printing files and separators.

**CHARS name**

specifies the CHARS being used to print the file.

**FCB name****FCB 6****FCB 8****FCB 10****FCB 12**

indicates the FCB being used to print the file.

**HOLD****PURGE**

indicates the system action taken towards spool files that cause 3800 load errors.

**LPP *nnn***

indicates the lines per page that the printer is using for the generation of separator pages. The LPP value is determined from the FCB loaded on the printer.

If no FCB has been loaded to the printer, the LPP will appear as zero. Since the FCB is actually loaded when a file is printed, it is possible that the LPP will appear as zero or the LPP value for the prior FCB after the START command with the FCB operand is issued.

**Note:** If the number of lines per page derived from the FCB data is less than 30 or greater than 255, the LPP for that printer will be set to a default value of 66 for impact printers, or 60 for 3800 printers.

**NOFOLD****FOLD**

indicates if lowercase characters are being translated (folded) into uppercase for printing.

**IMAGE *imagelib***

indicates the image library being used by the printer.

**CHARS *chars***

indicates the character set being used by the printer.

**FCB *name***

indicates the FCB being used by the printer.

**INDEX *nn***

indicates the character position on the page at which to begin printing.

**DEST *dest***

is the destination value. The operand *dest* is a 1- to 8-character value. OFF is the default destination for the device for the first (of four) destination values. The indicator - NONE - is shown for destination values that have not been set.

**AFP****NOAFP**

specifies whether the printer is to process files with advanced function printer (AFP) characteristics.

**MARK****NOMARK**

indicates whether 3800 separator trailer pages are being marked with separator bars.

**Note:** CP itself does not provide a response for *prtids*. The virtual machine associated with the *prtid* provides the response.

Responses for a Real Punch:

```
PUN rdev STARTED {SYSTEM} CLASS abcdefgh
                   {userid}

PUN rdev FORM operform {MANUAL} {SEP }
                       {AUTO } {NOSEP}

PUN rdev DEST {dest1} DEST {dest2 } DEST {dest3 } DEST {dest4 }
           {OFF }      {- NONE -}      {- NONE -}      {- NONE -}
```

***rdev***

is the real device number of the device.

**SYSTEM*****userid***

indicates which virtual machine files the device may service.

**CLASS *abcdefgh***

indicates which output classes the device can service.

**FORM *operform***

is the current form number processed on the device.

**MANUAL****AUTO**

indicates the mode of forms processing for the punch.

**SEP  
NOSEP**

indicates whether file separators are produced between output files.

**DEST *dest***

is the destination value. The operand *dest* is a 1- to 8-character value. OFF is the default destination for the device for the first (of four) destination values. The indicator - NONE - is shown for other destination values which have not been set.

Responses for Currently Active Devices:

When the system begins processing a spool file that has the MSG attribute, the response is:

```
{RDR} rdev {READING } userid FILE spoolid
{PRT} rdev {PRINTING} userid FILE spoolid RECS {nnnn} COPY [*] nnn SEQ sss
{PUN}      {PUNCHING}      {nnnK}
                               {nnnM}
CL c typ
```

**RDR  
PRT  
PUN**

indicates the type of device on which the file is being processed.

***rdev***

is the real device number.

***userid***

is the name of the spool file owner.

**FILE *spoolid***

is the spool file *spoolid* number.

**RECS *nnnn***

**RECS *nnnK***

**RECS *nnnM***

is the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines rounded to the nearest 1000 records. If the number is greater than 999499, then the number is shown as *nnnM*, where M represents the number of lines rounded to the nearest million.

**COPY [\*] *nnn***

specifies the number of file copies you want printed or punched when the file is produced.

An asterisk (\*) indicates that the 3800 printer prints each page from the spooled output files *nnn* times before going on to the next page. If a file is not spooled to the 3800 printer, the function performed by specifying the asterisk (\*) is ignored, and duplication occurs normally.

**SEQ *sss***

is the sequence number for the file on the printer or punch.

**CL *c***

is the spool file class.

***typ***

shows the device type that originally produced the spool file. The type can be RDR, PRT, PUN, CON, DMP, or SYS.

- HCP6005E Option *option* is not supported by z/VM.
- HCP6525E Authorization request failed.

## STOP

### Authorization

Privilege Class: G

### Purpose

Use STOP to do the following:

- Soft-stop your virtual processors
- Hard-stop selected virtual processors.

### Operands

**CPU** *cpuaddr*

**CPU** *cpuaddr1-cpuaddr2*

**CPU** ALL

specifies the processor or processors you want to place in hard stop. You can specify a single processor address, a list of processor addresses delimited by blanks, a nonwrapping pair of addresses separated by a hyphen (-) with no blanks, or ALL. If you omit this operand, all of your virtual processors are placed into soft stop.

### Usage Notes

1. If you enter the STOP command without operands, all of your virtual processors are placed into soft stop.
2. This command is useful with a TRACE command to suspend execution when a certain condition is reached.
3. Execution of the virtual processor or processors is suspended until a BEGIN, SYSTEM RESTART, ATTN, IPL, EXTERNAL, or REQUEST command is entered.
4. The STOP command causes suspension of virtual machine execution, regardless of the SET RUN setting.

### Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid
- HCP1454E CPU *nn* does not exist.
- HCP6026E The *command* command for CPU *nn* is invalid because the CPU is in check-stop state.

# STORE

---

## Purpose

Use STORE to alter any of the following locations in your real or virtual machine:

- First-level storage
- Second-level storage
- Third-level storage
- General registers
- Floating-point registers
- Control registers
- Storage keys
- The current program status word (PSW)

## Usage Notes

(General for Store)

1. Using a single command, you can store into the contents of multiple storage locations, registers, and control words. Separate each set of store requests from others by at least one blank. For example, if you want to store into hexadecimal location 40000 and the contents of register 5, enter **STORE 40000 10 G5 1F**.
2. If you enter a command line that contains an operand that is not valid, the STORE command terminates when it encounters that operand. Any previous valid operands are processed before termination occurs.
3. If you issue STORE with the ASIT operand and specify the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the STORE is rejected and error message HCPSTT6156E is issued. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value by using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:
  - SYSTEM CLEAR
  - IPL by NSS name
  - IPL by device with the CLear option
  - SET MACHine (to a different machine architecture)

## Messages

- HCP009E Invalid range - *range*
- HCP010E Invalid register - *register*
- HCP012E Invalid PSW - *psw*
- HCP026E Operand missing or invalid
- HCP033E Hexloc missing or invalid
- HCP060E {Dump failed|Printer output terminated}; virtual printer unavailable
- HCP160E Hexloc *hexloc* exceeds storage
- HCP163E STORE exceeds maximum register

## STORE

- HCP164E Hexloc *hexloc* non-addressable storage
- HCP260E {Command|*command* command} processing cannot complete due to errors.
- HCP261E *key* is an invalid storage key.
- HCP410E CP ENTERED; PAGING ERROR
- HCP422E The same option was specified twice.
- HCP657E The virtual machine's page zero is unavailable because it is damaged.
- HCP1001E An operand is missing for *option*.
- HCP1459E The virtual machine is placed in check-stop or system check-stop state due to a system malfunction with CPU *nn*.
- HCP2611E {Data|Key} cannot be stored into a read-only page.
- HCP6025E Operand {STATUS|STORE STATUS|RESTART} is invalid because CPU *nn* is in check-stop state.
- HCP6150E An option has been specified that is not valid in {ESA/390|ESA/XC|z/Architecture|z/XC} mode.
- HCP6151E Storage {operand} is not addressable because of { a protection | an addressing | a segment translation | a page translation | a translation specification | an ASN translation | an AFX translation | an ASX translation | an ALET translation | an ALEN translation | an ALE sequence | an ASTE validity | an ASTE sequence } exception.
- HCP6525E Authorization request failed.

## STORE (Guest Storage - ESA/XC, z/XC)

### Authorization

Privilege Class: G

### Purpose

Use STORE (Guest Storage - ESA/XC, z/XC) to store data into the storage of an ESA/XC or z/XC virtual machine.

### Operands

**L**

alters the contents of storage in an address space based on the setting of the address-space-control field in the guest PSW. This is the default.

If the virtual CPU is in primary-space mode, the contents of real storage in the host-primary address space are altered. If the virtual CPU is in the access-register mode and a nonzero BASE $nn$  operand is also specified, the contents of real storage in an AR-specified address space are altered.

If the virtual CPU is in access-register mode, but either the BASE $nn$  operand is not specified or is specified as 'BASE0', the contents of real storage in the host-primary address space are altered.

#### **ALET***alet.*

alters the contents of real storage in an access list entry token (ALET) specified address space. The *alet* may be 1 to 8 hexadecimal digits; leading zeros are optional. The ALET is used in conjunction with the virtual machine's host access list to determine the address space to store data in.

**AREG***areg*.

alters the contents of real storage in an access register specified address space. The *areg* may be specified as 1 hexadecimal or 2 decimal digits. The ALET within the access register is used in conjunction with the virtual machine's host access list to determine the address space to store data in.

**ASIT***asit*.

alters the contents of absolute storage in the address space identified by the specified address space identification token (ASIT). The *asit* may be 1 to 16 hexadecimal digits; leading zeros are optional.

**PRI**

alters the contents of real storage in the host-primary address space. This is the address space from which the virtual CPU is fetching instructions at the time the command is run.

**SPACE***spaceid*.

alters the contents of absolute storage in the address space identified by *spaceid*. The *spaceid* is a 1-character to 33-character string of the form:

where *owner* is an optional 1-character to 8-character user ID of the virtual machine that owns the address space, and *spacename* is the 1-character to 24-character address-space name assigned to the address space.

If *owner* is not specified, your virtual machine is assumed to be the owner of the address space. The *spacename* 'BASE' is preassigned by CP to be the name of your virtual machine's host-primary address space.

**N**

stores the data (in hexadecimal) in successive fullword locations starting at the address specified by *hexloc*. The smallest group of hexadecimal values that can be stored is one fullword. N is the default.

If *hexloc* is not on a fullword boundary, the store operation begins on the next lower fullword boundary. If *data* is less than one fullword (8 hexadecimal digits) in length, it is right-justified in the word and is filled in with zeros. If two or more hexadecimal words are specified, they must be separated with one or more blanks.

**K**

stores the data in the storage key for the 4 KB page in which *hexloc* is located. Two hexadecimal digits form the key for the page.

**S**

stores the data (in hexadecimal) without word alignment, starting at the address specified in *hexloc*. The shortest string that can be stored is 1 byte (2 hexadecimal digits). If the string contains an odd number of characters, the last character is not stored, an error message is issued, and the function terminates. If you specify the S operand, *data* must be a string of 2 or more hexadecimal digits with no embedded blanks.

**U**

stores the data starting at the address specified by *hexloc*. By default the data is treated as EBCDIC; if the X option is specified, the data is treated as ASCII. The data is stored in byte segments with no word alignment.

**hexloc**

specifies the starting storage location that is to be altered. The value *hexloc* can be 1 - 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. The default is zero.

If neither the BASE or INDEX operand is used, *hexloc* is the address of the first location to be altered. This address is treated as a 64-bit address, regardless of the addressing mode of the virtual CPU.

If either the BASE or the INDEX operand is used, *hexloc* is a displacement rather than an address. The first location to be altered is specified by the sum of *hexloc* and the contents of the registers that are specified with the BASE and INDEX operands. If general register 0 is specified in the BASE or INDEX

operand, it is always treated as containing zero when forming this sum. The sum is treated as a 24-bit, 31-bit, or 64-bit address according to the addressing mode of the virtual CPU.

**%**

indicates 31-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 31 bits at the specified address (the high-order bit is set to 0) are used as the address for the STORE command.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**&**

indicates 64-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 64 bits at the specified address are used as the address for the STORE command. A maximum of 16 indirection characters can be specified.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**BASEnn**

stores the contents of guest storage using the specified starting address (*hexloc*) as a displacement from the address in the specified general register. The specified register may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F.

If the virtual CPU is in access-register mode, and the L operand is specified (or defaulted), *nn* designates an access register/general register pair. Access register *nn* is implicitly used, in the same manner as if the AREG operand had been specified, in conjunction with the virtual machine's host access list to determine the address space in which to store. If the virtual CPU is not in the access-register mode, or if one of the other space-designation operands (PRI, AREG, ALET, SPACE, ASIT) is specified, access register *nn* is not implicitly used.

**INDEXnn**

stores the contents of guest storage using the specified starting address (*hexloc*) as a displacement from the address in the specified register. The specified register may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F.

**data**

is the data you want to insert into storage. The operand takes on different meanings depending on the type of STORE you are performing (N, S, K, or U). See the descriptions of each of these operands for the meaning of *data*.

## Usage Notes

- Special authorization is required to use this command to alter storage in any address space other than the host-primary address space of the virtual CPU. In order to use this command to alter storage in an address space, one of the following conditions must be satisfied:
  - Your virtual machine must be the owner of the address space. Your virtual machine is the owner of its host-primary address space and of any address space that it creates using the CREATE function of the ADRSPACE macro.
  - If the address space is owned by another virtual machine, your virtual machine must have read-write authorization to the address space. The owner of the address space can grant authorization to your virtual machine using the PERMIT function of the ADRSPACE macro.

Authorization is granted on a space-by-space basis, so that you may be authorized to alter one address space of a virtual machine but may not be authorized to alter a different space.
- When running with a saved segment, you can store storage locations outside the range of your virtual machine size if they are within the saved segment. If locations exist between the upper limit of your virtual machine and the address at which the saved segment was saved, any attempt to store those locations (or associated keys) causes the non-addressable storage response to be displayed.

## STORE (Guest Storage - ESA/XC)

3. The operands L, ALET, AREG, and PRI use the host access-register-translation (ART) process. The ART process performs special-case translation processes for certain ALET values and access registers:
  - The ALET X'00000000' always indicates the host-primary address space.
  - Access register 0 is always treated as containing ALET X'00000000'. The contents of access register 0 are not used during host access-register-translation processing.
4. General register 0 is always treated as containing the value 0 when used as the base or index register through the BASE or INDEX operands. The contents of general register 0 are never used.
5. In the XC environment, special rules govern the conversion of real addresses into absolute addresses. In some cases, prefixing is performed as usual to convert a real address to an absolute address, while in other cases prefixing is not performed and real addresses are treated unchanged as absolute addresses.

These rules have an effect on the interpretation of the addresses that specify the range of storage locations to be altered:

- When storage is specified using the ALET or AREG operand and the ALET used is not X'00000000', prefixing is not performed on the addresses that specify the range of storage in the target address space.
  - When storage in the host-primary address space is specified by using the PRI operand, or by using the ALET or AREG operand when the ALET used is X'00000000', prefixing is performed as usual on the addresses that specify the range of storage in the host-primary address space.
6. Although the R operand is not shown in the syntax for this command, it is accepted for compatibility with the STORE (Guest Storage) command used for XA and ESA virtual machines. The R operand performs the same function as the L operand and alters storage in the host-primary address space.
  7. The BASE operand lets you store the storage used by the virtual machine in one less step than would otherwise be possible. Without the BASE operand, you may need to store the contents of a general register, then add the displacement, and then enter the DISPLAY command to examine storage the program is using. With the use of access registers, the BASE operand additionally lets you alter storage without needing to know whether the program is currently in the access-register mode. This is done automatically for you by CP.
  8. When multiple STORE requests are entered on a single line, the BASE and INDEX operands are not applied to subsequent STORE requests on the command line. They must be explicitly entered for each STORE request.
  9. During STORE command processing, key-controlled protection and low-address protection is not used. However, all of the host-related protection mechanisms, such as host page protection and those mechanisms applied during host-access-register translation, are used as normal. For example, an attempt to store at an address in a host-page-protected page, or to change the key at an address in a host-page-protected page, results in an error message.
  10. If the ALET or AREG operand is specified, the STORE command uses the host access-register-translation (ART) process to determine the address space in which to store data. This translation process may fail because of one of several program exception conditions. If the translation does not succeed, the current request is rejected and processing of the command line is ended. The rejected operands are displayed along with a message indicating the nature of the exception condition.
  11. When the ASIT or SPACE operand is specified, the STORE request fails if the specified address space does not exist, or if you are not authorized to access the address space. The current request is rejected, and processing of the command line is terminated. The rejected operands are displayed along with a message indicating the nature of the error.
  12. If you use an underscore, it must be followed by 8 hexadecimal digits.

## Responses

Response 1:

Store complete

indicates that the data has been stored.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP005E Invalid hexdata - *hexdata*
- HCP010E Invalid register - *register*
- HCP012E Invalid PSW - *psw*
- HCP026E Operand missing or invalid
- HCP033E Hexloc missing or invalid
- HCP163E STORE exceeds maximum register
- HCP260E {Command||*command* command} processing cannot complete due to errors.
- HCP657E The virtual machine's page zero is unavailable because it is damaged.
- HCP6025E Operand {STATUS|STORE STATUS|RESTART} is invalid because CPU *nn* is in check-stop state.
- HCP6150E An option has been specified that is not valid in {ESA/XC|z/XC} mode.
- HCP6525E Authorization request failed.

## STORE (Guest Storage - ESA/390)

### Authorization

Privilege Class: G

### Purpose

Use STORE (Guest Storage - ESA/390) to store data in the second-level or third-level storage of an ESA/390 virtual machine.

### Operands

**L**

stores the data in second-level storage (storage that appears real to your virtual machine) if the virtual machine is operating in DAT OFF mode, or stores the data in third-level storage (storage that appears virtual to your virtual machine) if the virtual machine is operating in DAT ON mode. This is the default.

The address space selected corresponds to the setting of the address space control field in the guest PSW and is the primary, secondary, or (if the virtual machine is an ESA virtual machine) home space. When the PSW indicates access register mode, the primary space is selected unless a nonzero *BASEnn* operand is also specified and the virtual machine is an ESA virtual machine, in which case an access register specified address space is selected.

**R**

stores the data in second-level storage (storage that appears real to your virtual machine).

**ALETheyword.**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using the specified access list entry token (ALET). The ALET is used in conjunction with guest access register translation tables to locate the guest address space to store data in.

**ALraddr.**

specifies an access list (AL) to be used in conjunction with the ALET to locate the guest address space. The guest real address of the access list may be 1 to 8 hexadecimal digits.

**AREGareg.**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using the contents of the specified access register. The *areg* may be specified as 1 hexadecimal or 2 decimal digits. The access list entry token (ALET) within the access register is used in conjunction with guest access register translation tables to locate the guest address space to store data in.

**ASITasit.**

stores the data in absolute storage in the CP-created address space identified by the specified address space identification token (ASIT). The *asit* may be 1 to 16 hexadecimal digits; leading zeros are optional.

**ASNasn.**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using the specified address space number (ASN). The *asn* may be 1 to 4 hexadecimal digits. It used in conjunction with guest ASN-translation tables to locate a guest address space to store data in.

**ASTERaddr.**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using the segment table designation contained within the ASN second table entry (ASTE) located at guest real address *raddr*.

**HOME**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using guest control register 13.

**PRI**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using guest control register 1.

**SECO**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using guest control register 7.

**SPACEspaceid.**

stores the data in absolute storage in the CP-created address space identified by *spaceid*. The *spaceid* is a 1-character to 33-character string of the form:

where *owner* is an optional 1-character to 8-character user ID of the virtual machine that owns the CP-created address space, and *spacename* is the 1-character to 24-character address space name assigned to the address space.

If *owner* is not specified, your virtual machine is assumed to be the owner of the address space. The *spacename* 'BASE' is preassigned by CP to be the name of your virtual machine's host-primary address space.

**STDhexword.**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using the specified guest segment table designation (STD).

**N**

stores the data (in hexadecimal) in successive fullword locations starting at the address specified by *hexloc*. The smallest group of hexadecimal values that can be stored is one fullword. This is the default.

If *hexloc* is not on a fullword boundary, the store operation begins on the next lower fullword boundary. If the value being stored is less than one fullword (8 hexadecimal digits) in length, it is right-adjusted in the word and is filled in with zeros. If two or more hexadecimal words are specified, they must be separated with one or more blanks.

**K**

stores the data in the storage key for the 4 KB page in which *hexloc* is located. Two hexadecimal digits are used to form the key for the page. If one digit is provided, it becomes the lower digit, and the upper digit is zero.

**S**

stores the data (in hexadecimal) without word alignment, starting at the address specified in *hexloc*. The shortest string that can be stored is 1 byte (2 hexadecimal digits).

If the string contains an odd number of characters, the last character is not stored; an error message is issued, and the function terminates. If you specify the S operand, the data you enter must be a string of 2 or more hexadecimal digits with no embedded blanks.

**U**

stores the data starting at the address specified by *hexloc*. The data is treated as an EBCDIC string by default; it is treated as an ASCII string if the X option is specified. The data is stored in byte segments with no word alignment.

**hexloc**

is the starting storage location that is to be altered. The address *hexloc* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. The default is zero.

**%**

indicates 31-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 31 bits at the specified address (the high-order bit is turned off) are used as the new address for the STORE command.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**&**

indicates 64-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 64 bits at the specified address are used as the new address for the STORE command. A maximum of 16 indirection characters can be specified.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

**BASEnn**

stores the data in guest storage using the specified address (*hexloc*) as a displacement from the address in the specified general register (*nn*). The general register may be a specified as a decimal number from 0 to 15 or as a hexadecimal number from 0 to F. *nn* indicates an AR/GR pair if all of the following are true:

- The L operand is specified.
- The virtual machine is an ESA virtual machine in ESA/390 mode (the default mode).
- The virtual CPU is in access register mode.

The specified access register is used, in the same manner as if the *AREGareg.* operand had been specified, in conjunction with the guest access-register-translation tables to locate the guest address space to store data in.

### **INDEXnn**

stores the data in guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified register. The specified register may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F.

### **data**

is the data you want to place in storage. The operand takes on different meanings, depending on the type of STORE you are performing (N, K, S, or U). See the descriptions of each of these operands for the meaning of *data*.

## **Usage Notes**

1. An attempt to store at an address in a protected page, or to change the key at an address in a protected page, results in an error message. A protected page is a page of read-only storage.
2. The operands HOME, *AREGareg.*, *ALETheyword.*, and *ALETheyword.ALraddr.* are valid only if the virtual machine is an ESA virtual machine.
3. When you use the operand *ALETheyword.ALraddr.*, the primary list bit in the ALET is ignored.
4. The operands L, PRI, SECO, HOME, *ASTERaddr.*, *STDhexword.*, *ASNasn.*, *AREGareg.*, *ALETheyword.*, and *ALETheyword.ALraddr.* use the access register translation (ART), the ASN translation or the dynamic address translation (DAT) processes. These contain special case translation processes including the following:
  - ALET 0 always indicates the current primary address space designated by the STD in guest control register 1, regardless of the current contents of the dispatchable-unit access list.
  - ALET 1 always indicates the current secondary address space designated by the STD in guest control register 7, regardless of the current contents of the dispatchable-unit access list.
  - Access register 0 is always treated as containing the ALET 0. The contents of access register 0 are not used during ART processing.
  - General register 0 is always treated as containing the value 0 when used as the base or index register. The contents of GR 0 are never used.
5. The BASE operand is primarily intended for use in conjunction with the L operand. It allows a user to modify the storage the virtual machine uses in one less step than would otherwise be possible. Without the BASE operand, a user may need to display the contents of a general register, then add the displacement, and then enter the STORE command to modify storage the program is using. With the use of access registers, the BASE option allows the user to modify storage without needing to know whether the program is currently in access register mode. This is done automatically by CP.
6. If you use the *BASEnn* and *INDEXnn* operands together, the specified *hexloc* is used as a displacement from the address formed by the sum of the contents of the two specified registers.
 

The values in the registers specified by the *BASEnn* and *INDEXnn* operands are treated as 24-bit or 31-bit real addresses according to the addressing mode (A) bit in the virtual machine's PSW. That is, if the A bit is 1, the value is a 31-bit address. If the A bit is 0, the value is a 24-bit address. Address wrap-around is applied to the sum of the specified starting address and the contents of the two specified registers.
7. During STORE command processing, the authorization mechanisms used during normal address translation are not used.
8. Special authorization is required to use the SPACE or ASIT operand of this command to alter any address space other the host-primary address space of the virtual CPU. In order to use this command to alter storage in an address space, one of the following conditions must be satisfied:
  - Your virtual machine must be the owner of the address space. Your virtual machine is the owner of its host-primary address space and of any address space that it creates using the CREATE function of the ADRSPACE macro.

## STORE (Guest Storage - ESA/390)

- If the address space is owned by another virtual machine, your virtual machine must have read-write authorization to the address space. The owner of the address space can grant authorization to your virtual machine using the PERMIT function of the ADRSPACE macro.

Authorization is granted on a space-by-space basis, so that you may be authorized to alter one address space of a virtual machine but may not be authorized to alter a different space.

9. The operands V and W used to place data in third-level storage from guest primary and secondary are being supported for compatibility. The PRI and SECO operands replace the V and W operands.
10. When the ASIT or SPACE operand is specified, the STORE request fails if the specified address space does not exist, or if you are not authorized to alter the address space. The current request is rejected, and processing of the command line is terminated. The rejected operands are displayed along with a message indicating the nature of the error.
11. The STORE command requires a segment table designation (STD) to alter third-level storage (storage that appears virtual to your virtual machine). It may receive the STD as an operand, find it in a control register, or use the access-register translation (ART) process or the address space number (ASN) translation process to obtain the STD. The access-register translation and ASN translation processes may fail because of one of several program exception conditions. If the translation does not succeed, the current request is rejected, and processing of the command line is terminated. The rejected operands are displayed along with a response indicating the nature of the exception condition.
12. If you use an underscore, it must be followed by 8 hexadecimal digits.
13. If you issue STORE with the ASIT operand and specify the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the STORE command is rejected and error message HCPSTT6156E is issued. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value by using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:
  - SYSTEM CLEAR
  - IPL by NSS name
  - IPL by device with the CClear option
  - SET MACHine (to a different machine architecture)

## Responses

Response 1:

```
Store complete
```

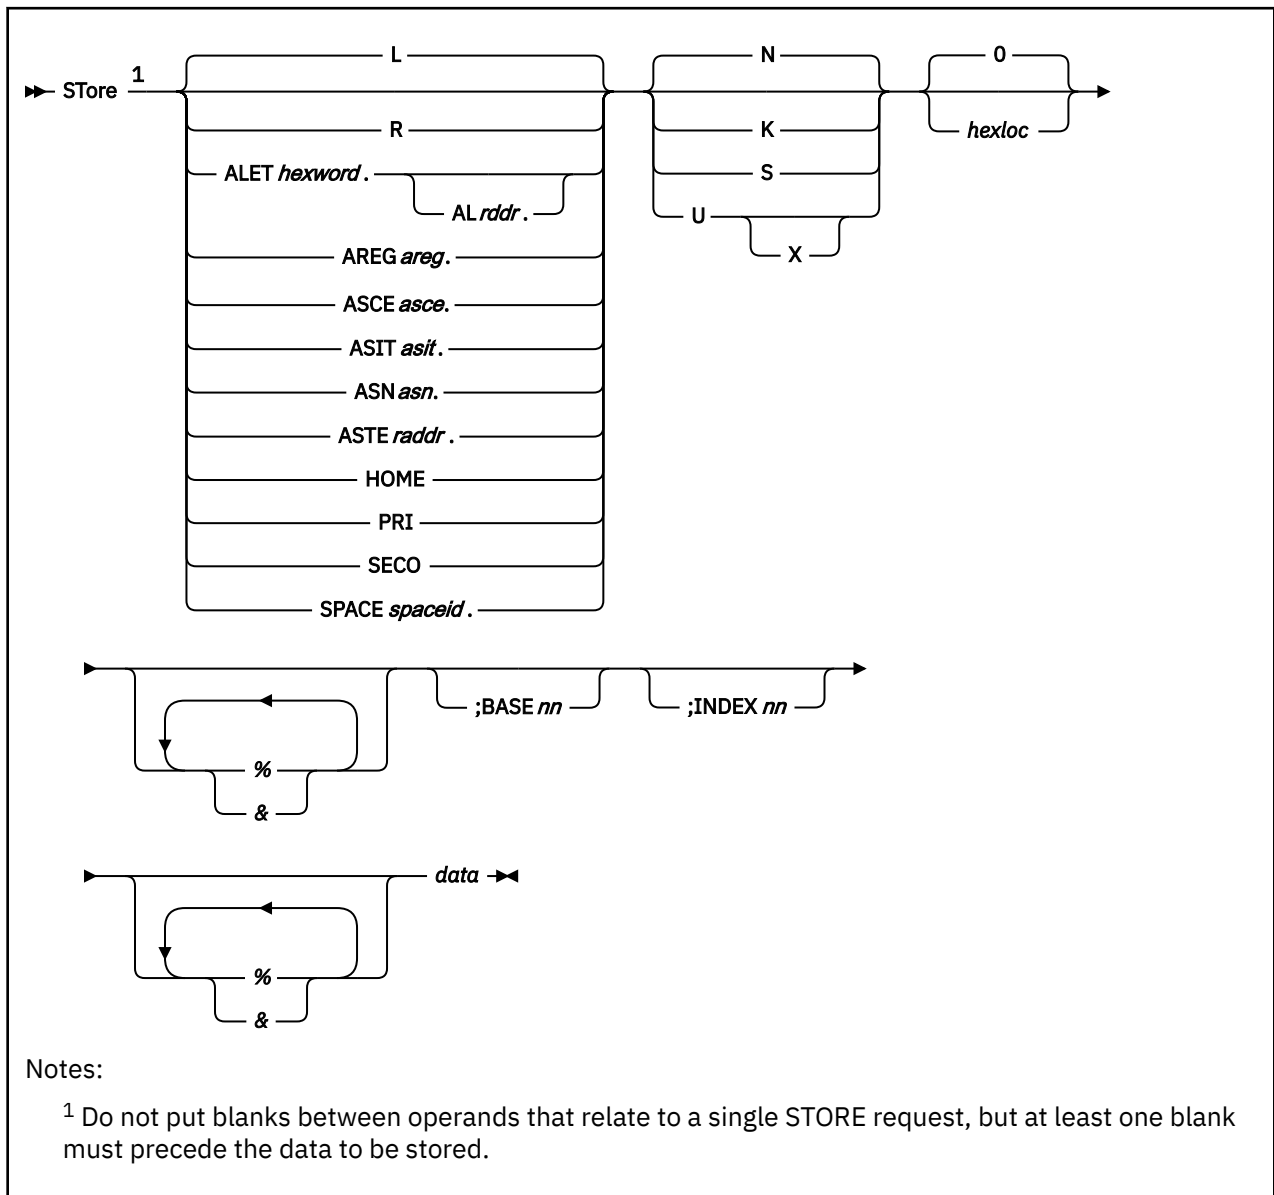

is issued when the command completes successfully.

## STORE (Guest Storage - z/Architecture)

### Authorization

Privilege Class: G

### Purpose

Use STORE (Guest Storage - z/Architecture) to store data in the second-level or third-level storage of a virtual machine in z/Architecture mode.

### Operands

L

stores the data in second-level storage (storage that appears real to your virtual machine) if the virtual machine is operating in DAT OFF mode, or stores the data in third-level storage (storage that appears virtual to your virtual machine) if the virtual machine is operating in DAT ON mode. This is the default.

The address space selected corresponds to the setting of the address space control field in the guest PSW and is the primary, secondary, or (if the virtual machine is an ESA virtual machine) home space. When the PSW indicates access register mode, the primary space is selected unless a nonzero *BASEnn* operand is also specified and the virtual machine is an ESA virtual machine, in which case an access register specified address space is selected.

**R**

stores your data in second-level storage (storage that appears real to your virtual machine).

**ALEThexword.**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using the specified access list entry token (ALET). The ALET is used in conjunction with guest access register translation tables to locate the guest address space to store data in.

**ALraddr.**

specifies an access list (AL) to be used in conjunction with the ALET to locate the guest address space. The guest real address of the access list may be 1 to 8 hexadecimal digits.

**AREGareg.**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using the contents of the specified access register. The *areg* may be specified as 1 hexadecimal or 2 decimal digits. The ALET within the access register is used in conjunction with guest access register translation tables to locate the guest address space to store data in.

**ASCEasce.**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using the specified address-space-control element (ASCE). The *asce* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability.

**ASITasit.**

stores the data in absolute storage in the CP-created address space identified by the specified address space identification token (ASIT). The *asit* may be 1 to 16 hexadecimal digits; leading zeros are optional.

**ASNasn.**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using the specified address space number (ASN). The *asn* may be 1 to 4 hexadecimal digits. It is used in conjunction with guest ASN-translation tables to locate the guest address space to store data in.

**ASTERaddr.**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using the segment table designation contained within the ASN second table entry (ASTE) located at guest real address *raddr*.

**HOME**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using guest control register 13.

**PRI**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using guest control register 1.

**SECO**

stores the data in third-level storage (storage that appears virtual to your virtual machine) using guest control register 7.

**SPACEspaceid.**

stores the data in absolute storage in the CP-created address space identified by *spaceid*. The *spaceid* is a 1-character to 33-character string of the form:

## STORE (Guest Storage - z/Architecture)

where *owner* is an optional 1-character to 8-character user ID of the virtual machine that owns the CP-created address space, and *spacename* is the 1-character to 24-character address space name assigned to the address space.

If *owner* is not specified, your virtual machine is assumed to be the owner of the address space. The *spacename* 'BASE' is preassigned by CP to be the name of your virtual machine's host-primary address space.

### N

stores the data (in hexadecimal) in successive fullword locations starting at the address specified by *hexloc*. The smallest group of hexadecimal values that can be stored is one fullword. This is the default.

If *hexloc* is not on a fullword boundary, the store operation begins on the next lower fullword boundary. If the value being stored is less than one fullword (8 hexadecimal digits) in length, it is right-adjusted in the word and is filled in with zeros. If two or more hexadecimal words are specified, they must be separated with one or more blanks.

### K

stores the data in the storage key for the 4 KB page in which *hexloc* is located. Two hexadecimal digits are used to form the key for the page. If one digit is provided, it becomes the lower digit, and the upper digit is zero.

### S

stores the data (in hexadecimal) without word alignment, starting at the address specified in *hexloc*. The shortest string that can be stored is 1 byte (2 hexadecimal digits).

If the string contains an odd number of characters, the last character is not stored; an error message is issued, and the function terminates. If you specify the S operand, the data you enter must be a string of two or more hexadecimal digits with no embedded blanks.

### U

stores the data starting at the address specified by *hexloc*. The data is treated as an EBCDIC string by default; it is treated as an ASCII string if the X option is specified. The data is stored in byte segments with no word alignment.

### *hexloc*

is the starting storage location that is to be altered. The address *hexloc* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. The default is zero.

### %

indicates 31-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 31 bits at the specified address (the high-order bit is set to 0) are used as the address for the STORE command.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

### &

indicates 64-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 64 bits at the specified address are used as the address for the STORE command. A maximum of 16 indirection characters can be specified.

When specified following the INDEX and BASE operands, the indirect address is determined after BASE and INDEX are applied.

### **BASEnn**

stores the data in guest storage using the specified address (*hexloc*) as a displacement from the address in the specified general register (*nn*). The general register may be specified as a decimal number from 0 to 15 or as a hexadecimal number from 0 to F. *nn* specifies an AR/GR pair if all of the following are true:

- The L operand is specified.
- The virtual machine is an ESA virtual machine in z/Architecture mode.

**Note:** An ESA virtual machine simulates ESA/390 architecture when initially defined. However, a guest may have the capability to switch the virtual machine from ESA/390 mode to z/Architecture mode.

- The virtual CPU is in access register mode.

The specified access register is used, in the same manner as if the *AREGareg.* operand had been specified, in conjunction with the guest access-register-translation tables to locate the guest address space to store data in.

### INDEXnn

stores the data in guest storage using the specified starting address (*hexloc1*) as a displacement from the address in the specified register. The specified register may be a decimal number from 0 to 15 or a hexadecimal number from 0 to F.

### data

is the data you want to place in storage. The operand takes on different meanings, depending on the type of STORE you are performing (N, K, S, or U). See the descriptions of each of these operands for the meaning of *data*.

## Usage Notes

1. An attempt to store at an address in a protected page, or to change the key at an address in a protected page, results in an error message. A protected page is a page of read-only storage.
2. The operands HOME, *AREGareg.*, *ALETheyword.*, and *ALETheyword.ALraddr.* are valid only if the the virtual machine is an ESA virtual machine.
3. When you use the operand *ALETheyword.ALraddr.*, the primary list bit in the ALET is ignored.
4. The operands L, PRI, SECO, HOME, *ASTERaddr.*, *ASCEasce.*, *ASNasn.*, *AREGareg.*, *ALETheyword.*, and *ALETheyword.ALraddr.* use the access register translation (ART), the ASN translation or the dynamic address translation (DAT) processes. These contain special case translation processes including the following:
  - ALET 0 always indicates the current primary address space designated by the ASCE in guest control register 1, regardless of the current contents of the dispatchable-unit access list.
  - ALET 1 always indicates the current secondary address space designated by the ASCE in guest control register 7, regardless of the current contents of the dispatchable-unit access list.
  - Access register 0 is always treated as containing the ALET 0. The contents of access register 0 are not used during ART processing.
  - General register 0 is always treated as containing the value 0 when used as the base or index register. The contents of GR 0 are never used.
5. The BASE operand is primarily intended for use in conjunction with the L operand. It allows a user to modify the storage the virtual machine uses in one less step than would otherwise be possible. Without the BASE operand, a user may need to display the contents of a general register, then add the displacement, and then enter the STORE command to modify storage the program is using. With the use of access registers, the BASE option allows the user to modify storage without needing to know whether the program is currently in access register mode. This is done automatically by CP.
6. If you use the *BASEnn* and *INDEXnn* operands together, the specified *hexloc* is used as a displacement from the address formed by the sum of the contents of the two specified registers. The values in the registers specified by the *BASEnn* and *INDEXnn* operands are treated as 24-bit, 31-bit, or 64-bit real addresses according to the addressing mode bits (EA and BA - bits 31 and 32) in the virtual machine's PSW. The addressing mode is determined as follows:

Bit 31	Bit 32	Addressing Mode
0	0	24-bit
0	1	31-bit
1	1	64-bit

## STORE (Guest Storage - z/Architecture)

7. During STORE command processing, the authorization mechanisms used during normal address translation are not used.
  8. Special authorization is required to use the SPACE or ASIT operand of this command to alter any address space other the host-primary address space of the virtual CPU. In order to use this command to alter storage in an address space, one of the following conditions must be satisfied:
    - Your virtual machine must be the owner of the address space. Your virtual machine is the owner of its host-primary address space and of any address space that it creates using the CREATE function of the ADRSPACE macro.
    - If the address space is owned by another virtual machine, your virtual machine must have read-write authorization to the address space. The owner of the address space can grant authorization to your virtual machine using the PERMIT function of the ADRSPACE macro.
- Authorization is granted on a space-by-space basis, so that you may be authorized to alter one address space of a virtual machine but may not be authorized to alter a different space.
9. The operands V and W used to place data in third-level storage from guest primary and secondary are being supported for compatibility. The PRI and SECO operands replace the V and W operands.
  10. When the ASIT or SPACE operand is specified, the STORE request fails if the specified address space does not exist, or if you are not authorized to alter the address space. The current request is rejected, and processing of the command line is terminated. The rejected operands are displayed along with a message indicating the nature of the error.
  11. The STORE command requires a segment table designation (ASCE) to alter third-level storage (storage that appears virtual to your virtual machine). It may receive the ASCE as an operand, find it in a control register, or use the access-register translation (ART) process or the address space number (ASN) translation process to obtain the ASCE. The access-register translation and ASN translation processes may fail because of one of several program exception conditions. If the translation does not succeed, the current request is rejected, and processing of the command line is terminated. The rejected operands are displayed along with a response indicating the nature of the exception condition.
  12. If you use an underscore, it must be followed by 8 hexadecimal digits.
  13. If you issue STORE with the ASIT operand and specify the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the STORE command is rejected and error message HCPSTT6156E is issued. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value by using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:
    - SYSTEM CLEAR
    - IPL by NSS name
    - IPL by device with the CClear option
    - SET MACHine (to a different machine architecture)

## Responses

Response 1:

```
Store complete
```

is issued when the command completes successfully.

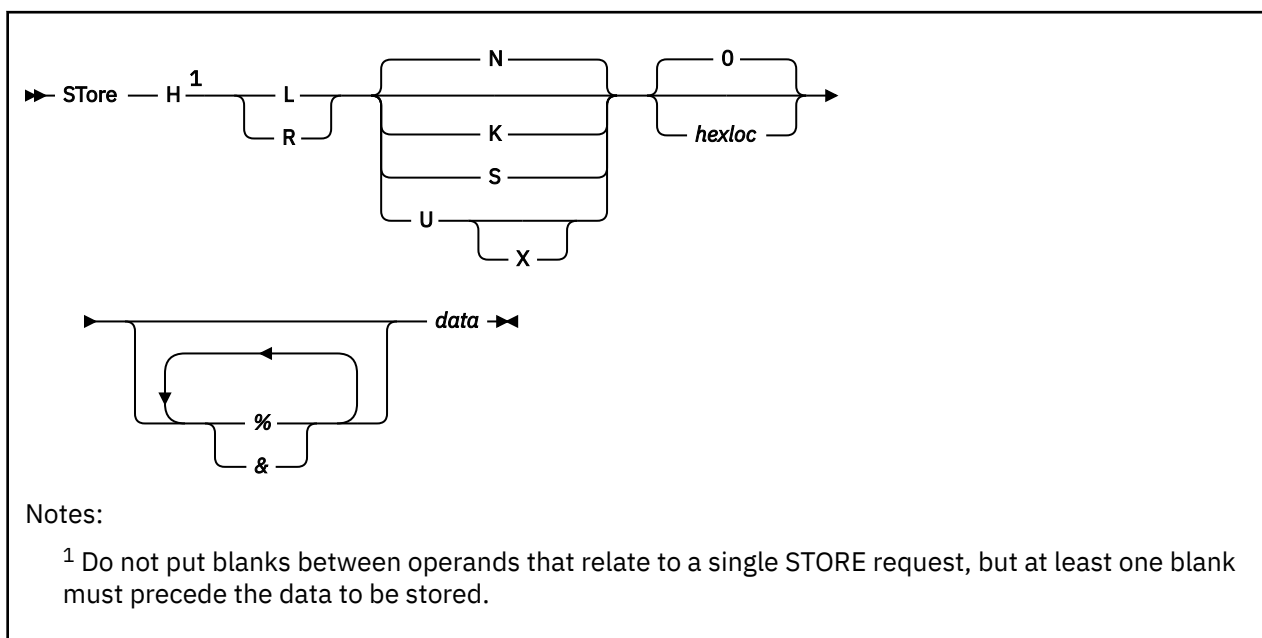

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

- HCP6525E Authorization request failed.

## STORE (Host Storage)

### Authorization

Privilege Class: C

### Purpose

Use STORE (Host Storage) to store data into host (first-level) storage.

**Attention:** Careless storage alterations can cause abnormal terminations of your system as well as security and integrity problems.

### Operands

**L**

specifies that the data is to be stored into host logical storage.

**R**

specifies that the data is to be stored into host real storage.

**N**

stores the specified (hexadecimal) data in successive fullword locations starting at the address specified by *hexloc*. The smallest group of hexadecimal values that can be stored is one fullword. This is the default.

If *hexloc* is not on a fullword boundary, the store operation begins on the next lower fullword boundary. If the value being stored is less than one fullword (four bytes) in length, it is right-adjusted in the word and is filled in with zeros. If two or more hexadecimal words are specified, they must be separated with one or more blanks.

**K**

stores the data in the storage key for the 4 KB page or frame in which *hexloc* is located. Two hexadecimal digits form the storage key. If one digit is provided, it becomes the lower digit, and the upper digit is 0.

If you are storing data into host logical storage, the storage key being changed is for the backing frame in host real storage at that moment.

**S**

stores the specified hexadecimal data without word alignment starting at the address specified in *hexloc*. The shortest string that can be stored is 1 byte (2 hexadecimal digits). If the string contains an odd number of characters, the last character is not stored; an error message is issued, and the function terminates. If you specify the S operand, the data you enter must be a string of 2 or more hexadecimal digits with no embedded blanks.

**U**

stores the specified data starting at the address specified by *hexloc*. By default the data is treated as EBCDIC; if the X option is specified, the data is treated as ASCII. The data is stored in byte segments with no word alignment.

**hexloc**

is the starting storage location that is to be altered. The address *hexloc* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability; leading zeros are optional. The default is zero.

This address must be within the bounds of addressable storage (see usage note “3” on page 1899).

**%**

indicates 31-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 31 bits at the specified address (the high-order bit is set to 0) are used as the address for the STORE command.

**&**

indicates 64-bit address indirection. Indirection means that the contents of the specified address are used instead of the address itself. In this case, the 64 bits at the specified address are used as the address for the STORE command.

**data**

is the data you want to place in storage. The operand takes on different meanings, depending on the type of STORE you are performing (N, S, K, or U). See the descriptions of each of these operands for the meaning of *data*.

**Usage Notes**

1. In a multiprocessor environment, each processor has a prefix register that it uses to relocate addresses between 0 and X'1FFF' (an 8 KB area known as the prefix area) to two other contiguous frames in real storage. The prefix register enables each processor to use a different prefix area to avoid conflict with other processors for such activity as interrupt code recording. Thus, the range 0 through X'1FFF' refers to different areas of storage, depending on which processor generates the address. All references to first-level storage are handled as if they were made on the IPL processor.
2. If an external security manager is installed on your system, you may not be authorized to enter this command. For additional information, contact your security administrator.
3. For host logical storage (the system execution space), addressable storage includes the system execution area, which resides below 2 GB, plus the system frame table and the system execution space page management table, which reside above 2 GB. To display the storage address ranges used for the system execution space, issue the QUERY SXSSTORAGE command. The storage locations that you alter with the STORE command must be within the same address range of the system execution space.  
  
For host real storage, addressable storage is the lesser of CP's configured storage size (if specified at system generation) and the real machine storage size. To display the size of host real storage, issue the QUERY STORAGE command.
4. When storing data into host logical storage, if you specify an address that is not backed with a real storage frame, error message HCP6151E is issued, even if the address is included in the ranges of in-use and usable addresses displayed by the QUERY SXSSTORAGE command.
5. If you use an underscore, it must be followed by 8 hexadecimal digits.

## STORE (Host Storage)

### Responses

Response 1:

```
Store complete
```

is issued when the command completes successfully.

### Messages

- HCP160E Hexloc *hexloc* exceeds storage
- HCP164E Hexloc *hexloc* non-addressable storage
- HCP6065E STORE HOST requires R (real) or L (logical) address type

## STORE PSW

### Authorization

Privilege Class: G

### Purpose

Use STORE PSW to alter the program status word (PSW).

### Operands

#### PSW

For an ESA/390 or ESA/XC guest:

This alters all or part of the PSW with the data you specify in *hexword1* and *hexword2*. If you specify only *hexword2*, it is stored in the second word of your virtual machine's current PSW. If you specify both *hexword1* and *hexword2*, *hexword1* is stored in the first word of your virtual machine's current PSW, and *hexword2* is stored into the address portion of the PSW.

For a z/Architecture or z/XC guest:

This is allowed only if a SET PSWTRANS ALL/STORE command has previously been issued for the virtual machine. If the appropriate SET PSWTRANS command has been issued, the hexwords are converted from an ESA/390-format PSW into a z/Architecture-format PSW as indicated below:

If only *hexword2* is specified, the z/Architecture PSW is stored as follows:

- bit 32 = *hexword2* bit 0
- bits 33-96 = 0
- bits 97-127 = *hexword2* bits 1-31
- rest of bits remain unchanged

If you specify *hexword1 hexword2*, the z/Architecture PSW is stored as follows:

- bits 0-31 = *hexword1* (bit 12 is set to 0)
- bit 32 = 1 if *hexword1* bit 31 is 1 otherwise, this bit will be set to *hexword2* bit 0
- bits 33-96 = 0
- bits 97-127 = *hexword2* bits 1-31

#### **hexword...**

identifies the data you want to store in the PSW. If the data is less than eight digits (four bytes), it is right-adjusted and padded with leading zeros.

### Usage Notes

1. To specify a 128-bit PSW, use the STORE PSWG command.

### Responses

Response 1:

## STORE PSW

Store complete

is issued when the command completes successfully.

## STORE PSWA

### Authorization

Privilege Class: G

### Purpose

Use STORE PSWA to alter the address portion only of the current PSW.

### Operands

#### PSWA

For ESA/390 or ESA/XC guest:

One *hexword* of data (*hexword2*) is accepted as the new address. The addressing mode bit in the current PSW remains unchanged.

For a z/Architecture or z/XC guest:

One or two *hexwords* are accepted as the new address. The *hexword(s)* are stored in the address portion of the PSW, the rest of the PSW remains unchanged. If only one *hexword* is specified it is stored in the right-most word of the address portion of the PSW, the left-most word of the address is set to 0.

#### *hexword...*

identifies the data you want to store in the address portion of the PSW. If the data is less than eight digits (four bytes), it is right-adjusted and padded with leading zeros.

### Messages

- HCPSTC026E Operand missing or invalid
- HCPSTC6149E The address specified is not valid in the current addressing mode

## STORE PSWG

### Authorization

Privilege Class: G

### Purpose

Use STORE PSWG to alter the program status word for a z/Architecture or z/XC virtual machine.

### Operands

#### PSWG

#### PG

alters all or part of the PSW with the data you specify in *flagw1*, *flagw2*, *addrw1*, and *addrw2*.

If you specify only *addrw2*, or *addrw2* and *addrw1* the contents are stored right-justified, in the address portion of your virtual machine's PSW. If *flagw1* and *flagw2* are also specified, the complete PSW is stored. Specifying three parameters results in an error, for example *flagw2 addrw1 addrw2*.

Data less than eight digits (four bytes), is right-adjusted and padded with leading zeros.

#### *flagw1*

the data (in hexadecimal) to be stored in the first word of the z/Architecture PSW. If omitted, this portion of the PSW is left unchanged.

#### *flagw2*

the data (in hexadecimal) to be stored in the second word of the z/Architecture PSW. If omitted, this portion of the PSW is left unchanged.

#### *addrw1*

the data (in hexadecimal) to be stored in the third word of the z/Architecture PSW. If omitted, this portion of the PSW is set to 0.

#### *addrw2*

the data (in hexadecimal) to be stored in the fourth word of the z/Architecture PSW. This parameter is required.

### Usage Notes

To store a PSW for an ESA/390 or ESA/XC virtual machine, use the STORE PSW command.

### Responses

Response 1:

```
Store complete
```

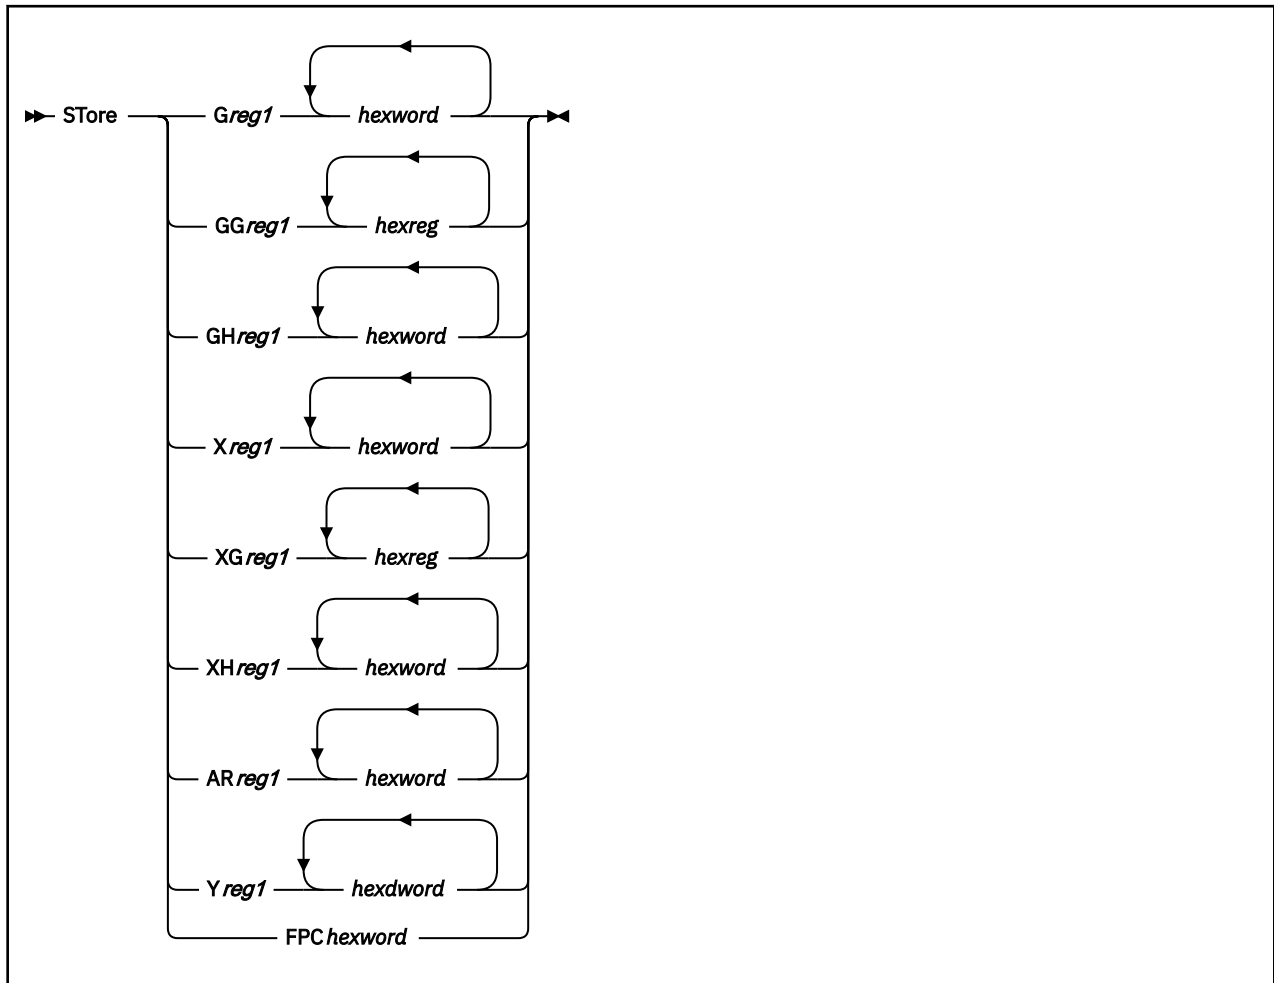

is issued when the command completes successfully.

### Messages

- HCPSTC026E Operand missing or invalid

## STORE (Registers)

### Authorization

Privilege Class: G

### Purpose

Use STORE (Registers) to store data into the following:

- General-purpose registers
- Control registers
- Access registers
- Floating-point registers
- Floating-point control register.

### Operands

#### *Greg1*

G indicates a full general-purpose register for an ESA/390 or ESA/XC guest, or the low-order half of the register for a z/Architecture or z/XC guest. *reg1* is a decimal number from 0 to 15, or a hexadecimal number from 0 to F, representing the first, or only, general register whose contents are to be assigned a value.

## STORE (Registers)

### **GGreg1**

G indicates a full general-purpose register (32 bits for an ESA/390 or ESA/XC guest, 64 bits for a z/Architecture or z/XC guest). *reg1* is a decimal number from 0 to 15, or a hexadecimal number from 0 to F, representing the first, or only, general register whose contents are to be assigned a value.

### **GHreg1**

GH indicates the high-order half of a general-purpose register for a z/Architecture or z/XC guest. This option is not valid for an ESA/390 or ESA/XC guest. *reg1* is a decimal number from 0 to 15, or a hexadecimal number from 0 to F, representing the first, or only, general register whose contents are to be assigned a value.

### **Xreg1**

X indicates a full control register for an ESA/390 or ESA/XC guest or the low-order half of the register for a z/Architecture or z/XC guest. *reg1* is a decimal number from 0 to 15, or a hexadecimal number from 0 to F, representing the first, or only, control register that is to be assigned a value.

### **XGreg1**

XG indicates a full control register (32 bits for an ESA/390 or ESA/XC guest, 64 bits for a z/Architecture or z/XC guest). *reg1* is a decimal number from 0 to 15, or a hexadecimal number from 0 to F, representing the first, or only, control register that is to be assigned a value.

### **XHreg1**

XH indicates the high-order half of a control register for a z/Architecture or z/XC guest. This option is not valid for an ESA/390 or ESA/XC guest. *reg1* is a decimal number from 0 to 15, or a hexadecimal number from 0 to F, representing the first, or only, control register whose contents are to be assigned a value.

### **ARreg1**

AR indicates access registers. *reg1* is a decimal number from 0 to 15, or a hexadecimal number from 0 to F, representing the first, or only, access register whose contents are to be assigned a value.

### **Yreg1**

Y indicates floating-point registers. *reg1* is a decimal number from 0 to 15, or a hexadecimal number from 0 to F, representing the first, or only, floating-point register whose contents are to be assigned a value.

### **FPC**

is the floating-point control register and is available only if floating-point extensions are installed and enabled for the virtual machine issuing the STORE command.

Some bits in the floating-point control register are reserved and cannot be altered (see the Principles of Operation for your processor). The data specified by the *hexword* for the FPC operand is checked for validity on this machine to ensure that none of the reserved bits are altered. If the *hexword* data for the FPC operand attempts to change any of the reserved bits, the message *HCP005E Invalid hexdata* is displayed and the floating-point control register is not changed.

### **hexword**

each *hexword* represents up to eight hexadecimal digits for G, GH, X, XH, and AR register stores. Only one hexword is allowed for FPC. If the value being stored is fewer than the eight digits, it is right-adjusted in the register, and the high-order bytes of the register are filled with zeros. If two or more values are specified, they must be separated by one or more blanks. The data is stored in successive registers.

### **hexdword**

each *hexdword* represents up to 16 hexadecimal digits for Y register stores. If the value being stored is fewer than 16 digits, it is left-adjusted in the register and is padded on the right with zeros. If two or more values are specified, they must be separated by one or more blanks. The data is stored in successive registers.

### **hexreg**

each *hexreg* represents up to eight hexadecimal digits for GG and XG stores for an ESA/390 or ESA/XC guest, or 16 hexadecimal digits, separated with an optional underscore, for a z/Architecture or z/XC guest. If the value being stored is less than the maximum number of hexadecimal digits allowed, it is right-adjusted in the register and is padded on the left with zeros. If two or more values are specified, they must be separated by one or more blanks. The data is stored in successive registers.

## Usage Notes

1. The G and X operands are valid for an ESA/390, ESA/XC, z/Architecture, or z/XC guest. For an ESA/390 or ESA/XC guest, these operands refer to the full four-byte register. For a z/Architecture or z/XC guest, these operands refer to the low-order four bytes of the full eight-byte register; the high-order half of the register remains unchanged.
2. The GG and XG operands are valid for an ESA/390, ESA/XC, z/Architecture, or z/XC guest. For an ESA/390 or ESA/XC guest, these operands refer to the full four-byte register. For a z/Architecture or z/XC guest, these operands refer to the full eight-byte register.
3. The GH and XH operands are valid only for a z/Architecture or z/XC guest. These operands refer to the high-order four bytes of the full eight-byte register.
4. When part of an SSI cluster, the validity of the FPC operand depends on the relocation domain of the issuing user, and may differ among users on the same system when they belong to different relocation domains.

## Responses

Response 1:

```
Store complete
```

is issued when the command completes successfully.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

## STORE STATUS

► Store — STATUS ◄

### Authorization

Privilege Class: G

### Purpose

Use STORE STATUS to store selected virtual machine data in certain low storage locations, simulating the hardware store status facility. These locations are permanently assigned locations in guest absolute storage.

The STATUS operand causes the following data to be stored in low storage at the guest absolute addresses shown:

Address		Length	Content
Dec	Hex		
163	A3	1	Architectural-mode id (X'00')
212	D4	4	Extended save area address. See note below.
216	D8	8	CPU timer
224	E0	8	Clock comparator
256	100	8	Current PSW
264	108	4	Prefix register
288	120	64	Access registers 0 through 15
352	160	32	Floating-point registers 0, 2, 4, 6
384	180	64	General registers 0 through 15
448	1C0	64	Control registers 0 through 15

**Note:** The extended save area address is used if it is provided. When the extended save area is available, the virtual machine's floating-point registers 0 through 15 and floating-point control register are stored there.

Address		Length	Content
Dec	Hex		
0163	00A3	1	Architectural-mode id (X'01')
4608	1200	128	Floating-point registers 0 through 15
4736	1280	128	General registers 0 through 15
4864	1300	16	Current PSW
4888	1318	4	Prefix register

Table 44. z/Architecture mode guest (continued)

Address		Length	Content
Dec	Hex		
4892	131C	4	Floating-point control register
4900	1324	4	TOD programmable register
4904	1328	8	CPU timer
4913	1331	7	Clock comparator
4920	1338	8	Breaking-event-address register
4928	1340	64	Access registers 0 through 15
4992	1380	128	Control registers 0 through 15

### Usage Notes

1. The STORE STATUS command stores data in the logout area.
2. The STORE STATUS command stores CPU timer and clock comparator values that may then be displayed on your console through the DISPLAY command. This procedure is one way to get timer information on your display.

### Responses

Response 1:

```
Store complete
```

is issued when the command completes successfully.

## SYNCDMS

### Authorization

Privilege Class: A, B, F

### Purpose

Use the SYNCDMS command to retrieve Miscellaneous Data Records (MDRs) from specified devices. MDRs contain error and usage data from buffered control units or communications controllers. The records are logged in the VM error recording area.

### Operands

#### DASD

will capture all MDRs for all DASDs.

#### TAPE

will capture all MDRs for 3480, 3490, and 3590 tape devices.

#### PRINTER

will capture all MDRs for all 3800 printer devices.

#### ALL

will capture all MDRs for all devices. If no operand is specified, ALL is the default.

### Usage Notes

- Events that trigger automatic retrieval of MDRs usually occur infrequently. Some of these events are:
  - overflow of statistical counters in a buffered control unit
  - DASD volume demounts
  - VARY OFFLINE commands.

The SYNCDMS command lets you retrieve MDR records more frequently.

- SYNCDMS is performed synchronously.
- SYNCDMS does not get data from offline devices.

### Responses

Response 1:

```
COMMAND COMPLETE
```

indicates that the command completed successfully.

### Messages

- HCP026E Operand missing or invalid

## SYSTEM

### Authorization

Privilege Class: G

### Purpose

Use SYSTEM to clear storage and to simulate the actions of RESET, RESTART, and STORE STATUS functions from a real console, as specified in [z/Architecture Principles of Operation](#).

### Operands

#### CLEAR

performs a system-reset-clear function on your virtual machine and places all processors in your configuration in a hard stop.

#### DETACH

detaches storage element 1, if it exists, before performing the system-reset-clear function. If element 1 does not exist, execution proceeds without error. The remaining assigned storage is cleared to zeros.

#### RESET

performs a system-reset-normal function on your virtual machine and places all processors in your virtual machine's configuration in a hard stop.

#### RESTART

simulates the hardware system RESTART function. If the virtual machine is in z/Architecture mode, this stores the current PSW into the quadword at guest real location 288 (120 hex) and loads the quadword from location 416 (1A0 hex) as the new PSW. Otherwise, it stores the current PSW into the doubleword at guest real location 8 and loads the doubleword from location 0 as the new PSW. Pending interruptions remain unaffected.

#### STORE STATUS

stores selected virtual machine data in certain low storage locations of the virtual machine, simulating the hardware store status facility. These locations are permanently assigned locations in guest absolute storage.

### Usage Notes

1. When the SYSTEM CLEAR command or the SYSTEM RESET command is entered from the virtual machine console as the first or only command on a CP command line (that is, while the terminal mode is CP, or CP READ is displayed or the command line begins with #CP), VM attempts to break out of certain wait conditions that might exist. Thus the SYSTEM CLEAR command or the SYSTEM RESET command may be entered to cause breakout of certain virtual machine wait conditions.

The breakout attempt occurs when the SYSTEM CLEAR command or the SYSTEM RESET command is entered, not when the command is processed. Command errors do not prevent the breakout attempt. In some cases, a breakout resets the virtual machine.

2. The RESET function and the CLEAR operands leave the virtual machine in a stopped state.

## SYSTEM

3. To resume operation after issuing the SYSTEM command with RESET specified, either store a PSW and enter BEGIN or enter BEGIN with a hexadecimal storage location specified. When doing either of these, be sure the wait state bit in the PSW is turned off before issuing BEGIN. The virtual machine automatically restarts at the location specified in the new PSW (which is loaded from the doubleword at location 0) after the SYSTEM RESTART command is processed.
4. The SYSTEM CLEAR or SYSTEM RESET command clears a virtual check-stop condition on the virtual processors.
5. The SYSTEM STORE STATUS command stores data in the logout area. It stores CPU timer and clock comparator values that may then be displayed on your display through the DISPLAY command. This procedure is one way to get timer information on your display.
6. You can use the CPU command to cause a restart interruption to occur on the virtual CPU of your choice. For example, "CPU 3 SYSTEM RESTART" generates the interruption on CPU 3.
7. SYSTEM RESTART cannot be used to resume execution on secondary processors that are not operational. In order for a secondary CPU to be started, the virtual machine must be in z/Architecture mode and the guest operating system must support secondary processors.
8. If the virtual storage configuration was defined with reserved or standby storage, then dynamic storage reconfiguration (DSR) is supported. Otherwise, DSR is not supported. If DSR is supported, then virtual storage is comprised of storage element 0 and storage element 1. Element 0 is always attached. You can use the DETACH option with SYSTEM CLEAR to detach storage element 1 before the system-reset-clear function is performed.
9. The SYSTEM RESET and SYSTEM CLEAR commands will fail if issued when VMRELOCATE is in progress.

### Responses

No response is issued by SYSTEM RESTART. The virtual machine resumes execution at the address in the virtual PSW loaded from virtual storage location 0.

Response 1:

```
STORAGE CLEARED - SYSTEM RESET
```

is issued by the SYSTEM CLEAR command.

Response 2:

```
SYSTEM RESET
```

is issued by the SYSTEM RESET command.

Response 3:

```
STORE COMPLETE
```

is issued by the SYSTEM STORE STATUS command.

Response 4:

If you enter the command SYSTEM RESTART, no response is given; the virtual machine resumes execution at the address in the virtual PSW loaded from virtual storage location 0.

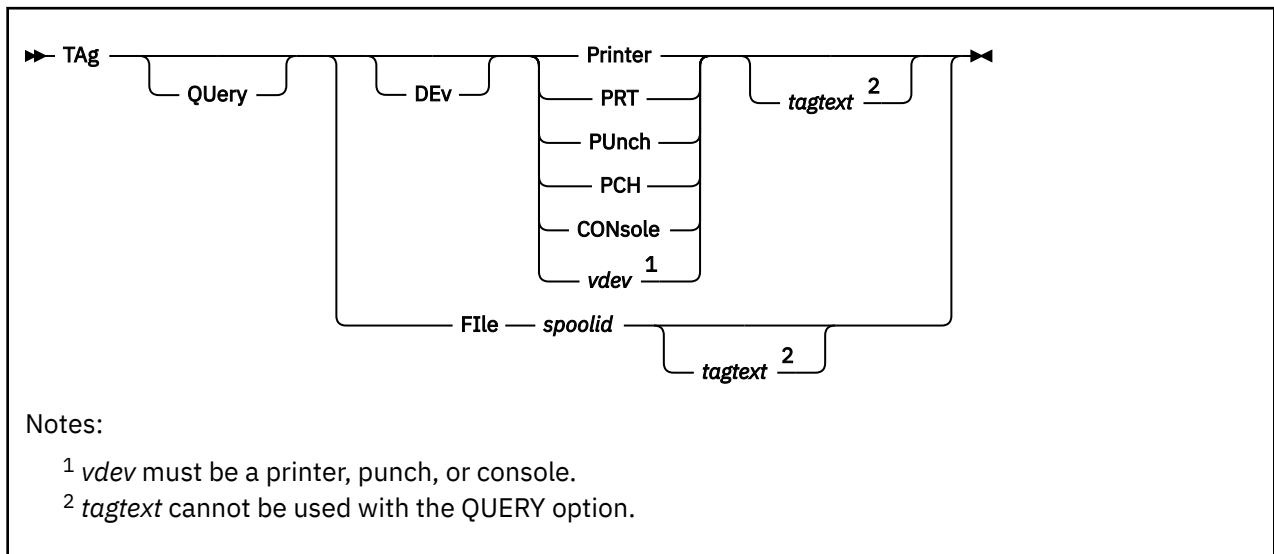

### Messages

- HCP6025E Operand {STATUS|STORE STATUS|RESTART} is invalid because CPU *nn* is in check-stop state.
- HCP6061I APPC wait canceled; virtual machine has been reset.
- HCP6086I Traceid *traceid1* no longer superseded by VMGROUP trace *traceid2*.
- HCP6525E Authorization request failed.

## TAG

## Authorization

Privilege Class: G

## Purpose

Use TAG to associate descriptive information with system spool files or spooled devices.

## Operands

### Q<sup>U</sup>ery

requests the display of the tag information associated with a particular virtual spooled device or spool file.

### D<sup>E</sup>v

specifies that a device is to be tagged or the tag information for a device is to be displayed.

### Printer

#### PRT

#### PUnch

#### PCH

#### CONsole

#### *vdev*

specifies a spooling device whose output is to be assigned the tag information. If you enter a generic device name, such as PRINTER or CONSOLE, all current virtual devices of that type are affected.

### File *spoolid*

indicates a closed spool file that you want to assign tag information. You can use this form of the TAG command only for spool files that are queued on your reader, printer, or punch queues.

The operand *spoolid* is the spool file identifier CP assigns when the spool file is closed.

### *tagtext*

is the information you want to associate with the specified spool device or spool file. The contents and format of this data are flexible; they are the responsibility of the file originator and the end user.

## Usage Notes

1. If you enter the TAG command without *tagtext* information and without the QUERY option, the tag area associated with the device or file is set to all blanks.
2. Even though you have created a spool file, after you spool it to another virtual machine, the other user owns it as soon as the file is closed. If you want to query or change the tag data, you must first reclaim the file by issuing the CHANGE or TRANSFER command.  
**Note:** If an external security manager (ESM) is installed on your system, you may not be authorized to transfer spool files with the CHANGE or TRANSFER command.
3. You may not be authorized to enter the TAG command if an ESM is installed on your system. For additional information, contact your security administrator.
4. The buffer that contains tag information is 136 characters long, including blanks. However, because specific terminals may allow fewer than 136 characters, a user may not be able to type that many characters on the command line.
5. The tag information for a file is updated when the file is opened or closed. If a TAG command for a device is issued after a file has been opened, the tag information is updated when the file is closed. If a file is open during system shutdown or abend, the tag information in the file reflects the tag when the file was opened.
6. It should be noted that in an environment where RACF NODEID protection is implemented, TAG command data is assumed to be NODEID data when audited/controlled by RACF. Because of this, applications such as RSCS that regularly use the TAG command with data other than NODEID information can be adversely affected. In these cases RACF definitions should be adjusted to exclude these user ID's from audit/control.
7. The RSCS control program interprets the tag information as being addressing and control parameters. When you spool a file to the RSCS virtual machine to be transmitted to a remote station, code the *tagtext* operand as follows:

where:

### **locid**

is the node ID (one to eight alphanumeric characters) of the location to which the file is being transmitted. Your system programmer can give you the IDs of remote nodes accessible to your virtual machine.

### **userid**

is the user ID of the virtual machine (a one- to eight-character user identification) where a file is being transmitted. This operand is used by remote stations when they transmit files to a virtual machine in a remote spooling network and want the files sent to a particular virtual machine. You can ignore this operand if you are not specifying a priority. However, if you are specifying a priority, you must code some *userid* operand; it is ignored in a remote spooling network.

### **priority**

is the requested transmission priority, a decimal number between 0 and 99. The highest transmission priority is 0, next highest is 1, and so on. If you wish to specify this operand, you must also specify a *userid* operand.

8. Files that appear in PRINTED status when queried will not be selected for TAG processing.

## Responses

Response 1:

```
type vdev TAG:
tagtext
```

## TAG

displays the tag information associated with a virtual spooling device.

### **type**

is PRT, PUN, or CON.

### **vdev**

is the virtual device number.

### **tagtext**

is the tag information associated with the device. This tag information may be up to 136 characters long.

Response 2:

One of the following appears for the tag information associated with a specified spool file.

```
tagtext
```

```
(TAG BLANK)
```

### **tagtext**

is the tag information associated with the file. This tag information may be up to 136 characters long.

### **(TAG BLANK)**

is displayed when the tag is all blanks.

Response 3:

```
type {vdev } TAG NOT SET
```

displays the tag information associated with a device if:

- You have not specified tag information
- You have explicitly set the tag fields to blanks.

### **type**

is PRT, PUN, or CON.

### **vdev**

is the virtual device number.

## Messages

- HCP003E Invalid option - command contains extra option(s) starting with *option*
- HCP008E Invalid spoolid - *spoolid*
- HCP016E TAG invalid for specified file type
- HCP018E Spoolid missing
- HCP022E A virtual device number was not supplied or it was invalid.
- HCP026E Operand missing or invalid
- HCP035E Device type missing or invalid
- HCP040E Device {*rdev*/*vdev*/*ldev*} does not exist
- HCP413E Command processing cannot complete due to a spool paging error.
- HCP417E *rdev*/*vdev* is not an output spooling device.

# TERMINAL

---

## Purpose

Use the TERMINAL command to control various characteristics of your virtual console.

## Usage Notes

(General for TERMINAL)

1. You can specify more than one function in a single entry of the TERMINAL command. For example, `terminal chardel off linesize 80` specifies two terminal characteristics:
  - The character delete function CHARDEL is set OFF
  - The maximum line length for terminal output LINESIZE is set to 80 characters.
2. If an error occurs during processing of the command, all functions preceding the one with the error are in effect.
3. You cannot use any of the letters A through Z, the numbers 0 through 9, or the bytes X'0E' (shift out) or X'0F' (shift in) as a symbol (*char*) in association with any of the CHARDEL, LINEDEL, LINEND, TABCHAR, or ESCAPE operands.
4. Use the QUERY TERMINAL command to determine the values set for the TERMINAL command functions.
5. CP automatically masks your password on typewriter terminals; however, to maintain compatibility with previous releases, CP accepts the MASK operand of the TERMINAL command as valid.
6. The system operator may specify system defaults for the TERMINAL LINEND, LINEDEL, CHARDEL, TABCHAR, and ESCAPE characters with the Character Defaults statement in the system configuration file. See the [z/VM: CP Planning and Administration](#) manual.
7. The character displayed depends on the code page used by the terminal emulator. The following characters are from code page 037 United States:

Character	Meaning
# X'7B'	SYSLEND LINEND
¢ X'4A'	SYSLDEL LINEDEL
@ X'7C'	SYSLCEL CHARDEL
" X'7F'	SYSLESCP ESCAPE
X'6A'	SYSTAB TABCHAR
[ X'AD'	SYSALDEL LINEDEL

## Messages

- HCP002E Invalid operand - *operand*
- HCP002E Invalid operand - SHIFT IN (X'0F') (double-byte character set only)
- HCP002E Invalid operand - SHIFT OUT (X'0E') (double-byte character set only)
- HCP006E Invalid device type - {*rdev/vdev/ldev*}
- HCP013E Conflicting option - *option*
- HCP026E Operand missing or invalid
- HCP262I The virtual console is not defined or is detached.

## TERMINAL

- HCP2104I DBCS output disabled by {APL|TEXT} ON because VTAM service machine controlling this terminal does not support DBCS and APL|TEXT output.
- HCP6005E Option *option* is not supported by z/VM.

## TERMINAL APL

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL APL to control APL character translation tables.

### Operands

#### OFF

#### ON

If you specify ON, CP uses the translation tables applicable to display stations equipped with the APL hardware feature. If you specify OFF, CP uses the normal terminal translation tables. Unless otherwise specified, APL OFF is in effect.

### Usage Notes

1. If you specify APL ON, TERMINAL TEXT is forced OFF.
2. TERM APL must be specified as OFF to allow a virtual machine to send mixed double-byte character set (DBCS) line mode output to its virtual console.
3. When you log on or reconnect, CP does not use the APL-character translation tables unless you specify the APL option on the LOGON command.
4. If the terminal is connected to VTAM through VSCS and the version of VSCS does not support DBCS, TERMINAL APL ON will cause DBCS output to be disabled. Error message HCPCFT2104I will be issued on the user's terminal screen.
5. For more information, see TERMINAL [“Usage Notes”](#) on page 1917.

## TERMINAL ASCIITBL

---

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL ASCIITBL to select the translation table used by your TTY terminal.

### Operands

**VM1**

**VM2**

specifies the translation table to be used. VM1 specifies the use of the translation table based on the TTY ANSI X3.4 1977 Standard. VM2 specifies the use of the translation table based on the TTY ANSI X3.26 1980 Standard.

### Usage Notes

1. TERMINAL ASCIITBL may be issued only from a TTY device; otherwise an error message is issued.
2. ASCIITBL is set to VM1 when you first log on or reconnect.
3. For more information, see TERMINAL [“Usage Notes” on page 1917](#).

## TERMINAL ATTN

---

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL ATTN to control attention interrupts to ASCII terminal keyboards and printers.

### Operands

#### ON

turns on attention interrupt signaling. When an attention interrupt occurs, CP displays an exclamation point (!).

#### OFF

turns off attention interrupt signaling. When an attention interrupt occurs, CP suppresses the display of the exclamation point and carriage return.

**Note:** OFF is the default for display terminals. ON is the default for ASCII devices.

### Usage Notes

1. TERMINAL ATTN ON controls the signaling of an attention interrupt only on the keyboards and printers or ASCII terminals. It is not valid for display type terminals.
2. ATTN is set ON when you log on or reconnect to an ASCII terminal.
3. For more information, see TERMINAL [“Usage Notes”](#) on page 1917.

## TERMINAL AUTO CR

---

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL AUTO CR to control whether a carriage return is performed following execution of the 3215 CCW X'01' (write without carriage return) to a graphic display operating in line mode.

### Operands

#### ON

#### OFF

controls carriage return. ON specifies that a subsequent line mode write-to-display starts on the line following the data just written. ON is the default.

OFF specifies that a subsequent line mode write-to-display start at the next column following the data just written.

### Usage Notes

1. AUTO CR is set ON when you first log on. Reconnecting does not affect the AUTO CR setting.
2. For more information, see TERMINAL [“Usage Notes”](#) on page 1917.

## TERMINAL BREAKIN

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL BREAKIN to allow the user to control CP break-in while operating in full-screen mode.

### Operands

#### IMMed

specifies that CP can break in on any full-screen reads and full-screen writes that have an inactive keyboard, as well as when the user presses the BRKKEY.

#### GUESTctl

specifies that only high-priority warnings from CP and output initiated during DIAGNOSE X'08' processing (with the exception of the MESSAGE \* command) will break in. Other messages will break in only when the user presses the BRKKEY, or one of the previously mentioned tasks break in.

#### MINimal

specifies that high-priority warnings from CP and messages issued synchronously during DIAGNOSE X'08' processing will break in. Generally, synchronous message processing is required by those command processors that have the potential to generate large volumes of output and are interruptible in line mode by the user pressing the PA1 key. Examples are the DISPLAY storage commands, and many of the QUERY commands such as QUERY NAMES and QUERY DASD.

Other messages will break in only when the user presses the BRKKEY, or one of the previously mentioned tasks break in.

### Usage Notes

1. If you enter TERMINAL BREAKIN with the GUESTCTL option or the MINIMAL option from an SNA/CCS terminal, and the VTAM Service Machine (VSM) controlling that terminal only supports the IMMEDIATE option, then the command is not processed and you receive a message indicating a invalid device type error.
2. BREAKIN is set IMMEDIATE when you first logon. If you change it to GUESTCTL or MINIMAL and reconnect to a local display, then the setting is not changed. If you reconnect to a SNA/CCS display, and the VTAM Service Machine (VSM) controlling that display cannot support the IMMEDIATE option, then BREAKIN is reset to IMMEDIATE and a message is issued to inform you of the change.
3. For more information, see TERMINAL [“Usage Notes”](#) on page 1917.

## TERMINAL BRKKEY

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL BRKKEY to define the key to control CP break-in for full-screen guests.

### Operands

#### **key**

must be one of the following: PA1, PA2, PF*nn*, or CLEAR. PF*nn* can be any PF key on your display station, from PF1 to PF24.

#### **NONE**

specifies that no BRKKEY can be defined.

### Usage Notes

1. The break key is in effect in line mode as well as in full-screen mode.
2. When you first logon, the default key to control break-in by CP for full-screen guests is PA1. However, if you intend to run an operating system in your virtual machine that requires the PA1 key for some other function, you can use this command to define an alternate break key.
3. After you enter this command, the new break key remains in effect for the duration of the session or until you reissue this command during the current session. If you use this command to define a new break key and then, at some point in the session, prefer to use the default break key again, the PA1 option lets you do so.
4. If you use this command to define a key other than PA1 as the break key, CP passes control of the PA1 key to your virtual machine.
5. When NONE is specified, the guest has complete control of the keyboard. If you are in full-screen you can only return to CP mode if the full-screen program provides a way for you or by typing #CP.
6. Entry to the protected application environment disables the BRKKEY. To reenale it within the protected application, enter the TERMINAL BRKKEY command. Upon exit from the protected application, CP restores the break key setting to what it was before entry into the same protected application. If the break key was changed while in the protected application, it remains unchanged when you exit the application.
7. For the BRKKEY option, only PA1 and NONE are supported for SNA/CCS terminals. If you enter TERMINAL BRKKEY with any other options from an SNA/CCS terminal, the command is not processed and you receive a message that indicates an invalid device type error.
8. If you change the break key setting while logged on to a local display, disconnect and reconnect to an SNA/CCS terminal. Your TERMINAL BRKKEY setting is affected in the following way during the reconnection processing:
  - If BRKKEY was previously set to NONE or PA1, it is not changed.
  - Otherwise, BRKKEY is set to PA1 and an informational message is issued to inform you of the change.

9. If a key other than PA1 is defined as the break key, then in line mode both the PA1 and this key will put the user in CP mode.
10. For more information, see TERMINAL [“Usage Notes”](#) on page 1917.

## TERMINAL CHARDEL

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL CHARDEL to define the logical character-delete symbol for your virtual machine.

### Operands

**ON**

**OFF**

*char*

defines your logical character delete function. If you specify ON, the system default symbol becomes your logical character-delete symbol. If you specify OFF, no logical character-delete symbol is used for your virtual machine.

If you specify *char*, that character becomes your logical character-delete symbol. The character you select should be unique and not common to the data stream being entered.

### Usage Notes

1. When you first log on, CHARDEL is set to the system default symbol. The system default symbol is an at sign (@) unless changed in the system configuration file by the system operator. You can override this default by specifying a different setting in your directory entry. Reconnecting does not affect the CHARDEL setting.
2. For more information, see [“Usage Notes” on page 1917](#).

## TERMINAL CNTL

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL CNTL to allow CP or an application program to insert TTY line-control characters into your TTY terminal output.

### Operands

#### SYS

#### USR

determines whether CP or the application is to insert the TTY line-control characters. SYS specifies that CP inserts TTY line-control characters into output directed to a TTY terminal. USR specifies that the application program inserts TTY line-control characters into output directed to a TTY terminal.

### Usage Notes

1. TERMINAL CNTL may be issued from a TTY device only; otherwise, an error message is issued.
2. If you specify USR, both TERMINAL TYPE and TERMINAL PROMPT must be set to TTY. If TYPE and PROMPT are not TTY and you select USR, TYPE and PROMPT are forced to TTY. These options cannot be changed while CNTL is set to USR, or an error message is issued. The setting remains as TTY.
3. TERMINAL CNTL has no effect if an application issuing the CMS WRTERM macro does not specify either the EDIT=NO or EDIT=LONG parameters on the macro.
4. CNTL is set to SYS when you first logon. Reconnecting does not affect the CNTL setting.
5. For more information, see TERMINAL [“Usage Notes” on page 1917](#).

## TERMINAL CONMODE

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL CONMODE to control the console mode of your display.

### Operands

#### 3215

#### 3270

defines the type of virtual I/O support CP provides for your display. If you specify 3215, 3215 CCW processing occurs; if you specify 3270, 3270 CCW processing occurs.

### Usage Notes

1. In order to use this command correctly, you need to be aware of the factors that affect your console mode:
  - a. The CONSOLE statement in your system directory determines the initial console mode of your display.
  - b. You can enter the TERMINAL CONMODE command to change your console mode.
  - c. You can enter the DEFINE CONSOLE command to change your console mode.

In brief, there are two commands you can use to actively change your console mode: TERMINAL CONMODE and DEFINE CONSOLE.
2. In order to change your console mode setting with DEFINE CONSOLE, you must first detach your console with the DETACH command. For various reasons, you may not always want to detach your virtual console. TERMINAL CONMODE lets you change your console mode setting without detaching your console.
3. Certain programs require a console mode that may differ from your usual or default console mode. If you attempt to run such a program with the incorrect console mode, results are unpredictable. In most instances, the program terminates abnormally.

Some programs reset the console mode internally. For instance, CMS requires a console mode of 3215 and sets CONMODE to 3215 when it is IPLed. You may not be aware that the console mode has been changed for you automatically. Problems result if you then start a program that requires the alternate console mode setting.

Therefore, you should remain aware of the significance of the console mode any time that you start a program in your virtual machine.

4. When you define a virtual machine console with a console mode of 3270, the real terminal must be a graphics device. If you enter TERMINAL CONMODE 3270 from an SNA/CCS terminal controlled by a VTAM service machine that does not support CONMODE 3270, the command is not processed and you receive a message indicating a not-valid device-type error. CONMODE 3270 is supported by ACF/VTAM version 3, release 1.1 for VM/SP (VM/VTAM) and later releases.

5. CONMODE 3270 is incompatible with virtual integrated 3270 mode, which is enabled using SYS3270 ON..
6. Use QUERY TERMINAL to determine the console mode.
7. For more information, see TERMINAL [“Usage Notes” on page 1917](#).

## TERMINAL ESCAPE

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL ESCAPE to define the logical escape symbol for your virtual machine.

### Operands

**ON**

**OFF**

*char*

controls logical escape symbol selection. If you specify ON, the default symbol becomes the logical escape character for your virtual machine. If you specify OFF, no logical escape character is allowed for your virtual machine.

If you specify *char*, that character becomes the logical escape character. The character you select should be unique and not common to the data stream you are entering.

### Usage Notes

1. When you first log on, the logical escape symbol is set to the system default symbol. The system default is a double quotation mark (") unless changed in the system configuration file by the system operator. You can override this default by specifying a different setting in your directory entry. Reconnecting does not affect the ESCAPE setting.
2. For more information, see TERMINAL [“Usage Notes”](#) on page 1917.

## TERMINAL HIGHLIGHT

---

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL HIGHLIGHT to highlight command redisplay on the virtual machine console.

### Operands

**ON**

**OFF**

controls command redisplay highlighting. When you specify OFF, user input is displayed at normal intensity. When you specify ON, user input is displayed at high intensity.

### Usage Notes

1. HIGHLIGHT is set to OFF when you first log on. Reconnecting does not affect the HIGHLIGHT setting.
2. The TERMINAL HIGHLIGHT command has no effect on the highlighting options specified on the SCREEN command.
3. For more information, see TERMINAL [“Usage Notes”](#) on page 1917.

## TERMINAL HOLD

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL HOLD to control whether CP displays the HOLDING status when the terminal screen is full and highlighted output appears on the screen.

### Operands

#### ON

tells CP to display the HOLDING status when the terminal screen is full and highlighted output appears on the screen. To have CP display queued output, clear the screen manually by pressing the CLEAR or PA2 key. ON is the initial setting when you log on the system.

#### OFF

tells CP not to display the HOLDING status when the terminal screen is full and highlighted output appears on the screen. You do not have to clear the screen manually. CP still switches the screen status to HOLDING if you enter a null command when the screen is in the MORE . . . state.

### Usage Notes

1. The TERMINAL HOLD command will give you an error message, HCP006E, if you enter it on a TTY device.
2. If you modify the HOLD value to something other than the default value of ON and reconnect to a SNA terminal controlled by a VTAM Service Machine that does not support the TERMINAL HOLD command, message HCP2556I is issued to inform you that the HOLD value has changed back to ON.
3. If you specify a HOLD value of OFF on a SNA terminal controlled by a VTAM Service Machine that does not support the TERMINAL HOLD command, message HCP006E is issued.
4. See [“TERMINAL MORE” on page 1937](#) for information on how to change the number of seconds that elapse between the time when CP:
  - issues the MORE . . . state and sounds the terminal alarm
  - sounds the alarm and clears the screen.

### Messages

- HCP002E Invalid operand - *operand*
- HCP006E Invalid device type - *vdev*
- HCP026E Operand missing or invalid

## TERMINAL LINEDEL

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL LINEDEL to define the logical line-delete symbol for your virtual machine.

### Operands

**ON**

**OFF**

***char***

defines the logical line-delete function. If you specify ON, the system default symbol becomes the logical line-delete symbol for your virtual machine. If you specify OFF, no logical line-delete symbol is allowed for your virtual machine.

If you specify *char*, that character becomes the logical line-delete symbol. The character you select should be unique and not common to the data stream you are entering.

**Note:** For ASCII devices the default symbol is a left bracket ([).

### Usage Notes

1. When you first log on, LINEDEL is set to the system default symbol. The system default symbol is a cent sign (¢) unless changed in the system configuration file by the system operator. You can override this default by specifying a different setting in your directory.
2. If your LINEDEL is the cent sign (¢) and you reconnect to an ASCII device, LINEDEL is changed to the left bracket ([). If your LINEDEL is the left bracket ([) because you were on an ASCII device earlier, LINEDEL is changed back to the cent sign (¢).
3. For more information, see TERMINAL [“Usage Notes”](#) on page 1917.

## TERMINAL LINEND

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL LINEND to define the logical line-end symbol for your virtual machine.

### Operands

**ON**

**OFF**

***char***

controls logical line-end symbol definition. If you specify ON, the system default symbol becomes the logical-line end symbol for your virtual machine. If you specify OFF, no logical line end symbol is allowed for your virtual machine.

If you specify *char*, that character becomes the logical line-end character. The character you select should be unique and not common to the data stream you are entering.

### Usage Notes

1. When you first log on, LINEND is set to the system default symbol. The system default symbol is a pound sign (#) unless changed in the system configuration file by the system operator. You can override the default by specifying a different setting in your directory entry. Reconnecting does not affect the LINEND setting.
2. For more information, see TERMINAL [“Usage Notes”](#) on page 1917.

## TERMINAL LINESIZE

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL LINESIZE to control display screen line length.

### Operands

*nnn*

OFF

controls allowable line length. The value you specify for *nnn* can be any number from one through 255. OFF specifies that the output line length is not to be adjusted by CP; in other words, CP does not split a long output line into two or more shorter ones.

### Usage Notes

1. If TERMINAL APL ON is specified, CP defines an output length of 1760 and assumes that the APL system has inserted the appropriate carriage-control characters into the output data.
2. If LINESIZE is set too small to display one byte of data per line, CP uses the smallest value for LINESIZE that it can in order to display one byte of data per line. For instance, if LINESIZE=2 but the message to be displayed consists of mixed DBCS data, the smallest value needed to display one byte of DBCS data is 4, so this value will display that message.
3. LINESIZE is set to the character width of the terminal when you log on or reconnect.
4. For more information, see TERMINAL [“Usage Notes”](#) on page 1917.

## TERMINAL MODE

---

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL MODE to control the display station attention environment.

### Operands

**CP**

**VM**

controls the attention environment. If you specify CP, one or more attentions force your virtual machine into the CP environment. If you specify VM, one or more attentions are reflected to your virtual machine. VM is the default for all users except the primary system operator.

### Usage Notes

1. This command has meaning only in line mode.
2. For more information, see TERMINAL [“Usage Notes” on page 1917](#).

## TERMINAL MORE

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL MORE to change the number of seconds that elapse between the time when CP issues the MORE . . . state and sounds the terminal alarm and between the time when CP sounds the alarm and clears the screen.

### Operands

#### *mmm*

tells CP the number of seconds that should pass after the MORE . . . status is displayed before CP sounds the terminal alarm. *mmm* must be a number between 0 and 255. When you first log on the system, CP sets *mmm* to 50 seconds.

#### *nnn*

tells CP the number of seconds that should pass after CP sounds the terminal alarm before it clears the screen. *nnn* must be a number between 0 and 255. When you first log on the system, CP sets *nnn* to 10 seconds.

Initial Setting:

50 10

### Usage Notes

1. The TERMINAL MORE command will give you an error message, HCP006E, if you enter it on a TTY device.
2. If you specify MORE values other than 50 10 on a SNA terminal controlled by a VTAM Service Machine that does not support the TERMINAL MORE command, message HCP006E is issued.
3. If you modify the MORE values to something other than the default values of 50 10 and reconnect to a SNA terminal controlled by a VTAM Service Machine that does not support the TERMINAL MORE command, message HCP2555I is issued to inform you that the MORE values have changed back to 50 10.
4. See “TERMINAL HOLD” on page 1932 for information on how to prevent CP from presenting a HOLDING status when the terminal screen fills up and highlighted messages appear on the screen.

### Messages

- HCP002E Invalid operand - *operand*
- HCP006E Invalid device type - *vdev*
- HCP026E Operand missing or invalid

## TERMINAL PRECEDENCE

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL PRECEDENCE to determine how the issuer's virtual console output is delivered when it is eligible for routing to both a secondary user and the local virtual machine through IUCV. Output is eligible for routing to the secondary user when

1. A secondary user is set.
2. The secondary user is logged on.
3. Either the secondary user is connected to a console or has a connection to \*MSG or \*MSGALL.
4. If mandatory access controls are active, the SECLABEL of the secondary user either is equivalent to or dominates that of the primary user.

Output is eligible for routing to the local virtual machine through IUCV when

1. The user has a connection to \*MSGALL, or
2. The user has a connection to \*MSG and the control governing the routing of the class of output being written (SET MSG, SET WNG, SET EMSG, SET IMMSG, SET SMSG, SET CPMCONIO, or SET VMCONIO) is set to IUCV.

### Operands

#### SECuser

#### STARmsg

SECUSER means that output eligible for delivery to both a secondary user and to the local virtual machine via IUCV is delivered to the secondary user. STARMMSG means that such output is delivered to the virtual machine via IUCV.

### Usage Notes

1. If the virtual console output is not eligible for routing as described above then this setting has no effect on how it is delivered.
2. The default setting at LOGON is SECUSER.

## TERMINAL PROMPT

---

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL PROMPT to control the prompting sequence in a TTY device.

### Operands

#### VM

#### TTY

controls cursor position. The VM option causes the cursor to be positioned in column 1 of the input line for a read operation. The TTY option enables the normal TTY prompt sequence of a period in column 1 and the cursor in column 2.

### Usage Notes

1. TERMINAL PROMPT can be issued from a TTY device only; otherwise, an error message is issued.
2. If a user disconnects from the system and then logs on again, the PROMPT options are reset to the system defaults. PROMPT is set to TTY when you first logon or reconnect.
3. For more information, see TERMINAL [“Usage Notes” on page 1917](#).

## TERMINAL SCROLL

---

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL SCROLL to control the number of display screen lines scrolled.

### Operands

*nnn*

**CONT**

controls screen lines scrolled. The option *nnn* specifies the number of lines scrolled up before scrolling stops with an indication of more lines to follow. Pressing the NEW LINE key (character mode) or the SEND key (block mode) causes another cycle of *nnn* lines to be scrolled. For normal frame by frame scrolling, make *nnn* equal to the number of data lines on the screen. The operand CONT specifies continuous scrolling to the end of the output.

### Usage Notes

1. TERMINAL SCROLL can be issued from a TTY device only; otherwise, an error message is issued.
2. SCROLL is set to CONT when you first logon or reconnect.
3. For more information, see TERMINAL [“Usage Notes” on page 1917](#).

## TERMINAL SYS3270

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL SYS3270 to control whether the virtual machine console (3215) emulates an integrated 3270 device.

### Operands

#### **SYS3270**

#### **SYSGRAF**

SYSGRAF is a synonym for SYS3270.

#### **ON**

#### **OFF**

determines if CP provides virtual integrated 3270 support for the console device.

### Usage Notes

1. In order to use this command correctly, you need to be aware of the factors that affect your console mode:
  - a. You can enter the TERMINAL SYS3270 command to control whether your virtual machine console emulates an integrated 3270 device.
  - b. From the virtual machine's perspective, issuing SYS3270 ON has the same effect as opening the Integrated 3270 window on the Hardware Management Console.
  - c. From the virtual machine's perspective, issuing SYS3270 OFF has the same effect as closing the Integrated 3270 window on the Hardware Management Console.
  - d. When you specify SYS3270 ON, the real terminal must be a 3270 device.
  - e. SYS3270 ON is incompatible with 3270 console mode, which is enabled using CONMODE 3270.
  - f. The guest operating system must not use the virtual console as a conventional I/O device, despite the fact that it has a virtual device number and subchannel identifier. The real integrated 3270 device does not have these characteristics, so the guest must behave as though they do not exist. For example, the device may need to be logically varied offline before its mode is changed to SYS3270 ON. Otherwise, device behavior may be unpredictable.
2. Use QUERY TERMINAL to determine if the virtual console is emulating a 3270 device. The response section of the query will display SYS3270 ON or SYS3270 OFF.
3. For more information, see TERMINAL [“Usage Notes” on page 1917](#).

## TERMINAL TABCHAR

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL TABCHAR to define logical tab characters for a display device.

**Note:** QUERY TERMINAL displays the current logical tab character.

### Operands

**ON**

**OFF**

*char*

defines logical tab characters. ON sets the logical tab character to the system default symbol. OFF resets the logical tab character to undefined. The operand *char* defines the logical tab character. It may be any valid specific graphic character—that is, a character other than A through Z or 0 through 9.

### Usage Notes

1. When a not valid character is specified, an error message is issued to the display, and the logical tab character remains unchanged.
2. When you first log on, TABCHAR is set to the system default symbol. The system default symbol is a vertical broken bar (|) unless changed in the system configuration file by the system operator. Reconnecting does not affect the TABCHAR setting.
3. For more information, see TERMINAL [“Usage Notes” on page 1917](#).

## TERMINAL TEXT

---

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL TEXT to control the use of text translation tables.

### Operands

#### ON

#### OFF

If you specify ON, CP uses the translation tables applicable to display terminals equipped with the text hardware features. If you specify OFF, CP uses the normal translation tables. Unless otherwise specified, TEXT OFF is in effect.

### Usage Notes

1. If TEXT is set ON, a previous specification of TERMINAL ON is negated.
2. TEXT must be set OFF to allow the virtual machine to send mixed double-byte character set (DBCS) line mode output to its virtual console.
3. If the terminal is connected to VTAM through VSCS and the version of VSCS does not support DBCS, TERMINAL TEXT ON will cause DBCS output to be disabled. Error message HCP2104I will be issued on the user's terminal screen.
4. For more information, see TERMINAL [“Usage Notes”](#) on page 1917.

## TERMINAL TIMESTAMP

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL TIMEStamp/TIMESTMp to control whether messages and command responses on the virtual machine console are prefixed with the local time of day.

### Operands

**CP**

**ON**

**OFF**

If you specify CP, control program messages and command responses on the console are prefixed with the local time of day. ON causes all virtual machine and CP messages to be identified with time stamps. If you specify OFF, messages are displayed with no prefix.

### Usage Notes

1. Time stamps are not produced for some CP command responses (for example, to QUERY READER ALL) to preserve readability.
2. Messages sent to a secondary user for a primary user with TIMEStamp CP are not prefixed with a time stamp, for compatibility with earlier releases of VM. The time stamp prefix generation that occurs for a secondary user depends on the TIMEStamp settings of both the primary and secondary users. The sources of time stamps are summarized in the table below.

*Table 45. Time Stamp Prefix Sources*

Secondary User TIMEStamp Setting	Primary user TIMEStamp Setting		
	CP	ON	OFF
CP	None	Primary user	None
ON	Secondary user	Both users	Secondary user
OFF	None	Primary user	None

3. The system default is TIMEStamp OFF except for the primary system operator whose TIMEStamp setting is CP.

## TERMINAL TYPE

---

### Authorization

Privilege Class: G

### Purpose

Use TERMINAL TYPE to define a device as a 3101 or a TTY.

### Operands

#### 3101

#### TTY

defines the device.

- When TTY is specified, the terminal is regarded as a typewriter terminal.
- When 3101 is specified, the terminal is regarded as a display screen and keyboard ASCII device. The 3101 operand:
  1. Allows the use of program function keys 1 through 24
  2. Causes output to begin at column 1 of line 24 on the display
  3. Allows editing of previously entered information without requiring that the entire text be rekeyed.

### Usage Notes

1. TERMINAL TYPE can be issued from a TTY device only; otherwise, an error message is issued.
2. The device is defined as a TTY when you first log on or reconnect.
3. For more information, see TERMINAL [“Usage Notes” on page 1917](#).

## TRACE

---

### Authorization

Privilege Class: G

### Purpose

Use the TRACE command to monitor events that occur in your virtual machine. z/VM lets you trace a number of events, including:

- Instruction execution
- Storage alteration
- Register alteration
- I/O activity.

Each traced event results in a *trace entry*, a command response that you can have sent to your virtual console, to a virtual printer, or to both. The trace entry is made up of significant information about the event. You can use trace entries to analyze the operation of your virtual machine and to debug problems.

Note that in this manual the TRACE documentation is primarily for reference.

For a full explanation of *how* to use the trace facility, along with examples, see [Tracing Programs in Your Virtual Machine in z/VM: Virtual Machine Operation](#).

### Usage Notes

(General for TRACE)

1. All of the primary TRACE operands establish *trace traps*. A trace trap is a programming function that, as its name implies, captures information about an event in your virtual machine.

When you establish a trap, you can assign it any unique 1-character to 4-character name (with the exception of the name ALL). If you do not assign a name, the system assigns the trap a unique number from 1 to 9999. You use this unique identifier (name or number) to alter a trap with the TRACE TRAP command or to delete a trap with the TRACE DELETE command.

The options (unique and common) available with each primary operand and with the TRAP operand allow you to specify exactly how you want the trap to process. For example, you may want the trap to function only when an event occurs within a particular address range. In this case, you specify the common option FROM with the address range you choose. At the same time, you may want to trace events only when your virtual machine is running in supervisor state. In this case, you also specify the common option SUPERVISOR.

2. All trace traps must be contained in units of control called sets. A “trace set” is a collection of one or more traps that run together.

You create a set using the TRACE GOTO command. When you create the set, you assign it a unique 1-character to 8-character name. If you do not assign the set a name, the system assigns a unique name for you.

If you do not create a set before you establish a trap, z/VM creates a set for you named INITIAL.

Only one set may be active at any given time.

The following commands exist for manipulating sets:

- TRACE GOTO
- TRACE CALL
- TRACE RETURN
- TRACE CLEAR

- TRACE END
  - TRACE APPEND.
3. You can define up to 255 trace sets and trace traps in any combination during a single trace session. (For example, you can create two trace sets with no more than 253 traps between them, five trace sets with no more than 250 traps between them, or 20 trace sets with no more than 235 traps between them).
  4. If you have RUN set ON, it will be turned off when a trace trap is established in a non-suspended trace set.
  5. For information on how to display your current trace settings, see the QUERY TRACE command. The QUERY TRACE command can be especially useful if you need to know the identifiers the system has assigned to your traps or sets. The command QUERY TRACE ALL displays the attributes of all trace traps within all trace sets.
  6. The IPL command for z/VM suspends all user tracing through the TRACE command during the IPL process. Tracing is then automatically reset as it was and continues normally.
  7. DATOFF is a synonym for NODAT. DATOFF is allowed whenever NODAT is allowed.
  8. Depending on the model, TRACE events for general register alteration may or may not be recognized for vector instructions.
  9. Self-modifying instructions or instructions that change the contents of registers used to compute operand addresses cause erroneous processing of trace output. For this reason, question marks (?) are displayed in the address field instead of erroneous output.
  10. If your virtual machine initiates full-screen I/O operations to your virtual console while CP is displaying trace entries there, the full-screen I/O operations may not complete successfully. This is most likely to occur if TERMINAL CONMODE has been set to 3270.
  11. The TRACE command will fail if issued when VMRELOCATE is in progress.
  12. When z/VM does not provide full trace support for an instruction, the command response will not include operand addresses. See TRACE RESPONSE for more details

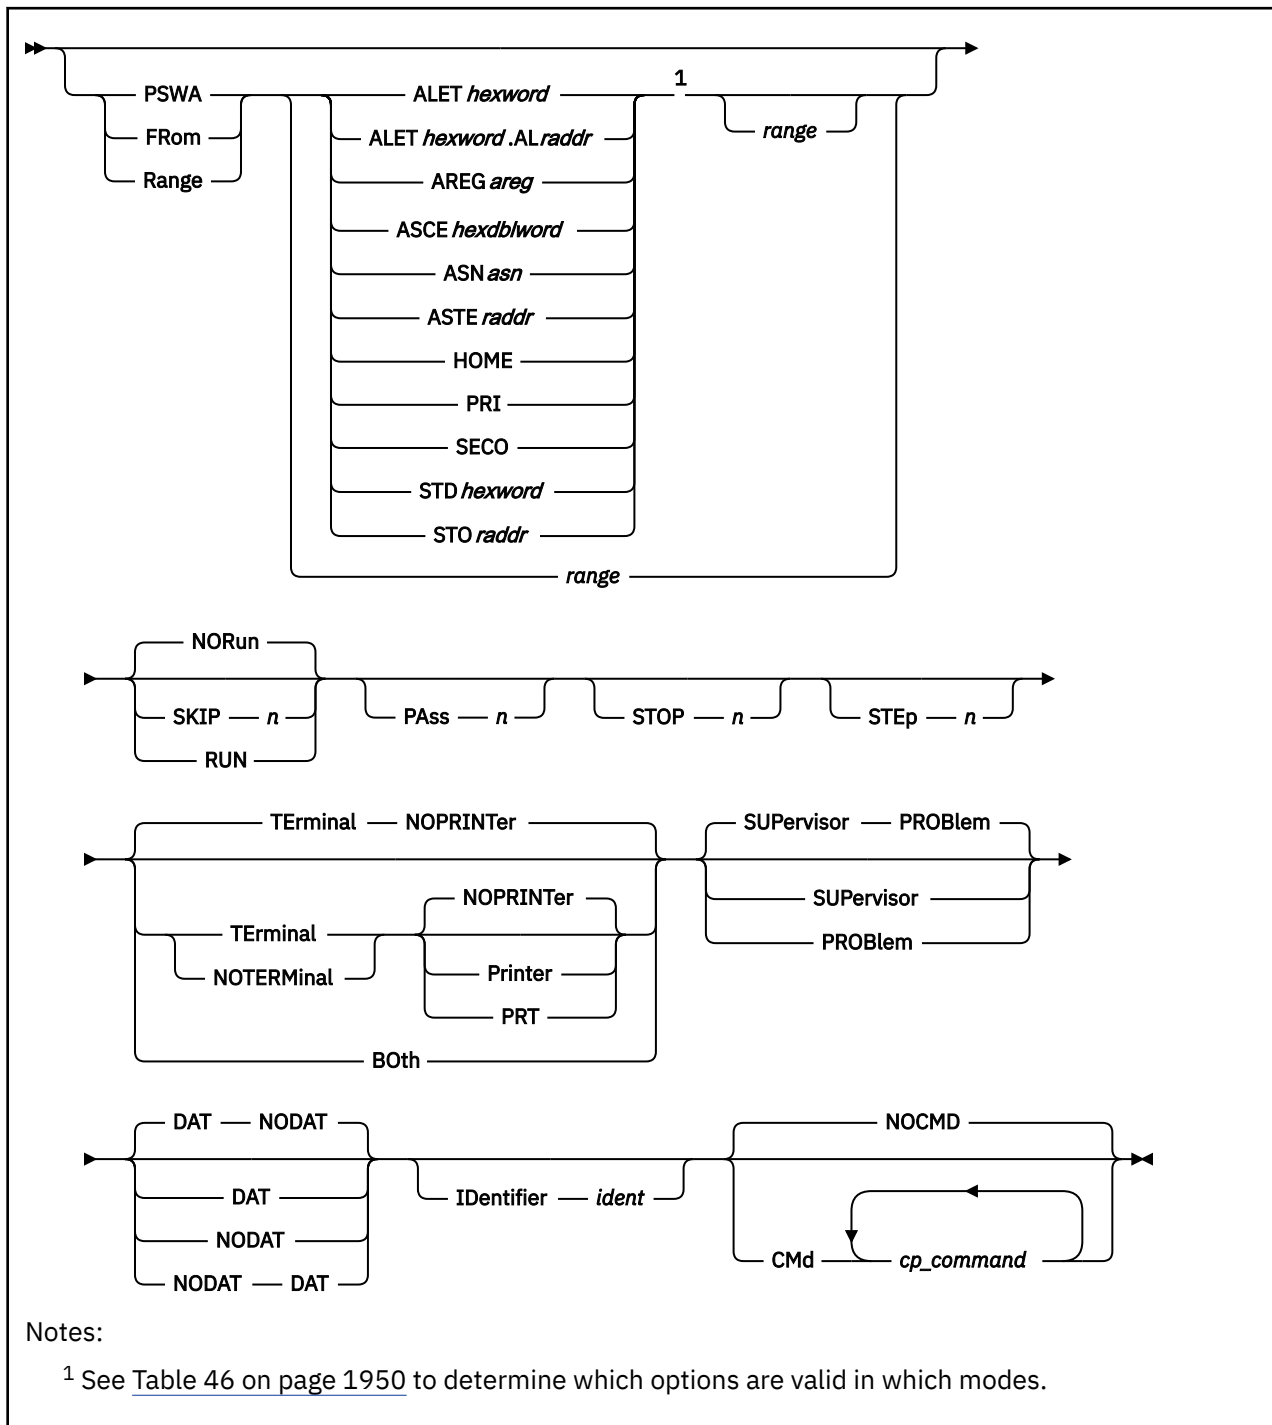

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - *{option|command contains extra option(s) starting with option}*
- HCP009E Invalid range - *range*
- HCP010E Invalid register - *register*
- HCP013E Conflicting option - *option*
- HCP026E Operand missing or invalid
- HCP033E Hexloc missing or invalid
- HCP167E The mask is invalid for the specified data range.
- HCP180E Trace not in effect
- HCP1001E An operand is missing for - *option*
- HCP1005E An invalid character was encountered.
- HCP1025E A recursive trace call cannot be done.
- HCP1026E The trace return cannot be done because there is no matching trace call.
- HCP1027I An active trace set has turned RUN off.
- HCP1032E A syntax error was encountered.
- HCP1035E A trace set cannot be appended to itself.
- HCP1036E *{traceset|The current trace set}* is an empty trace set.
- HCP1037E The command cannot be processed because the maximum number of TRACE traps is already defined.

## TRACE

- HCP1040E TRACE suspended - Incompatible with virtual machine's use of PER instruction-fetching-nullification facility.
- HCP2106I TRACE caused a guest transaction at *tbegin\_address* to be aborted at *abort\_address*
- HCP2107E The virtual machine's use of PER Event Suppression conflicts with TRACE *txsusp*.
- HCP6150E An option has been specified that is not valid in {ESA/390|ESA/XC|z/Architecture|z/XC} mode.
- HCP6151E Storage {operand} is not addressable because of { a protection |an addressing | a segment translation | a page translation | a translation specification | an ASN translation | an AFX translation | an ASX translation | an ALET translation | an ALEN translation | an ALE sequence | an ASTE validity | an ASTE sequence } exception.
- HCP6156E Access register | ALET |ASIT | Address Space Identifier (spaceid) does not designate an address space to which you have the appropriate access.
- HCP6577E Invalid ALET - *alet*
- HCP6578E Invalid {access register|ASIT|address space identifier} - *option*

## TRACE: Options

### Purpose

If you specify any of these options without a primary trace operand, they are applied to all events in the current trace set. If you specify the TRAP operand, these operands are applied to a single event.

### Options

[Table 46 on page 1950](#) shows which TRACE options are valid in which modes.

Option	ESA/390	z/Architecture	ESA/XC, z/XC
ALET	x	x	x
AREG	x	x	x
ASCE	x	x	
ASN	x	x	
ASTE	x	x	
HOME	x	x	
PRI	x	x	x
SECO	x	x	
STD	x		
STO	x		

**PSWA range****FRom range****Range range**

specifying the program status word address (PSWA) restricts instruction tracing to a given address range. It permits a trap to be taken if the PSWA (commonly known as the instruction counter) points to an instruction in the specified range. The range may be a single address, a pair of addresses separated by a hyphen (-), or an address followed by a period (.) followed by a byte count. An instruction is considered to be within the range if the first byte is within the range.

The *FROM* option is not supported for the TRACE AIF command.

The instruction addresses specified for the range cannot exceed FFFFFFFF FFFFFFFF.

FROM and RANGE are synonyms for PSWA used in those subcommands where a potential for confusion exists. For example, TRACE BRANCH allows two instruction ranges to be specified, a FROM range and an INTO range. FROM and RANGE are allowed wherever PSWA is allowed.

For executed instructions (that is, instructions that are issued by means of the assembler language EXECUTE instruction), the instruction is within the range if either:

- The first byte of the EXECUTE instruction is within the range
- The first byte of the target instruction is within the range.

For external interrupts, the PSW address at the time of the interrupt is inspected to see if it is within the range.

When a program event recording (PER) event is reflected to your virtual machine, the PER event address is checked.

For any other program exception, the old PSW instruction address is inspected if a nullification exception occurs; for all others, the old PSW instruction address is adjusted by the instruction length.

**ALETheyword**

indicates that access register translation be used to locate the address space to be traced. The access list entry token (ALET) is used in conjunction with the guest access register translation tables to locate the STO of the address space to be traced.

**ALETheyword.ALraddr**

restricts tracing to events in an address space using the specified access list entry token (ALET) and access list (AL). The ALET and AL are used in conjunction with the guest access register translation tables to locate the STO of the address space to be traced.

**AREGareg**

indicates that access register translation be used to locate the address space to be traced. The access register (*areg*) is specified as one hexadecimal or two decimal digits. The access list entry token (ALET) within the access register is used in conjunction with the guest access register translation tables to locate the STO of the address space to be traced.

**ASCEhexdblword**

indicates that an address space control element (ASCE) be used to locate the address space to be traced.

**ASNasn**

indicates that an address space number (*asn*) be used to locate the address space to be traced. The specified ASN may be one to four hexadecimal digits. The ASN is used in conjunction with guest ASN translation tables to locate the STO of the address space to be traced.

**ASTERaddr**

indicates that an ASN second table entry (ASTE) be used to locate the address space to be traced. The operand *raddr* is the guest real address of the ASTE that contains the segment table origin (STO) of the address space to be traced.

**HOME**

restricts tracing to events in the guest's current home address space as pointed to by the guest control register 13.

**PRI**

restricts tracing to events in the guest's current primary address space as pointed to by the guest control register 1.

**SECO**

restricts tracing to events in the guest's current secondary address space as pointed to by the guest control register 7.

**STDhexword**

indicates that a segment table designation (STD) be used to locate the address space to be traced. The STD contains the segment table origin (STO) of the address space to be traced.

The STD option is not valid in z/Architecture mode.

**STOraddr**

indicates that a segment table origin (STO) be used to locate the address space to be traced. The operand *raddr* is the segment table origin of the address space to be traced and is a guest real address.

The STO option is not valid in z/Architecture mode.

**SKIP n**

requests that the associated event be completely ignored *n* times. When used with the NOSIM option, however, it specifies the number of times that an instruction is simulated normally.

**RUN**

specifies that virtual machine execution is not to pause when the specified event occurs. RUN is assumed if TERMINAL is not specified or assumed. RUN is incompatible with NORUN, STEP, and STOP.

**NORun**

specifies that virtual machine execution is to pause when the specified event occurs. NORUN is assumed if TERMINAL is specified or assumed. NORUN is incompatible with RUN, STEP, and STOP.

**PAss n**

is a repeating SKIP specification. If you do not specify a SKIP option, PASS takes effect immediately. If you do specify a SKIP count, PASS takes effect after the SKIP count expires and the specified event has been recognized.

For example:

- PASS 2 displays every third event
- PASS 8 displays every ninth event
- SKIP 2 PASS 8 displays the third event, the twelfth event, and every ninth event thereafter.

**STOP *n***

requests a number of displays for the command. Your virtual machine pauses after the specified number of displays. Unless a STEP count is specified, a pause occurs for each subsequent display.

**STEp *n***

is a repeating STOP specification. If you do not specify a STOP option, STEP takes effect immediately. If you do specify a STOP count, STEP takes effect after the first pause.

For example:

- STEP 3 pauses every third event
- STEP 9 pauses every ninth event
- STOP 3 STEP 9 pauses after the third and twelfth displays and for every ninth display thereafter.

**TErMinal**

specifies that output for the current command be sent to the virtual console. This is the default setting for newly created tracing specifications with neither terminal nor printer output specifications. TERMINAL and NOTERMINAL are incompatible options.

**NOTERMinAl**

specifies that output for the current command is not to be sent to the virtual console. TERMINAL and NOTERMINAL are incompatible options.

**BOth**

specifies that the output for the current command be sent to the virtual console and to the virtual printer.

**Printer**

specifies that output for the current command be sent to the virtual printer having the lowest virtual device number. PRINTER may be abbreviated to PRT; PRINTER and NOPRINTER are incompatible options.

**NOPRINTEr**

specifies that output for the current command is not to be sent to the virtual printer. NOPRINTER may be abbreviated to NOPRT; PRINTER and NOPRINTER are incompatible options.

**SUPervisor**

requests that the specified tracing be restricted to events occurring while the machine is in supervisor state. If specified in addition to PROBLEM, or if neither SUPERVISOR nor PROBLEM is specified, both problem state and supervisor state events are traced.

**PROBLEM**

requests that the specified tracing be restricted to events occurring while the machine is in problem state. If specified in addition to SUPERVISOR, or if neither SUPERVISOR nor PROBLEM is specified, both problem state and supervisor state events are traced.

**DAT**

requests that the specified tracing be restricted to events occurring while the virtual machine has virtual dynamic address translation enabled. If you specify DAT in addition to NODAT, or if you specify neither DAT nor NODAT, events occurring in both DAT and non-DAT mode are traced.

**NODAT**

requests that the specified tracing be restricted to events occurring while the virtual machine has virtual dynamic address translation disabled. If you specify NODAT in addition to DAT, or if you specify neither DAT nor NODAT, events occurring in both DAT and non-DAT mode are traced.

**IDentifier *ident***

specifies an identifier for a trace trap describing the event. It must be one to four characters long. If a trap already exists with the given identifier, it is replaced by the trap for the newly defined event. If you do not specify an ID, a unique number from 1 to 9999 is assigned as the identifier, with leading zeros removed. You cannot use the word ALL as an identifier. You may specify the IDentifier option only when defining a trace trap, not when modifying one with TRACE TRAP or the TRACE command without a primary trace operand.

**CMd *cp\_command***

specifies a CP command or set of CP commands to be processed when the specified event occurs.

Multiple commands must be separated by line-end characters. Actual line-end characters end the trace command. For example, if the pound sign (#) is your logical line-end character, and if the double quotation mark (") is your logical escape character, **trace svc cmd d 20#d 30** issues a TRACE SVC command that displays location 20, and then issues DISPLAY to display location 30.

The command **trace svc cmd d 20"d 30** issues one TRACE command; it displays locations 20 and 30 whenever an SVC instruction is executed.

You can use this option with TRACE GOTO, TRACE CALL, and TRACE RETURN to allow conditional and unconditional branching and subroutine calls between trace environments.

All characters between the CMD option and the end of the TRACE command line are considered part of the CMD field; thus, it must be the last option on the line. No command syntax verification is made on the set of CP commands to be processed until the specified event occurs. Terminal output from the set of commands is not affected by the TERM or NOTERM specification of the trace event.

### NOCMD

specifies that no CP command be run when the specified event occurs. Use NOCMD to delete CMD fields from existing trace events.

### Usage Notes

1. Guest control register values and translation table contents define the address space structure of the virtual machine. Program execution (and the STORE command) can change that structure over time. The TRACE command operands that specify a guest address space to be traced by a trace trap use the current guest control register and translation table values to determine the segment table origin (STO) of the address space to be traced (at the time the TRACE command is issued). The STO or ASCE is contained in the trace trap and can be examined by use of the QUERY TRACE command—that is, you specify an address space based on the state of your virtual machine at the time the TRACE command is issued.
2. A trace trap generated with a specific address space specification (STO or ASCE) always identifies that address space using the STO or ASCE generated from the control registers, the translation tables, or both. If your program execution changes the control register values and translation table contents to represent a different address space structure, there is *no* change to the trace traps. The trace traps remain in effect with the address space specified at the time of the TRACE command execution.
3. If a guest specifies an address space option from which an ASN can be derived, then trace will trap events in all subspaces which are members of the group identified by the ASN whenever possible.

An ASN can be derived from the following address space options.

- PRI
  - SECO
  - ASN
  - AREG0
  - AREGx, where the ALET in ARx is zero or one
  - ALETn, where n is zero or one
4. For more information, see TRACE [“Usage Notes” on page 1946](#).

## TRACE: Command Responses

---

### Purpose

In this section are illustrated the command responses for each of the TRACE command operands. These response descriptions use the following symbols:

**aaaaaaaa**

**aaaaaaaaaaaaaaaaaaaa**

**aaaaaaaa\_aaaaaaaa**

A storage address, followed by a single quotation mark (') if a primary address space storage address or a double quotation mark (") if a home address space storage address.

For external and I/O interruptions, it is the instruction address at the point of interruption, taken from the corresponding old PSW.

For program interruptions, it is the address of the instruction that encountered the program interruption. More specifically:

- For a PER event (either alone or accompanied by some other program interruption condition), it is the PER event address.
- For a nullifying program interruption not accompanied by a PER event, it is the instruction address in the program old PSW.
- For a suppressing, terminating, or completing program interruption not accompanied by a PER event, it is the instruction address in the program old PSW, minus the instruction length code.<sup>1</sup>

When a program interruption occurs during transactional-execution mode, two addresses are generally reported. First, the instruction at the point of the transaction abort is shown. Then, on the program-interruption (PROG) line, the address at left shows the address of the TBEGIN or TBEGINC instruction of the outermost aborted transaction. In some cases, the location of the abort is not known; the instruction display line is then omitted, and the PROG line shows the instruction address from the program old PSW. This is either the address after the TBEGIN or the address of the TBEGINC.

**tttttttt**

**tttttttt\_tttttttt**

**tttttttttttttttt**

A transfer address, followed by a single quotation mark (') if DAT.<sup>2</sup>

**xxxxxxxx**

An instruction, CSW status, and other such items.

**gggggggg**

A second-level channel command word, CSW status, and other guest output.

**hhhhhhhh**

A first-level channel command word, CSW status, and other such host output.

**oooo**

A first-level CCW offset.

**address1**

The address of operand 1 (for SI and SS formats only).<sup>2</sup>

**address2**

The address of operand 2 (for RX, RS, S, and SS formats only).<sup>2</sup>

<sup>1</sup> The number of hexadecimal digits displayed depends on the virtual machine mode: eight for ESA/390-mode and ESA/XC-mode machines; 16 for z/Architecture-mode and z/XC-mode machines. If SET UNDERSCORE is set on, the 16 digits are separated in the middle with an underscore for easier readability.

<sup>2</sup> The number of hexadecimal digits displayed depends on the guest addressing mode: eight for 24-bit or 31-bit addressing mode; 16 for 64-bit addressing mode.

The operands *address1* and *address2* may be question marks if:

- the address cannot be resolved because the base or index registers used to compute them have been altered by the instruction
- the operand is ignored by the instruction.

***address3/address4/address5***

Addresses of storage alterations.<sup>2</sup>

***content1***

The contents of the R1 field (RRE format only).<sup>1</sup>

***content2***

The contents of the R2 field (RRE format only).<sup>1</sup>

***vvvv***

A virtual device number.

***vsch***

A virtual subchannel number.

***mnem***

The mnemonic for an instruction. This is a 7-character field in which the mnemonic is left-justified.

***code***

An interruption code number in hexadecimal.

***name***

An interruption name (for example, OPERATION, ADDRESSING) which may be combined with TRANSACTION ABORT, PER or PROGRAM EVENT RECORDER.

***CC n***

The condition code number (0, 1, 2, or 3).

**Note:** The condition code will not always be displayed.

***Gnn***

A general register with altered contents.

***ccccccc***

***ccccccccccccccc***

***ccccccc\_cccccc***

The address generated and loaded by a LOAD ADDRESS or LOAD ADDRESS EXTENDED instruction.<sup>2</sup>

***ss***

A status byte.

***FSA=nnnnnnnn***

***FSA=nnnnnnnnnnnnnnnn***

***FSA=nnnnnnnn\_nnnnnnn***

The failing storage address if valid. If it is not valid, nothing is shown.<sup>2</sup>

***zz***

An altered byte of an EXECUTE instruction, formed by inclusive-ORing the low byte of R1 with the second byte of the executed instruction.

***\*\*\****

A prefix indicating virtual machine interruption.

***\*TN***

A prefix indicating a virtual machine program interruption occurred during transactional execution mode. The address that follows is the start of the aborted transaction when the instruction at the point of the abort is also displayed in the preceding line. When the abort point cannot be determined, the interrupting instruction is not shown, and the address that follows \*TN is the instruction address from the program old PSW. This is either the address after the TBEGIN or the address of the TBEGINC.

## TRACE: Command Responses

->

As a prefix indicating transfer of control, this symbol is present at the beginning of a line whenever the displayed instruction does not immediately follow the last instruction displayed. As a suffix for a successful branch instruction, it precedes the address being transferred to.

-

A suffix used on storage operand addresses to indicate that the address being displayed is one byte past the end of the storage altered by the instruction.

>>

An indication of storage alteration, followed by the operand address.

=

A prefix used with LOAD ADDRESS or LOAD ADDRESS EXTENDED to show that the actual data is shown rather than computing the operand address by base and displacement.

### **AR***reg*

An access register with altered contents.

### **SPACE***owner:space\_name*

identifies the owner's user ID and the name of the address space in which the trace event occurred. It is displayed only for XC virtual machines.

### **ASIT***asit*

identifies the address space identification token of the address space in which the trace event occurred. It is displayed only for XC virtual machines.

Basic Instruction Display (when full trace support is provided)

```
aaaaaaaa mnem xxxxxxxx address1 address2 CC n
aaaaaaaa_aaaaaaaa mnem xxxxxxxx address1
                                address2 CC n
```

Basic Instruction Display (when full trace support is not provided)

```
aaaaaaaa mnem xxxxxxxx CC n
```

Executed Instructions

**Note:** If the target of an EXECUTE instruction modifies a register that was also used to address the target instruction, that is, base or index registers, trace output starting with *address1* and continuing to the end of the trace entry will be incorrect.

```
aaaaaaaa EX xxxxxxxx address1 mnem xxxxxxxx address1 address2 CC n
aaaaaaaa_aaaaaaaa EX xxxxxxxx
                                address1 mnem xxxxxxxx address1 address2 CC n
```

Load Address and Load Address Extended (LA or LAE) Instructions

```
aaaaaaaa mnem xxxxxxxx = ccccccc CC n
aaaaaaaa_aaaaaaaa mnem xxxxxxxx = ccccccc CC n
```

RRE Format Instructions using General Registers

```
aaaaaaaa mnem xxxxxxxx content1 content2 CC n
aaaaaaaa_aaaaaaaa mnem xxxxxxxx content1
                                content2 CC n
```

RRE Format Instructions using Floating Point Registers

```
aaaaaaaa mnem xxxxxxxx CC n
```

Perform-Locked-Operation Instructions

```

aaaaaaaa PLO xxxxxxxx >> address1 address2
                        [address3 address4 address5] CC n
aaaaaaaa_aaaaaaaa PLO xxxxxxxx >> address1
                        address2 [address3 address4]
                        [address5] CC n

```

### RI Format Instructions

```

aaaaaaaa mnem xxxxxxxx CC n

```

### Instructions Altering Storage

```

aaaaaaaa mnem xxxxxxxx >> address1 address2 CC n

```

### Successful Branch Instructions (including SVC and LPSW)

```

aaaaaaaa mnem xxxxxxxx -> tttttttt CC n

```

### Instructions Satisfying GPR Alteration Tracing

```

aaaaaaaa mnem xxxxxxxx address1 address2
CC n Gnn=xxxxxxxx
     Gnn=xxxxxxxx     Gnn=xxxxxxxx     Gnn=xxxxxxxx     ...

```

```

aaaaaaaa_aaaaaaaa mnem xxxxxxxx address1 address2
CC n Gnn=xxxxxxxx_xxxxxxx
     Gnn=xxxxxxxx_xxxxxxx     Gnn=xxxxxxxx_xxxxxxx     Gnn=xxxxxxxx_xxxxxxx

```

### Instructions Satisfying Access Register Alteration Tracing

```

aaaaaaaa mnem xxxxxxxx address1 address2
CC n ARareg=xxxxxxxx
     ARareg=xxxxxxxx     ARareg=xxxxxxxx     ARareg=xxxxxxxx     ...

```

```

aaaaaaaa_aaaaaaaa mnem xxxxxxxx address1 address2
CC n ARareg=xxxxxxxx
     ARareg=xxxxxxxx     ARareg=xxxxxxxx     ARareg=xxxxxxxx     ...

```

### External Interruptions

```

*** aaaaaaaaa EXT code -> tttttttt

```

### Program Interruptions

(Instruction displayed where possible)

```

*** aaaaaaaaa PROG code -> tttttttt name

```

### Transactions Aborted by Program Interruptions

(Instruction displayed where possible)

```

*TN aaaaaaaaaaaaaaaaaa PROG code -> tttttttttttttt

```

### Adapter Interruption Facility Interruptions

```

*** aaaaaaaaa ADAPTER INT -> tttttttt ISC x SCH TYPE y

```

where:

aaaaaaaa = I/O Old PSW (where your program was interrupted)

ttttttt = I/O New PSW (the I/O interruption handler)

ISC x = the Interruption Subclass (bits 2–4 of the  
Host Interruption Identification Word)

## TRACE: Command Responses

SCH TYPE *y* = the Subchannel Type (bits 17–19 of the Host Interruption Identification Word)

Virtual Machine Check Interruptions

(Instruction displayed where possible)

```
*** aaaaaaaaa
MCH -> tttttttt type type ...
      (FSA=nnnnnnnn)
```

### **aaaaaaaa**

identifies the address contained in the second word of the old PSW, if valid, of the machine check. If the PSW instruction address is marked not valid, question marks appear in place of the address.

### **tttttttt**

identifies the address contained in the second word of the new PSW for the machine check.

### **type**

identifies one or more of the machine check codes found in [z/Architecture Principles of Operation](#). The major virtual machine check codes are:

### **FSA=nnnnnnnn**

identifies the FAILING STORAGE ADDRESS if valid. If it is not valid, nothing is shown.

Table 47. Machine Check Codes

Number	Code	Machine Check
0	SD	System damage
1	PD	Instruction processing damage
2	SR	System recovery
3	TD	Interval timer damage
4	CD	Timing facility damage
5	ED	External damage
6	Unused	
7	DG	Degradation
8	W	Warning
9	CP	Channel report pending
10	SP	Service processor damage
11	CK	Channel subsystem damage
12	Unused	
13	Unused	
14	B	Backed up

I/O interruptions

```
*** aaaaaaaaa
I/O vvvv -> tttttttt
SCH vsch PARM xxxxxxxx
```

I/O instructions

```
aaaaaaaa SSCH xxxxxxxx address2
CC 0 SCH vsch DEV vvvv
```

```
CPA xxxxxxxx PARM xxxxxxxx
KEY x FPI xx LPM xx
```

SSCH instructions for Transport Mode I/O may also include the following data structures, if valid:

```
TCW +00000 xxxxxxxx xxxxxxxx ...
TCB +00000 xxxxxxxx xxxxxxxx ...
TSB +00000 xxxxxxxx xxxxxxxx ...
TIDAW xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
DATA +00000 xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
```

**CPA**

identifies the channel program address specifying the absolute address of the first channel command word to be processed on the device.

**PARM**

identifies the interruption parameter to be returned with any interruption for the specified channel command words.

**KEY**

identifies the storage protection key to be used.

**FPI**

identifies the format, prefetch, initial status control byte.

**LPM**

identifies the logical path mask.

**TCW**

the Transport Command Word (Transport Mode only).

**TCCB**

the Transport Command Control Block (Transport Mode only).

**TSB**

the Transport Status Block (Transport Mode only).

**TIDAW**

the Transport Indirect Data Address Word (Transport Mode only).

**DATA**

the data associated with a TIDAW (Transport Mode only).

```
aaaaaaaa TSCH xxxxxxxx address2 CC 0 SCH vsch DEV vvvv
CCWA xxxxxxxx DEV STS xx SCH STS xx CNT xxxx
KEY x FPI xx CC x CTLS xxxx
SENSE DATA: xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
              xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx
```

```
aaaaaaaa TSCH xxxxxxxx address2 CC 1 SCH vsch DEV vvvv
KEY x FPI xx CC x CTLS xxxx
```

**CCWA**

identifies the ending channel command word address when I/O is completed.

**DEV STS**

identifies the unit status for the device.

**SCH STS**

identifies the channel status for the subchannel.

**CNT**

identifies the residual CCW count upon I/O completion.

**KEY**

identifies the key used for storage protection.

**FPI**

identifies the format, prefetch, initial status control byte used. It also indicates a no path available condition and a confirmed I/O condition code 0.

## TRACE: Command Responses

### CC x

identifies the condition code for the requested I/O operation.

### CTLS

identifies the function and activity control bytes.

### SENSE DATA

identifies optional concurrent sense data when concurrent sense is enabled and a unit check has occurred.

```
aaaaaaaa TPI xxxxxxxx address2 CC 1  
SCH xxx DEV xxx PARM xxxxxxxx
```

### SCH

identifies the subchannel requesting the interruption.

### DEV

identifies the subchannel device.

### PARM

identifies the interruption parameter supplied by the virtual machine; it is zero if the interruption is unsolicited.

### Instructions/Condition Codes

```
aaaaaaaa mnem xxxxxxxx address2  
CC n SCH vsch DEV vvvv
```

### Executed I/O Instructions

```
aaaaaaaa EX xxxxxxxx aaaaaaaaa mnem xxxxxxxx address2

## TRACE AIF

---

### Authorization

Privilege Class: G

### Purpose

Use TRACE AIF to trace the interruptions generated by the Adapter Interruption Facility.

### Operands

#### *options*

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

The FROM option is not valid for TRACE AIF.

### Responses

For more information, see [“Usage Notes” on page 1946](#).

## TRACE ALL

---

### Authorization

Privilege Class: G

### Purpose

Use TRACE ALL to trace the following:

- All program, external, and I/O interrupts
- All instructions executed.

### Operands

#### *options*

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

### Usage Notes

1. Because ALL encompasses system events in your entire address range, the PSWA option has no function if used with TRACE ALL. If an address range is specified by the PSWA operand, it is ignored.
2. Each TRACE ALL command replaces an active TRACE ALL command.
3. For more information, see TRACE [“Usage Notes” on page 1946](#).

### Responses

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE APPEND

---

```
▶ TRace — APPEND — name ▶
```

### Authorization

Privilege Class: G

### Purpose

Use TRACE APPEND to merge the trace traps from two trace sets into one.

### Operands

#### *name*

specifies the trace set whose traps are to be merged into the current trace set.

### Usage Notes

1. The TRACE APPEND command causes all trace traps from the named trace set to be added to the current trace set.

If a trap exists in both trace sets with the same identifier and the trap was named using the ID option on the TRACE command, the trap in the named set replaces the trap in the current trace set.

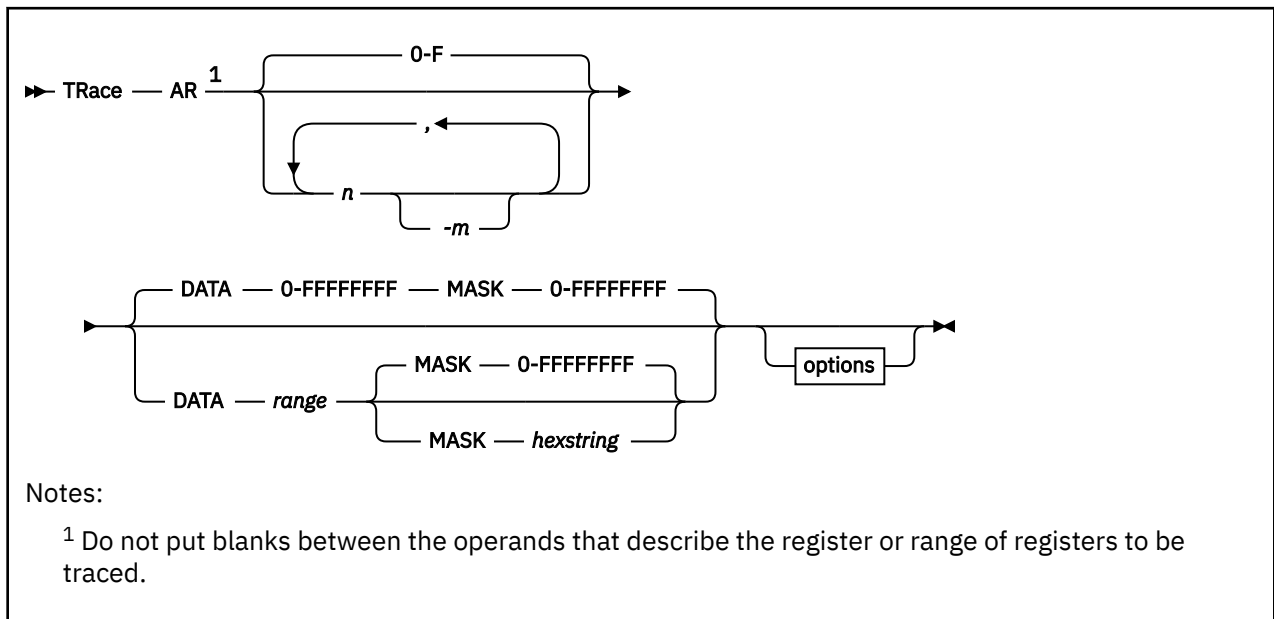

If two traps have the same identifier but were not named with the ID option (for example, the identifier was assigned by the system), both traps remain, and the trap from the named trace set is assigned a new identifier.

2. The current trace set cannot be appended to itself.
3. For more information, see TRACE [“Usage Notes”](#) on page 1946.

### Responses

For response information, see [“TRACE: Command Responses”](#) on page 1954.

## TRACE AR

## Authorization

Privilege Class: G

## Purpose

Use TRACE AR to trace changes to the virtual machine access registers. You can trace all changes, or only those that cause a particular register or set of access registers to assume a specified value.

## Operands

### AR...

is the access register or range of access registers whose alterations you want to trace. If you are specifying a range of access registers, use a hyphen between the first register number and last register number in the range.

### DATA range

specifies a data value or range of data values to be checked to see if any of the changed registers assume a value within the range. The range may be a single value or a pair of values separated by a period (.) or a dash (-). A dash denotes a starting and ending range. A period denotes a starting range for a byte count. Range values are viewed as unsigned 32-bit integers. If no data range is specified for general-register alteration tracing, 0-FFFFFFFF is assumed. Wrap-around data ranges are not allowed.

### MASK string

specifies a hexadecimal string that forms a mask for data comparison. The MASK string is logically applied to both the register and the data range before a comparison is made.

### options

For an explanation of the options, see [“TRACE: Options”](#) on page 1949.

## Usage Notes

1. You may specify the register numbers in either decimal or hexadecimal. Wrap-around ranges (that is, ranges whose ending register is less than the starting register) are permitted. For example: `trace`

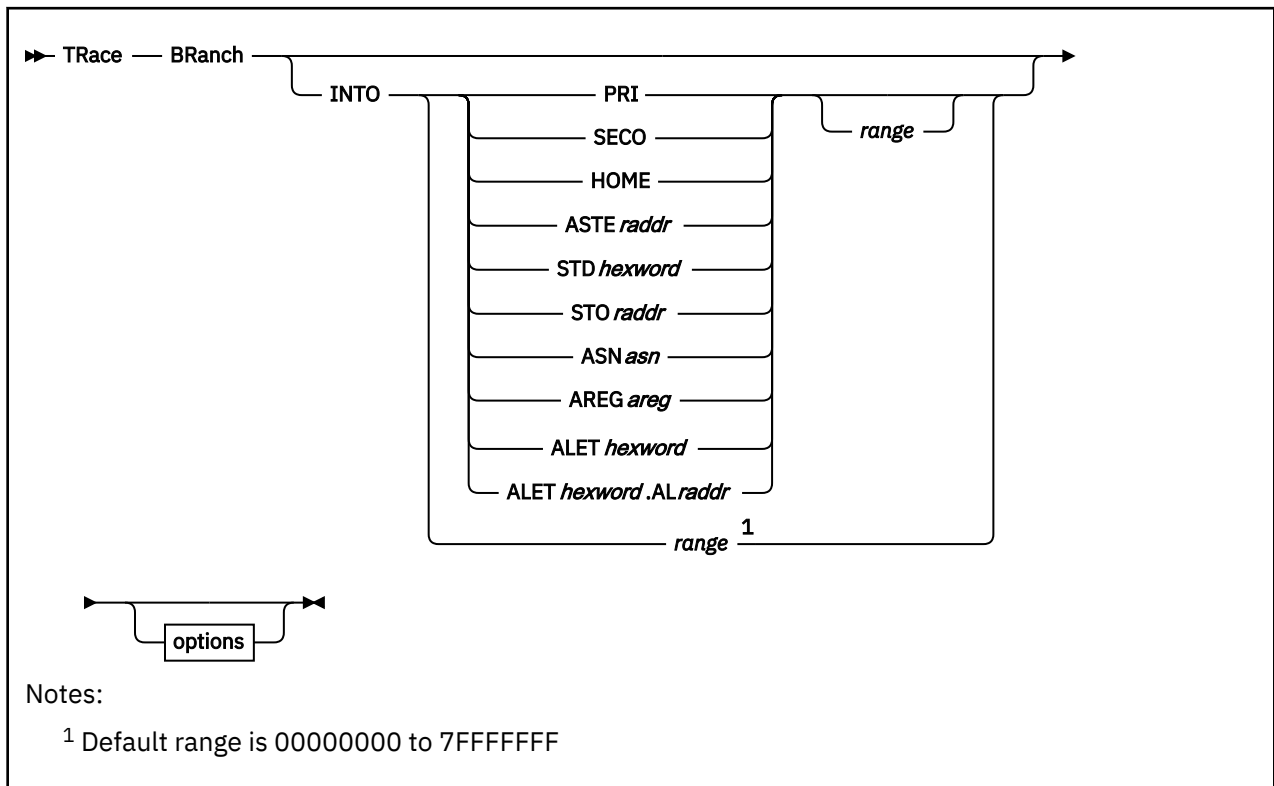

AR10-2 is a valid range; it establishes tracing of alterations to registers 10, 11, 12, 13, 14, 15, 0, 1, and 2.

2. Your virtual machine runs very slowly when you enter the TRACE AR command.
3. For more information, see TRACE [“Usage Notes” on page 1946](#).

## Responses

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE BRANCH

### Authorization

Privilege Class: G

### Purpose

Use TRACE BRANCH to trace successful branch instructions, including load PSW and SVC instructions that do not load a wait PSW.

### Operands

#### PRI

restricts tracing to events in the guest's current primary address space as pointed to by guest control register 1.

#### SECO

restricts tracing to events in the guest's current secondary address space as pointed to by guest control register 7.

#### HOME

restricts tracing to events in the guest's current home address space as pointed to by guest control register 13.

#### ASTE*raddr*

specifies that an ASN second table entry (ASTE) is to be used to locate the address space to be traced. The operand *raddr* is the guest real address of the ASTE that contains the segment table origin (STO) of the address space to be traced.

#### STD*hexword*

specifies that a segment table designation (STD) is to be used to locate the address space to be traced. The STD contains the segment table origin (STO) of the address space to be traced.

**STOraddr**

specifies that a segment table origin (STO) is to be used to locate the address space to be traced. The operand *raddr* is the segment table origin of the address space to be traced and is a guest real address.

**ASNasn**

specifies that an address space number (ASN) is to be used to locate the address space to be traced. The specified ASN may be one to four hexadecimal digits long. The ASN is used in conjunction with guest ASN translation tables to locate the STO of the address space to be traced.

**AREGareg**

specifies that access register translation is to be used to locate the address space to be traced. The access register (*areg*) is specified as one hexadecimal or two decimal digits. The ALET contained within the access register is used in conjunction with the guest access register-translation tables to locate the STO of the address space to be traced.

**ALETheyword**

specifies that access register translation is to be used to locate the address space to be traced. The ALET is used in conjunction with the guest access register-translation tables to locate the STO of the address space to be traced.

**ALETheyword.ALraddr**

restricts tracing to events in an address space using the specified access list entry token (ALET) and access list (AL). The ALET and AL are used in conjunction with the guest access register-translation tables to locate the STO of the address space to be traced.

**INTO range**

permits a trap to be taken if the destination of a successful branch instruction is within the specified range.

You may specify the range as a single address or a pair of addresses separated by a period (.) or a dash (-). A dash denotes a starting and ending range; a period denotes a starting range for a byte count. A branch destination is considered to be within the range if any byte is within the range.

The addresses are real or virtual as determined by the setting of the dynamic address translation (DAT) bit in the PSW at the time the event is detected. For BRANCH tracing, the address or range of addresses can be odd or outside of the address space; the event is detected after the branch instruction, but before any attempt is made to fetch the next instruction.

**options**

For an explanation of options, see [“TRACE: Options” on page 1949](#).

**Usage Notes**

1. Your virtual machine runs very slowly after you enter the TRACE BRANCH instruction.
2. While TRACE BRANCH is active, a record of branch instructions is maintained in the traceback table. You can use the TRACE TABLE command to display the traceback table.
3. Guest control register values and translation table contents define the address space structure of the virtual machine. Program execution (and the STORE command) can change that structure over time. The TRACE command operands that specify a guest address space to be traced by a trace trap use the current guest control register and translation table values to determine the segment table origin (STO) of the address space to be traced (at the time the TRACE command is issued). The STO is contained in the trace trap and can be examined using the QUERY TRACE command—that is, you specify an address space based on the state of your virtual machine at the time of the TRACE command that establishes the trace trap.

A trace trap generated with a specific address space specification (STO) will always identify that address space using the STO generated from the control registers, the translation tables, or both. If your program execution changes the control register values and translation table contents to represent a different address space structure, there is *no* change to the trace traps. The trace traps remain in effect with the address space specified at the time of the TRACE command execution.

## TRACE BRANCH

4. The operands HOME, AREG*areg*, ALE*hexword*, and ALE*hexword*.AL*raddr* are valid only if the virtual machine is an ESA or XA virtual machine.
5. When the operand ALE*hexword*.AL*raddr* is used, the primary list bit in the ALET is ignored. Because this bit will choose between access lists, and the access list has been explicitly specified, its function is ignored.
6. The operands PRI, SECO, HOME, ASTE*raddr*, STD*hexword*, ASN*asn*, AREG*areg*, ALE*hexword*, and ALE*hexword*.AL*raddr* use the access-register-translation (ART), the ASN translation and the dynamic-address-translation (DAT) processes. These contain special case translation processes including the following:
  - ALET 0 always indicates the current primary address space designated by the STD in guest control register 1, regardless of the current contents of the dispatchable unit access list.
  - ALET 1 always indicates the current secondary address space designated by the STD in guest control register 7, regardless of the current contents of the dispatchable unit access list.
  - Access register 0 is always treated as containing ALET 0. The contents of access register 0 are not used during ART processing.
7. A traced address space is identified by its segment table origin (STO). The STD operand is provided for consistency with the DISPLAY, DUMP, and STORE commands. The STO is extracted from the STD provided and all other STD fields are ignored.
8. If an ESA mode guest specifies an address space option from which an ASN can be derived, then trace will trap events in all subspaces which are members of the group identified by the ASN whenever possible.

An ASN can be derived from the following address space options.

- PRI
  - SECO
  - ASN
  - AREG0
  - AREG*x*, where the ALET in AR*x* is zero or one
  - ALET*n*, where *n* is zero or one
9. For more information, see TERMINAL [“Usage Notes” on page 1946](#).

## Responses

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE CLEAR

---

### Authorization

Privilege Class: G

### Purpose

Use TRACE CLEAR to delete all traps in a named trace set.

**Note:** The trace set itself is deleted if it is not active, and if it is not found in the RETURN list constructed by TRACE CALL commands.

### Operands

#### *name*

deletes all traps in the named trace set. If you do not specify a name, the active trace set is cleared.

### Usage Notes

1. For usage information, see TRACE [“Usage Notes”](#) on page 1946.

### Responses

For response information, see [“TRACE: Command Responses”](#) on page 1954.

## TRACE COUNT

---

►► TRace — COunt ◄◄

### Authorization

Privilege Class: G

### Purpose

Use TRACE COUNT to count the successful trace events in your virtual machine.

### Usage Notes

1. The TRACE COUNT function lets you count the number of successful trace events in the current trace set. While TRACE COUNT is active, no other trace output is produced. The virtual machine does not stop after each event, even if you specify NORUN.
2. You can use the TRACE END COUNT command to end TRACE COUNT. However, when you enter any valid TRACE command, the system displays the value of the current count, and TRACE COUNT terminates.

If you enter TRACE COUNT when COUNT is already active, the system displays the current count, and the count resumes from 0.

When the TRACE COUNT reaches 16 million, the system displays that count and resumes from 0.

3. The current COUNT is also included in the QUERY TRACE response.
4. For more information, see TRACE [“Usage Notes”](#) on page 1946.

### Responses

Response 1:

```
Trace count is nnnnnnnn
```

is returned before the display of trace traps if TRACE COUNT is active.

**nnnnnnnn**

represents the successful trace events in the current trace set.

**Note:** For other response information, see [“TRACE: Command Responses”](#) on page 1954.

## TRACE DELETE

---

```
▶▶ TRace — DElete — ident ▶▶
```

### Authorization

Privilege Class: G

### Purpose

Use TRACE DELETE to delete a named trace trap.

### Operands

#### DElete

deletes an event from the current set.

#### *ident*

identifies a trace trap describing the event; it must be one to four characters long. You cannot use the word ALL as an identifier; on the TRACE DELETE command, this option is not valid.

### Usage Notes

1. For more information, see TRACE [“Usage Notes”](#) on page 1946.

### Responses

For response information, see [“TRACE: Command Responses”](#) on page 1954.

## TRACE END

### Authorization

Privilege Class: G

### Purpose

Use TRACE END to delete all trace traps and all trace sets.

**Note:** No return list remains.

### Operands

#### ALL

deletes all trace traps and trace sets. ALL is the default.

#### COUNT

requests the display of the current value of the TRACE COUNT and the termination of TRACE COUNT.

### Usage Notes

1. For usage information, see TRACE [“Usage Notes”](#) on page 1946.

### Responses

Response 1:

```
Trace ended
```

is returned if tracing is in effect when you enter TRACE END ALL. If tracing is not in effect, the system displays no message.

Response 2:

```
Trace count is nnnnnnnn
Trace count ended
```

is returned if TRACE COUNT is active when you enter TRACE END COUNT.

#### **nnnnnnnn**

identifies the number of successful trace events in the current trace set.

**Note:** For other response information, see [“TRACE: Command Responses”](#) on page 1954.

## TRACE EXTERNAL/PROGRAM

### Authorization

Privilege Class: G

### Purpose

Use TRACE EXTERNAL or TRACE PROGRAM to trace external or program interrupts, or a range of external or program interrupts.

**Note:** Where possible, the instruction that caused the program interrupt is displayed also.

### Operands

#### *range*

is a hexadecimal range of external or program interrupts. You can express this range as a single value, a pair of values separated by a hyphen (-) or an address followed by a period (.) and followed by a byte count. Wrap-around ranges are not allowed.

#### *options*

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

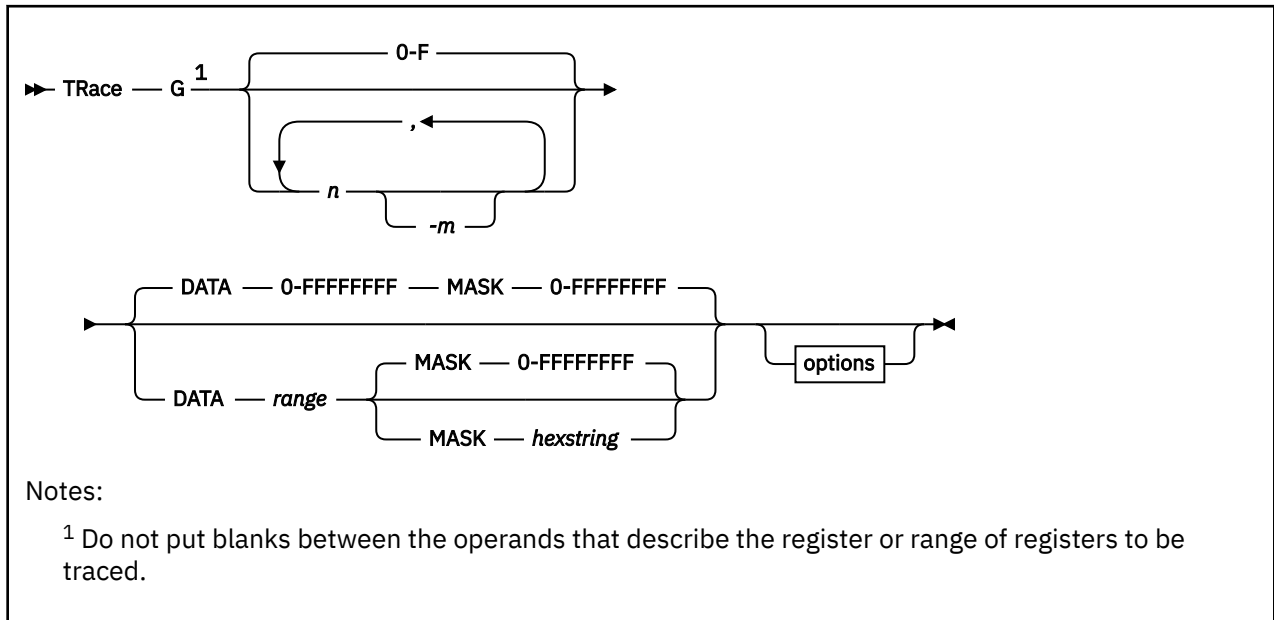

### Usage Notes

1. Because a PER event may occur concurrently with another program interruption, a TRACE PROG trap may hit on either a PER event alone, a PER event with another program interruption, or a program interruption alone. For example: TRACE PROG 80 will trap all PER events, whether or not they have another program interruption occurring concurrently. TRACE PROG 4 will trap all PROG 4 interruptions whether or not they have a PER event occurring concurrently. TRACE PROG 84 will trap a PROG 84 (protection exception with a PER event) only.
2. For additional usage information, see TRACE [“Usage Notes” on page 1946](#).

### Responses

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE G

**Authorization**

Privilege Class: G

**Purpose**

Use TRACE G to trace changes in your virtual machine general purpose registers.

**Note:** You can trace all changes or only those that cause a particular register, or set of registers, to assume a specified value.

**Operands****G...**

identifies the general register or range of general registers whose alterations you want to trace. If you are specifying a range of general purpose registers, use a hyphen between the first register number and last register number in the range.

You may specify the register numbers in either decimal or hexadecimal. Wrap-around ranges (that is, ranges whose ending register is less than the starting register) are permitted. For example, **trace G10-2** is a valid range; it establishes tracing of alterations to registers 10, 11, 12, 13, 14, 15, 0, 1, and 2.

**DATA range**

specifies a data value or range of data values to be checked to see if any of the altered registers assume a value within the range. The range may be a single value or a pair of values separated by a period (.) or a hyphen (-). A hyphen denotes a starting and ending range. A period denotes a starting range for a byte count. Range values are viewed as unsigned 32-bit integers. If no data range is specified for general register alteration tracing, 0-FFFFFFFF is assumed. Wrap-around data ranges are not allowed.

**MASK hexstring**

specifies a hexadecimal string that forms a mask for data comparison. The MASK string is logically applied to both the register and the data range before a comparison is made.

**options**

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

## Usage Notes

1. Your virtual machine runs very slowly after you enter the TRACE G command.
2. For more information, see TRACE [“Usage Notes”](#) on page 1946.

## Responses

For response information, see [“TRACE: Command Responses”](#) on page 1954.

## TRACE GG

### Authorization

Privilege Class: G

### Purpose

Use TRACE GG to trace changes in your virtual machine general purpose registers. TRACE GG is valid in all modes. If the virtual machine is in ESA/390 or ESA/XC mode it will operate on a four-byte register. If it is in z/Architecture or z/XC mode, it will operate on an eight-byte register.

If the data with the mask applied results in a value greater than FFFFFFFF, a TRACE GG trap will never hit unless the guest is in z/Architecture or z/XC mode.

If the DATA and MASK options are not specified, TRACE GG will trap all alterations of a register regardless of the virtual machine mode.

**Note:** You can trace all changes or only those that cause a particular register, or set of registers, to assume a specified value.

### Operands

#### GG...

identifies the general register or range of general registers whose alterations you want to trace. If you are specifying a range of general purpose registers, use a hyphen between the first register number and last register number in the range.

You may specify the register numbers in either decimal or hexadecimal. Wrap-around ranges (that is, ranges whose ending register is less than the starting register) are permitted. For example, `trace GG10-2` is a valid range; it establishes tracing of alterations to registers 10, 11, 12, 13, 14, 15, 0, 1, and 2.

#### DATA range

specifies a data value or range of data values to be checked to see if any of the altered registers assume a value within the range. The range may be a single value or a pair of values separated by a

period (.) or a hyphen (-). A hyphen denotes a starting and ending range. A period denotes a starting range for a byte count.

In ESA/390 or ESA/XC mode, range values are viewed as eight hexadecimal digits. Wrap-around data ranges are not allowed. If no data range is specified for general register alteration tracing, 0-FFFFFFFF is assumed.

In z/Architecture or z/XC mode, range values are viewed as 16 hexadecimal digits. If no data range is specified for general register alteration tracing, 00000000-FFFFFFFF\_FFFFFFFF is assumed. Wrap-around data ranges are not allowed. An optional delimiter (underscore) can be used to separate the two words of a 16 hexadecimal digit input value. If the underscore delimiter is used there must be exactly eight hexadecimal digits to the right of the delimiter. Leading zeroes on the word to the left of the delimiter can be omitted.

**MASK hexstring**

specifies a hexadecimal string that forms a mask for data comparison. The MASK string is logically applied to both the register and the data range before a comparison is made.

In ESA/390 or ESA/XC mode, the mask string is eight hexadecimal digits. The default is FFFFFFFF.

In z/Architecture or z/XC mode, the mask string is 16 hexadecimal digits. The default is FFFFFFFF\_FFFFFFFF.

**options**

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

**Usage Notes**

1. Your virtual machine runs very slowly after you enter the TRACE GG command.
2. For more information, see TRACE [“Usage Notes” on page 1946](#).

**Responses**

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE GOTO/CALL/RETURN

### Authorization

Privilege Class: G

### Purpose

Use TRACE GOTO, TRACE CALL, and TRACE RETURN to activate TRACE sets by name.

### Operands

#### GOTO *name*

causes a trace set by the given name to become active. Specify *name* as a unique 1- to 8-character identifier. If no trace set exists by that name, a new, empty set is created. No program degradation occurs from an empty (null) trace set. The previous trace set is unchanged but no longer active. If empty, it may be deleted automatically.

You can use TRACE GOTO as the first command in a tracing session to establish the name of an initial trace set. If traps are created without issuing a TRACE GOTO, the initial trace set containing them is named INITIAL.

#### CALL *name*

causes a trace set by the given name to become active. If no trace set exists by that name, a new, empty set is created. No program degradation occurs from an empty (null) trace set. The previous trace set is unchanged and is placed in a return list on a last-in, first-out basis.

You can enter the QUERY TRACE RETURNS command to display a list of trace sets currently in the return list; the order is from most to least recent. Recursive calling is not allowed; it is not permitted to call any trace set that has itself called a trace set.

TRACE CALL is designed to be used with TRACE RETURN.

#### RETurn

causes the first trace set on the return list to be removed from the list and become active. The previous trace set is unchanged but no longer active; if empty, the previous trace set is deleted automatically.

#### SUSpend

causes the trace set being loaded to have no effect until the next TRACE GOTO, TRACE CALL, or TRACE RETURN occurs. You can enter TRACE commands to place traps for trace events in the set without affecting the program that is currently in operation. A suspended trace set causes no program degradation.

### Usage Notes

1. You can construct trace sets by coding a program that runs in your virtual machine. The program would retrieve commands from storage and pass them to the control program using DIAGNOSE instructions.

In most cases, the commands are to be applied to a subsequent program that is not yet in operation. You can use the SUSPEND option to ensure that the trace set has no effect until the next TRACE GOTO, TRACE CALL, or TRACE RETURN occurs.

2. For more information, see TRACE [“Usage Notes”](#) on page 1946.

## Responses

For response information, see [“TRACE: Command Responses”](#) on page 1954.

## TRACE INSTRUCTION

### Authorization

Privilege Class: G

### Purpose

Use TRACE INSTRUCTION to trace instructions in your virtual machine, regardless of the success of command execution.

### Operands

#### **DATA *string***

specifies a string of data to be compared against the instruction data.

#### ***options***

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

### Usage Notes

1. If you use TRACE INSTRUCTION in conjunction with the PSWA option, only instructions within the range of the address specified by PSWA are traced.
2. You may use the DATA option to limit tracing to certain instructions or sequences of instructions. For example, `trace instr data 183f` causes the tracing of all LR 3,15 instructions; the command `trace instr data 183f50` traces all LR 3,15 instructions only if they are followed by a STORE (ST) instruction.
3. For more information, see TRACE [“Usage Notes” on page 1946](#).

### Responses

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE I/O

### Authorization

Privilege Class: G

### Purpose

Use the **TRACE I/O** command to control virtual machine tracing of I/O events.

### Operands

#### *range*

identifies a range of devices. The range may be expressed as a single device number or pair of device numbers separated by a hyphen (-), or a starting device number followed by a period (.) and followed by a number representing the number of consecutive device addresses to be traced. Wrap-around ranges are not allowed.

#### **Instruction**

specifies tracing of I/O instructions for a TRACE I/O command. If neither INSTRUCTION nor CCW nor INTERRUPT is specified, INSTRUCTION and INTERRUPT are assumed.

#### **NOCCW**

specifies that CCWs are not to be displayed. NOCCW is assumed if CCW is not specified.

#### **CCW**

specifies that CCWs are to be displayed with RIO, SIO, SIOF, SSCH, and RSCH instructions that successfully start I/O.

#### **IODATA nnnn**

For Command Mode CCWs and Transport Mode structures handled by the Virtual Channel Simulator, IODATA specifies the number of data bytes to be displayed for each CCW. *nnnn* can be a value from 0 - 3800, with a default of 64. If *nnnn* is greater than 64, TRACE I/O will display *nnnn* bytes of data following the CCW and prefixed with a hexadecimal offset:

```
cp trace io 500 inst int ccw iodata 64
... (other SSCH / IO INT trace output) ...
VDEV 0500 CCW 72200080 00E58968 STS 00
      DATA +000 D0010600 F0F0F1F7 F3F2F0F0 F5C9C2D4
      DATA +010 E5D4F0F0 F0F0F0F0 F0F0F0F0 F0F00200
      DATA +020 D0020000 F0F0F1F7 F3F1F0F0 F5C9C2D4
      DATA +030 E5D4F0F0 F0F0F0F0 F0F0F0F0 F0F00200 STS 0C
```

Transport Mode I/O data is displayed in the following format:

```
tr io 6c7 ccw int instr iodata 128
SSCH / IO INT trace output) ...
VDEV 6C7
  TCW +00000 00000000 004E0000 00000000 00000000
  TCW +00010 00000000 00300000 00000000 00010A40
  TCW +00020 00000000 00010800 00000000 0000C000
  TCW +00030 00000000 00000000 00000000 00000000
  TCCB +00000 7F000000 00000054 1FFE0000 00000000
```

## TRACE I/O

```

0000BF80 BYTES NOT DISPLAYED
```

### **SIM**

specifies normal simulation of instructions. If neither SIM nor NOSIM is specified, SIM is assumed.

### **NOSIM**

specifies suppression of instruction simulation. Program interrupts for guest PER events are also suppressed. By using NOSIM and the CMD option, you can define a CP command or set of CP commands to be processed in place of the suppressed instruction. The PSW is left pointing to the next sequential instruction.

### **INTerrupt**

specifies tracing of I/O interrupts for a TRACE I/O command. If neither INSTRUCTION nor CCW nor INTERRUPT is specified, INSTRUCTION and INTERRUPT are assumed.

### **options**

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

### **Usage Notes**

1. For z/VM I/O, the device range applies to the device number, and not the subchannel number.
2. I/O interrupt addresses are not subject to the instruction range (if any) specified by PSWA, FROM, or RANGE.
3. For more information, see TRACE [“Usage Notes” on page 1946](#).

### **Responses**

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE MCH

---

### Authorization

Privilege Class: G

### Purpose

Use TRACE MCH to intercept machine check interrupts.

### Note:

1. Where possible, the instruction that caused the program interrupt will be displayed also.
2. If you enter TRACE MCH and a machine check occurs, the tracing facility saves information from an operation preceding the machine check.

### Operands

#### *options*

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

### Usage Notes

1. For usage information, see TRACE [“Usage Notes” on page 1946](#).

### Responses

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE mnemonic1

### Authorization

Privilege Class: G

### Purpose

Use TRACE *mnemonic1* to trace the execution of specific assembler language instructions.

### Operands

#### *mnemonic1*

must be one of the following standard assembler opcode mnemonics:

BSA	PC	SSK
BSG	PFMF	SSKE
CONCS	PGIN	SSM
CSP	PGOUT	STAP
CSPG	PR	STCPS
DISCS	PT	STCRW
EPSW	PTI	STCTG
ESSA	PTLB	STCTL
IDTE	RCHP	STFL
IPTE	RDD	STFLE
ISK	RDP	STIDC
ISKE	RRB	STIDP
IUCV	RRBE	STSI
LASP	SAL	STNSM
LCTL	SCHM	STOSM
LCTLG	SCK	STPX
LPSW	SERV	TB
LPSWE	SIE	TPROT
LPSWEY	SIGP	WRD
PALB	SPX	

Tracing is limited to those instructions that do not produce an operation or privileged operation exception.

The IUCV operand traces both IUCV and APPC/VM macro functions.

**Note:** For information on the [IUCV Overview](#) see *z/VM: CP Programming Services*.

#### **SIM**

specifies normal simulation of instructions. If neither SIM nor NOSIM is specified, SIM is assumed.

#### **NOSIM**

specifies suppression of instruction simulation. Program interrupts for guest PER events are also suppressed. By using NOSIM and the CMD option, you can define a CP command or set of CP commands to be processed in place of the suppressed instruction. The PSW is left pointing to the next sequential instruction.

You can embed instructions in your assembled code as breakpoints and use TRACE *mnemonic1* to stop execution, or you can use TRACE *mnemonic1* to stop program execution before a questionable instruction is executed. The PSW is left pointing to the next sequential instruction.

**options**

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

**Usage Notes**

1. When you are tracing mnemonics and an instruction causes an operation exception, the instruction is not displayed.
2. For more information, see TRACE [“Usage Notes” on page 1946](#).

**Responses**

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE mnemonic2

### Authorization

Privilege Class: G

### Purpose

Use TRACE *mnemonic2* to trace specific I/O instructions within a device range.

### Operands

#### *mnemonic2*

must be one of the following standard assembler opcode mnemonics:

CLRCH	MSCH	SSCH
CLRIO	RIO	STSCH
CSCH	RSCH	TCH
EQBS	SIGA	TIO
HDV	SIO	TPI
HIO	SIQF	TSCH
HSCH	SQBS	XSCH

Tracing is limited to those instructions that do not produce an operation or privileged operation exception.

#### *range*

is a range of devices. The range may be expressed as:

- a single device number (100)
- a pair of device numbers separated by a hyphen (100-103)
- device number followed by a period and the number of consecutive device addresses to be traced (100.4).

Wrap-around ranges are not allowed.

#### **SIM**

specifies normal simulation of instructions. If neither SIM nor NOSIM is specified, SIM is assumed.

#### **NOSIM**

specifies suppression of instruction simulation. Program interrupts for guest PER events are also suppressed. By using NOSIM and the CMD option, you can define a CP command or set of CP commands to be processed in place of the suppressed instruction. The PSW is left pointing to the next sequential instruction.

#### *options*

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

### Usage Notes

1. For usage information, see TRACE [“Usage Notes” on page 1946](#).

### Responses

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE RIO/RSCH/SIO/SIOF/SSCH

### Authorization

Privilege Class: G

### Purpose

Use TRACE RIO, TRACE RSCH, TRACE SIO, TRACE SIOF, or TRACE SSCH to trace RIO, RSCH, SIO, SIOF, or SSCH instructions for all I/O devices, or for a range of devices.

**Note:** Tracing is limited to those instructions that do not produce an operation or privileged-operation exception.

### Operands

#### *range*

is a hexadecimal range of device numbers.

A range may be expressed as:

- A single device number
- A device number followed by a period, followed by a number that represents the number of consecutive device addresses to be traced
- A pair of device numbers separated by a period (.), or a hyphen (-).

Wrap-around ranges are not allowed.

#### **SIM**

specifies normal simulation of instructions. If neither SIM nor NOSIM is specified, SIM is assumed.

#### **NOSIM**

specifies suppression of instruction simulation. Program interrupts for guest PER events are also suppressed. By using NOSIM and the CMD option, you can define a CP command or set of CP commands to be processed in place of the suppressed instruction. The PSW is left pointing to the next sequential instruction.

#### **NOCCW**

specifies that CCWs are not displayed. If you specify neither CCW or NOCCW, NOCCW is assumed.

#### **CCW**

specifies that CCWs be displayed with the SIO, SIOF, SSCH, RIO, and RSCH instructions that successfully start I/O.

#### *options*

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

### **Usage Notes**

1. RIO, RSCH, SIO, SIOF, and SSCH instructions that cause an operation or privileged operation exception are not displayed.
2. For usage information, see TRACE [“Usage Notes” on page 1946](#).

### **Responses**

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE STORE (ESA/390, z/Architecture)

### Authorization

Privilege Class: G

### Purpose

Use TRACE STORE (ESA/390, z/Architecture) to trace processor alterations made to virtual storage for an ESA/390 or z/Architecture virtual machine. You can trace all alterations, or only those alterations causing a specified set of logical locations to assume a specified value.

There is another version of the TRACE STORE command for ESA/XC and z/XC virtual machines. See [“TRACE STORE \(ESA/XC, z/XC\)”](#) on page 1995.

### Operands

#### INTO

restricts tracing to a specific storage location or range of locations. Unless an address space is specified, changes to storage are traced in all address spaces.

#### PRI

restricts tracing to events in the guest's current primary address space as pointed to by guest control register 1.

#### SECO

restricts tracing to events in the guest's current secondary address space as pointed to by guest control register 7.

**HOME**

restricts tracing to events in the guest's current home address space as pointed to by guest control register 13.

**ASTERaddr**

specifies that an ASN second table entry (ASTE) be used to locate the address space to be traced. The operand *raddr* is the guest real address of the ASTE that contains the segment table origin (STO) of the address space to be traced.

**STDhexword**

specifies that a segment table designation (STD) be used to locate the address space to be traced. The STD contains the segment table origin (STO) of the address space to be traced.

**STOraddr**

specifies that a segment table origin (STO) be used to locate the address space to be traced. The operand *raddr* is the segment table origin of the address space to be traced and is a guest real address.

**ASCEhexdblword**

specifies that the address space control element (ASCE) be used to locate the address space to be traced. The guest must be in z/Architecture mode for INTO ASCE to be valid. The ASCE option must be followed by 16 hexadecimal digits (no underscore allowed). To specify a range after that you need a blank between the ASCE value and the range:

```
TRACE STOR INTO ASCE1234567812345678 0.0007FFFFFF
```

**ASNasn**

specifies that an address space number (ASN) be used to locate the address space to be traced. The specified ASN may be 1 to 4 hexadecimal digits. The ASN is used in conjunction with guest ASN translation tables to locate the STO of the address space to be traced.

**AREGareg**

specifies that access register translation be used to locate the address space to be traced. The access register (*areg*) is specified as 1 hexadecimal or 2 decimal digits. The access list entry token (ALET) within the access register is used in conjunction with the guest access register translation tables to locate the STO of the address space to be traced.

**ALETheyword**

specifies that access register translation be used to locate the address space to be traced. The access list entry token (ALET) is used in conjunction with the guest access register translation tables to locate the STO of the address space to be traced.

**ALETheyword.ALraddr**

restricts tracing to events in an address space using the specified access list entry token (ALET) and access list (AL). The ALET and AL are used in conjunction with the guest access register translation tables to locate the STO of the address space to be traced.

**range**

restricts tracing to changes within the specified range.

The range can be a single address or a pair of addresses separated by a period (.) or a hyphen (-). A hyphen denotes a starting and ending range. A period denotes a starting address and a byte count. A data location is considered to be within the range if the first byte is within the range.

**hexloc**

restrict tracing to a specific location for the conditions set by the DATA and MASK operands. The operand *hexloc* can be any valid address. It cannot be a range of addresses.

**DATA hexstring**

specifies a hexadecimal data string to be matched when a store occurs into the specified *hexloc*. The length of the data string determines the bounds of the test. If the MASK option is also specified, the mask is logically applied to both storage and the DATA string before the comparison is made. The DATA operand requires the INTO *hexloc* operand.

**MASK hexstring**

specifies a hexadecimal string that forms a mask for data comparison when a store occurs in the specified *hexloc*. When you specify the MASK option, the mask is logically applied to both storage and the DATA string before the comparison is made. Only those bits and bytes that are binary ones are checked. The MASK operand requires the INTO *hexloc* operand and the DATA option. The length of the MASK string must be the same as the length of the string you specified for the DATA option.

**options**

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

**Usage Notes**

1. TRACE STORE might not trace storage alterations caused by the following instructions:
  - All DIAGNOSE instructions
  - All cryptographic facility instructions
  - Asynchronous I/O instructions
  - IUCV/VMCF/APPC
  - COMPRESSION CALL (CMPSC)
  - Monitor Call (MC)
  - Perform Frame Management Function (PFMF)
2. If the DATA option is specified, the length of the virtual storage that is monitored for alteration is defined by the length of the DATA string. If this length added to the specified hexloc generates a wraparound address range, the ending address of the storage to be monitored is set to the end of storage as defined by CP's current architecture.
3. Guest control register values and translation table contents define the address space structure of the virtual machine. Program execution (and the STORE command) can change that structure over time. The TRACE command operands that specify a guest address space to be traced by a trace trap use the guest control register and translation table values to determine the segment table origin (STO) of the address space to be traced at the time the TRACE command is issued. The STO is contained in the trace trap and can be examined by use of the QUERY TRACE command—that is, you specify an address space based on the state of your virtual machine at the time of the TRACE command that establishes the trace trap.
 

A trace trap generated with a specific address space specification (STO) always identifies that address space using the STO generated from the control registers and/or translation tables. If your program execution changes the control register values and translation table contents to represent a different address space structure, there is *no* change to the trace traps. The trace traps remain in effect with the address space specified at the time of the TRACE command execution.
4. When the operand *ALEThexword.ALraddr* is used, the primary list bit in the ALET is ignored. This bit chooses between access lists when the access list is not explicitly specified.
5. The operands PRI, SECO, HOME, *ASTERaddr*, *STDhexword*, *ASNasn*, *AREGareg*, *ALEThexword*, and *ALEThexword.ALraddr* use one or more of the access register translation (ART), ASN translation, and dynamic address translation (DAT) processes. These contain special case translation processes:
  - ALET X'00000000' always indicates the current primary address space designated by the STD in guest control register 1, regardless of the current contents of the dispatchable unit access list.
  - ALET 1 always indicates the current secondary address space designated by the STD in guest control register 7, regardless of the current contents of the dispatchable unit access list.
  - Access register 0 is always treated as containing ALET X'00000000'. The contents of access register 0 are not used during ART processing.
6. A traced address space is identified by its segment table origin (STO). The STD operand is provided for consistency with the DISPLAY, DUMP, and STORE commands. The STO is extracted from the STD provided, and all other STD fields are ignored.

7. If a guest specifies an address space option from which an ASN can be derived, then trace will trap events in all subspaces which are members of the group identified by the ASN whenever possible.

An ASN can be derived from the following address space options.

- PRI
- SECO
- ASN
- AREG0
- AREGx, where the ALET in ARx is 0 or 1
- ALETn, where n is 0 or 1

8. For more information, see TRACE [“Usage Notes”](#) on page 1946.

### Responses

For response information, see [“TRACE: Command Responses”](#) on page 1954.

## TRACE STORE (ESA/XC, z/XC)

### Authorization

Privilege Class: G

### Purpose

Use TRACE STORE (ESA/XC, z/XC) to trace processor alterations made to virtual storage for an ESA/XC or z/XC virtual machine. You can trace all alterations, or only those alterations causing a specified set of logical locations to assume a specified value.

There is another version of the TRACE STORE command for ESA/390 and z/Architecture virtual machines. See [“TRACE STORE \(ESA/390, z/Architecture\)”](#) on page 1991.

### Operands

#### INTO

restricts tracing to a specific storage location or range of locations. Unless an address space is specified, changes to storage are traced in all address spaces.

#### ALET*hexword*

specifies that access register translation be used to locate the address space to be traced. The access list entry token (ALET) is used in conjunction with the host-access register translation tables to locate the address space to be traced.

#### AREG*areg*

specifies that access register translation be used to locate the address space to be traced. The access register (*areg*) is specified as one hexadecimal or two decimal digits. The access list entry token within

the access register is used in conjunction with the host-access register translation tables to locate the address space to be traced.

**ASIT***asit*

restricts tracing to events in the address space identified by the address space identification token, *asit*.

**PRI**

restricts tracing to the current primary address space.

**SPACEowner:space\_name**

limits tracing to the address space identified by *owner:space\_name*, where *owner*: specifies the user ID that owns the address space and *space\_name* is the name of the address space—the owner's user ID can be omitted if the owner is the user issuing the command. The space name is a string of alphanumeric and national characters, 1 to 24 characters long.

**range**

limits tracing to changes to at location within the specified range.

The range can be a single address or a pair of addresses separated by a period (.) or a hyphen (-). A hyphen denotes a starting and ending range. A period denotes a starting address and a byte count. A data location is considered to be within the range if the first byte is within the range.

**hexloc**

limits tracing to a specific location for the conditions set by the DATA and MASK operands. The operand *hexloc* can be any valid address. It cannot be a range of addresses.

**DATA hexstring**

specifies a hexadecimal data string to be matched when a store occurs into the specified *hexloc*. The length of the data string determines the bounds of the test. If the MASK option is also specified, the mask is logically applied to both storage and the DATA string before the comparison is made. The DATA operand requires the INTO *hexloc* operand.

**MASK hexstring**

specifies a hexadecimal string that forms a mask for data comparison when a store occurs in the specified *hexloc*. When you specify the MASK option, the mask is logically applied to both storage and the DATA string before the comparison is made. Only those bits and bytes that are binary ones are checked. The MASK operand requires the INTO *hexloc* operand and the DATA option. The length of the MASK string must be the same as the length of the string you specified for the DATA option.

**options**

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

## Usage Notes

1. TRACE STORE might not trace storage alterations caused by the following instructions:
  - All DIAGNOSE instructions
  - All cryptographic facility instructions
  - Asynchronous I/O instructions
  - IUCV/VMCF/APPC
  - COMPRESSION CALL (CMPSC)
  - Monitor Call (MC)
  - Perform Frame Management Function (PFMF)
2. If the DATA option is specified, the length of the virtual storage that is monitored for alteration is defined by the length of the DATA string. If this length added to the specified hexloc generates a wraparound address range, the ending address of the storage to be monitored is set to the end of storage as defined by CP's current architecture.
3. The operands PRI, AREG*areg*, ALET*hexword* use the host-access register translation (ART) process, which includes these special cases:
  - ALET X'00000000' always indicates the current host-primary address space.

- Access register 0 is always treated as containing ALET X'00000000'. The contents of access register 0 are not used during ART processing.
4. TRACE STORE traps that are set for a specific address space while the virtual machine is using the XC architecture do not cause instructions to be traced when the architecture is changed to ESA. In contrast, traps that apply to all address spaces remain effective when the virtual machine architecture is changed and function as though they had been created in the new architecture.
  5. For more information, see TRACE [“Usage Notes”](#) on page 1946.

## **Responses**

For response information, see [“TRACE: Command Responses”](#) on page 1954.

## TRACE SVC/DIAGNOSE/MC

### Authorization

Privilege Class: G

### Purpose

Use TRACE SVC, TRACE DIAGNOSE, and TRACE MC to trace the following:

- Supervisor calls (SVC)
- DIAGNOSE instructions
- Monitor calls (MC).

**Note:** Tracing is limited to those instructions that cannot result in an operation or privileged operation exception.

### Operands

#### *range*

identifies a hexadecimal range of SVC numbers, DIAGNOSE codes, or monitor call codes. A range may be specified as a single number or pair of numbers separated by a period (.) or a hyphen (-). Wrap-around ranges are not allowed.

#### **SIM**

specifies normal simulation of instructions. If neither SIM nor NOSIM is specified, SIM is assumed.

#### **NOSIM**

specifies suppression of instruction simulation. Program interrupts for guest PER events are also suppressed. By using NOSIM and the CMD option, you can define a CP command or set of CP commands to be processed in place of the suppressed instruction. The PSW is left pointing to the next sequential instruction.

#### *options*

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

### Usage Notes

1. SVC, DIAGNOSE, and MC instructions that cause an operation or privileged operation exception are not displayed.
2. TRACE MC will not provide output for the Monitor Call instructions when the enhanced-monitor facility is used and a monitor-event-counting operation is performed.
3. For general usage information for TRACE commands, see TRACE [“Usage Notes” on page 1946](#).

### Responses

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE TABLE

► TRace — TAbLe ◄

### Authorization

Privilege Class: G

### Purpose

Use TRACE TABLE to display the traceback table.

### Usage Notes

1. The traceback table is a list of successful branch instructions that is maintained while branch tracing is active. It contains the most recent branch instructions processed. If the same instruction is processed with no intervening branch instructions, the number of times the instruction was processed will be maintained.

Up to six instructions are maintained in the traceback table. The most recent branch is displayed as the last entry in the table.

The contents of the breaking-event-address register are displayed after the traceback table if the PER-3 facility is available.

2. For more information, see TRACE [“Usage Notes”](#) on page 1946.

### Responses

Response 1:

```
INST-ADDR INST-STO MNEM  OP-OPER   DEST-ADR DEST-STO COUNT
aaaaaaaa ssssssss mnem xxxxxxxxxxxx -> tttttttt ssssssss nn
```

Last Breaking-Event-Address = aaaaaaaaa

is displayed if there is at least one entry in the traceback table and all entries in the table were collected in ESA/390 mode. This may be repeated for up to six entries. The operand *nn* specifies the number of times in a row this branch instruction was processed. This value is not displayed if *n*=1.

The STO fields are filled with blanks when branch instructions are running in the real address mode.

Response 2:

```
INST-ADDR      MNEM  OP-OPER   DEST-ADDR      COUNT
aaaaaaaa_aaaaaa mnem xxxxxxxxxxxx -> tttttttt_tttttttt nnnnnnnnn
ASCE=ssssssssssssssssssss ASCE=ssssssssssssssssssss
```

Last Breaking-Event-Address = aaaaaaaaa\_aaaaaa

is displayed if there is at least one entry in the traceback table and at least one entry in the table was collected in z/Architecture mode. This may be repeated for up to six entries. The operand *nn* specifies the number of times in a row this branch instruction was processed. This value is not displayed if *n*=1.

The STO and ASCE fields are filled with blanks when branch instructions are running in the real address mode.

The response below shows output with two ESA/390 and three z/Architecture table entries:

```
INST-ADDR      MNEM  OP-OPER   DEST-ADDR      COUNT
aaaaaaaa_aaaaaa mnem xxxxxxxxxxxx -> tttttttt_tttttttt nnnnnnnnn
```

## TRACE TABLE

```
STO =ssssssss          STO =ssssssss
aaaaaaaa_aaaaaaaaa mnem xxxxxxxxxxxxxxxx -> tttttttt_tttttttt nnnnnnnnnn
STO =ssssssss          STO =ssssssss
aaaaaaaa_aaaaaaaaa mnem xxxxxxxxxxxxxxxx -> tttttttt_tttttttt nnnnnnnnnn
ASCE=ssssssssssssssss ASCE=ssssssssssssssss
aaaaaaaa_aaaaaaaaa mnem xxxxxxxxxxxxxxxx -> tttttttt_tttttttt nnnnnnnnnn
ASCE=ssssssssssssssss ASCE=ssssssssssssssss
aaaaaaaa_aaaaaaaaa mnem xxxxxxxxxxxxxxxx -> tttttttt_tttttttt nnnnnnnnnn
ASCE=ssssssssssssssss ASCE=ssssssssssssssss
Last Breaking-Event-Address = aaaaaaaaa_aaaaaaaaa
```

Entries collected in z/Architecture mode are formatted with ASCE=ssssssssssssssss; entries collected in ESA/390 mode are formatted with STO=ssssssss.

Whether or not an underscore is used in the address fields depends on the SET UNDERSCORE setting.

Response 3:

```
Traceback table is empty
```

is returned when there are no entries in the traceback table.

## TRACE TPI

### Authorization

Privilege Class: G

### Purpose

Use TRACE TPI to trace test pending interruption instructions.

**Note:** TRACE TPI is accepted if your virtual machine is an ESA or XC virtual machine; tracing is limited to those instructions that do not produce an operation or privileged-operation exception.

### Operands

#### *range*

is a range of device numbers. If you specify a device range, only those TPI instructions that store an interruption is traced. If you do not specify a range, all TPI instructions are traced. The device range applies to the device name, and not the subchannel address.

The range may be a single device number, a device number followed by a period and followed by a number that represents the number of consecutive device addresses to be traced, or pair of device numbers separated by a period (.) or a hyphen (-). Wrap-around ranges are not allowed.

NOSIM and a device range are not compatible options.

#### **SIM**

specifies normal simulation of instructions. If neither SIM nor NOSIM is specified, SIM is assumed.

#### **NOSIM**

specifies suppression of instruction simulation. Program interrupts for guest PER events are also suppressed. By using NOSIM and the CMD option, you can define a CP command or set of CP commands to be processed in place of the suppressed instruction. The PSW is left pointing to the next sequential instruction.

This operand is not valid when TPI specifies a device range.

#### *options*

For an explanation of the options, see [“TRACE: Options” on page 1949](#).

### Usage Notes

1. For usage information, see TRACE [“Usage Notes” on page 1946](#).

### Responses

For response information, see [“TRACE: Command Responses” on page 1954](#).

## TRACE TRAP

### Authorization

Privilege Class: G

### Purpose

Use TRACE TRAP to alter a named trace trap.

### Operands

#### TRAP

applies the options you specify to a single event.

All primary TRACE operands establish units of control called traps. Each trap, except for TRACE ALL, is assigned a unique identifier and has its own set of options, such as TERM, PRINT, RUN, and STEP.

TRACE ALL creates a unique set of traps replacing any active TRACE ALL command. These traps each have an identifier of "ALL," which may be used for changing trace options or deleting the trap. For those traps for which SIM and NOSIM are valid options, you can specify SIM or NOSIM with TRAP.

Any valid option you may specify with the TRAP operand you may specify without any primary TRACE operand. Not specifying a primary TRACE operand has the same effect as a TRACE TRAP command processed for each event in the current trace set.

#### *ident*

identifies a trace trap describing the event; it must be one to four characters long. If a trap already exists with the given identifier, it is replaced by the trap for the newly defined event. You cannot use the word ALL as an identifier; on the TRACE TRAP command, this option is not valid.

#### *options*

except for ID, you can specify any of the options. For a full explanation of the options, see ["TRACE: Options" on page 1949](#).

### Usage Notes

1. Note that you cannot specify the ID option with TRACE TRAP to change the identifier of an existing trap. In order to change the identifier, you must redefine the trap.
2. With the exception of SIM and NOSIM, you can use TRACE TRAP to modify *only* those options listed here. To change unique options not listed here, you must redefine the trap. However, you can use TRACE TRAP to modify the SIM and NOSIM on any trap for which they are valid options.
3. For more information, see TRACE ["Usage Notes" on page 1946](#).

### Responses

For response information, see ["TRACE: Command Responses" on page 1954](#).

## TRACE TXSUSPEND/NOTXSUSPEND

### Authorization

Privilege Class: G

### Purpose

Use TRACE TXSUSPEND and TRACE NOTXSUSPEND to suppress (or to not suppress) trace events during transactional execution.

### Operands

#### TXSUSPend

marks the active trace set so that tracing will be suspended while the virtual CPU is in transactional-execution mode. This allows guest transactions to complete without interference from TRACE. TRACE does not recognize, report or act on any events that occur within a transaction.

#### NOTXSUSPend

marks the active trace set so that tracing will remain active during transactional execution. This ensures that such events will not occur unreported. However, this setting can cause transactions to be persistently aborted. See [“Usage Notes” on page 2003](#).

### Usage Notes

1. TXSUSPEND and NOTXSUSPEND apply per trace set but can only be altered for the active trace set. The initial setting when a trace set is created is NOTXSUSPEND. This setting affects trace traps of types INSTRUCTION, STORE, BRANCH, G, GG, and AR.
2. Trace traps of type INSTRUCTION, STORE, BRANCH, G, GG or AR can interfere with transactional execution (for example, with using the TBEGIN instruction) in the virtual machine. If these traps cause an event to be recognized in transactional-execution mode, then the transaction is aborted, message HCP2106I is displayed and the virtual machine is placed in CP READ.

This interference can occur even for events that do not match the criteria specified in the trace traps. For example, address ranges specified on multiple traps can be merged, resulting in recognition of events in the gaps. Likewise, tracing register alterations triggers an event after every instruction, to determine whether the specified registers have changed.

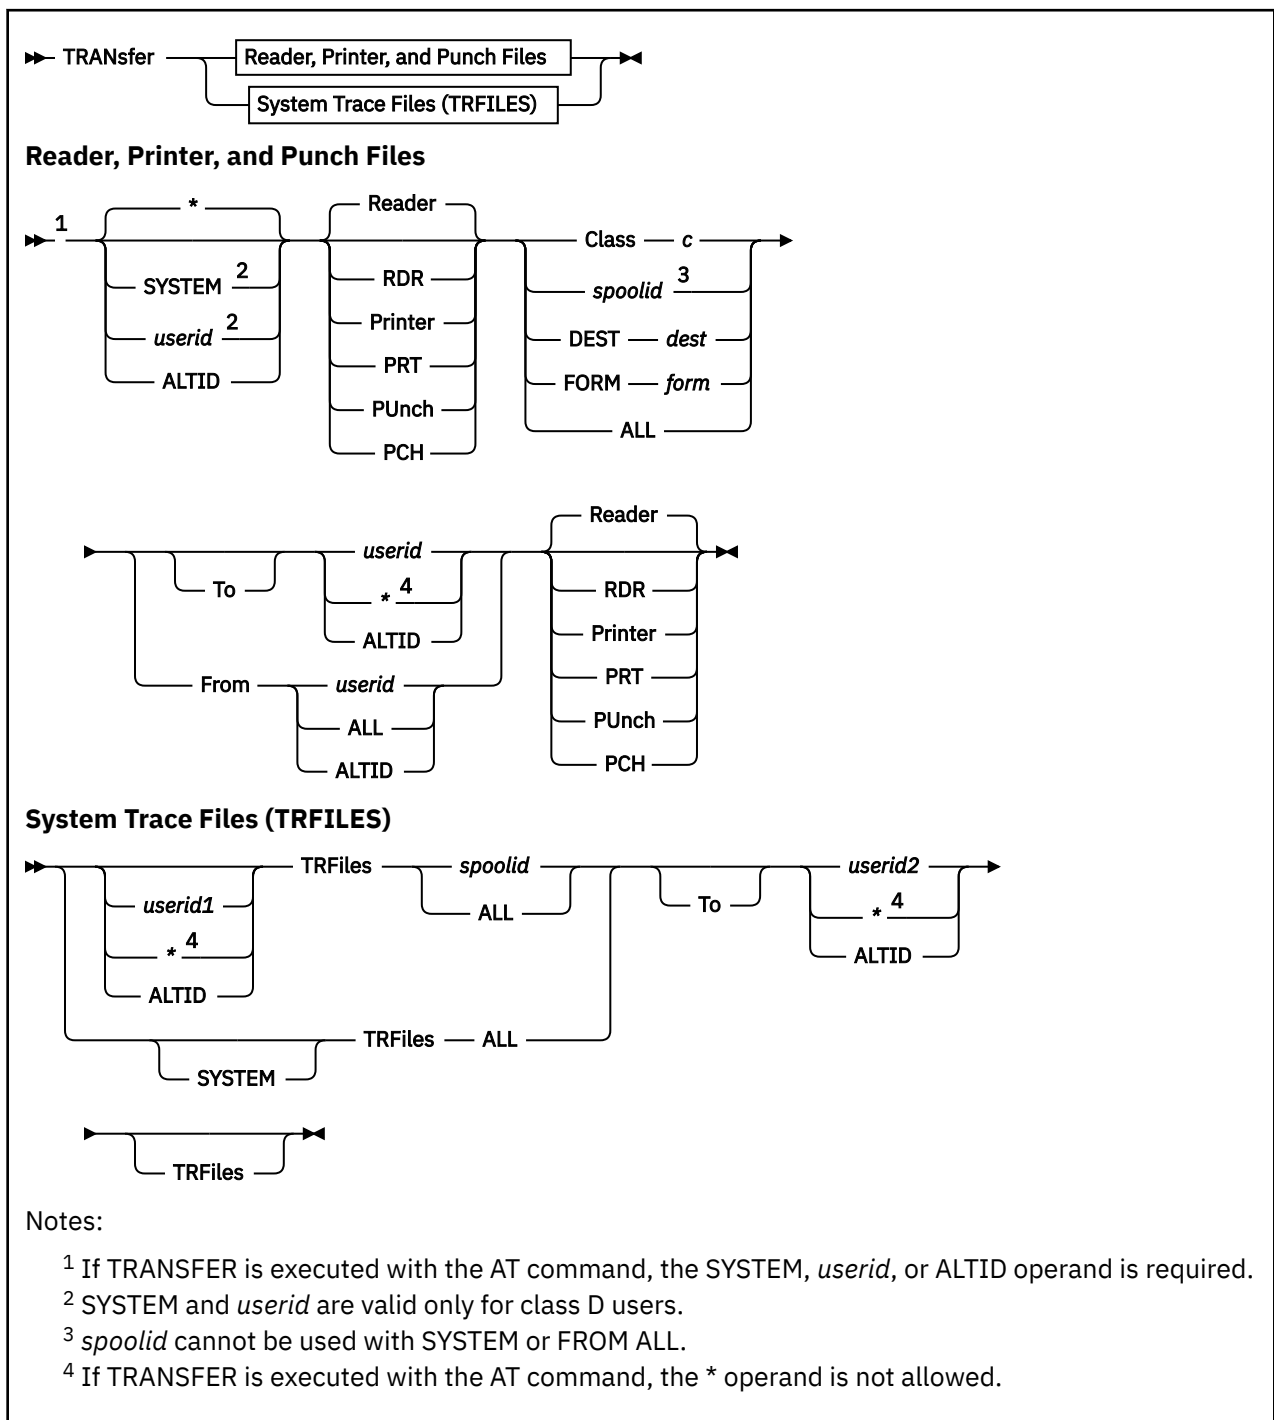

Without additional intervention following the HCP2106I message, the virtual machine will next run from the transaction abort instruction address. This might result in the transaction being retried and a perpetual cycle of trace events to occur causing the transaction to abort. The user has the option to suppress trace events whenever the virtual machine is running in transactional execution mode by issuing TRACE TXSUSPEND.

3. TRACE (NO)TXSUSPEND uses the Program Event Recording (PER) event-suppression control in the machine. If the guest program is also using PER, the TRACE setting for this control must agree with the guest's use. Otherwise, message HCP2107E is generated, and the virtual machine can not be resumed until the conflict is resolved, for example by changing the TXSUSPEND setting or switching to a null trace set.
4. For more information, see TRACE [“Usage Notes” on page 1946](#).

**Responses**

For response information, see [“TRACE: Command Responses”](#) on page 1954.

# TRANSFER

## Authorization

Privilege Class: D, G

## Purpose

## TRANSFER

Use TRANSFER to send files to, or retrieve them from, the reader, printer, or punch queue of another user. The TRANSFER command may also be used to send system trace files (TRFILES) to another user's TRFILE queue.

Class G users can manipulate files that they originate or own on their primary or alternate user IDs. Class D users can transfer any spool files in the system, regardless of ownership or origin.

If you do not specify any of the options (SYSTEM, *userid*, or asterisk [\*]), the default (\*) is to transfer or reclaim your own spool files.

**Attention:** You should not attempt to use this command to transfer a store-and-forward file away from RSCS and then back to it. The file might be lost.

### Operands

#### SYSTEM

allows the Class D user to manipulate all spool files in the system, regardless of their ownership. This is not allowed with the *spoolid* option.

#### *userid*

\*

#### ALTID

identifies the user whose spool files are to be transferred or reclaimed. If you are manipulating your own files, you may specify *userid* as an asterisk (\*). This is the default. You may specify ALTID to manipulate files owned by your alternate user ID.

The *userid* option allows the Class D user to manipulate files belonging to any user on the system. Class G users can use the *userid* option to manipulate files that they currently own or have originated.

#### Reader

#### RDR

#### Printer

#### PRT

#### PUnch

#### PCH

specifies the queues to which CP transfers files and from which files are reclaimed. READER is the default.

#### Class *c*

is the class of spool files you wish to transfer. The operand *c* is a 1-character alphanumeric field with values from A to Z and from 0 to 9.

#### FORM *form*

selects spool files with the specified form for transferring. For the Class G user, the *form* is a 1- to 8-character form name. For the Class D user, *form* is a form name when you specify asterisk (\*) or default to your user ID. Otherwise, *form* is the operator form number.

#### DEST *dest*

selects spool files with the specified destination for transferring. The field *dest* is a 1- to 8-character name.

#### ALL

specifies a transfer of all files in a reader/printer/punch queue.

#### *spoolid*

identifies the file that you want to transfer or reclaim. This operand is not valid with the SYSTEM or FROM ALL keywords.

#### TRFiles

specifies that the spool file is coming from or going to the system trace file queue.

## Options

### TO *userid*

### TO \*

### TO ALTID

identifies the user to whom you want to transfer the files. If you omit the optional keyword TO, *userid* cannot be TO or T. You can use an asterisk (\*) to denote your own user ID. ALTID indicates that you want to transfer files to your alternate user ID.

### FROM *userid*

### FROM ALL

### FROM ALTID

identifies the user from whom you want to reclaim spool files of the specified reader, printer, or punch queue. You can specify ALL to reclaim all files that you originally created and transferred to the reader/printer/punch queues of other users. You can specify ALTID to get files that belong to your alternate user ID.

## Usage Notes

1. SET IMSG OFF suppresses informational messages for this command.
2. You cannot use the TRANSFER command to transfer any active spool files.
3. If the NORETURN option is specified when the file is created by DIAGNOSE X'94', the originator of the file cannot retrieve that file from the current owner. If you try, you receive the following message:

```
FILE NOT TRANSFERRED;
FILE CREATED WITH THE NORETURN OPTION
```

4. When a file changes ownership, as when it is changed to or from another user, the spool file ID number also changes. The new number is obtained from the pool of available IDs of the recipient of the file. Thus, if user BINGLE changes file number 3 to user BOGUS, BINGLE gets the response:

```
RDR FILE 0003 SENT TO BOGUS RDR AS 0018
RECS 1000 COPY 001 A NOHOLD NOKEEP
```

BOGUS now has a file number 18.

5. If a converted file (a file that has been preprocessed by the print server) is transferred to a new user, the old file descriptor is kept. A new file is created for the new owner, but the old file descriptor remains until the print server acknowledges that the old file is no longer wanted.
6. If DEST is not specified on a command that can select files by DEST, the destination value of the file is ignored.
7. System trace files (TRFILES) may only be transferred from one user's TRFILES queue to another user's TRFILES queue. Only system trace files may be transferred to a TRFILES queue.
8. System trace files (TRFILES) cannot be retrieved from another user with the FROM option of the TRANSFER command. To retrieve TRFILES, either the new file owner or a Class D user must use the TO option of the TRANSFER command.
9. If an external security manager is installed on your system, you may not be authorized to enter this command. For additional information, contact your security administrator.
10. In an SSI cluster, no files are transferred if all of the following conditions are true:
  - The command issuer is defined as a multiconfiguration virtual machine.
  - The file being transferred is a copy of a file that was created on another member of the SSI cluster.
  - The command issuer is the user to whom the file is being transferred.

## Examples

```
transfer 0123 to usera
```

## TRANSFER

transfers the spool file with spoolid 0123 from your reader queue to the reader queue of USERA. Note that the file is in the reader queue, which is the default. If you want to transfer a printer or punch file, you must specify the device type in the command line.

```
transfer prt 0123 to usera
```

transfers the spool file with spoolid 0123 from your print queue to the reader queue of USERA.

```
transfer prt all to * rdr
```

transfers all the spool files on your print queue to your reader queue. Note that you do not need to specify the default, RDR.

```
transfer rdr class b to * pch
```

transfers all the Class B files on your reader queue to your own punch queue.

```
transfer prt all from all rdr
```

reclaims all spool files that you sent to the printer queues of other users and places them on your reader queue.

## Responses

Response 1:

Both the current and the previous owners of the file receive the following response when the previous owner issues a TRANSFER command with the TO option. It is also the response that the previous owner of the file receives if the previous owner issues a TRANSFER command with the FROM option.

**Note:** In the response sent to the user ID receiving the file, *spd1* and *spd2* will be in the reverse order of that shown in the following response.

```
{RDR} FILE spd1 SENT {TO } userid {RDR} {AS } spd2 RECS {nnnn}  
{PRT}                {FROM}      {PRT} {WAS}      {nnnK}  
{PUN}                {PUN}      {PUN}      {nnnM}
```

Continued:

```
CPY [*] nnn c {HOLD } {KEEP }  
              {NOHOLD} {NOKEEP}
```

or, for system trace files (TRFILES):

```
TRF FILE spd1 SENT {TO } userid TRF AS spd2 RECS nnnn  
                  {FROM}      nnnK  
                          nnnM
```

### RDR PRT PUN TRF

(first occurrence). If you are transferring a file to another user's virtual machine, this field indicates the queue in which the file originated. If you are receiving a file from another user, this field indicates the file queue from which the file has been added.

### **spd1**

identifies the file at the time the command is issued.

### **TO userid**

identifies the new file owner.

### **FROM userid**

identifies the previous file owner.

**RDR**  
**PRT**  
**PUN**  
**TRF**

(second occurrence). If you are transferring a file to another user's virtual machine, this field indicates the queue to which the file has been added. If you are receiving a file from another user, this field indicates the file queue in which the file originated.

**spd2**

identifies the file when the command is completed.

**RECS *nnnn***

**RECS *nnnK***

**RECS *nnnM***

identifies the number of logical records in the spool file. If the number is greater than 9999, the number is shown as *nnnK*, where K represents the number of lines rounded to the nearest 1000 records. If the number is greater than 999499, the number is shown as *nnnM*, where M represents the number of lines rounded to the nearest million.

**CPY [\*] *nnn***

is the remaining number of copies of the file to be produced. The asterisk (\*) is for the CP-driven 3800 printer and allows the printer to copy each page *nnn* times before going on to the next page.

**c**

is a 1 character alphanumeric field representing the class with a value from A to Z and from 0 to 9.

**HOLD**

**NOHOLD**

is the user HOLD status associated with the file.

**KEEP**

**NOKEEP**

is the KEEP status associated with the file.

Response 2:

You receive the following response when a converted file is transferred to a new owner, or to the reader or punch queue. CP assigns a new *spoolid* to the file and marks it as unconverted.

```
SPOOLID spd1 HAS BEEN CHANGED TO spd2
```

**spd1**

identifies the file before it is transferred.

**spd2**

identifies the file after it is transferred.

Response 3:

```
{nnnnnnn} FILE(S) TRANSFERRED
{          NO}
```

identifies the number of files transferred. NO indicates that there are no files matching the characteristics (such as CLASS and FORM) specified on the TRANSFER command.

# TRSAVE

## Authorization

Privilege Class: A, C

## Purpose

Use TRSAVE to specify where the following data is to be saved:

- CP trace table data
- Data from traces defined by TRSOURCE.

**Note:** CP trace table data may be saved in system trace files (TRFILEs) or on tape. Data from traces defined by TRSOURCE may be saved only in system trace files.

For more information, see [“QUERY TRFILES” on page 1231](#) and [z/VM: Diagnosis Guide](#).

## Operands

### ID *traceid*

indicates that this TRSAVE applies to data generated by *traceid*, which was defined by the TRSOURCE command.

### CP ON

indicates that the recording of CP trace table data should begin.

### CP OFF

stops CP system trace table data recording. Any remaining buffers of data are written to the output medium. Either a tape mark is written, or the DASD file is closed, depending on the output medium. Tapes are rewound and unloaded.

### CP CANCEL

stops CP system trace table data recording. Any pending I/O is canceled. Any data collected, but not written, is lost. When tape is the output medium, a tape mark is written, and the tape is rewound and unloaded, regardless of the previous tape positioning option.

### DEFERIO

indicates that no trace data is to be recorded on DASD or TAPE until the *traceid* is disabled or, for CP trace table recording, until TRSAVE CP OFF is issued. Until that time, when all in-storage buffers are filled tracing wraps to the oldest buffer. DEFERIO is not valid for TYPE GT BLOCK mode traces.

### FRAMES *nnnnn*

specifies the number of real storage frames to be used for the in-storage-wrap buffers. The default is 512 frames. The minimum is 8 frames. The maximum is 99999 frames per trace, but may be further limited by the number of pageable pages in the system dynamic paging area that are eligible for DEFERIO traces. See usage note [“17” on page 2014](#) for usage notes regarding DEFERIO and FRAMES.

### DASD

indicates that trace data is to be recorded in system trace files. DASD is the default.

### TO *userid*

\*

The operand *userid* specifies the user ID to receive the system trace file containing the trace data.

The operand asterisk (\*) specifies that the user who issues the command should receive the system trace file containing the trace data. The operand asterisk (\*) is the default.

### NAME *fname*

specifies the file name to be assigned to the system trace file. For CP system trace table data, CPTRACE is the default name. For trace data generated by traces defined by the TRSOURCE command, the trace ID is the default name.

### SIZE *nnnn*

indicates the maximum size of the system trace files. The operand *nnnn* is a decimal number that specifies 4 KB pages of trace data. Once the file reaches the limit, it is closed and a new file is opened when the next trace record is received. The default is 256 pages. The minimum is eight pages. The maximum is 9999 pages.

### KEEP *n*

specifies the total number of trace files to be kept on DASD for this recording function. The default is two files. The maximum is nine files.

### TAPE

indicates that trace data is to be recorded on tape. This option is valid only for recording CP system trace tables.

### *rdev1* [*rdev2*]

indicates that the CP trace table data captured by this trace should be recorded on the tape drive at the specified device number. Either one or two tape drives can be specified on any tape option. These tape drives must be system drives and must not be attached to any users.

If two tape drives are specified, CP automatically switches to the alternate tape drive when it encounters an end-of-tape mark.

### MODE mode

selects the recording format in which data will be written on the tape. On 3422 tape devices, you can specify the recording format (the MODE) only at the beginning of a tape volume. No changes in the format can be made after this initial designation. On 3480, 3490 (including 3490Es), and 3590 tape devices, you can change the recording format (the MODE) each time you choose to write to a tape volume. After you write to a volume, the MODE value returns to the default value for that particular tape device. If you wish to write to the tape in a different recording format next time, you must again specify the MODE value.

The table below specifies the valid and default mode option values for supported tape devices:

Device Type	Valid Device-Dependent (MODE mode) Option Values	Valid Device-Independent (MODE nnnn) Option Values	Device (MODE mode) Default Value
3422	1600, 6250	n/a	1600
3480	38K	n/a	38K
3480 w/IDRC	XF, 38K	COMP	38K
3490	3490C	COMP	3490C
3590	n/a	COMP	COMP

To determine which device to use, attach the tape device to your *userid* and issue the 'Q V TAPE' command. Then detach the tape device.

### RUN

specifies that the tape is rewound and unloaded when it fills. This is the default.

### REWIND

specifies that the tape is rewound but not unloaded when it fills. Recording continues to either the other tape drive devoted to CP tracing or the tape drive on which the tape was just filled.

## Usage Notes

1. The destinations for trace data are not saved across system hard abends. Therefore, the destination for the trace data should be saved in EXECs.
2. The parameter TAPE and tape options can only be used on TRSAVE FOR CP commands.
3. TRSAVE FOR ID *traceid* cannot be issued when *traceid* has been enabled using the TRSOURCE command.
4. The optional destination parameters, TO, NAME, SIZE, and KEEP for DASD, and MODE, RUN, REWIND for TAPE may be specified in any order.
5. For TRSAVE FOR ID *traceid*, the specified parameters remain in effect until the trace ID is dropped or they are changed on a subsequent TRSAVE command. For example, if you enter the command `trsave id debug keep 5 size 9`, and then enter `trsave id debug size 20`, the *traceid* DEBUG has TRSAVE options *traceid* recorded to system trace files with a file name of DEBUG, a size of 20 pages, a keep maximum of five files, and a receiver of your user ID.
6. The use of two tape drives is recommended to minimize loss of data. With one tape drive, data may be lost while you rewind and reset for the next tape. If two tape drives are used, both tape drives must support the specified MODE.

The use of the REWIND option is also recommended. If the REWIND option is not used, a full tape is rewound and unloaded. If one tape drive is used without the REWIND option, data may be lost until the operator mounts another tape. Even if two tape drives are used, data may be lost on heavily loaded systems when the second tape drive becomes full if the operator has not yet:

- Mounted another tape on the first tape drive
  - Completed the operation intervention on the first drive.
7. Table 48 on page 2014 shows the default file names for system trace files and their file types. The file names may be changed with the NAME *fname* option.

Table 48. Default File Names and File Types for System Trace Files

Source of Trace	File Name	File Type
CP system trace data	CPTRACE	CP
TRSOURCE ID <i>traceid</i> TYPE DATA	<i>traceid</i>	DATA
TRSOURCE ID <i>traceid</i> TYPE IO	<i>traceid</i>	IO
TRSOURCE ID <i>traceid</i> TYPE GT FOR USER	<i>traceid</i>	VM
TRSOURCE ID <i>traceid</i> TYPE GT FOR VMGROUP	<i>traceid</i>	VMG

8. When a trace is active, the files associated with it have a class of W. After tracing is complete, the associated files have a class of A.
9. On stressed systems, the trace table may wrap before all entries are saved. In this case, a special trace entry is made to denote data loss.
10. TRSAVE CANCEL immediately terminates the TRSAVE function. Any I/O that is pending is canceled, and any information that has been merged and not written is lost. To ensure that all information collected has been written, use the OFF option on the TRSAVE command.
11. TRSAVE ON is valid only when TRSAVE is not currently active. Likewise, TRSAVE OFF is valid only when TRSAVE is currently active. You may use TRSAVE CANCEL while TRSAVE OFF is in process (for example, when the tape is in a state that requires intervention), but it terminates any I/O that is currently pending.
12. The system attempts to write a tape mark at the end of the data on tape when OFF and CANCEL processing is completed. This attempt may fail because of irrecoverable I/O errors on the tape, but you may still process the tape using the TRACERED utility.
13. KEEP and SIZE may be used together to manage the system spool space. They limit the total amount of space available to record trace data for this trace request. CP limits the amount of data in each file, according to the SIZE specified. By designating a number of files to be kept, TRSAVE allows CP to purge the oldest trace file, keeping the most recent data and continuing to trace when the allowable space limit is reached.
14. Each time a trace becomes active, the trace data is recorded in another file or set of files. For example, if you enter the following commands, you can generate up to six files:

```
trsave for cp dasd keep 3
trsave off
trsave for cp dasd keep 3
trsave off
```

15. For 3490 tape devices, models A01, A02, B02, B04, D31, and D32 should be treated as type 3480 devices. All other 3490 device models should be treated as type 3490 devices. For a complete breakdown of 3480 and 3490 device types by model number, see [Defining I/O Devices in z/VM: CP Planning and Administration](#).
16. If an external security manager is installed on your system, you may not be authorized to enter the TRSAVE command with the TO operand. For additional information, contact your security administrator.
17. Usage notes regarding DEFERIO
- a. The frames are allocated from the system's dynamic paging area when the traceid is enabled or, for CP trace table data, when TRSAVE CP ON DEFERIO FRAMES *nnnnn* is issued. System performance could be impacted because of the frames not being available for system dynamic paging.

- b. A certain amount of the pageable (non-fixed) pages in the system dynamic paging area are eligible to be allocated for DEFERIO traces. That amount is a percentage (75%) of the total amount of pageable pages in the system dynamic paging area.

A disabled DEFERIO traceid could have the entire amount of eligible pages in the system dynamic paging area specified regardless of the amount of frames specified for other DEFERIO traces. In order to enable the traceid however, no more than the entire amount of eligible pageable pages in the system dynamic paging area can be allocated for the sum of all active DEFERIO traces.

If an attempt is made to enable a DEFERIO traceid that could result in more than the eligible amount of pageable pages in the system dynamic paging area being allocated to active DEFERIO traces, then that TRSOURCE ENABLE command would fail.

Use QUERY TRSAVE FRAMES command to determine how many frames have been allocated from the system dynamic paging area for active DEFERIO traces and to determine how many pageable pages in the system dynamic paging area remain eligible to be used for DEFERIO traces.

Keep in mind that the number of pageable pages in the system dynamic paging area is affected by the locking and unlocking of pages for various reasons, so the amount of pages eligible to be allocated to DEFERIO traces is a fluctuating amount. You should avoid specifying a FRAMES value that is borderline to the total amount of eligible pages. If the total amount of eligible pages were to decrease after the TRSAVE command has accepted the frames value and before you enable the traceid, then the TRSOURCE ENABLE command could fail because of the inability to allocate the frames at that time.

- c. For every 990 frames, or up to 990 frames allocated for a DEFERIO trace, CP locks an additional frame in the dynamic paging area for its use.
- d. If a large number of frames are specified, then it may take some time to steal those frames. The TRSOURCE ENABLE command will not complete (and CP trace table recording will not be turned on) until the specified amount of frames is allocated. When the number of FRAMES specified on the TRSAVE command for a DEFERIO traceid trace is greater than 512, informational messages will be issued to document the progress of obtaining the frames.

If a large number of frames are specified, then it may take some time for the TRSOURCE DISABLE command to complete (and for CP trace table recording data to be written) because at that time all of the frames must be written to DASD or to TAPE. When the number of frames to be written out for a DEFERIO traceid trace is greater than 3, informational messages will be issued to document the progress of writing the frames.

Because the issuing virtual machine will be in 'command wait' until the command completes, you should not enter the TRSOURCE ENABLE or TRSOURCE DISABLE commands from a virtual machine that may be adversely affected by command wait, such as a server virtual machine, a secondary virtual machine, or a PROP virtual machine.

- e. When a DEFERIO trace is eventually recorded on DASD, the SIZE and KEEP operands affect the size and number of trace files that are kept. You should specify a combination of SIZE and KEEP that is equivalent to the number specified for FRAMES. That is,  $SIZE * KEEP = FRAMES$ .
- f. If the system terminates with a DEFERIO trace active, then no data is recorded on DASD or TAPE for that trace. However, the trace data can be extracted from a CP dump.

### Examples

- To record system trace table entries on DASD and specify USERA as the file owner, enter **trsave for cp on dasd to usera**.
- To turn off TRSAVE for CP, enter **trsave for cp off**.
- To turn on TRSAVE for the trace defined by TRSOURCE ID DEBUG, save the recorded data in a file named FILEB, and allow DUSER to process the files, enter **trsave for id debug dasd to duser name fileb**.
- To use in-storage wrap for the same traceid so that data is not written to DASD until the traceid is disabled, enter **trsave for id debug deferio frames 1000 size 500 keep 2**.

## Responses

Response 1:

For CP tracing:

```
TRSAVE function { started }
                { completed }[: nnnn files purged]
                { canceled }[: nnnn files purged]
```

### **nnnn**

is the number of trace files that have been purged during the time the trace service tool function was active because of the wrapping of the keep limit. When the keep limit is reached, the oldest file is purged. If the response states that 9999 files were purged, it is possible that more than 9999 files were purged.

You receive this when you enter `trsave for cp` and the TRSAVE command is started, completed, or canceled. If you are not logged on, the completed and canceled responses are sent to the system operator.

No response is issued when TRSAVE FOR ID *traceid* commands complete because, while TRSAVE defines the destination of traces defined by TRSOURCE, recording of those traces is started and stopped by the ENABLE and DISABLE parameter of the TRSOURCE command.

With both the TRSAVE `function completed` and the TRSAVE `function canceled` responses, the trace service tool function is turned off. The second of these responses is issued only when DASD was specified on the TRSAVE ON command. (It is not issued for CP traces to tape.)

## Messages

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}

- HCP053E [XAUTOLOG failed for *userid*:] *userid/value* not in CP directory
- HCP140E *type {rdev/ldev}* attached to *userid*
- HCP143E *type rdev* in use by system
- HCP410E CP ENTERED; PAGING ERROR
- HCP422E The same option was specified twice.
- HCP423E The function requested is incompatible with a previously specified operand.
- HCP475I Fatal I/O error trying to read directory from *valid* [for user *userid*]
- HCP479E Traceid *traceid* currently enabled
- HCP1001E An operand is missing for *option*.
- HCP1013E An invalid operand was supplied for *option - operand*.
- HCP1105E Tape *rdev* not attached; tape assigned elsewhere.
- HCP1107E *command* failed; I/O error on tape *rdev*
- HCP1917E Tape device(s) {*rdev[-rdev]|vdev[-vdev]*} attached MULTIUSER.
- HCP6076E TRSAVE is not active.

- HCP6077E TRSAVE is already active.
- HCP6079E Tape drive *rdev* does not support mode *mode*.
- HCP6085E The TRSAVE command cannot be processed because the function is in a transition state.
- HCP6087E DEFERIO FRAMES specified exceeds the amount of frames eligible for DEFERIO traces.
- HCP6089E DEFERIO FRAMES specified causes total DEFERIO frames to exceed the amount of frames eligible for all DEFERIO traces.
- HCP6091I The amount of frames used for DEFERIO trace exceeds the amount of pages that will be saved on DASD.
- HCP6099E DEFERIO trace is invalid for a TYPE GT BLOCK mode trace.
- HCP6525E External Security Manager is unavailable.

## TRSOURCE

---

### Authorization

Privilege Class: C

### Purpose

Use the TRSOURCE command to support definitions and control of I/O, data, and guest tracing.

The TRSOURCE command is functionally organized as follows:

- TRSOURCE ID defines a trace. TRSOURCE ID associates an event (such as execution of a particular piece of code or an interrupt on a specific device) with a name (*traceid*) and, optionally, with a set of other traces (*traceset*).

The TYPE operand of TRSOURCE ID assigns a trace ID to one of the four trace types. These types are:

1. IO (I/O tracing). The IO trace lets you trace all I/O activity for a specific real device or range of real devices. The times, channel programs, SCSWs and data transferred for each I/O operation to the specified devices are made available for data analysis.
  2. DATA (data tracing). The data trace allows the user to define trace entries dynamically to record execution of most code paths in CP. The LOC parameter specifies what instruction, when executed, triggers recording of information. Data link parameters define what information is collected when the trap starts.
  3. GT (guest tracing). The guest trace allows CMS or GCS to record events in a system trace file.
  4. LAN (LAN tracing). The LAN trace allows a virtual switch or guest LAN to be traced. The trace collects the network traffic flowing over the simulated LAN segment. The traffic flowing over the OSA port (in the case of a virtual switch) might also be recorded.
  5. MONITOR CALL instructions placed in code paths that execute in transactional-execution mode will cause the executing transaction to abort if a monitor event is recognized. This restriction affects the use of TRSOURCE GT and the deployment of class 10 MONITOR CALL instructions.
- TRSOURCE ENABLE activates the tracing of individual trace IDs and of trace IDs within trace sets.
  - TRSOURCE DISABLE deactivates the tracing of individual trace IDs and of trace IDs within trace sets.
  - TRSOURCE DROP disables and drops all CP knowledge of individual trace IDs and trace IDs within trace sets.
  - TRSOURCE DISPLAY displays the status resulting from the TRSOURCE commands you have issued.

See [Using the TRSOURCE Command](#) in *z/VM: Diagnosis Guide* for examples that show how TRSOURCE is used.

### Usage Notes

(General for TRSOURCE)

1. All traces are disabled at system termination.
2. The definitions of traces are not saved across system IPLs. Therefore, the definitions of any commonly defined traces should be saved in EXECs.
3. When a new member of an enabled set is defined, that member is not automatically enabled. It must be enabled separately. Attempts to enable trace IDs that are already enabled do not alter anything and do not result in an error message.
4. The definition of what is being traced for each trace ID cannot be altered while the trace ID is enabled. Any trace ID may be altered while it is disabled.

5. Use of the DROP keyword directed toward a trace set removes any record of all the trace IDs in the set. To remove or *ungroup* a member of a set, either assign the trace ID to another, possibly unused, trace set name or assign the trace ID to a trace set name of NULL.
6. The destination of trace data can be altered with the TRSAVE command while the trace is disabled. See [“TRSAVE” on page 2011](#) for details.
7. Enabling a trace for which TRSAVE has not been issued invokes the TRSAVE destination defaults.
8. If an error message is generated for a trace definition, enter **query trsource id traceid** to verify that the trace definition is correct.
9. Data traced from this command is stored as a system data file (SDF), specifically a trace file (TRF), as opposed to a printer or reader file. Use the TRACERED utility to merge and format the files. TRACERED can send the output to your virtual printer, to a CMS file, or to an OS QSAM file. For more information, see [“TRACERED” on page 2244](#).
10. If an external security manager is installed on your system, you may not be authorized to issue this command. For additional information, contact your security administrator.
11. Instructions whose simulation as part of TRSOURCE would be disruptive are classified as TRSOURCE-ineligible. These include LGG, LLGFSG, PPA, TABORT, TBEGIN, TBEGINC, and TEND.
12. Several instructions are treated as NOPs by TRSOURCE, including BPP, BPRP, and NIAI.

## Examples

The following examples provide an overview of the ways TRSOURCE can be used. For further examples, see [z/VM: Diagnosis Guide](#).

1. This example defines and enables a trace ID of type DATA. The trace ID is DSPLOOP, it is defined at address 4B248, and the data link string specified is G4+8%.2. 'label' is a label that is included with the datalink data in the trace record to identify that datalink's data. The destination is specified as a system trace file for the issuer with a maximum size of 2000.

```
trsource id dsploop type data loc 4b248 5820c846
trsource id dsploop dl g4+8%.2=label
trsave id dsploop dasd to * size 2000
trsource enable id dsploop
```

2. This example defines, enables, and disables two trace IDs of type IO. These trace IDs, IO1 and IO2®, are put into trace set IOSET. IO1 traces I/O to devices in the range C41-C47; up to 200 bytes of transferred data is traced. IO2 traces I/O for USER1 to devices in the range A81-A87; up to 400 bytes of transferred data is traced. The destination options default (because TRSAVE was not issued) and the trace files are named IO1 and IO2 with a maximum size of 256 pages and a maximum number of 2.

```
trsource id io1 set ioset type io
dev c41-c47 iodata 200

trsource id io2 set ioset type io
dev a81-a87 iodata 400 user user1

trsource enable set ioset
trsource disable id io1
trsource disable id io2
```

3. This example defines, enables, and drops two trace IDs of type GT. These trace IDs, GT1 and GT2, are put into trace set GTSET. The destinations are specified as system trace files for user ID USER3 with a default size of 256 pages.

```
trsource id gt1 set gtset type gt for user user2
trsource id gt2 set gtset type gt for vmgroup gcsgroup
trsave id gt1 dasd to user3
trsave id gt2 dasd to user3
trsource enable id gt2
trsource enable id gt1
trsource drop set gtset
```

## Messages

- HCP002E Invalid operand - *operand*

- HCP479E Traceid *traceid* currently enabled
- HCP568E Maximum number of devices exceeded for traceid *traceid*.
- HCP644E Unknown/unauthorized CP command: *command*
- HCP816I {Traceid|Traceset} *operand* does not exist
- HCP819I Traceid *traceid* disabled; group *group* enabled by *traceid*
- HCP847E Maximum system spool file limit exceeded
- HCP1003E {*CP module name|rdev|ldev*} {is|was} not found.
- HCP1100E A logical device number was not supplied or it is invalid.
- HCP6081I Ten trace files have been purged for {CP|traceid *traceid[userid]*}. Further warnings are suppressed.
- HCP6084I The maximum number of trace files for {CP|traceid *traceid[userid]*} has been exceeded. The oldest file is purged.
- HCP6086I Traceid *traceid1* is no longer superseded by VMGROUP trace *traceid2*.
- HCP6088I Trace data for traceid *traceid[userid]* was not saved by TRSAVE.
- HCP6089E DEFERIO FRAMES specified causes total DEFERIO frames to exceed the amount of frames eligible for all DEFERIO traces.
- HCP6091I The amount of frames used for DEFERIO trace exceeds the amount of pages that will be saved on DASD.
- HCP6093E You are not allowed to switch modes for traceid *traceid*.
- HCP6094I User *userid* will not be traced by trace *traceid*.
- HCP6095I User *userid* is no longer being traced by trace *traceid*.
- HCP6096I Trace *traceid* is being disabled.

- HCP6097I User *userid* has restricted tracing to traces defined as BLOCK.
- HCP6098E Trace *traceid* can not be enabled.
- HCP6099E DEFERIO trace is invalid for a TYPE GT BLOCK mode trace.
- HCP6160E *token1* was not expected; *xxxxx* was expected.
- HCP6161E Constant definition incorrect: *reason*.
- HCP6162E Maximum nesting depth of IF statement exceeded.
- HCP6163E Internal error during command processing: *module + offset*
- HCP6426I {Allocating|Writing} the DEFERIO frames for traceid *traceid*.
- HCP6427I X% of the DEFERIO frames for traceid *traceid* have been {allocated|written}.
- HCP6525E External Security Manager is unavailable.

## TRSOURCE DISABLE

### Authorization

Privilege Class: C

### Purpose

Use TRSOURCE DISABLE to end tracing of individual trace IDs and tracing of trace IDs within trace sets.

**Note:** The trace file containing the trace data gathered by the trace ID is closed when the trace ID is disabled.

### Operands

#### ID *t1...*

specifies the trace IDs to be deactivated.

#### SET *s1...*

specifies the trace sets to be deactivated.

#### ALL

deactivates all existing trace IDs.

#### DISPlay

displays the status for each trace ID or trace set specified on this command. If you specify DISPLAY, it must be the last operand entered.

### Usage Notes

1. For usage information, see TRSOURCE [“Usage Notes”](#) on page 2018. For disabling a DEFERIO trace, see TRSAVE Usage Note [“17”](#) on page 2014.

## TRSOURCE DISPLAY

---

▶▶ TRSource — DISPlay ▶▶

### Authorization

Privilege Class: C

### Purpose

Use TRSOURCE DISPLAY to display the status of trace IDs and trace sets.

### Usage Notes

1. TRSOURCE DISPLAY provides the same information as QUERY TRSOURCE ALL. For more information about these responses, see [“QUERY TRSOURCE”](#) on page 1239.
2. To display the status of a particular trace ID or trace set, include the DISPLAY operand at the end of a TRSOURCE command. For example, if you enter **trso id me type gt for user operator display**, you receive the following output:

ID	TYPE	SET	STATUS	ORIGINID
ME	GT	NULL	DISABLED	OPERATOR

3. For more information, see TRSOURCE [“Usage Notes”](#) on page 2018.

## TRSOURCE DROP

### Authorization

Privilege Class: C

### Purpose

Use TRSOURCE DROP to disable the specified trace ID or trace sets and delete from CP all individual trace IDs and the trace IDs within trace sets.

### Operands

#### ID *t1...*

specifies the trace IDs to be disabled and deleted.

#### SET *s1...*

specifies the trace sets to be disabled and deleted.

#### ALL

disables and deletes all existing trace IDs regardless of whether they are enabled.

#### DISPlay

displays the status for each trace ID or trace set specified on this command. If you specify DISPLAY, it must be the last operand entered.

### Usage Notes

1. The trace IDs or trace sets cannot be reenabled without being redefined.
2. Use of the DROP keyword directed toward a trace set removes any record of all the trace IDs in the set. To remove or *ungroup* a member of a set, the user should either assign the trace ID to another, possibly unused, trace set name or assign the trace ID to a trace set name of NULL.
3. For more information, see TRSOURCE “Usage Notes” on page 2018.

## TRSOURCE ENABLE

### Authorization

Privilege Class: C

### Purpose

Use TRSOURCE to activate the trace of individual trace IDs and of trace IDs within trace sets.

### Operands

#### ID *t1...*

specifies the trace IDs to be activated.

#### SET *s1...*

specifies the trace sets to be activated.

#### ALL

activates all existing trace IDs.

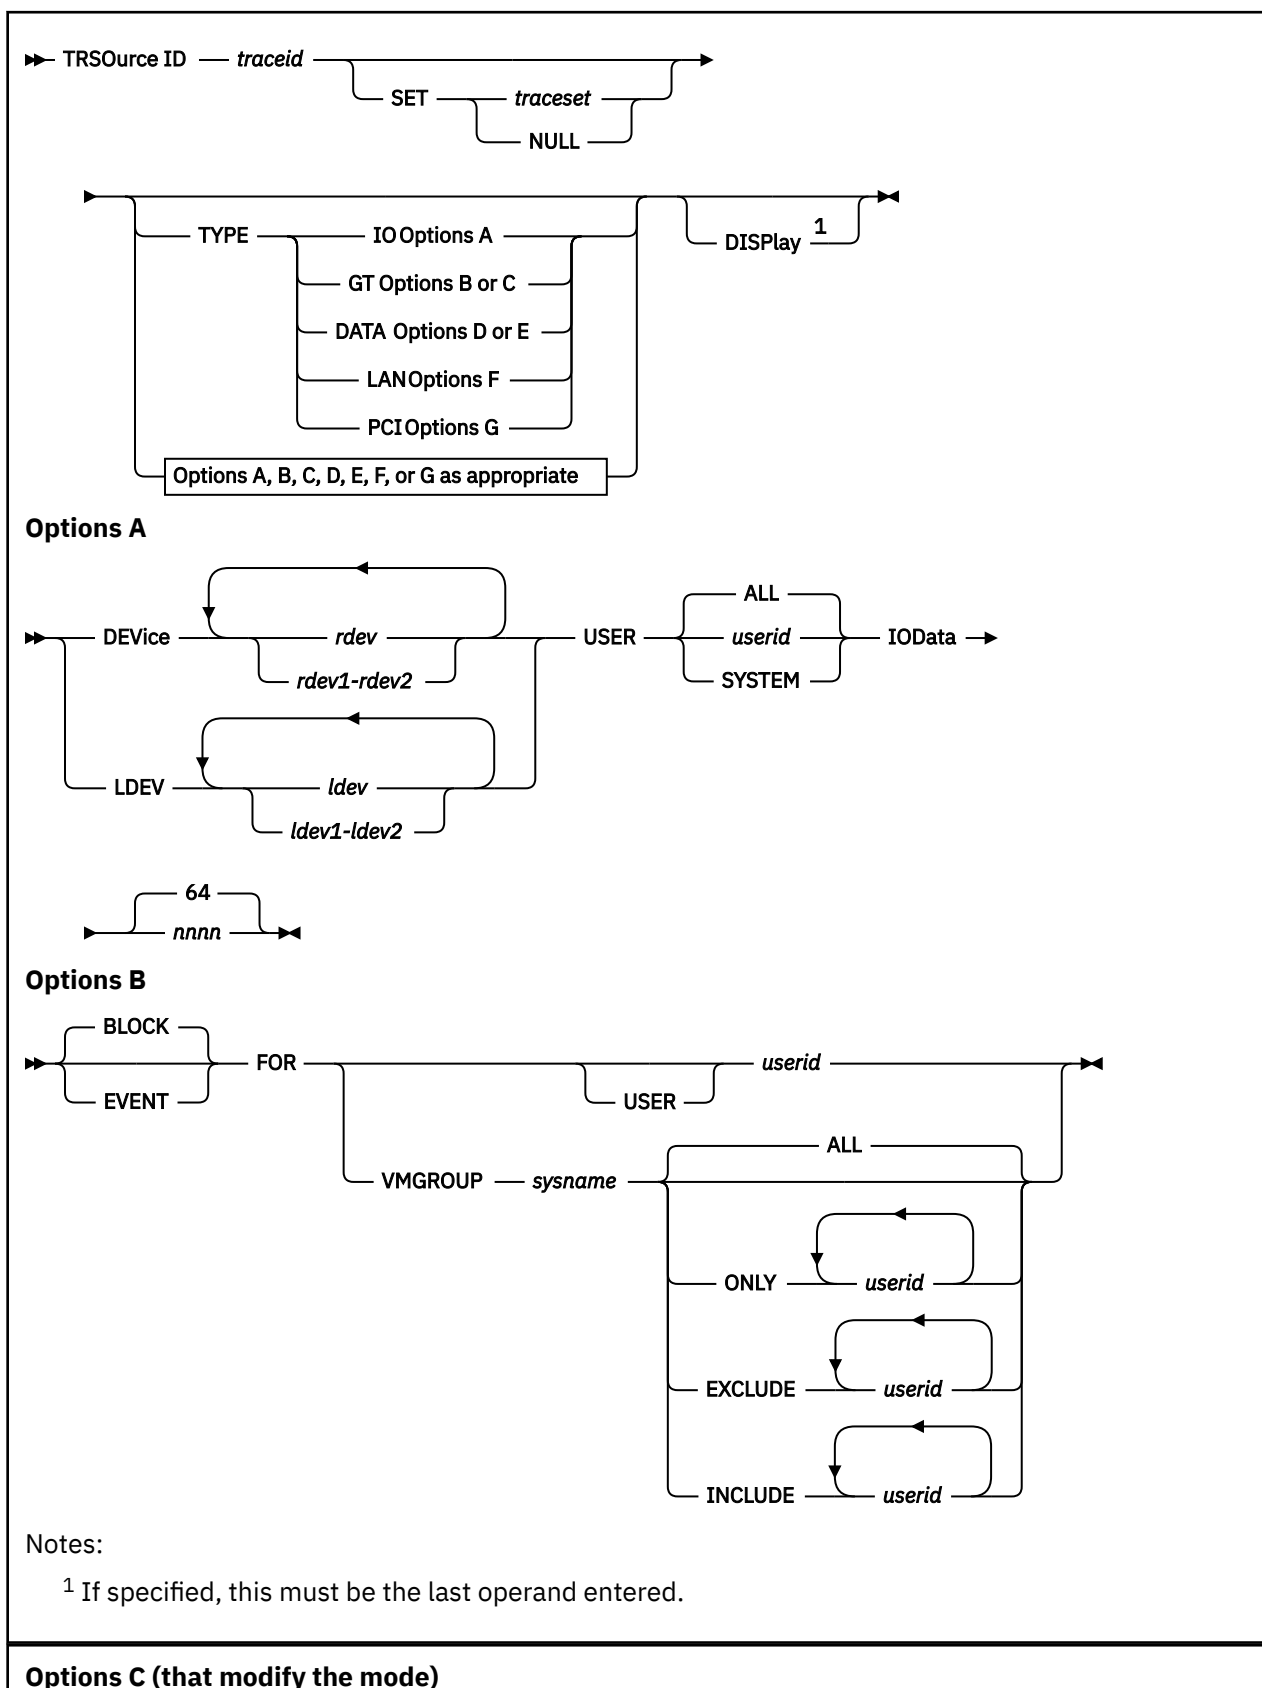

#### DISPlay

displays the status for each trace ID or trace set specified on this command. If you specify DISPLAY, it must be the last operand entered.

### Usage Notes

1. For usage information, see TRSOURCE “Usage Notes” on page 2018. For enabling a DEFERIO trace, see TRSAVE usage note “17” on page 2014.

## TRSOURCE ID (Definition Operands)

**Options D**

**Options E**

**THEN and ELSE**

**Notes:**

<sup>1</sup> Use of the DL, IF, THEN, ELSE, and ENDIF keywords is dependent on the keywords that have already been specified. For example, 'THEN' can not be specified unless an 'IF' phrase immediately precedes it. Likewise, 'DL' could not be specified if a 'THEN' is expected. See the "Examples" section below.

<sup>2</sup> IF statements may be nested up to 16 levels deep.

**Option F**

## Authorization

Privilege Class: C

## Purpose

Use TRSOURCE ID to define trace traps—that is, to associate a tracing condition with a name (*traceid*) and, optionally, with a set of other traces (trace set). Also, use the TYPE operand to assign a trace ID to one of the trace types (I/O, data, guest, LAN, or PCI tracing).

You do not need to specify all of the definition operands on each invocation of the TRSOURCE command; you can build the definition piecemeal on a number of TRSOURCE commands. Note, however, that the TYPE operand and certain TYPE parameters must be associated with a trace ID before that trace can be enabled.

## Operands

### *traceid*

identifies the trace; it is a user-defined, alphanumeric, 1- to 8-character string. You can specify *traceid* as a target on the ENABLE, DISABLE, and DROP operands to activate, deactivate, or delete a particular trace; you can also use *traceid* as a target for the TRSAVE command, which can alter the recording options for a trace.

Used with the SET operand, trace IDs can be grouped to form trace sets. A *traceid* cannot be a member of more than one trace set at a time.

The trace ID also serves as the default name of the system trace file for the trace data. The operand trace IDs cannot duplicate any of the following TRSOURCE keywords or any accepted abbreviation of these keywords: ID, SET, TYPE, ENABLE, DISABLE, DROP, DISPLAY, and ALL.

### SET *traceset*

#### SET NULL

is a user-defined, alphanumeric, 1- to 8-character string; it identifies the trace set that includes the specified trace ID. Creating trace sets lets you group individual traces that are functionally or logically related. You can then specify *traceset* as the target of the ENABLE, DISABLE, and DROP operands to activate, deactivate, or delete all of the trace IDs in *traceset*.

A trace set can contain trace IDs of more than one type. A trace set of NULL indicates that the trace ID is not a member of any specific set. Set operations cannot be performed on the NULL set.

A trace ID cannot be made a member of a set while it is enabled. Trace sets cannot duplicate any of the following TRSOURCE keywords or any accepted abbreviation of these keywords: ID, SET, TYPE, ENABLE, DISABLE, DROP, DISPLAY, and ALL.

**TYPE IO****TYPE GT****TYPE DATA****TYPE LAN****TYPE PCI**

specifies a system-defined trace type. The trace type determines which parameters are allowed and which are required for trace ID. The TYPE operand need only be specified once for a given trace ID but must be specified before or at the same time as any type parameter for that trace ID.

Different trace IDs of the same trace type can be placed in the same or different trace sets. Trace types cannot be used as targets of the ENABLE, DISABLE, and DROP operands. Grouping of trace IDs is done with the SET operand, not the TYPE operand.

***type parameters***

The parameters and descriptions for the respective trace types are documented in the following sections:

- "The I/O Trace"
- "The GT Trace"
- "The Data Trace"
- "The LAN Trace"
- "The PCI Trace"

**DISP**

displays the status for each trace ID or trace set specified on this command. If you specify DISPLAY, it must be the last operand on the command line.

**The I/O Trace**

The I/O trace lets you trace all I/O activity on a user-specified real or logical device, a list of such devices, or range of such devices. The times, channel programs, SCSWs, and data transferred for each I/O operation to the specified devices are made available for data analysis. If concurrent sense data is received then this information is made available as well.

**Note:** One of the following I/O parameters must be specified on a TRSOURCE command.

```
DEVICE  rdev1[-rdev2] [rdev3[-rdev4]]...
LDEV    ldev1[-ldev2] [ldev3[-ldev4]]...
```

**DEVICE rdev1...**

specifies the device number or ranges of device numbers whose I/O activity is to be traced. The number of devices or ranges that can be traced with one trace ID of type IO is limited to 255. A device is a member of only one enabled trace ID. If you re-specify a DEVICE for a previously defined trace, the new device will be appended to the definition. If you attempt to enable the same device from two or more different trace IDs, you will receive an error message.

**LDEV ldev1...**

specifies the logical device number or ranges of logical device numbers whose I/O activity is to be traced. A logical device number is comprised of an optional letter "L" followed by one to four hexadecimal digits. The number of logical devices or ranges that can be traced with one trace ID of type IO is limited to 255. A logical device is a member of only one enabled trace ID. If you re-specify an LDEV for a previously defined trace, the new logical device will be appended to the definition. If you attempt to enable the same logical device from two or more different trace IDs, you will receive an error message.

**Note:** Any or none of the following I/O parameters may be specified in any order on a TRSOURCE command.

```

USER      { userid }
          { ALL   }
          { SYSTEM }

IOData    { nnnn }
          { 0    }
    
```

**USER *userid***

**USER ALL**

**USER SYSTEM**

specifies which user's I/O should be traced. I/O done by the system on behalf of the user is traced. Tracing can only be done for one user per trace ID and any respecification of the user parameter replaces the existing definition. The user ID SYSTEM is a valid user ID for I/O traces. Only one user's I/O or all I/O is traced. The default value, ALL, specifies that all I/O to the specified device is traced for all user IDs.

**IOData *nnnn***

specifies how many bytes, if possible, of the transferred data should be traced. The valid range for *nnnn* is 0 to 3800 decimal and the default is 64 bytes.

The GT Trace

Traces of type GT allow a guest virtual machine to record events. Guests can record in block or event mode. All user IDs specified for a trace ID must support the same mode of recording.

```

[BLOCK] FOR { [USER] userid
[EVENT]      {
                VMGROUP sysname [ALL
                                [ONLY u1 u2... ]
                                [EXCLUDE u1 u2... ]
                                [INCLUDE u1 u2... ]
                }
    
```

**BLOCK**

**EVENT**

specifies the recording mode for tracing. This mode must match the capabilities of the guest virtual machine.

If you specify BLOCK, the guest virtual machine must be able to intercept the monitor call program interrupt, collect the trace entry data in a buffer, and then pass blocks of trace data to the control program. These blocks are written to a system trace file (TRFILE). BLOCK is the default.

If you specify EVENT, the virtual machine uses the monitor call class 10 interface (CP intercepts the MC program interrupt) to pass individual records directly to the control program. Each trace record is written to a system trace file.

EVENT trace records will not be created when the guest uses MC class 10 with the enhanced-monitor facility and a monitor-event-counting operation is performed.

See *z/VM: Diagnosis Guide* for examples.

**FOR USER *userid***

specifies the user for which trace events are recorded.

**FOR VMGROUP *sysname***

specifies the VMGROUP for which trace events are recorded.

**ALL**

specifies that every virtual machine in the VMGROUP *sysname* is included in the defined GT trace. This is the default.

**ONLY**

specifies that the virtual machines included in the defined GT trace are limited to user IDs *u1 u2.....*

**EXCLUDE**

specifies that every virtual machine in the VMGROUP *sysname* is included in the defined GT trace except those virtual machines with *userid*s *u1 u2...*

**INCLUDE**

specifies that user IDs *u1 u2...* should be added to those virtual machines that currently comprise the VMGROUP *sysname* in the defined GT trace.

After a VMGROUP trace has been defined, parameters may be specified to allow further changes in the group of virtual machines that comprise the GT trace. The VMGROUP trace is identified with the ID parameter. These modifications can be entered at any time; the trace specified does not need to be disabled.

Parameters may be specified to change the mode of the TYPE GT trace before it is enabled. The mode must match the capabilities of the guest virtual machine.

*Type GT Parameters that Modify the Mode:*

```
[BLOCK]
[EVENT]
```

**BLOCK**

**EVENT**

specifies the recording mode for tracing. This mode must match the capabilities of the guest virtual machine.

If you specify BLOCK, the guest virtual machine passes blocks of trace data to the control program. These blocks are written to a system trace file.

If you specify EVENT, the virtual machine passes individual records directly to the control program. Each trace record is written to a system trace file.

The DATA Trace

Trace type DATA allows the user to dynamically define trace entries to record execution of most code paths in CP. The LOC parameter specifies which instruction, when executed, triggers recording of information. Data link parameters define what information is collected when the trace springs.

**Note:** Any or none of the following DATA parameters may be specified on a TRSOURCE command. Specification of a given parameter must be consistent with the state of the traceid as defined by previously entered parameters, including parameters entered via previous invocations of the TRSOURCE command.

```
LOC  { address instruction }
     { modname + disp instruction }

DL   datalinks

IF   datalink { EQ } { datalink }
     {          } { constant }
     {          } {          }
     {          } {          }
     {          } {          }
     {          } {          }
     {          } {          }

THEN { DL datalinks }
     {          }
     IF ... ENDIF

ELSE { DL datalinks }
     {          }
     IF ... ENDIF

ENDIF
```

**LOC address**

specifies the address in the CP nucleus that identifies the trace point at which the data is to be collected.

**LOC modname + disp**

specifies the CP module name and displacement into that module that identifies the trace point at which the data is to be collected. If the module is written in a higher-level language, an 8-character module name must be supplied.

See Type Data Usage Note [“6” on page 2037](#) for a list of restricted locations.

**instruction**

identifies in hexadecimal characters the contents of storage at the specified trace point. Matching the specified instruction with the contents of storage verifies that the trace point is at the intended location in the CP nucleus. The instruction supplied must be at least as long as the instruction to be verified. Only that instruction is verified, and any extraneous hexadecimal data is ignored. If the verification fails, the LOC parameters are not accepted, and a message is sent to the user who entered the command.

**DL datalinks**

identifies the data to be traced. The following character groups can be used to make up a data link string:

1. Addresses: substrings consisting of characters 0 to 9 and A to F.
2. Registers: substrings beginning with G or GG (for general purpose registers) or X or XG (for control registers) followed by a hexadecimal digit. A range of registers may be specified by using a colon between the two registers, such as *GO:4*.
3. Indirection: a percentage sign (%) or an ampersand (&). Indirection means that the contents of an address are used instead of the address itself. A percentage sign uses a four-byte indirect address; an ampersand uses an eight-byte indirect address.
4. Address type: L or R. L indicates that the address derived from the preceding expression, and all subsequently derived addresses, should be treated as host logical storage addresses. R indicates that the address derived from the preceding expression, and all subsequently derived addresses, should be treated as host real storage addresses. For each Datalink, addresses are treated as host logical storage addresses until the first occurrence of R, if any.
5. Arithmetic: a plus sign (+) or a minus sign (-).
6. Length delimiter: a period (.).
7. Mnemonic marker: an equals sign (=).

The data link strings specify how to combine these groups to reach the data to be traced. The following is a Backus-Naur definition of the syntax of data link strings:

```

<datalink> ::= <main> | <main>=<mnemonic>
    <main> ::= <anchor> | <anchor><vector> | <anchor>.<length> |
              <anchor><vector>.<length> | <range>
    <anchor> ::= <reg> | 0..FFFFFFFF
    <vector> ::= <modifier> | <vector><modifier>
    <modifier> ::= +<d> | -<d> | +<reg> | -<reg> | % | & | R | L
    <length> ::= 0..F00
    <range> ::= G<digit>:<digit> | X<digit>:<digit> | GG<digit>:<digit>
              | XG<digit>:<digit>
    <reg> ::= G<digit> | X<digit> | GG<digit> | XG<digit>
    <digit> ::= 0..15 | 0..9, A, B, C, D, E, F
    <d> ::= 0..7FFF
    <mnemonic> ::= mmmmmmm
    
```

where mmmmmmm indicates a user-generated 1- to 8-character alphanumeric string.

Data can be identified by either using the current register contents as pointers or knowing the real location of the data to be traced. Data links define the procedure to be used to locate the desired data.

**Note:** To interpret Backus-Naur Form, the symbol colon colon equal (::<=) may be interpreted as “can be specified as”. Thus, a statement such as

```
<location> ::= <register> | <address>
```

can be read as “Location can be specified as register or address”. Any symbol on the right-hand side of the colon colon equal (::<=) can be defined on another statement in the Backus-Naur Form.

#### **IF datalink**

identifies the data to be used as the first operand for data comparison that determines whether a subsequent THEN statement or ELSE statement is executed.

Up to 16 nested IF statements are allowed. Each IF statement must be paired with an ENDIF statement.

#### **EQ datalink**

#### **NE datalink**

#### **GT datalink**

#### **GE datalink**

#### **LT datalink**

#### **LE datalink**

identifies the compare operation to be performed and identifies the data to be used as the second operand for data comparison that determines whether a subsequent THEN statement or ELSE statement is executed.

The allowable conditional operators are:

#### **EQ**

(first operand equal to second operand),

#### **NE**

(first operand not equal to second operand),

#### **GT**

(first operand greater than second operand),

#### **GE**

(first operand greater than or equal to second operand),

#### **LT**

(first operand less than second operand),

#### **LE**

(first operand less than or equal to second operand).

The comparison is a logical compare. The length of the data compared is the lesser of the length determined by the first operand datalink or by the second operand datalink.

#### **EQ constant**

#### **NE constant**

#### **GT constant**

#### **GE constant**

#### **LT constant**

#### **LE constant**

identifies the compare operation to be performed and identifies a constant to be used as the second operand for data comparison that determines whether a subsequent THEN statement or ELSE statement is executed.

The allowable constants are:

**X'...';**

where ... are an even number of up to 16 hexadecimal digits (0 to 9 and A to F), or

**C'....';**

where .... are up to 64 characters. Blanks and single quotation marks may be used in the constant string. Use two consecutive single quotation marks to specify one single quotation.

The comparison is a logical compare. The length of the data compared is the lesser of the length determined by the first operand datalink or by the (second operand) constant.

**THEN DL *datalinks***

identifies the data to be traced if the result of the preceding IF statement is true. A THEN statement may be followed by any number of datalinks, all of which are executed only if the result of the preceding IF statement is true.

A subsequent IF statement (not preceded by an ELSE statement or ENDIF statement; that is, a nested IF statement) would be executed only if the result of the preceding IF statement is true.

**THEN IF**

identifies a nested IF statement. Such an IF statement would be executed only if the result of the preceding IF statement is true.

Up to 16 nested IF statements are allowed. Each IF statement must be paired with an ENDIF statement.

**ELSE DL *datalinks***

identifies the data to be traced if the result of the preceding IF statement is false. An ELSE statement may be followed by any number of datalinks all of which are executed only if the result of the preceding IF statement is false.

A subsequent IF statement (not preceded by an ENDIF statement, thus a nested IF statement) would be executed only if the result of the preceding IF statement is false.

**ELSE IF**

identifies a nested IF statement. Such an IF statement would be executed only if the result of the preceding IF statement is false.

Up to 16 nested IF statements are allowed. Each IF statement must be paired with an ENDIF statement.

**ENDIF**

identifies the end of conditional datalinks associated with the last unclosed IF statement.

Each IF statement must be closed with an ENDIF statement before the traceid can be enabled.

The LAN Trace

The LAN trace type allows a virtual switch or guest LAN to be traced. The trace collects the network traffic flowing over the simulated LAN segment. When a trace is defined with the default options, all traffic on the specified LAN will be traced regardless of VLAN ID. A total of 512 bytes per datagram will be collected and discarded as well as delivered datagrams will be recorded. The traffic flowing over the OSA port (in the case of a virtual switch) will also be recorded. The following options are valid on a LAN trace:

**OWNER *ownerid***

specifies the owner of the guest LAN or virtual switch to be traced. The owner of a virtual switch is always SYSTEM. The owner id must be a valid user ID or SYSTEM.

**LANNNAME *lanname***

specifies the name of the guest LAN or virtual switch to be traced. The LAN must be defined before the trace id is enabled.

**VLAN *vlanid***

**VLAN ALL**

specifies which vlan traffic should be traced. Up to four different vlan ids can be specified. In order to trace all traffic regardless of vlan id, specify VLAN ALL.

**LENGTH *length*****LENGTH 512****LENGTH FULL**

specifies how many bytes of the packet should be traced. The default is 512 bytes. If FULL is specified, a total of 2048 bytes will be recorded. The specified LENGTH can be between 64 and 2048.

**NIC *userid vdev***

specifies that only traffic inbound or outbound for the specific *userid vdev* pair will be traced. This option allows the data collection to be filtered for a specific guest connection. The *vdev* specified should be the address of the data device.

**TRUNK**

specifies that only traffic flowing over the virtual switch OSA (RDEV) connection will be traced. If TRUNK is specified on a guest LAN, no data is collected.

**DROPPED**

specifies that only dropped packets will be collected. A dropped packet is a datagram that could not be delivered to a host or datagram that had an error, such as a missing header causing the packet to be too short. Without this option, dropped packets and successful packets are both recorded.

For more information on [CP TRSOURCE TYPE LAN Command](#), see *z/VM: Connectivity*.

The PCI Trace

The PCI trace type allows I/O operations on a PCI function to be traced. The following options are valid on a PCI trace:

**Note:** The following PCI parameter must be specified on a TRSOURCE command.

```
PCIFunction rpfid1[-rpfid2] [rpfid3[-rpfid4]]...
```

**PCIFunction *rpfid1*...**

specifies a real PCI function ID or a range of PCI function IDs whose I/O activity is to be traced. Specify a PCI function ID as 8 hexadecimal digits. You may omit leading zeros. The number of real PCI functions or ranges of real PCI functions that can be traced with one trace ID of type PCI is limited to 255. A function is a member of only one enabled trace ID. If you re-specify a PCI for a previously defined trace, the new *rpfid* will be appended to the definition. If you attempt to enable the same *rpfid* from two or more different trace IDs, you will receive an error message.

**Note:** Any or none of the following PCI parameters may be specified in any order on a TRSOURCE command.

```
USER      { userid }
           { ALL   }
           { SYSTEM }
```

**USER *userid*****USER ALL****USER SYSTEM**

specifies which user's I/O should be traced. I/O done by the system on behalf of the user is traced. Tracing can only be done for one user per trace ID and any re-specification of the user parameter replaces the existing definition. The user ID SYSTEM is a valid user ID for I/O traces. Only one user's I/O or all I/O is traced. The default value, ALL, specifies that all I/O to the specified function is traced for all user IDs.

**Usage Notes**

(General for TRSOURCE ID)

1. If you use the ID operand to define a trace ID, ID must be the first operand on the command line.

2. While specific type-dependent operands are optional on the TRSOURCE command, certain type-dependent operands may be required for a trace ID before it can be enabled. Refer to the description of the specific trace types to determine which operands are required before a trace ID of that trace type can be enabled.
3. The TYPE operand, if used, must directly precede any type-dependent operands.
4. All type-dependent operands must be contiguous. The order depends on the requirements of the trace type.

### Type I/O Usage Notes

1. You can define an I/O trace for a nonexistent device—that is, a device that has no RDEVICE definition. If a trace with *only* such devices is enabled, message HCP477E is issued:

```
Traceid (TRACEid) not enabled; incomplete definition
```

Note, however, that a trace with a nonexistent device and a real device (whether the latter be online or offline) *can* be enabled, and the response to QUERY TRSOURCE indicates that a trace for the nonexistent device is activated.

2. System trace files reside on system spool space. Tracing I/O to system spool space causes trace recursion and may cause severe performance degradation, especially for large values of IODATA.

### Type GT Usage Notes

1. Specification of a TYPE GT trace for a VMGROUP makes it easier to control and define guest traces for the members of a group.

A trace TYPE GT for a VMGROUP is used to sift TRSOURCE definition and TRSAVE destination information from the VMGROUP to the virtual machines that are members of the VMGROUP. (The system name specified on the VMGROUP parameter is the name of the named saved system that was IPLed by its members.)

2. Multiple TYPE GT traces can be defined for each virtual machine. Only one TYPE GT trace can be enabled for each virtual machine.
3. A TYPE GT USER trace for a virtual machine that has been defined before the virtual machine becomes a member of a VMGROUP for which a TYPE GT trace is enabled is automatically disabled when the virtual machine becomes a member of the VMGROUP. The USER TYPE GT trace remains in its disabled state after the virtual machine either leaves the VMGROUP, is removed from the VMGROUP by a later TRSOURCE command that excludes that virtual machine's user ID from the VMGROUP trace or the VMGROUP trace is disabled. A TRSOURCE ENABLE command is required to reenble the USER TYPE GT trace.
4. If you need to redefine the destination of the trace data for one of the members of a VMGROUP trace, you must exclude the virtual machine's user ID from the VMGROUP trace and then enable a TYPE GT USER trace containing the desired destination information for the virtual machine.
5. A message is sent to the user who defined a USER TYPE GT trace whenever a defined and enabled USER TYPE GT trace is disabled because of VMGROUP TYPE GT trace activity for a VMGROUP member.
6. A message is sent to the user who defined a USER TYPE GT trace whenever a virtual machine that is a member of a VMGROUP trace is excluded from the VMGROUP by a later TRSOURCE command. This user is also notified if the virtual machine was a member of a VMGROUP for which tracing was disabled.
7. Use the BLOCK or EVENT keyword to tell CP whether the guest virtual machine will collect all the guest trace data in a buffer. Unpredictable results occur when TRSOURCE ENABLE is issued if the trace setup does not match the capabilities of the guest virtual machine.
8. If specified, the BLOCK or EVENT keyword must precede other TYPE GT parameters.
9. The mode, BLOCK or EVENT, may not be changed after a trace is enabled; even if it has been disabled. You must cancel the trace first.

10. A virtual machine may declare to CP that it will be sending trace data in BLOCK mode. CP rejects any TRSOURCE ENABLE command that specifies EVENT mode.

#### Type DATA Usage Notes

1. Data collection for trace IDs of trace type DATA occurs before execution of the overlaid instruction. If no data links are specified for the trace ID, a trace entry is created in the system trace file, but no data is collected.
2. To calculate the exact amount of data that can be collected in a trace record, use the following formula:  

$$(3 \text{ times the number of data links specified}) + (\text{the total lengths of the data links}) + (\text{the total number of bytes to be collected}).$$

The sum must be less than or equal to 4 KB (in decimal).

Also, the maximum number of data links allowed for any given trace ID is 255. The maximum data link length is 250.
3. DATA traces should always be placed at instruction boundaries. The TRSOURCE command can verify only that the specified location is on a halfword boundary and that it contains a valid operation code; if these conditions are not met, the command fails, with an error message.  

If the verification is successful, the TRSOURCE command overlays the specified location with a data trace SVC instruction. If the location is not an instruction boundary, unpredictable results can occur, including a system failure.
4. If an error is made while entering a data link, the entire trace must be dropped and redefined to remove the data link from the definition. This is because there is no way of deleting a data link from a trace definition. It is therefore recommended that the definitions of commonly used type DATA traces be saved in EXECs. Locations can be changed for defined but disabled DATA traces.
5. Specification of extra data links for a defined but disabled trace results in an addition to the definition.
6. The following is a list of restricted locations for the definition of trace points. These locations are restricted because enabling DATA traces in them would cause recursion or interlocks.
  - a. Locations not on halfword boundaries.
  - b. Locations not mapped in the system execution space.
  - c. Locations of already enabled DATA traces. Note that multiple DATA traces may be defined at the same location but only one trace at a time may be enabled at that location.
  - d. Locations within a module loaded with the CPXLOAD command.
  - e. Locations that contain a NOOP (4700xxxx) preceded by a Subtract Halfword instruction.
  - f. Locations that contain an enabled dynamic CP exit.
7. Trace data is not collected during system termination.
8. It is recommended that records defined for any code path traveled when writing a system trace file (including paging and spooling code paths and some code paths in IOS) be kept under a page in length.
9. Users should avoid placing traces in code paths that hold spin locks, as this situation increases the path length under the spin lock and seriously decreases system performance.
10. Users should avoid placing data traces on instructions that are targets of EXECUTE instructions; otherwise, results are unpredictable.
11. If interpretation of a data link string during execution results in a negative or invalid address, a record is added to the system trace file to indicate that the error occurred. However, there is no external indication that the error occurred.
12. To trace data located in the absolute page zero, reverse prefixing must be used. When the value of the prefix register is added to the datalink string, values are obtained from absolute page zero. On the other hand, if the address calculated from a data link is less than hexadecimal 2000, the value recorded is obtained from the prefix page of the processor in which the data trace event occurs.

13. If a traceid contains conditional statements (at least one IF statement) and the condition when the trace point is encountered results in the execution of no datalinks, then no trace record is made, not even a trace record containing only header information. It is as though the trace event never occurred.
14. It is possible to specify lower case characters in a character constant definitions. This cannot be done by typing a CP command because all characters in the command are converted to upper case before the TRSOURCE command parser receives the command. To specify lower case, use the Diagnose X'08' interface from an EXEC or from an assembler program. Only the character constant should be specified in lower case. The following is an example of an EXEC that defines a character constant that contains lower case characters and single quotation marks.

```

/* */
cpcmd="TRSOURCE ID TT TYPE DATA IF G3.20 EQ C'Specify ''vdev'' "
response = ''
parse value Diag('8',cpcmd) with response '15'x
if response =v then say 'response=response'
    
```

**Examples**

**Examples of Data Link Usage:** The following examples are based on the status of the registers and the storage pictured below.

Registers	Host Logical Storage				
G1  00001000	4000	00005008	00000000	0000A000	00000000
	5000	0000A004	00001144	00005555	00000000
	6000	00000000	00000000	0000A000	00000000
G4  00004000	...				
	A000	0000B000	0000C000	0000D000	0000E000
	B000	C4C1E3C3	E3D9C1D7	11110000	00000000
G5  00005000	C000	C4C1E3C3	E3D9C1D7	FFFF0000	00000000
	D000	DDDDDDDD	00000000	00000000	00000000
G6  00006000					

Ex.	Datalink	Data Collected
1)	4000	00005008
2)	4000%	00005555
3)	5000%.8	0000C000 0000D000
4)	G5	00005000
5)	G5.4	0000A004
6)	G5+4	00001144
7)	G5+4%	contents of 1144
8)	G5+G6+8%	contents of 11110000
9)	G5%.C	C4C1E3C3 E3D9C1D7 FFFF0000
10)	G4:6	00004000 00005000 00006000
11)	G6+A.2	A000
12)	G4+8%+4%.A	C4C1E3C3 E3D9C1D7 FFFF
13)	G5%+4	0000D000
14)	G5%+4%	DDDDDDDD
15)	IF G5%.8 EQ G4+8%+4% THEN DL G4+8 ELSE DL G4 ENDIF	0000A000

**Note:** Registers, when specified alone as in example 4 above, do not default to an indirection and a length of 4, as other data link values do. In this case, the data collected is simply the contents of the register.

**Examples of Data Link Definition:** The following example shows how multiple TRSOURCE command invocations are used to set up a conditional data link trace.

```

1) TRSOURCE ID TRC1 TYPE DATA LOC HCPNOS + 34 5840C08C
2) TRSOURCE ID TRC1 DL GB
3) TRSOURCE ID TRC1 IF GB+80.8 EQ C'OPERATOR'
4) TRSOURCE ID TRC1 THEN DL G0:F
5) TRSOURCE ID TRC1 ELSE IF GB+80.8 EQ C'MAINT'
6) TRSOURCE ID TRC1      THEN DL GC.30
7) TRSOURCE ID TRC1      ENDIF
8) TRSOURCE ID TRC1      DL G8
9) TRSOURCE ID TRC1 ENDIF

```

-----

These TRSOURCE commands could be defined in an EXEC file. In this example, line 1 defines where the trace is defined. Line 2 shows that when this instruction in HCPNOS executed, an unconditional data link will show the contents of register 11. Lines 3 through 9 define a conditional data link. Notice that in lines 6 and 8, spaces are used to improve readability.

**Examples of TRSOURCE TYPE LAN:** The following example shows how to set up a trace on a virtual switch and collect only data for vlan id 4, 5, and 7 as well as collecting 1000 bytes of data:

```

CP TRSOURCE ID ex1 TYPE LAN OWNER SYSTEM LANNAME VSWITCH1 VLAN 4 5 7 LENGTH
1000

```

If instead an entire guest LAN had to be traced, the following would be specified:

```

CP TRSOURCE ID ex2 TYPE LAN OWNER BOLINDA LANNAME GLAN

```

The trace can also be more specific and capture only packets related to Guest TCPIP1.

```

CP TRSOURCE ID ex3 TYPE LAN OWNER SYSTEM LANNAME VSWITCH1 NIC TCPIP1 2D02

```

## UNCOUPLE

```
▶▶ UNCOUPLE — vdev ◀◀
```

### Authorization

Privilege Class: G

### Purpose

Use UNCOUPLE to disconnect a virtual CTCA from a coupled CTCA device, or to disconnect a virtual network adapter from a guest LAN or a virtual switch. You can also uncouple a virtual CTCA by using an improper form of the COUPLE command. For example,

```
COUPLE vdev TO * vdev
```

would disconnect *vdev* from the current partner and leave it disconnected because it is not possible to connect a CTCA to itself.

### Operands

#### *vdev*

specifies the virtual device number (hex) of the adapter to be disconnected. You may specify the virtual device number of any device that is defined as part of the adapter. However, CP responses refer to each virtual adapter by its *base* device address; this is the first device in the range.

### Usage Notes

When *vdev* is a virtual OSA device type, it represents a virtual network adapter created by the DEFINE NIC command. You can use any *vdev* on the command line that is part of the virtual adapter configuration. However, CP responses use the base device number to identify the virtual adapter.

### Responses

Response 1: (virtual CTCA uncoupled by partner)

```
CTCA vdev DROPPED BY invoker vdev
```

is the response from a partner's console after a virtual CTCA device is uncoupled by the other user.

Response 2: (virtual CTCA uncoupled by user)

```
CTCA vdev DROPPED FROM userid vdev  
CTCA vdev is uncoupled now
```

is the response from an invoker's console after a virtual CTCA device is uncoupled by the user.

Response 3: (virtual NIC uncoupled)

```
NIC vdev is disconnected from LAN ownerid lanname
```

is the response from the invoker's console after a virtual network adapter is uncoupled.

Response 4: (virtual NIC uncoupled)

```
NIC vdev is disconnected from switch SYSTEM switchnm
```

is the response from the invoker's console after a virtual network adapter is uncoupled from a virtual switch.

**Messages**

- HCP006E Invalid device type - *vdev*
- HCP040E Device *vdev* does not exist

## UNDIAL

---

» UNDIAL «

### Authorization

Privilege Class: Any

### Purpose

Use UNDIAL to logically disconnect your terminal from a z/VM guest system and return control of that terminal to the host z/VM system.

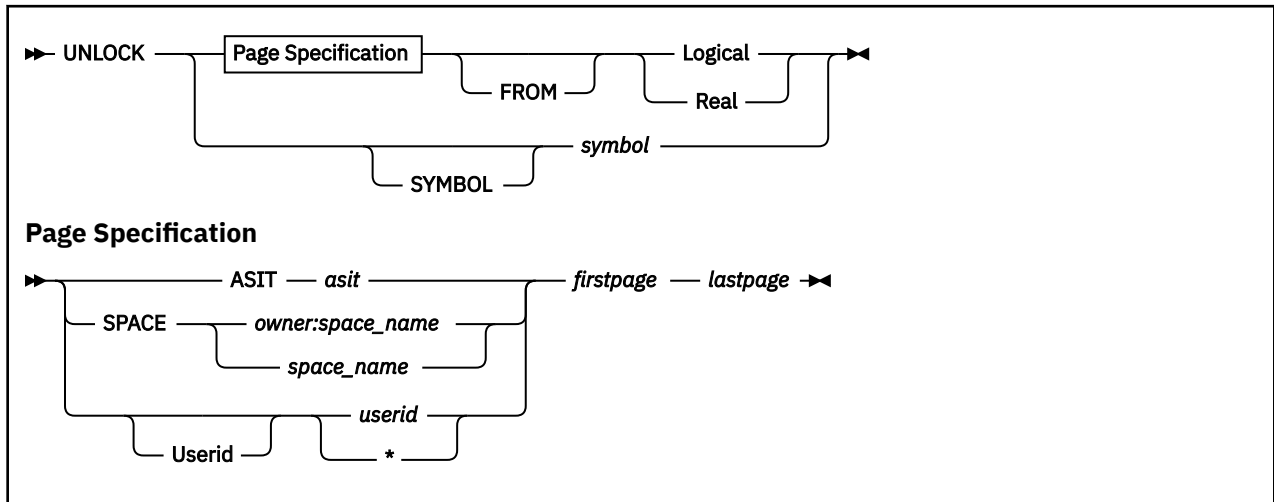

### Usage Notes

1. If UNDIAL is issued from a terminal that is being controlled by a host z/VM system, an error message will be issued.
2. UNDIAL can be issued only from a terminal that is not logged on. That is, UNDIAL can be issued before the LOGON command or after the LOGOFF or DISCONNECT commands.
3. UNDIAL cannot be used if the terminal is connected to a VTAM service machine (VSM) running in the guest system. If this is the case, the connection to the VSM must be terminated before the CP UNDIAL command can be used.
4. When UNDIAL is issued from a terminal that is dialed to the guest VM system as a logical terminal or a non-SNA TTY terminal and is not logged on, UNDIAL has the same effect as the LOGOFF command.

### Messages

- HCP2101E This terminal is not dialed to a virtual machine.
- HCP2102E This terminal is logged on to a virtual machine. You must logoff or disconnect before issuing UNDIAL.
- HCP2103E This terminal is connected to a VTAM Service Machine. You must disconnect from the service machine before issuing UNDIAL.

## UNLOCK

## Authorization

Privilege Class: A

## Purpose

Use UNLOCK to release guest pages kept in host storage by the LOCK command.

## Operands

### ASIT *asit*

unlocks pages in the address space identified by the address-space-identification token, *asit*. The *asit* must be padded to 16 hexadecimal digits with leading zeros.

### SPACE *owner:space\_name*

unlocks pages in the address space identified by the space ID, *owner:space\_name*, where *owner* is the user ID of the virtual machine that owns the address space and *space\_name* is the name assigned to the address space.

If *owner:* is not specified, your virtual machine is assumed to be the owner of the address space.

The space name is a string of alphanumeric and national characters, 1 to 24 characters long. The space name "BASE" is preassigned by CP to be the name of the issuer's host-primary address space.

### USERID *userid*

#### *userid*

unlocks pages in the primary address space of the virtual machine identified by *userid*. The virtual machine must be logged on. If you are unlocking pages of your own virtual machine's storage, you can specify *userid* as an asterisk (\*).

### *firstpage*

is the hexadecimal number of the first user or address space page to be unlocked from host storage.

Usage note [“2” on page 2044](#) explains how to derive page numbers from storage addresses.

### *lastpage*

is the hexadecimal number of the last user or address space page to be unlocked from host storage. If only one page is to be unlocked, *lastpage* must be the same as *firstpage*.

### Logical

unlocks the guest pages from host logical storage pages.

## UNLOCK

### Real

unlocks the guest pages from real storage frames.

### SYMBOL *symbol*

has no effect and is retained only for compatibility purposes. All symbols are considered resident, which means they cannot be locked or unlocked.

## Usage Notes

1. In the primary address space, the first and last page numbers are treated as *guest real* addresses. They are prefixed with the prefix register value of the base virtual CPU of the target virtual machine. In other address spaces, the first and last page numbers are treated as *guest absolute* addresses. Prefixing is not applied to these addresses.
2. Specify page numbers for the *firstpage* and *lastpage* operands, not addresses. Page numbers are assigned beginning with zero; each page is X'1000'. For example, to unlock storage locations X'12000' to X'2CFFF' of USERA's primary address space from host logical storage, enter the following command:

```
unlock usera 12 2c from logical
```

3. The LOCK and UNLOCK commands operate independently of the DIAGNOSE code X'98' page locking facility. Pages locked by the LOCK command cannot be unlocked by DIAGNOSE code X'98', nor can real I/O pages locked by DIAGNOSE code X'98' be unlocked by the UNLOCK command.
4. If you issue the LOCK command to lock a page in a shared segment and do not issue an UNLOCK command, the page is unlocked when the last user of the shared segment releases the storage with the LOGOFF command or another command that clears storage.
5. Host storage must be unlocked in the same way it was locked. If you issued the LOCK command with the LOGICAL operand to lock a guest page to a host logical storage page, the corresponding real storage frame was also locked by CP. To release both the host logical storage page and the real storage frame, you must also specify the LOGICAL operand on the UNLOCK command.
6. A guest page can be locked only once in host logical storage and once in real storage. If you issued the same LOCK command multiple times, only one UNLOCK command is needed.
7. If you issue UNLOCK with the ASIT operand and specify the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the UNLOCK command is rejected and error message HCPCPW033E is issued. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value by using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:
  - SYSTEM CLEAR
  - IPL by NSS name
  - IPL by device with the CLeAr option
  - SET MACHine (to a different machine architecture)

## Responses

Response 1:

```
Command complete
```

is issued when the command finished successfully. This response is displayed even if you did not have any pages locked in host storage.

## Messages

## VARY CHPID

### Authorization

Privilege Class: B

### Purpose

Use VARY CHPID to enable or disable a real connection between the host system and one or more real devices.

**Attention:** The VARY ON CHPID command should be used instead of the corresponding function at the SE Hardware Console. Using the SE Hardware Console may cause channel path-type changes or channel path availability to be unrecognized by VM.

### Operands

#### ONline

tells CP to enable the specified channel path.

#### OFFline

tells CP to disable the specified channel path.

#### CHPID *nn*

identifies the path that is to become enabled (physically available) or disabled (unavailable) for use by the system to communicate with the specified device or devices.

#### FORCE

specifies that the path be unconditionally disabled for use by the system.

### Usage Notes

1. To successfully change the availability status of a CHPID, the CHPID must already have been defined to the system.
2. In order to take a real CHPID offline in an orderly fashion, you must disable the software's use of that CHPID. At the very least, this means you will need to vary the logical path offline (VARY OFF PATH). If the CHPID to be removed represents the last path to a device, then you will also need to vary the device offline (VARY OFF rdev) as well.
3. The FORCE operand will cause the REAL path (CHPID) to become unavailable in the hardware without regard for any software dependencies that may exist. In other words, if you choose to use the FORCE operand, the CHPID will be brought offline immediately without regard to any active I/O on the channel path. This operand is analogous to making the CHPID offline by using the hardware system console. This FORCE operand is not recommended for general use and should only be considered in such situations that are deemed critical to system survival.
4. If a CHPID is defined which has control units and devices defined to it (and these are all powered up), CP will immediately drive all the devices through device initialization when you issue the VARY ON CHPID command. For a device that is already online, CP will logically add the path to the device. Devices that are found to be offline will come online as long as CP can obtain all the needed device information.

5. If a CHPID is defined which has no control units or devices defined to it, then only the CHPID is brought online when you issue the VARY ON CHPID command. If you then define a control unit and devices to the CHPID, they will only come online if you issue the VARY ON *rdev* command.

## Responses

Response 1:

To enable CHPID 21, enter the following VARY CHPID command:

```
vary online chpid 21
Channel path 21 was successfully varied online
```

Response 2:

If the CHPID was already online:

```
vary online chpid 21
Channel path 21 is already online
Ready;
```

Response 3:

To disable CHPID 21, enter the following VARY CHPID command:

```
vary offline chpid 21
Channel path 21 was successfully varied offline
Ready;
```

Response 4:

If the CHPID was already offline:

```
vary offline chpid 21
Channel path 21 is already offline
Ready;
```

Response 5:

To disable CHPID 21 unconditionally, enter the following VARY CHPID command:

```
vary offline chpid 21 force
Channel path 21 was successfully varied offline
Ready;
```

## Messages

- HCP0003E Invalid option - command contains extra option(s) starting with *option*
- HCP0026E Operand missing or invalid
- HCP0846E Invalid channel path identifier.
- HCP6811E Vary {online | offline} CHPID *nn* failed with return code *nnnn*.
- HCP6814E Command is not valid on this processor.
- HCP6818E Vary command failed. Channel path *nn* is logically online.

## VARY CORE

### Authorization

Privilege Class: B

### Purpose

Use VARY CORE to add a processor or core to the configuration or remove it from the configuration. The status of multithreading determines whether the VARY CORE command will affect a processor or a core. The term *core* refers to a physical CPU resource. In a logical partition (LPAR), logical CPUs (processors) are dispatched on cores when multithreading is not installed or not enabled. However, when multithreading is enabled, the core might contain multiple threads, and logical CPUs are dispatched on the threads of the core.

When multithreading is not installed or not enabled, the terms processor and core are synonymous, and the VARY CORE command configures or deconfigures processors. However, when multithreading is enabled, only whole cores can be configured or deconfigured. You cannot configure or deconfigure individual processors. When a core is varied online, the number of threads per core that are supported by the hardware, the z/VM system, and the current multithreading settings are made available for use. The multithreading settings are set by the MULTITHREADING configuration statement and may be modified by the SET MULTITHREAD command. When a core is varied offline, all of the threads online on that core are stopped and removed.

### Operands

#### ONline

when multithreading is not installed or not enabled, adds a processor to the configuration and makes it available for use by CP. When multithreading is enabled, this operand adds a core to the configuration and makes its processors (threads) available for use by CP.

#### OFFline

when multithreading is not installed or not enabled, stops the use of a processor and removes it from the configuration. When multithreading is enabled, this operand stops the use of a core and removes its processors (threads) from the configuration.

#### CORE *nnnn*

specifies the processor or core to be made available or unavailable. When multithreading is not installed or not enabled, the value *nnnn* is a hexadecimal number (0000 - 004F) that identifies the address of the processor. When multithreading is enabled, the value *nnnn* is a 1- to 4-digit hexadecimal number that identifies the core ID.

### Usage Notes

1. Before using the VARY CORE command when multithreading is enabled, it might be useful to issue the QUERY PROCESSORS command to display a list of processors and their associated core IDs. For an example of how the core ID corresponds to a processor address, see [“QUERY MULTITHREAD” on page 1026](#).
2. The last active primary processor or core cannot be varied offline. A primary processor or core is one whose CPU type matches the CPU type of the system's IPL processor.

3. When multithreading is not installed or not enabled, if the last unparked processor of a secondary processor type is varied offline while all other online processors of that type are parked, CPU affinity will be temporarily suppressed until one of those processors can be unparked.

When multithreading is enabled, if the last core that contains unparked processors of a secondary processor type is varied offline while all other online processors of that type are parked, CPU affinity will be temporarily suppressed until one of those processors can be unparked.

A secondary processor is a processor whose CPU type does not match the CPU type of the system's IPL processor.

4. If the last processor of a secondary processor type is varied offline, CPU affinity will be suppressed for all user IDs and resource pools defined on the system that have CPU affinity on for that secondary processor type. As soon as a secondary processor of that type is varied online, CPU affinity will be unsuppressed. A resource pool that limits a secondary processor type (like IFL) and that has CPU affinity suppressed will apply the resource pool limit against the number of CP CPUs on the system. For example, if the resource pool limit is set to CAPACITY 1.5, then the resource pool is limited to 1.5 CP CPUs when CPU affinity is suppressed. If the resource pool limit is set to LIMITHARD 20%, then the resource pool is limited to 20% of the CP CPU resource when CPU affinity is suppressed and 20% of the IFL CPU resource when CPU affinity is unsuppressed.

## Responses

Response 1:

```
Command accepted
Core nnnn online Proc pppp[-pppp]
```

indicates that the specified core and its associated processor or processors are now online and operational.

Response 2:

```
Command accepted
Core nnnn offline Proc pppp[-pppp]
```

indicates that the specified core and its associated processor or processors are now offline and not operational.

## Messages

- HCP1463I CPU affinity is suppressed for the specified CPU type *type*
- HCP1465I CPU affinity is no longer suppressed for the specified CPU type *type*

## VARY CRYPTO

### Authorization

Privilege Class: B

### Purpose

Use VARY ONLINE CRYPTO to bring crypto adapters online and make them available for use.

Use VARY OFFLINE CRYPTO to take crypto adapters offline and make them unavailable for use.

If a crypto adapter is varied offline while resources on the adapter are attached to a virtual machine for dedicated use, or while resources are attached to the system for shared use, then the assignments remain intact while the adapter is offline. When the adapter is brought back online, the resources will be re-attached to the virtual machines or to the system as they were prior to the vary offline.

The FORCE option is required when the last functioning and usable resource in the shared pool is varied offline.

The FORCE option is required when the last functioning and usable resource that is dedicated to a virtual machine is varied offline.

### Operands

#### ONline

brings a crypto adapter online and makes it available for use.

#### OFFline

brings a crypto adapter offline and makes it unavailable for use.

#### *n*

#### *n1-n2*

specifies a single adapter number, a list of adapter numbers, a range of adapter numbers or a combination of these, to be varied online or offline. If you are specifying a list of numbers, insert at least one blank between the numbers you specify. If you are specifying a range of numbers, insert a hyphen (-) between the numbers you specify. The number is a decimal number between 0 and 255.

#### FORCE

The FORCE option is required when the last functioning and usable resource in the shared pool is varied offline.

The FORCE option is required when the last functioning and usable resource that is dedicated to a virtual machine is varied offline.

### Usage Notes

1. If an adapter is being brought online for the first time, VARY ONLINE CRYPTO should be followed by one of the following to make the specific resources available to a virtual machine or to the system:

- ATTACH CRYPTO
- Logon a virtual machine with a CRYPTO APDEDICATED statement in the directory entry.

If the adapter was previously online, existing resource assignments remain intact when it is brought back online, and the resources are again available for these virtual machines.

2. VARY OFFLINE CRYPTO with the FORCE option will cause the adapter to be taken offline even if it is the last resource attached to the system for shared use, or if it is the last resource attached to a virtual machine for dedicated use.
3. If CP is unable to take the adapter online or offline at the hardware level, the adapter will become logically online or offline. The operational status of the resources on the adapter will be reported in the Q CRYPTO response. A logically online resource could be deconfigured or in an error state, which would make it unusable. A logically offline resource could be operational, which would make it usable if it is dedicated to a virtual machine. CP will not use offline crypto resources that are in the shared pool.
4. For information on planning and managing crypto resources on a z/VM system, see [Crypto Planning and Management in z/VM: CP Planning and Administration](#).

## Responses

Response 1:

This response indicates that the specified adapter is now online.

```
CRYPTO AP apnum VARIED ONLINE
CRYPTO AP apnum VARIED ONLINE by userid
```

Response 2:

This response indicates that the specified adapter is now offline.

```
CRYPTO AP apnum VARIED OFFLINE
CRYPTO AP apnum VARIED OFFLINE by userid
```

Response 3:

This response is sent to the primary system operator when the command issuer is not the system operator.

```
CRYPTO AP apnum VARIED ONLINE by userid
CRYPTO AP apnum VARIED OFFLINE by userid
```

### ***apnum***

is the crypto adapter number.

## VARY CRYPTO

- HCP1743E The VARY command cannot complete because the physical vary failed. AP *apnum* is logically online.
- HCP1743E The VARY command cannot complete because the physical vary failed. AP *apnum* is logically offline.
- HCP2768E Missing crypto AP number
- HCP6706E Invalid Crypto AP number

## VARY PATH

### Authorization

Privilege Class: B

### Purpose

Use VARY PATH to enable or disable a logical connection between the host system and one or more real devices.

### Operands

#### ONline

#### OFFline

enables or disables the logical connection.

#### yy

identifies the path to become logically available or logically unavailable for use by the system to communicate with the specified device or devices.

**Note:** If the specified path is the last available path to the specified device, CP attempts to vary the device offline. If the device cannot be varied offline, the VARY OFFLINE PATH request is denied.

#### rdev

#### rdev1-rdev2

is the real device number of the devices to which the specified path is made logically available or logically unavailable. You may specify a single device, a list, or a range of devices. If you specify a range of real device numbers, all the valid devices in the range, including the first and last devices you specified, will be processed. The maximum number of devices allowed in a range is 256. For a device in the active configuration, the device number entered can be a 4-digit hexadecimal number between X'0000' and X'FFFF'. For a device in the active or standby configuration, the device can be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is configured. A range of devices cannot span subchannel sets.

#### ALL

specifies that the path be made logically available or logically unavailable to all real devices that have access to it.

#### FORCE

specifies that an attempt be made to bring the path online even if another function had previously varied it offline.

## Usage Notes

1. The VARY PATH command does not start the service processor or cause any hardware functions to be performed.
2. If you specify a list or range of devices, an attempt is made to vary the specified path online or offline to each device. An error message is issued for every device for which the specified path cannot be varied online or offline. Check examples after these usage notes.
3. Paths leading to dedicated non-dynamic pathing devices that allow RESERVE/RELEASE are not varied offline.  
 To determine if RESERVE/RELEASE is allowable, enter the QUERY DASD command and see if the response from the device indicates that the device is SHARED, RESERVED, or has a RESERVE PENDING (see the Responses section of the QUERY DASD command).
4. Inoperational paths may be varied online because no I/O is issued to validate the path when a non-dynamic pathing device is reserved or is dedicated to a guest and supports RESERVE/RELEASE.
5. When varying a path offline:
  - Vary the path offline from the guest operating system if the guest (such as MVS/ESA) supports a VARY PATH command.
  - Vary the path offline from the host system (z/VM).
6. When varying a path online:
  - Make the path physically available.
  - Vary the path online to the host (z/VM).
  - Vary the path online to the guest operating system if the guest supports a VARY PATH command.
7. If the IBM Service Representative indicates that the service on the path is complete but the control unit initiated resume did not successfully vary the affected path online, the FORCE option may be used to vary the quiesced path back online.

## Examples

Enter vary on path c2 to 140 to make path C2 leading to device 140 available to that device. A typical response may appear as follows:

```
Vary path c2 online command initiated
Vary path c2 online command complete
```

Enter vary off path c2 from 0190-0197 to make path C2 unavailable to devices 0190 through 0197. A typical response may appear as follows:

```
Vary path c2 offline command initiated
Path c2 not varied offline from device 0192
because it is the last path to device
Vary path c2 offline command complete
```

## Responses

Response 1: Vary Initiated:

```
VARY PATH yy {ONLINE } COMMAND INITIATED
           {OFFLINE}
```

indicates that the request has been initiated.

**yy**

is the path requested to be varied online or offline.

Response 2: Vary Complete:

```
VARY PATH yy {ONLINE } COMMAND COMPLETE
             {OFFLINE}
```

indicates that command processing is complete. An attempt was made to make the specified path available or unavailable (whichever was specified—online or offline) to each device specified. While command processing is now complete, check carefully any console messages that might indicate that not all processing was successful.

***yy***

is the path requested to be varied online or offline.

Response 3: Path Not Operational:

```
PATH yy NOT VARIED ONLINE
TO   DEVICE rdev; PATH NOT OPERATIONAL
```

indicates that the specified path has not been made available (varied online) for the specified device because the path is not operational. Make the path operational and then retry the command.

***yy***

is the path not made operational.

***rdev***

is the real device number.

Response 4: Last Path to Device:

```
PATH yy NOT VARIED OFFLINE FROM DEVICE rdev
BECAUSE IT IS THE LAST PATH TO DEVICE
```

indicates that the specified logical path is the last path to the specified device. CP tried unsuccessfully to vary the device offline. Use the VARY command to vary the device offline, then retry the VARY PATH command.

***yy***

is the path CP tried to make unavailable (vary offline) to the specified device.

***rdev***

is the real device number.

Response 5: Path Not Installed To Device:

```
PATH yy NOT VARIED {ONLINE TO } DEVICE rdev;
                   {OFFLINE FROM}
```

Continued:

```
PATH DOES NOT EXIST TO THE DEVICE
```

indicates that the specified path was not installed for the specified device.

***yy***

is the path requested to be made logically available (varied online) or unavailable (varied offline) to the specified device.

***rdev***

is the real device number.

Response 6: Device Reserve Held:

```
PATH yy NOT VARIED OFFLINE FROM DEVICE rdev;
RESERVED PATH
```

indicates that the specified path was not taken offline because there is a reserved allegiance to that path, which could not be moved to another path. (See Usage Note “3” on page 2054.)

***yy***

is the number for the path not taken offline.

## VARY PATH

### **rdev**

is the real device number.

Response 7: First Path:

```
FIRST PATH yy TO DEVICE rdev  
VARIED ONLINE; DEVICE VARIED ONLINE
```

indicates that the device was previously offline because all of its channel paths were varied offline. The path requested to be varied online was the first path to the device to be varied online, and therefore the device as well as the path was varied online.

### **yy**

is the path that was requested to be made available (varied online) to the specified device.

### **rdev**

is the real device number.

Response 8: Last Path:

```
LAST PATH yy TO DEVICE rdev  
VARIED OFFLINE; DEVICE VARIED OFFLINE
```

indicates that the path requested to be varied offline was the last path to the device and therefore the device (and the path) were varied offline.

### **yy**

is the path that was requested to be made unavailable (varied offline) to the specified device.

### **rdev**

is the real device number.

Response 9: Pending Reserve:

```
PATH yy NOT VARIED OFFLINE FROM  
DEVICE rdev; DEVICE RESERVE PENDING
```

indicates that the path requested to be varied offline could not be varied offline because a reserve request was pending to that device. Check the other system sharing this device; it may be hung, holding the reserve, thus prohibiting CP's reserve request from being granted.

### **yy**

is the number of the path not varied offline because of a pending reserve request.

### **rdev**

is the real device number.

Response 10: Path Not Physically Available:

```
PATH yy NOT VARIED ONLINE TO DEVICE rdev;  
PATH NOT AVAILABLE TO THE DEVICE
```

indicates that the path is not physically available to the device. Ensure that the path is switched in and varied online from the system's service console.

### **yy**

is the number of the path not physically available to the device.

### **rdev**

is the real device number.

Response 11: Path Already Varied Offline:

```
PATH yy HAS ALREADY BEEN VARIED OFFLINE  
FOR DEVICE rdev
```

indicates that the system operator has already varied the path offline.

***yy***

is the path that was both requested to be and then varied offline.

***rdev***

is the real device number.

Response 12: Path Already Online:

```
PATH yy ALREADY ONLINE FOR DEVICE rdev
```

indicates that the path is already online.

***yy***

is the number of the path already online.

***rdev***

is the real device number.

Response 13: Configuration Change Detected:

```
PATH yy NOT VARIED ONLINE TO DEVICE rdev;  
A CONFIGURATION CHANGE WAS DETECTED.
```

indicates that a configuration change was detected.

***yy***

is the number of the path not varied online.

***rdev***

is the real device number.

Response 14: Path Offline By Configuration Manager:

```
PATH yy NOT VARIED ONLINE TO DEVICE rdev;  
PATH OFFLINE BY CONFIGURATION MANAGER
```

indicates that the path is not varied online because the configuration manager has varied it offline.

**CAUTION:** If it is necessary to bring the path online, reissue the VARY PATH command with the FORCE option.

***yy***

is the channel path identifier.

***rdev***

is the real device number.

Response 15: Path Offline Due to a Control Unit Initiated Request:

```
PATH yy NOT VARIED ONLINE TO DEVICE rdev  
BECAUSE IT IS QUIESCED FOR MAINTENANCE.
```

indicates that the path is not varied online because a control unit initiated quiesce request has varied it offline. If an IBM Service Representative has indicated that the service on the path is complete and the control unit initiated resume request has failed to successfully vary the affected path online, the FORCE option of the VARY ONLINE PATH command may be used to vary the quiesced path back online.

***yy***

is the channel path identifier.

***rdev***

is the real device number.

Response 16: Subchannel Disabled:

```
PATH yy NOT VARIED ONLINE TO DEVICE rdev  
SUBCHANNEL IS DISABLED.
```

## VARY PATH

indicates that the path was not varied online because the associated subchannel for this device is disabled (offline). The subchannel needs to be varied online to be enabled. Once the subchannel is enabled, the path can be varied online.

***yy***

is the channel path identifier.

***rdev***

is the real device number.

Response 17: Device is BOXED:

```
PATH yy NOT VARIED ONLINE TO DEVICE rdev
Device is BOXED.
```

indicates that the path has not been made available (varied online) to the device because the device is BOXED.

If the path specified was marked 'offline by an authorized user' (as a result of a previous VARY OFF PATH command), then this path will no longer be marked that way. If a previous VARY ON DEVICE command failed because no paths were available to this device, then it may have been due to all paths to the device being in the 'offline by authorized user' state. If so, then a subsequent VARY ON DEVICE command may now be successful because it can use this path.

***yy***

is the number of the path not varied online because the device is BOXED.

***rdev***

is the real device number.

Response 18: Incompatible High Performance FICON feature:

```
PATH yy NOT VARIED ONLINE TO DEVICE rdev; path offline
due to incompatible High Performance FICON feature.
```

indicates that incompatible paths cannot be varied online logically unless the FORCE option is specified.

***yy***

is the number of the path not varied online.

***rdev***

is the real device number.

## Messages

- HCP003E Invalid option - *{option|command}* contains extra option(s) starting with *option*}

## VARY PCIFUNCTION

### Authorization

Privilege Class: B

### Purpose

Use VARY PCIFUNCTION to configure or deconfigure a PCI function.

### Operands

#### ONline

configures a PCI function.

#### OFFline

deconfigures a PCI function.

#### PCIFunction

used for specifying PCI function(s).

#### *rpfid*

#### *rpfid1-rpfid2*

specifies a real PCI function ID or a range of PCI function IDs that are to be enabled or disabled for the user. Specify a PCI function ID as a 1- to 8-digit hexadecimal number between X'00000000' and X'7FFFFFFF'. The total number of PCI functions specified cannot exceed 256.

### Responses

Response 1:

```
rpfid varied {online }
             {offline}
```

indicates that the specified real PCI function ID is now online or offline.

Response 2:

```
rpfid already {online }
              {offline}
```

indicates that the specified real PCI function ID is already online or offline.

Response 3:

```
nnn PCI function(s) specified; nnn PCI function(s) successfully varied {online }
                                                                           {offline}
```

is a summary response indicating how many PCI functions were successfully varied online or offline.

Response 4:

```
PCI function rpfid not varied online; PCI function could not be configured.
```

indicates that the PCI function specified to be varied online could not be configured.

Response 5:

```
PCI function rpfid not varied offline; PCI function could not be
deconfigured.
```

indicates that the PCI function specified to be varied offline could not be deconfigured.

### Messages

- HCP002E Invalid operand - *operand*
- HCP009E Invalid range - *range*
- HCP021E A real PCI function ID was not supplied or it is invalid.
- HCP040E PCI function {*rpfid*} does not exist
- HCP040E PCI function {*rpfid*} attached to *userid*.
- HCP1163I PCI function *rpfid* cannot be allowed online because PCI support is not enabled for the system.
- HCP1163I PCI function *rpfid* initialization has failed; return code *rc*, response code *respcode*.
- HCP1167E PCI function *rpfid* cannot be brought online because it is of an unknown type.
- HCP6000E The range of PCI function IDs cannot exceed 256.
- HCP6790I VARY processing halted. The next function that would have been processed is *rpfid*

## VARY PROCESSOR

### Authorization

Privilege Class: B

### Purpose

When multithreading is not installed or not enabled, use VARY PROCESSOR to add a processor to the configuration for use by CP or to remove a processor from the configuration. When multithreading is enabled, the VARY PROCESSOR command is not valid and the VARY CORE command must be used.

### Operands

#### ONline

adds a processor to the configuration and makes it available for use by CP.

#### OFFline

stops the use of a processor and removes it from the configuration.

#### PROcEssor *nnnn*

specifies the processor to be made available or unavailable. The value *nnnn* is a hexadecimal number (0000 - 004F) that identifies the address of the processor.

### Usage Notes

1. The last active primary processor cannot be varied offline. A primary processor is a processor whose CPU type matches the type of the system's IPL processor.
2. If the last unparked processor of a secondary processor type is varied offline while all other online processors of that type are parked, CPU affinity will be temporarily suppressed until one of those processors can be unparked.  
  
A secondary processor is a processor whose CPU type does not match the CPU type of the system's IPL processor.
3. If the last processor of a secondary processor type is varied offline, CPU affinity will be suppressed for all user IDs and resource pools defined on the system that have CPU affinity on for that secondary processor type. As soon as a secondary processor of that type is varied online, CPU affinity will be unsuppressed. A resource pool that limits a secondary processor type (like IFL) and that has CPU affinity suppressed will apply the resource pool limit against the number of CP CPUs on the system. For example, if the resource pool limit is set to CAPACITY 1.5, then the resource pool is limited to 1.5 CP CPUs when CPU affinity is suppressed. If the resource pool limit is set to LIMITHARD 20%, then the resource pool is limited to 20% of the CP CPU resource when CPU affinity is suppressed and 20% of the IFL CPU resource when CPU affinity is unsuppressed.

### Responses

Response 1:

```
PROCESSOR nnnn ONLINE
```

indicates that the specified processor is now online and operational.

Response 2:

```
PROCESSOR nnnn OFFLINE
```

indicates that the specified processor is now offline and not operational.

### Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP026E Operand missing or invalid
- HCP039E Processor address missing or invalid
- HCP880E The command processing cannot complete because processor *nnnn* is already online.
- HCP881E The command processing cannot complete because processor *nnnn* is already offline.
- HCP882E The VARY command processing cannot complete due to an initialization failure.
- HCP883E The command processing cannot complete because processor *nnnn* is not responsive.
- HCP884E The command processing cannot complete because processor *nnnn* is the only active primary processor.
- HCP885E The VARY processing cannot complete because the physical vary failed; processor *nnnn* is logically offline.
- HCP886E The VARY command processing cannot complete because processor *nnnn* is not available.
- HCP1321E VARY PROCESSOR is not valid because multithreading is enabled.
- HCP1463I CPU affinity is suppressed for the specified CPU type *type*
- HCP1465I CPU affinity is no longer suppressed for the specified CPU type *type*

## VARY (Real Device)

### Authorization

Privilege Class: B

### Purpose

Use VARY (real device) to do the following:

- Enable or disable a device for the control program (CP)
- Enable or disable a device for the user.

### Operands

#### ONline

#### OFFline

enables or disables the logical connection.

#### *rdev*

#### *rdev1-rdev2*

is the number of the real device to be varied online or offline. You may specify a list or range of devices. If you specify a range of real device numbers, all valid devices in the range, including the first and last devices you specify, are varied online or offline. For a device in the active configuration, the device number entered can be a 4-digit hexadecimal number between X'0000' and X'FFFF'. For a device in the active or standby configuration, the device can be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is configured. A range of devices cannot span subchannel sets.

#### NOASSIGN

#### ASSIGN

tells CP to try to ASSIGN or UNASSIGN the device to CP at vary on time. If the ASSIGN fails, the device is not varied online.

#### FORCE

specifies that an attempt be made to bring the device online even if another function has prevented the device from coming online.

#### TEST

specifies that CP bring the device online even if conditions exist that would normally prevent the device from successfully being brought online.

## Usage Notes

1. When a device is being brought online, the system will attempt to generate a device equivalency ID (EQID). However, a user-defined EQID might have already been assigned to the device. In this case, if the system successfully generates an EQID, it will override whatever EQID the user had assigned the device, and you will receive message HCP6627I. Note that this does not apply to the following device types: CTCA, FCP, HiperSockets, and OSA.
2. If you specify a list or range of devices, an attempt is made to vary them online or offline regardless of whether an error is encountered with any one of the specified devices. An error message is issued for every device that cannot be varied online or offline. A summary message is issued to indicate the number of devices successfully varied online or offline.
3. An UNASSIGN is issued to all tape devices that support ASSIGN/UNASSIGN during the vary off process.
4. If the IBM Service Representative indicates that the service on a quiesced device or set of devices is complete, but the control unit initiated resume did not successfully vary the affected device(s) online, the FORCE operand may be used to vary the device(s) back online.
5. The TEST operand provides the ability for a device that would not normally be allowed online by CP, to be brought online in *test mode* so that it can be attached to a virtual machine for the execution of diagnostics in problem determination. For a device to be eligible for *test mode*, it must be predefined either in the system configuration file or through a SET RDEVICE, as an unsupported device.

## Responses

Response 1:

```
rdev VARIED {ONLINE }
             {OFFLINE}
```

indicates that the specified device is now online or offline.

Response 2:

```
type rdev IS ALREADY {ONLINE }
                    {OFFLINE}
```

indicates that the specified device is already online or offline.

Response 3:

```
nnn DEVICE(S) SPECIFIED; nnn
DEVICE(S) SUCCESSFULLY VARIED {ONLINE }
                               {OFFLINE}
```

is a summary response indicating how many devices were successfully varied online or offline.

Response 4:

```
type rdev CANNOT BE VARIED ONLINE;
DEVICE HAS NO ONLINE CHANNEL PATHS
```

indicates that the device specified to be varied online has no online (logically available) channel paths. A previous vary path request has made the last path to the device unavailable causing the device to be varied offline.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP006E Invalid device type - *rdev*
- HCP009E Invalid range - *range*
- HCP021E A real device number was not supplied or it is invalid.

- HCP026E Operand missing or invalid
- HCP040E Device {*rdev/vdev/ldev*} does not exist
- HCP049E *Type rdev* in use
- HCP123E DASD *rdev* CP-owned
- HCP124E DASD *rdev* in use by *nnnnn* users
- HCP140E *Type rdev* attached to *userid*
- HCP142E *Type rdev* not drained
- HCP143E *Type rdev* in use by system
- HCP362I Device *rdev* cannot be varied online because the subchannel-id is invalid.
- HCP1150E DASD *rdev* is not a valid base exposure.
- HCP1250I Device *rdev* cannot be varied online because a time-out condition occurred.
- HCP1251I Device *rdev* cannot be varied online because it requires operator intervention.
- HCP1280E Device *vdev* not usable; reserve lost [by *userid* as *vdev*].
- HCP1281I Path *channel* to device *Device* now offline; path group ID mismatch.
- HCP1550E *Rdev* is an invalid device class.
- HCP1917E Tape device(s) {*rdev[-rdev]*|*vdev[-vdev]*} attached MULTIUSER.
- HCP3591E The hardware/software is not at the correct level to support LUN reset. Device *deviceFunction: function*
- HCP3593E *fp\_ioctl* for SCIOLCMD failed. resource name=*name*, return value=*rv*.Function: *function*
- HCP3594E *fp\_ioctl* for GET\_ROUTER\_STATE failed. resource name=*name*, return value=*rv*.Function: *function*
- HCP3595E *fp\_ioctl* for SET\_ROUTER\_STATE failed. resource name=*name*, return value=*rv*.Function: *function*
- HCP3597E *fp\_ioctl* for MODESENSE failed. resource name=*name*, return value=*rv*.Function: *function*
- HCP3598E *fp\_ioctl* for RTADDPATH failed. resource name=*name*, return value=*rv*.Function: *function*
- HCP3599E The cache settings for LUN *lun* will allow cached data to be lost if path failover occurs.
- HCP3603E Paths to disk *disk* do not go to same device.Function: *function*
- HCP6000E The range of device numbers cannot exceed 256.
- HCP6276I Device *rdev* cannot be varied online because the subchannel is not operational.
- HCP6277I Device *rdev* cannot be varied online because I/O errors occurred.
- HCP6280I Device *rdev* cannot be varied online because an error occurred while attempting to establish a path group.
- HCP6281I Device *rdev* cannot be varied online because of conflicting device identification information.
- HCP6282I Device *rdev* cannot be varied online because the subchannel is invalid.
- HCP6283I Device *rdev* cannot be varied online because no channel path is available.
- HCP6284I Device *rdev* cannot be varied online due to conflicting device classification information.
- HCP6285I Device *rdev* cannot be varied online due to conflicting device numbers.
- HCP6286I Device *rdev* cannot be varied online because the subchannel cannot be modified.
- HCP6287I Device *rdev* cannot be varied online because it did not respond to a no-op command.
- HCP6288I Device *rdev* cannot be varied online because the subchannel is varied offline
- HCP6289I Device *rdev* cannot be varied online because it is quiesced for maintenance.
- HCP6290I Device *rdev* cannot be varied online because it is uninstalled or unsupported.
- HCP6291I Device *rdev* cannot be varied online because it is assigned elsewhere.
- HCP6291I Device *rdev* cannot be varied online because it is reserved to another system.

## VARY (Real Device)

- HCP6292I Device *rdev* cannot be varied online because the ASSIGN option was specified and the device does not support assign.
- HCP6293I Device *rdev* cannot be varied online because it is a spare volume within the DASD subsystem.
- HCP6295I DASD *rdev* cannot be varied online because an associated DASD does not exist in the primary subchannel set.
- HCP6627I User-defined EQID replaced by system-generated identifier for device *rdev*.
- HCP6785I Unable to identify device *rdev* dynamically.
- HCP6861I Device *rdev* cannot be varied online because it is an alias Parallel Access Volume for which the base could not be located.
- HCP8700I Emulated Device *rdev* cannot be varied online because CP was unable to open the device.
- HCP8700I Emulated Device *rdev* cannot be varied online because its size is greater than 2,147,483,640 512-byte blocks.
- HCP8700I Emulated Device *rdev* cannot be varied online because there are no valid paths defined to the device.
- HCP8701I Path FCP\_DEV *rdev1* WWPN *wwpn* LUN *lun* was deleted from EDEV *rdev2* because it conflicts with online EDEV *rdev3*.
- HCP8701I Path FCP\_DEV *rdev1* WWPN *wwpn* LUN *lun* was deleted from EDEV *rdev2* because the FCP device is currently reserved for the EXPLORE command.
- HCP8701I FBA DASD *rdev* cannot be varied online because its size is greater than 2,147,483,640 512-byte blocks.

## VARY SUBCHANNEL

### Authorization

Privilege Class: B

### Purpose

Use VARY SUBCHANNEL to enable or disable one or more subchannels.

### Operands

#### ONline

tells CP to enable the specified subchannel, subchannels, or range of subchannels.

#### OFFline

tells CP to disable the specified subchannel, subchannels, or range of subchannels.

#### SUBchannel *rdev*

#### SUBchannel *rdev1-rdev2*

is the number of the real device whose associated subchannel is to be enabled or disabled. You may specify a list or range of devices. If you specify a range of real device numbers, all valid devices in the range, including the first and last devices you specify, will have their designated subchannels enabled or disabled. The maximum number of devices allowed in a range is 256. For a device in the active configuration, the device number entered can be a 4-digit hexadecimal number between X'0000' and X'FFFF'. For a device in the active or standby configuration, the device can be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set where the device is configured. A range of devices cannot span subchannel sets.

### Usage Notes

1. Each RDEV has only one associated subchannel which defines this device to the hardware I/O configuration. Through this command CP will either set or reset the ENABLED bit in the associated subchannel for the given device.
2. Once you have successfully disabled the subchannel for the given device, no further I/O requests and I/O interrupts will be accepted for the device.
3. You must use the VARY command to take a device offline before you can disable its subchannel. Before you can VARY the device back online, you must enable the subchannel through the use of VARY SUBCHANNEL.

### Responses

Response 1:

To VARY a subchannel online, enter the following VARY SUBCHANNEL command:

```
vary on sub 701
0701 subchannel varied online
1 device(s) specified; 1 device(s) successfully varied subchannel online
Ready;
```

## VARY SUBCHANNEL

Response 2:

To VARY a range of subchannels offline, enter the following VARY SUBCHANNEL command:

```
vary off sub 701-703
0701 subchannel varied offline
0702 subchannel varied offline
0703 subchannel varied offline
3 device(s) specified; 3 device(s) successfully varied subchannel offline
Ready;
```

Response 3:

If the subchannel is already enabled:

```
vary on sub 702
0702 subchannel is already online
1 device(s) specified; 0 device(s) successfully varied subchannel online
Ready;
```

Response 4:

If the subchannel is already disabled:

```
vary off sub 701
0701 subchannel is already offline
1 device(s) specified; 0 device(s) successfully varied subchannel offline
Ready;
```

### Messages

- HCP009E Invalid range - *range*
- HCP0026E Operand missing or invalid
- HCP0040E Device *rdev* does not exist
- HCP0267E A subchannel number was not supplied or is invalid
- HCP1150E DASD *rdev* is not a valid base exposure.
- HCP1249I Device *rdev* cannot be varied subchannel {disable|enable} because a time-out condition occurred
- HCP6760E Device *rdev* is not offline.

## VDELETE

### Authorization

Privilege Class: G

### Purpose

Use VDELETE to delete selected messages from the list of messages generated by the QUERY VMSG/ PVMSG command and directed to your system console.

The z/VM control program, as part of its service processor simulation, intercepts system console messages issued by a guest operating system and displays them on the virtual machine operator console. Until an intercepted message is deleted, it remains on the z/VM message list and may be recalled by the virtual machine console operator.

Messages may be deleted in these ways:

- Your virtual machine operating system, through communication with the service processor, may delete it.
- The VDELETE command may be issued against the message.
- The message list is limited to 16 current entries; older messages are removed from the list.

### Operands

#### VMSG

indicates that nonpriority messages are to be deleted. The message numbers, accepted as parameters on this command, are displayed on the virtual machine operator console when QUERY VMSG is issued to recall outstanding nonpriority messages.

#### PVMSG

indicates that priority messages are to be deleted. The message numbers, accepted as parameters on this command, are displayed on the virtual machine operator console when QUERY PVMSG is issued to recall outstanding priority messages.

#### msg1 [-msgn ]

designates the numbers of the messages to be deleted. These numbers are displayed on the virtual machine operator console when QUERY VMSG/PVMSG is issued.

### Usage Notes

1. z/VM treats each line of multiple-line message text as a separate message when it is displayed on your operator console and saved for recall by using QUERY VMSG/PVMSG. However, when any individual line of a multi-line message is deleted, all of the multiple-line message is deleted.
2. The message numbers preceding the operating system message text are assigned by the QUERY VMSG/PVMSG command processor and QUERY must be entered before a message may be deleted using VDELETE.

### Messages

- HCP002E Invalid operand - *operand*
- HCP026E Operand missing or invalid

## VDELETE

- HCP6532I There is no {priority|non-priority} message currently outstanding with message number *nnnn* assigned to it.

## VINPUT

### Authorization

Privilege Class: G

### Purpose

Use VINPUT to request the z/VM control program to send the accompanying data to the operating system running in your virtual machine. To the operating system, the data appears to have been entered from the system console.

z/VM, as part of its service processor hardware simulation, assigns to your virtual machine operator console a subset of system console functions. If the operating system running in your virtual machine is able to receive commands from the system console, the specified command is sent by the control program to the operating system where it is interpreted and processed as though it had been entered from the system console.

### Operands

#### VMSG

requests that the command is to be sent as a nonpriority command.

#### PVMSG

requests the command is to be sent as a priority command.

#### *data*

is the command to be sent to the operating system running in your virtual machine.

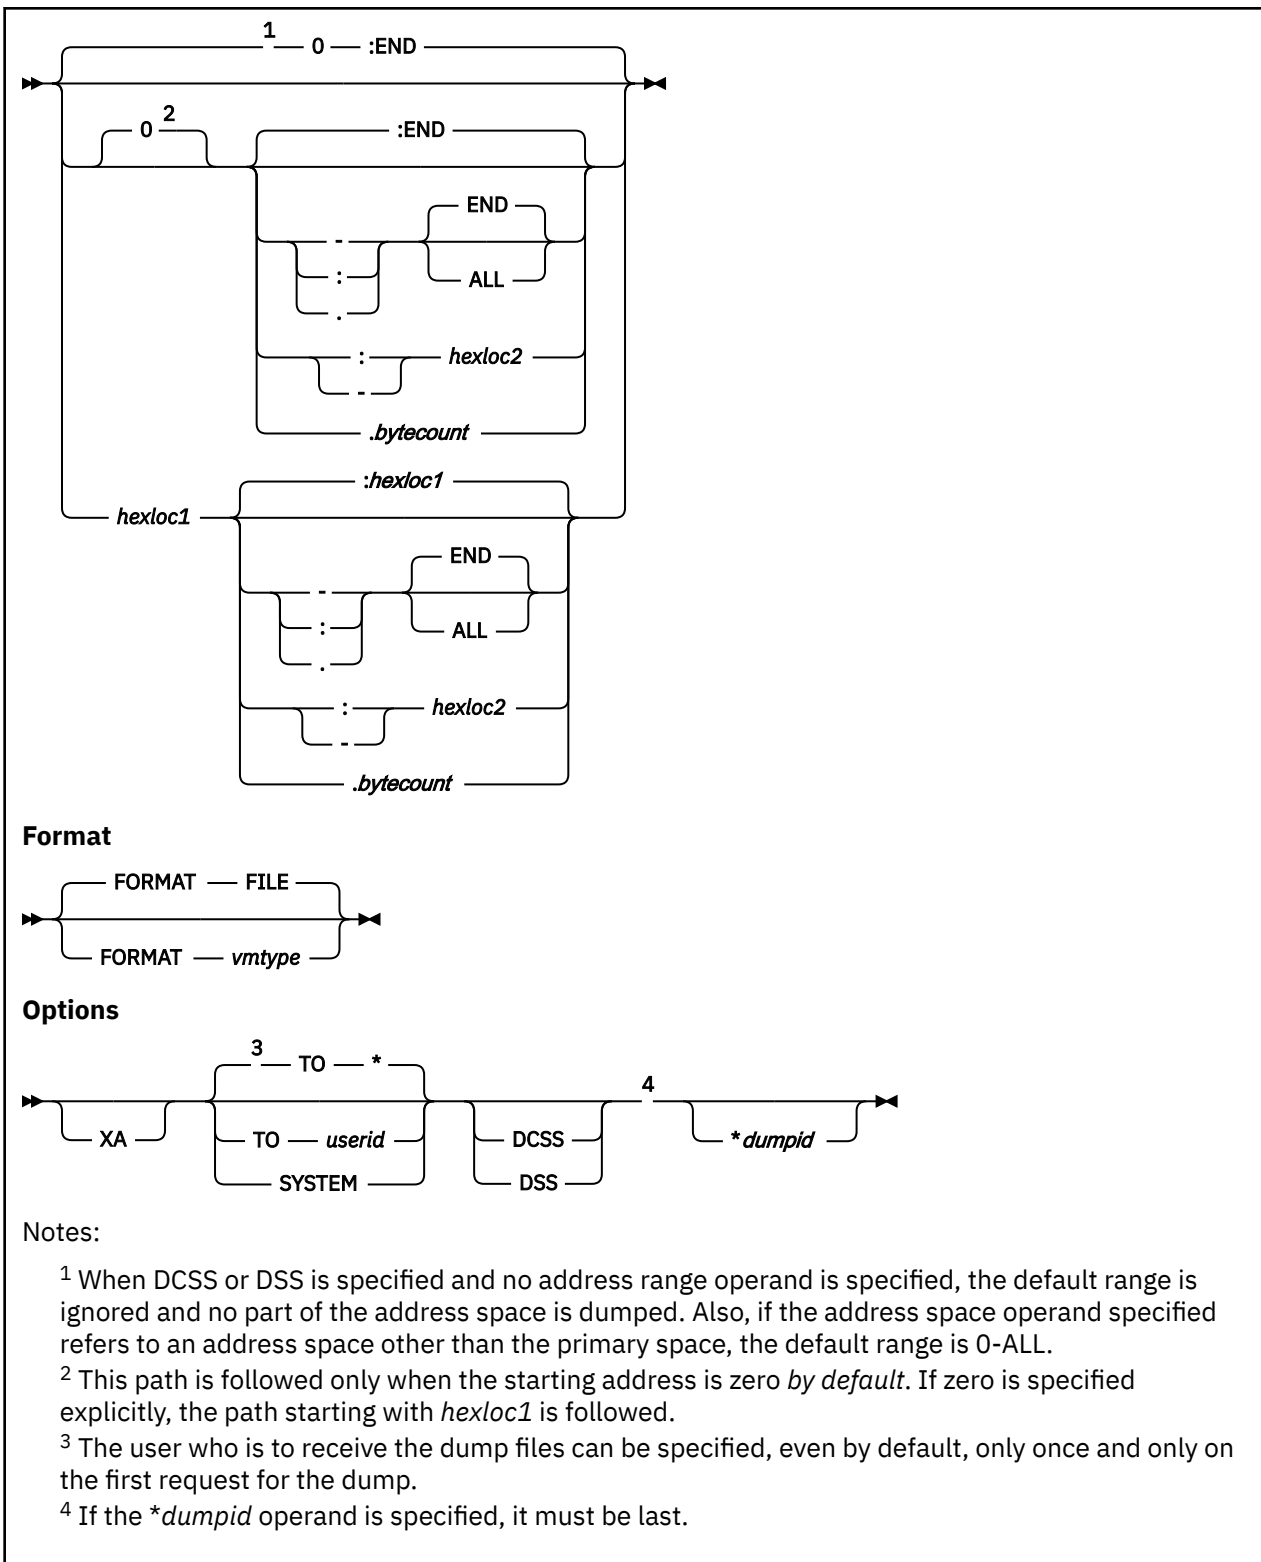

### Messages

- HCP026E Operand missing or invalid
- HCP6531E The operating system will not accept commands from the service processor.

## VMDUMP

### Authorization

Privilege Class: G

### Purpose

Use VMDUMP to dump all or selected pages from second-level storage.

## Operands

**Note:** An address space operand (PRIMARY, SPACE, ALET, ASIT, or AREG) qualifies the operands that follow it. It determines the target of all storage range, FORMAT, and dump ID operands until another address space operand or the end of the command string.

### PRImary

is the default and causes the information to be taken from the primary address space.

PRIMARY can be used only by XC virtual machines.

### SPACE *userid:space\_name*

causes the information to be taken from the address space identified by *userid:space\_name*, where *userid*: is the user ID of the owner of the address space followed by a delimiting colon (it is optional and defaults to the user issuing the command), and *space\_name* is the name of the address space. The space name is 1 to 24 characters long.

The CP QUERY SPACES command returns *userid:space\_name* in the "SPACE IDENTIFICATION" field.

SPACE can be used only by XC virtual machines.

### ALET *alet*

causes the information to be taken from the address space identified by the ALET, *alet*. The ALET is 1 to 8 hexadecimal digits long. Leading zeros are optional.

ALET can be used only by XC virtual machines.

### ASIT *asit*

causes the information to be taken from the address space identified by the ASIT, *asit*. The ASIT is 1 to 16 hexadecimal digits long. Leading zeros are optional.

The CP QUERY SPACES command returns *asit* in the "ASIT" field.

ASIT can be used only by XC virtual machines.

### AREG *areg*

causes the information to be taken from the address space identified by the ALET in the access register *areg*. The register can be specified in hexadecimal characters (leading zeros are optional) or in decimal digits.

AREG can be used only by XC virtual machines.

### *hexloc1*

0

is the starting guest real address to be dumped. The address *hexloc1* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability, leading zeros are optional. If the value you specify for *hexloc1* is not a multiple of 4 KB, the system rounds down the value to a 4 KB boundary. The value you specify must be within the specified address space, and not greater than the maximum address that VMDUMP can dump (see Usage Notes "[11](#)" on page 2078). If you omit the *hexloc1* operand, the default is zero.

See Usage Note "[12](#)" on page 2078 for examples of range specifications.

### *-hexloc2*

**-END**

**-ALL**

**:*hexloc2***

**:END**

**:ALL**

is the ending guest real address in the range of storage locations to be dumped. END is the default. The address *hexloc2* may be 1 to 16 hexadecimal digits, separated with an optional underscore for readability, leading zeros are optional. The value you specify for *hexloc2* must be equal to or greater than *hexloc1*, within the specified address space, and not greater than the maximum address that VMDUMP can dump (see Usage Note "[11](#)" on page 2078). If the value you specify for *hexloc2* is equal to the starting location, the system dumps the single page of storage containing that location. If the

value you specify for *hexloc2* is not equal to the starting location and is not a multiple of 4 KB, the system rounds up the value to the next 4 KB boundary.

Specify END to dump the remaining contents of configured storage of the specified address space up to the maximum address that VMDUMP can dump (see Usage Note “11” on page 2078). If you specify ALL, VMDUMP dumps from *hexloc1* to the end of the virtual machine address space up to the maximum address that VMDUMP can dump (see Usage Note “11” on page 2078). A virtual machine address space consists of configured guest storage as well as discontinuous saved segments in use by the virtual machine. For address spaces that a user does not own, both END and ALL dump the contents of the entire address space up to the maximum address that VMDUMP can dump (see Usage Note “11” on page 2078), including DCSSs.

If END or ALL was specified or defaulted and storage exceeds the maximum address that VMDUMP can dump (see Usage Note “11” on page 2078), pages over that address will not be dumped. An information message describing this situation will be displayed.

If you specify only the dash (-) or colon (:) range delimiter, and omit either *hexloc2* or END, END is the default. However, if you omit both the range delimiter and *hexloc2* or END, the system dumps the single page of storage starting at *hexloc1*. If you omit both *hexloc1* and *hexloc2* or END, *hexloc1* defaults to zero, *hexloc2* defaults to END, and VMDUMP dumps all of configured guest storage up to the maximum address that VMDUMP can dump (see Usage Note “11” on page 2078). (Note that in this case specification of the range delimiter is irrelevant.)

See Usage Note “12” on page 2078 for examples of range specifications.

#### **.bytecount**

#### **.END**

#### **.ALL**

is a hexadecimal number indicating the number of bytes of storage to be dumped, starting with the first byte at *hexloc1*. The value you specify for *bytecount* must be at least 1 and can be from 1 to 16 hexadecimal digits; leading zeros are optional. The ending storage address resulting from *bytecount* must be within the specified address space and not greater than the maximum address that VMDUMP can dump (see Usage Note “11” on page 2078). If the ending storage address is not a multiple of 4 KB, the system rounds up the value to the next 4 KB boundary.

Specify END to dump the remaining contents of configured storage of the specified address space up to the maximum address that VMDUMP can dump (see Usage Note 10). If you specify ALL, VMDUMP dumps from *hexloc1* to the end of the virtual machine address space up to the maximum address that VMDUMP can dump (see Usage Note “11” on page 2078). A virtual machine address space consists of configured guest storage as well as discontinuous saved segments in use by the virtual machine. For address spaces that a user does not own, both END and ALL dump the contents of the entire address space up to the maximum address that VMDUMP can dump (see Usage Note “11” on page 2078), including DCSSs.

If END or ALL was specified or defaulted and storage exceeds the maximum address that VMDUMP can dump (see Usage Note “11” on page 2078), pages over that address will not be dumped. An information message describing this situation will be displayed.

If you specify only the period (.) range delimiter and omit either *bytecount* or END, END is the default. However, if you omit both the range delimiter and *bytecount* or END, the system dumps the single page of storage starting at *hexloc1*. If you omit both *hexloc1* and *bytecount* or END, *hexloc1* defaults to zero, *bytecount* defaults to END, and VMDUMP dumps configured guest storage up to the maximum address that VMDUMP can dump (see Usage Note “11” on page 2078). (Note that in this case specification of the range delimiter is irrelevant.)

See Usage Note “12” on page 2078 for examples of range specifications.

#### **T0 \***

#### **userid**

transfers the dump to the virtual card reader of the specified user ID. If you enter an asterisk (\*) after the keyword T0, or do not specify the T0 at all, the system sends the dump to the virtual card reader of the virtual processor from which you issued the VMDUMP command.

**SYSTEM**

transfers the dump to the virtual card reader of the user ID specified on the SYSTEM\_USERIDS configuration file statement. (This is the user ID designated to receive any CP abend dumps.) For further details, see the description of the SYSTEM\_USERIDS Statement in *z/VM: CP Planning and Administration*.

**FORMAT *vmtype*****FORMAT FILE**

specifies the type of virtual machine being dumped. For *vmtype*, specify the 1- to 8-character name of the system that was running in the virtual machine (for example, CMS, RSCSNET, or PVM). If you omit the FORMAT operand, the default is FILE.

The dump viewing facility uses the FORMAT operand to identify the type of system or virtual machine dumped.

**DCSS****DSS**

specifies that CP take a dump of all discontinuous saved segments associated with the primary address space and not within user storage. If the user has DCSSs that are wholly within user storage, these are not added to the dump in response to the DCSS/DSS option. If a DCSS is partly within user storage and partly outside, only those segments outside user storage are dumped in response to this option.

If the DCSS or DSS keyword is specified with no *hexloc1*, no *hexloc2*, and no range delimiter, it is assumed that no ranges within configured guest storage are desired. In this case, the defaults are not used and only the user's discontinuous saved segments are dumped.

You can use this option only for your own host-primary address space.

**XA**

has no effect. XA is retained only for compatibility with previous releases. All dumps are in z/VM format.

**\**dumpid***

is a 1- to 100-character (including any imbedded blanks and special characters) identifier that is associated with the storage dumped for each address space for which the operand is specified. When specifying *dumpid*, you must precede it with an asterisk (\*). The system eliminates any blanks between the asterisk and the first nonblank character of the dump ID. If you specify a dump ID that is more than 100 characters in length *after* the blanks following the asterisk are eliminated, the system truncates it on the right to a length of 100 characters. If specified, the dump ID must be the last operand on the command line.

**CLOSE**

specifies that CP should close the VMDUMP system data file currently open for the issuing user, if one has been created by a previous request in continuous output mode.

**CANCEL**

specifies that CP should close and purge the VMDUMP system data file currently open for the issuing user, if one exists.

**CONt**

specifies that VMDUMP is to operate in continuous output mode, leaving the output file open after each request, until explicitly closed or canceled, or until a request is processed after continuous output mode has been reset.

**NOCont**

specifies that at the completion of subsequent VMDUMP requests, the output file is to be closed.

**Usage Notes**

Combining operands on the VMDUMP command

1. The CONT, NOCONT, CLOSE, and CANCEL operands are not valid in conjunction with any other VMDUMP operands.

2. When invoking VMDUMP to dump guest storage in continuous output mode, certain restrictions apply to the use of other command operands:
  - The SYSTEM and TO operands, which pertain to ownership of the file and its structure, can be specified only when the file is opened, that is, on the first request not counting any requests specifying CONT, NOCONT, CLOSE, or CANCEL. Subsequent requests that merely repeat the current setting of the operand are ignored, but requests that attempt to change the setting of the operand (whether it was set explicitly or by default) are rejected with an error message.
  - Operands used to designate which areas of guest storage to dump are valid on any of the series of requests in continuous output mode. These operands are:
    - PRIMARY
    - SPACE *userid:space\_name*
    - ALET *alet*
    - ASIT *asit*
    - AREG *areg*
    - address-range
    - DCSS
  - The FORMAT and *\*dumpid* operands can be specified on more than one request, but only the last value specified for a particular address space is recorded.
3. You can specify more than one address range on a single VMDUMP command, and they can be in any order.
4. With the exception of the address space operands and the dump ID, you can specify the operands in any order. The dump ID must be the last operand in the string of operands begun by an address space operand.

The contents of a virtual machine dump

5. VMDUMP processing always creates and records a symptom record when creating a dump.
6. When you dump any address space, you get pages that have been referred to and the storage keys for those pages. In addition, VMDUMP dumps this information for your virtual machine (not necessarily in this order):
  - The program status word (PSW)
  - General registers
  - Control registers
  - Access registers
  - Floating point registers
  - Floating point control register
  - The TOD clock
  - The TOD clock comparator
  - The TOD programmable register
  - The processor timer
  - The prefix register
  - The prefix page(s) for all virtual processors dumped
  - The ASIT and the space ID (*userid:space\_name*) for the primary address space.
  - The host access list associated with the primary address space.

**Note:** VMDUMP dumps processor information for each defined virtual processor, up to 64 processors.
7. When using the collaborative memory management assist, the VMDUMP command dumps pages in the stable block-usage state only.

8. Each page of virtual machine storage is dumped only once to a file. If a page is specified in separate calls to the same address space or on more than one request in continuous output mode, only the first request for the page is honored; later requests are suppressed. Likewise, if a DCSS or DSS associated with an address space is specified on more than one request in continuous output mode, only the first request results in the DCSS being written to the dump file.
9. Dumps for a V=V virtual machine do not contain pages that have never been referred to. When a VMDUMP request for a V=V virtual machine contains only ranges within pages that have not been referred to, only the virtual processor information that is automatically dumped is placed in the dump (see Usage Note “6” on page 2077). In continuous mode, this information is added to the dump on the first request that opens the dump file. Therefore, subsequent requests to dump ranges within pages that have not been referred to do not result in additions to the dump file.
10. VMDUMP supports the DEFINE STORAGE CONFIG command and will dump any specified storage ranges in discontinuous configured storage up to the maximum address that VMDUMP can dump (see Usage Note “11” on page 2078).
11. The maximum address that VMDUMP can dump is X'7FFFFFFF' for ESA/390 and ESA/XC virtual machines, and X'7FFFFFFFFF' (512 Gigabytes) for z/Architecture and z/XC virtual machines.
12. This table shows the effects of different combinations of parameters.

Parameters	What gets dumped
<i>hexloc</i> - <i>hexloc</i> . <i>hexloc</i>	Storage 0 through <i>hexloc</i> from address space
<i>hexloc</i> : <i>hexloc</i> - <i>hexloc</i> .	Storage <i>hexloc</i> through highest configured address of the address space but not more than the maximum address that VMDUMP can dump.
<i>hexloc1</i> <i>hexloc1</i> : <i>hexloc2</i> where <i>hexloc1</i> equals <i>hexloc2</i>	Single page of storage containing <i>hexloc1</i>
: . -	All of configured storage of the address space but not more than the maximum address that VMDUMP can dump.
Address space operand not indicating the primary space, and END or ALL	All of addressable storage of the address space but not more than the maximum address that VMDUMP can dump.
Primary space and END	Entire contents of the primary address space, up to maximum address that VMDUMP can dump, not including DCSSs.
Primary space and ALL	Entire contents of the primary address space, up to maximum address that VMDUMP can dump, including DCSSs.
Address space operand but no address ranges, DCSS, or DSS	All of addressable storage of the address space but not more than the maximum address that VMDUMP can dump.
No address space operands, address ranges, DCSS, or DSS	All of configured storage of the address space but not more than the maximum address that VMDUMP can dump.
DCSS or DSS but no address range	If DCSSs do not exist for the primary space, error message 013E is issued. If DCSSs do exist, the DCSSs associated with the primary address space are dumped.

Parameters	What gets dumped
DCSS or DSS, an address space operand and address ranges	If DCSSs do not exist, only the address ranges specified are dumped. If DCSSs do exist, the DCSSs associated with the primary address space are dumped, and the specified address ranges up to the maximum address that VMDUMP can dump.

#### Address space operands

13. An ALET operand of ALET 00000000 indicates the primary address space. Access register 0 is always taken as containing X'00000000'.
14. For non-XC virtual machines, address ranges are always prefixed. For XC virtual machines:
  - Addresses in the primary address space are prefixed (PRIMARY or ALET 00000000 is specified). Low-address protection may apply and fetch-protection checking may be performed.
  - Addresses in any other address space are never prefixed (ASIT, SPACE, and ALETs other than X'00000000'). Low-address protection never applies, and fetch-protection checking is always performed.

#### The FORMAT operand

15. In continuous output mode, a file type is assigned to the dump file when it is opened. This file type is assigned by the FORMAT operand of the first address space dumped. It is not changed until the file is closed. As a result, until the dump file is closed, QUERY READER shows the initial FORMAT value, not the value specified last. To see the file type that the dump file receives when it is closed, use the QUERY VMDUMP command.
16. For certain programs running in virtual machines, the Dump Viewing Facility provides a special dump-processing format. The Dump Viewing Facility identifies these programs by checking the file type of the reader spool file created by VMDUMP. The file type is an assigned name that you should specify for *vmtype* on the FORMAT operand when dumping a virtual machine in which one of these programs is running. The IBM-defined programs and their assigned names are:

Program	Assigned name
APPC/VM VTAM Services	AVS
Customer Information Control System (CICS®/VM)	CICSVM
Conversational Monitor System (CMS)	CMS
Group Control System for Extended Architecture (GCS/XA)	GCS
VM/Pass-Through Facility Program Product	PVM
Remote Spooling Communication Subsystem (RSCS) Networking Program Product	RSCSV2
RSCS Networking Program Product Version 2	RSCSV2
RSCS Networking Program Product Version 3	RSCSV3
RSCS Networking for z/VM, function level 530	RSCSV3
Shared File System	SFS
Transparent Services Access Facility	TSAF

There may be additional assigned names, peculiar to your installation, for programs that are a part of your system. Ask your system programmer for a complete list of FORMAT names.

#### Continuous mode

17. If a continuous mode dump file is open when the VMDUMP NOCONT command is issued, that file remains open until completion of the next VMDUMP request that causes a write to the file. For this reason, to ensure that a new file is created in response to your VMDUMP request, first enter the

VMDUMP NOCONT CLOSE command if a noncontinuous dump is to be created, or the VMDUMP CONT CLOSE command if a new continuous mode file is desired. This ensures that any files still open from previous requests are closed, and that continuous and noncontinuous mode is set as desired.

18. If a continuous mode dump file for a particular virtual machine is open while that machine is logging off, or if a dump file for that virtual machine was very recently closed before logging off, the virtual machine may be prevented for a short time from logging back on again. While the system completes work resulting from the close of the dump spool file, the user receives message:

```
HCP361E LOGOFF/FORCE pending for user ...
```

in response to logon attempts. Logon should be possible within a few minutes.

#### DCSSs

19. When VMDUMP CONT is issued, the DCSSs that are loaded at that time are the only DCSSs that appear in the dump until VMDUMP NOCONT is issued. For example, if VMDUMP CONT is issued, then DCSS T1 is loaded, and then VMDUMP DCSS is issued, DCSS T1 is not included in the dump.
20. When you specify an unaddressable range (an inline range that starts above guest storage and does not fall within a discontinuous saved segment), an informational message is issued, and that range is ignored.

#### Using a virtual machine dump

21. If you specify TO SYSTEM, VMDUMP sends the dump file to the user ID of SYSTEM. However, if you specify only SYSTEM, the system sends the dump file to the user ID designated to receive dumps at your installation.
22. You can view the dump interactively using the Dump Viewing Facility. For more information on viewing the dump produced by the [VMDUMP Command](#), see *z/VM: Dump Viewing Facility*.
23. After the system has written the dump to a reader spool file, you can use the DUMPLOAD utility to load it from the spool file into a CMS file.
24. In general, use the VMDUMP command to create dump files that can be used with the Dump Viewing Facility, and use the DUMP command to create dumps that you intend to read without the aid of the Dump Viewing Facility. For more information, see [Dumping, Displaying, Altering Virtual Machine Storage](#) in *z/VM: Virtual Machine Operation*.
25. If an external security manager is installed on your system, you may not be authorized to enter the VMDUMP command with the TO option. For additional information, contact your security administrator.
26. Long-running VMDUMP commands can be halted by the user by entering #CP CPHX. Another user can halt a user during VMDUMP processing by using the CPHX or FORCE command. A TERM BRKKEY (normally set to PA1 key) will not halt VMDUMP processing.
27. The VMDUMP command does not dump vector registers.

## Responses

Response 1:

```
Command complete
```

is issued when the command has finished successfully.

## Examples

These examples are for a virtual machine in XC mode. Virtual processor information includes registers, processor addresses, and access lists.

1. To dump processor information for up to 64 virtual processors and the contents of the current primary address space, enter

```
vmdump
```

2. You can specify several address spaces. For example,

```
vmdump pri asit 0BGE9A4000000007 2000 space joe:space1 1000-5000
```

creates a dump including processor information for up to 64 virtual processors, the entire contents of the primary address space, the page at address 2000 of the address space identified by the ASIT 0BGE9A4000000007, and the pages at addresses 1000 through 5000 of the address space JOE:SPACE1.

3. `vmdump pri dcsc format cms space user1:sfs 10000-20000 pri *cms abend`

creates a dump including processor information for up to 64 virtual processors, the DCSSs associated with the current primary address space, and the pages at addresses 10000-20000 in the address space USER1:SFS. The format associated with the primary address space is CMS and the dump ID is "\*CMS ABEND". The format for address space USER1:SFS defaults to FILE and there is no dump ID for that address space.

- HCP6186I {Range *hexloc1-hexloc2*|DCSS or DSS} was previously dumped; it will not be dumped again.
- HCP6187E A soft abend occurred during VMDUMP processing.

## VMDUMP

- HCP6189I VMDUMP command is unable to add more data to the current virtual machine dump.
- HCP6190E VMDUMP processing is unable to complete due to a paging error.
- HCP6191I Storage range *hexloc1-hexloc2* is unaddressable and will not be dumped.
- HCP6525E Authorization request failed.
- HCP6577E Invalid ALET - *alet*.
- HCP6578E Invalid {access register|ASIT|address space identifier} - *option*
- HCP6790I VMDUMP processing halted.

# VMRELOCATE

**Note:** One or both of the MAXQUIESCE and MAXTOTAL options must be specified for a MODIFY command. In this case, there are no defaults for those options.

## Authorization

Privilege Class: A

## Purpose

Use VMRELOCATE to move an eligible, running z/VM virtual machine transparently from one z/VM system to another within an SSI cluster, and to monitor and cancel virtual machine relocations that are already in progress.

## Operands

### MOVE

moves the specified virtual machine, while it continues to run, to the specified system within the SSI cluster. The virtual machine being moved must be logged on to the system on which this command is issued.

### MODIFY

modifies the time limits associated with the relocation already in progress for the specified user. The virtual machine being moved must be logged on to the system on which this command is issued.

### TEST

tests the specified virtual machine and reports whether or not it is eligible to be relocated to the specified system. In the event that the specified virtual machine is not eligible for relocation, explanatory messages are displayed on the command issuer's terminal. The virtual machine being tested must be logged on to the system on which this command is issued.

### STATUS

displays information about relocations currently in progress. The STATUS operation can be initiated from either the source or the destination system.

### CANCEL

stops the relocation of the specified virtual machine. The virtual machine is not relocated to another system and will continue running normally, as though the relocation had not been attempted. The cancel operation can be initiated from either the source or the destination system. Once the request from the source system to start the virtual machine on the destination system has been sent, the relocation cannot be canceled.

The CPHX command can also be used to cancel a relocation. This is useful when VMRELOCATE was issued with the SYNCHRONOUS option. CPHX cannot be used to cancel an asynchronous relocation.

### USER *userid*

the userid of the target virtual machine for the VMRELOCATE command. Specify the USER keyword to make the following user ID unambiguous. The target userid cannot be the command issuer.

### TO *destination*

the SSI name of the destination system to which the specified virtual machine will be relocated or tested for relocation eligibility. Specify the TO keyword to make the following destination name unambiguous.

### ALL

specifies that the status of all relocations currently in progress on this system are to be displayed.

### INcoming

specifies that the status of only incoming relocations are to be displayed. An incoming relocation is a relocation resulting in a virtual machine being relocated from some other system to the system on which the STATUS command is issued.

### OUTgoing

specifies that the status of only outgoing relocations are to be displayed. An outgoing relocation is a relocation resulting in a virtual machine being relocated from the system on which the STATUS command is issued to some other system.

## Options

### FORCE ARCHITECTURE

indicates that relocation is to be attempted even though the virtual machine is currently running on a system with hardware architecture facilities, or CP-supplied features not available on the destination system, for example, when relocating to a system running an earlier release of CP. This option should only be used if it is known that the virtual machine and its applications do not use any facilities or features that are unavailable on the destination system. Other eligibility requirements, such as DCSS or device availability, will be respected and the relocation will be rejected if they are not met. Extreme care should be taken when using this option. If the unavailable hardware features or CP capabilities are important to the virtual machine or its applications, it is likely that the virtual machine or its applications will fail after the relocation is complete. This option is not needed to relocate a guest outside of its domain unless doing so would cause the guest's virtual architecture to lose facilities.

FORCE ARCHITECTURE is used in two circumstances:

- To allow out-of-domain relocation to a member that does not support all the current architectural features of the virtual machine.
- To allow a virtual machine to relocate to an excluded member of its domain.

### FORCE DOMAIN

indicates that relocation is to be attempted even though the virtual machine would be moved outside of its domain. This option does not permit relocation outside of the guest's domain if this move would cause the guest's virtual architecture to lose hardware facilities or CP capabilities. The FORCE ARCHITECTURE option must be used to make that kind of relocation occur.

**Note:** Both options (that is, FORCE ARCHITECTURE DOMAIN) must be specified to move a guest outside its domain if that move would cause a downgrade of the guest's virtual architecture.

### FORCE STORAGE

indicates the relocation should proceed if CP determines there are insufficient storage resources available on the destination for the following memory capacity assessment checks:

- Does the guest's maximum storage size (including CP supporting structures) exceed available space (central storage and auxiliary paging) on the destination?
- Does the guest's current storage size (including CP supporting structures) exceed auxiliary paging capacity on the destination system?
- Does the guest's maximum storage size (including CP supporting structures) exceed auxiliary paging capacity on the destination system?

The guest's maximum storage size includes any standby and reserved storage that could be configured for the virtual machine using dynamic storage reconfiguration.

These tests are performed several times during relocation. When FORCE STORAGE is not included on the VMRELOCATE command, then failure of any one of these tests results in termination of the relocation with appropriate message(s) (HCP1811I, HCP1812I, HCP1813I). Be sure to consider the size of the relocating guest along with the available storage resources and existing workload on the destination system prior to initiating the relocation. Use of the FORCE STORAGE specification with the VMRELOCATE command may increase your risk of a system outage.

Regardless of whether FORCE STORAGE is specified, relocation always checks to ensure the guest's current storage size (including CP supporting structures) fits in the available space (central storage and auxiliary paging) on the destination system. If relocation determines the guest won't fit, the relocation is terminated with message HCP1810I.

### ASYNChronous

causes the VMRELOCATE command to complete with a return code as soon as initial eligibility checks have passed and the relocation has started. This frees up the issuing virtual machine so that other commands can be entered while the actual relocation takes place.

### SYNChronous

causes the VMRELOCATE command to complete only after the relocation is complete. The success or failure of the operation is reflected in the return code. If SYNChronous is specified, the CPHX

command can be used to stop execution and effectively cancel the relocation. SYNCHRONOUS is the default.

**IMMEDIATE**

causes the VMRELOCATE command to do one early pass through virtual machine storage and then go directly to the quiesce stage. This option will likely decrease the total time required to move the virtual machine but, depending on guest activity, increase the amount of time the virtual machine is stopped during the quiesce stage. The defaults for both MAXTOTAL and MAXQUIESCE are NOLIMIT when IMMEDIATE is specified.

**MAXTotal nnnnnnnn SEC**

indicates the maximum total time (in seconds) that the command issuer is willing to wait for the entire relocation to complete. If the system determines that the relocation is taking longer than the specified total time then the relocation is canceled and the target virtual machine continues to run on the source system. Note that when VMRELOCATE MODIFY is issued without this option, the MAXTOTAL time is not changed to the default; instead the MAXTOTAL time remains unchanged from its previous value. The allowable values of nnnnnnnn are 1 to 99999999 seconds.

**MAXTotal NOLIMIT**

indicates that there is no limit on the total amount of time the system should allow for this relocation. The relocation is not canceled due to time limit constraints. This is the default.

**MAXQuiesce nnnnnnnn SEC**

indicates the maximum quiesce time for this relocation. This is the amount of time (in seconds) a virtual machine may be stopped during a relocation attempt. The relocation is canceled if the system determines the amount of time the virtual machine has been stopped is longer than *nnn* seconds. If the relocation is canceled for this reason, the virtual machine continues to run on the source system. The default for MAXQUIESCE is NOLIMIT if the IMMEDIATE option is specified or 10 seconds if not. Note that when VMRELOCATE MODIFY is issued without the MAXQUIESCE option, the maximum quiesce time is not changed to the default; instead the MAXQUIESCE time remains unchanged from its previous value. The allowable values of nnnnnnnn are 1 to 99999999 seconds. See usage notes for a more detailed explanation of this option.

**MAXQuiesce NOLIMIT**

indicates that there is no limit on the amount of time the system should allow for the quiesce phase of this relocation. The relocation is not canceled due to quiesce time limit constraints. This is the default if IMMEDIATE is specified. Otherwise the default is 10 seconds.

**Usage Notes**

1. A virtual machine cannot use the VMRELOCATE command to relocate itself.
2. The SET VMRELOCATE command can be used to indicate whether relocation is an option for this virtual machine and if so, in which relocation domain it is allowed to move. See the description of the SET VMRELOCATE command for more details. The QUERY VMRELOCATE command can be used to determine the current setting. The QUERY RELODOMAIN command can be used to determine which systems belong in the user's relocation domain, and therefore to which systems it is eligible to relocate.
3. Before a virtual machine is relocated, the capacity of the destination system should be carefully considered.
4. The number of concurrent relocations on one system should be limited as the overhead of a relocation can have an adverse effect on the performance of both the source and destination systems.
5. Relocation occurs in several steps. Much of the data transmission, in particular the virtual machine's storage (memory) contents, is done with the virtual machine still running so that the amount of down time can be minimized. Once most of the virtual machine storage has been transmitted, the virtual machine is stopped for the next step. Since there is likely to be a maximum period of time the guest can tolerate being unavailable, the MAXQuiesce option can be used to specify this period. If this is exceeded, relocation will be automatically canceled, and the virtual machine will resume operation on the original system.

6. Any CP monitor data that is being collected for this virtual machine on the source system will not automatically be collected on the destination system. If that data is required, the proper MONITOR commands must be issued on the destination system to start monitor for this virtual machine once it has been relocated.
7. If SET CPTRACE for this virtual machine is active, the relocation will occur but the CPTRACE setting will not carry over to the destination system.
8. APPLMON data collection will continue on the destination system without the need for manual intervention if diagnose x'DC' was used to start collection previously on the source system.
9. If the VM Resource Manager (VM/RM) is using Collaborative Memory Management (CMM) to adjust a Linux guest's storage utilization, the Linux virtual machine must be listed in the configuration file for VM/RM on both the source and destination systems.
10. Unpredictable results may occur if a relocation is done and there are local modifications to CP, in particular to the VMDBK.
11. When a virtual machine is relocated, its current share settings may or may not be appropriate on the destination system. Some thought must be given to what this user's share should be on the new system and the settings changed using the SET SHARE command if necessary.
12. A virtual machine's SET RESERVED setting is not preserved upon a successful relocation. The capacity and workload on the destination system should be considered when deciding whether to reestablish reserved frames for this virtual machine on the destination system.
13. If the virtual machine has any locked pages (via the LOCK command) they will be unlocked during relocation. Once relocation unlocks pages, they remain unlocked even if the relocation is subsequently terminated or canceled prior to completion.
14. Use the FORCE STORAGE option with caution. You should evaluate the amount of central storage, auxiliary paging capacity, and workload on the destination system to ensure you are confident the relocating guest will not exceed the capacity of the system. Also consult the z/VM CP Planning and Administration documentation for guidelines regarding paging space.
15. A guest that has been relocated should be given sufficient time to stabilize before being relocated again. Generally, this requires less than 60 seconds. More time may be required due to factors such as the number and type of devices being transferred, the number of outstanding I/O requests being transferred, and the CPU load and storage availability on the destination system. In particular, allow the guest to recover active OSA and FCP devices before initiating another relocation of the same guest.
16. If a relocation appears to be hung, use the VMRELOCATE STATUS command to determine if it is progressing. If not, the relocation may be delayed because the guest is in a state where intervention is required for the guest. An example of why the guest could be waiting is the password prompt on a CP LINK command.
17. When a guest on a virtual switch without priority queuing enabled relocates to a virtual switch with priority queuing enabled (and reversal), the guest's performance could be affected.
18. For relocation networking considerations, see [Live Guest Relocation Networking Considerations in z/VM: Connectivity](#).
19. APVIRT crypto users can relocate if there is an exact match in crypto capability between source and destination systems.

APVIRT crypto users can also relocate if there is not an exact match, and if the following conditions are true:

- APVIRT users are assigned to a relocation domain where the member systems have the Live Guest Relocation (LGR) for mixed APVIRT feature.
- The destination system is configured with a compatible shared crypto pool. Compatibility requires that crypto facilities that are presented to the guest at the source system are supported at the destination system.

APVIRT users that are assigned to a relocation domain where the member systems run LGR for mixed APVIRT see a virtual CEX adapter with the following characteristics:

## VMRELOCATE

- The virtual CEX adapter has characteristics that are common to all the members of that relocation domain that run shared pools of the same mode.
- The virtual CEX adapter presents the maximal common subset of capabilities for that mode.

For example, the subset of member systems of a relocation domain that run an accelerator mode shared pool present a virtual CEX adapter with accelerator capabilities. The adapter presents the maximal common subset of accelerator capabilities to any guest with a virtual accelerator. Member systems of a relocation domain that run a CCA-coprocessor mode shared pool present a virtual CEX adapter with CCA coprocessor capabilities. That adapter presents the maximal common subset of CCA coprocessor capabilities to any guest with a virtual CCA coprocessor.

For more information, see [Crypto Planning and Management](#) in *z/VM: CP Planning and Administration*.

20. The relocation process does not verify that the destination system has security keys for a secure IPL. If a guest is relocated to a system that does not have appropriate security keys, a secure IPL is not possible. Security keys are required on all members of a relocation domain where a guest might be relocated and later IPLed with the secure option. For more information, see [Guest Secure IPL](#) in *z/VM: Running Guest Operating Systems*.

## Responses

Responses issued by VMRELOCATE MOVE

This response is sent to the command issuer and system operator when different. The "by *userid*" text is only included in the system operator's version.

```
Relocation of user userid from source to destination
started (by userid) with FORCE ARCHITECTURE|DOMAIN|STORAGE in effect.
```

The following is sent to the command issuer and system operator when different. If the relocating guest generates a console file, this response is written to that file on both the source and destination systems.

```
User userid has been relocated from source to destination
```

```
Relocation of user userid from source to destination
did not complete. Guest has not been moved.
```

The following is sent to the command issuer and system operator when different.

```
Relocation of user userid from source to destination
did not complete. Guest has not been moved.
```

Response issued by VMRELOCATE TEST

```
User userid is eligible for relocation to destination
```

Response issued by VMRELOCATE CANCEL

This response is sent to user who canceled relocation, the user who started relocation if different, and the system operator if different.

```
Relocation of user userid from source to destination
has been canceled by userid on sysname_where_cancel_issued
```

Response issued by VMRELOCATE STATUS

```
No matching virtual machine relocation is currently
in progress on this system
```

User	From	To	By	Status	Elapsed
<i>userid</i>	<i>source</i>	<i>dest</i>	<i>userby</i>	<i>status</i>	<i>hh:mm:ss</i>

Response issued by VMRELOCATE STATUS *userid* DETails

User	From	To	By	Status	Elapsed
<i>userid</i>	<i>source</i>	<i>dest</i>	<i>userby</i>	<i>status</i>	<i>hh:mm:ss</i>

The following does not display when status = test.

```
Options: options
Max Total Time maxtotal
Max Quiesce Time maxquiesce

Total pages sent mmmmmmm in pp passes; sssss
pages sent in pass cc
```

Where:

***userid***

is the userid of the virtual machine being relocated.

***source***

is the system from which this virtual machine is moving.

***dest***

is the system to which this virtual machine is moving.

***options***

**synch, immed, or force.**

***userby***

is the user that initiated relocation for this virtual machine.

***status***

is the point in the relocation process that the virtual machine has currently reached. The value can be any of the following:

- Connecting - the source system is connecting to the destination system
- Elig Checks - relocation eligibility checking is in progress
- Creating Guest - Creating skeleton guest on destination system
- Moving Memory - The virtual machine's memory is being transferred to the destination system
- Stopping Guest - The virtual machine is being stopped on the source system
- Moving Guest - The virtual machine state is being moved to the destination system
- Final Mem Copy - Last pass of guest memory done to move the final changes to the destination
- Final I/O Check - Last I/O device eligibility checks done to ensure all necessary devices are still available on the destination
- Resume Guest - The virtual machine is being started on the destination system
- Cleaning Up - The relocation is finished and cleanup work is being done
- Terminating - The relocation had an error or was canceled and is in the process of terminating
- Test - a VMRELOCATE TEST is in progress for this virtual machine
- Comm Error - The VMRELOCATE STATUS command was issued on the destination system and a communications error occurred when attempting to retrieve the current status from the source system.

***hh:mm:ss***

shows a time in hours, minutes and seconds. This is the elapsed since the VMRELOCATE command was issued.

***synch***

indicates whether the VMRELOCATE command was issued synchronously or asynchronously. The value here will either be "ASYNCH" or "SYNCH".

**immed**

indicates whether the IMMED option was specified when the VMRELOCATE command was issued. *immed* will be displayed either as "IMMED YES" or as "IMMED NO".

**force**

indicates whether the FORCE option was specified when the VMRELOCATE command was issued. The FORCE option can be specified with one or more of several different options (ARCHITECTURE, DOMAIN, STORAGE). The FORCE output is displayed followed by some or all of those options, depending on which were specified on the command. For example, the Options line of output could look similar to any of the following:

```
Options: SYNCH IMMED YES FORCE ARCHITECTURE STORAGE
Options: SYNCH IMMED NO FORCE ARCHITECTURE DOMAIN
Options: SYNCH IMMED NO FORCE DOMAIN
```

**Max Total Time *maxtotal***

*maxtotal* can be either of the following two forms:

- **NO LIMIT** - which means the command issuer wants the relocation to complete with no limit on the total time it takes.
- ***n* SEC** - which is the maximum number of seconds the command issuer specified for the relocation to complete.

**Projected Total Time *n* Sec**

Projected total number of seconds to relocation completion. This is an estimate of the total time it will take to complete this relocation from start (command is issued) to finish (relocation completed). It is not the estimated remaining time. This may be zero if the VMRELOCATE STATUS command is issued early in the relocation and an estimate has not yet been calculated.

**Max Quiesce Time *maxquiesce***

*maxquiesce* can be either of the following two forms:

- **NO LIMIT** - which means the command issuer wants the relocation to complete with no limit on the amount of quiesce time it takes.
- ***n* SEC** - which is the maximum number of seconds the command issuer specified for maximum quiesce time for the relocation to complete.

**Projected Quiesce Time *n* Sec**

Projected number of seconds the virtual machine will be stopped during the processing of this relocation. This may be zero if the VMRELOCATE STATUS command is issued early in the relocation and an estimate has not yet been calculated.

**EXCEEDS TARGET**

shown after Projected Time or Projected Quiesce to indicate the projected time exceeds the user's specified target time.

***mmmmmm***

shows the total number of pages that have been transferred to the destination system thus far. (Note that an individual page may be sent more than once if it is changed between passes, and so an individual page may be counted more than once in this total.)

***pp* passes**

shows the total number of memory passes we have made for this relocation thus far. This number includes the current pass if one is in progress.

***ssss***

shows the total number of pages that were transferred in the memory transfer pass most recently completed.

***cc***

shows the number of the memory transfer pass most recently completed.

## Messages

- HCP003E *userid*: A failure occurred moving the content of the virtual machine's memory to the destination system
- HCP004E Relocation of *userid* to *destination* failed because a time out occurred while waiting for an expected response
- HCP013I *userid*: Using the maximum configurable size of the virtual machine would exceed available G auxiliary paging space on the destination system
- HCP026E Relocation is not in progress for *userid*
- HCP045E *userid* not logged in
- HCP263E Too many operands were supplied for this command
- HCP1161I *userid*: Virtual machine has a dedicated PCI function
- HCP1399E *userid*: Guest frame at virtual address *addr* was found still pinned during the last pass of memory move.
- HCP1802E *userid*: Message versions incompatible, message type = *type*, subsystem = *ssname*, source version = *sversion*, destination version = *dversion*
- HCP1803E *userid*: A failure occurred moving the content of the virtual machine's memory to the destination system
- HCP1804E Relocation of *userid* to *destination* failed because a time out occurred while waiting for an expected response
- HCP1805I *userid*: Guest is obtaining data from a service processor
- HCP1806E *userid*: The reserve status for DASD *vdev* could not be determined on the source system
- HCP1807E *userid*: The reserve held by DASD *vdev* cannot be relocated to the destination system
- HCP1807E *userid*: The reserve status for DASD *vdev* could not be determined on the destination system
- HCP1807E *userid*: The reserve held by DASD *vdev* cannot be relocated to the destination system because another system acquired it via an unconditional reserve
- HCP1808E Relocation of *userid* to *destination* failed because the destination is the same as the source
- HCP1810I *userid*: Current storage use *guest\_footprint* exceeds available capacity on destination *destination\_resource* by *difference*
- HCP1810I *userid*: Current storage use exceeds capacity on destination
- HCP1811I *userid*: Maximum storage use *guest\_footprint* exceeds available capacity on destination *destination\_resource* by *difference*
- HCP1812I *userid*: Current pageable storage use *guest\_footprint* exceeds available auxiliary paging space on destination *dest\_aux\_stg* by *difference*
- HCP1813I *userid*: Maximum pageable storage use *guest\_footprint* exceeds available auxiliary paging space on destination *dest\_aux\_stg* by *difference*
- HCP1820I *userid*: Virtual machine has directory authorization to use the virtual Multi-Path Lock Facility
- HCP1828I *userid*: A matching crypto facility does not exist on the destination
- HCP1924I *userid* Virtual machine is not in the destination system CP directory
- HCP1926E Relocation is not in progress for *userid*
- HCP1927E System *sysname* is not a member of an SSI cluster
- HCP1928E Cannot communicate with partner system *destination*
- HCP1929E Cannot relocate *userid* because *member* is not joined
- HCP1930I *userid*: The maximum *quiesce/total* time was exceeded
- HCP1931W Relocation of *userid* to *destination* can occur but the virtual machine may not be able to return to *source*

## VMRELOCATE

- HCP1932E Relocation of *userid* to *destination* is terminated as a result of a virtual machine action - *action*
- HCP1933E Cannot relocate *userid* because the SSI cluster is not STABLE or INFLUX
- HCP1934E A relocation MOVE|TEST of this virtual machine by *userid* is already in progress
- HCP1935E *userid*: Relocation processing error: RC=*code*
- HCP1936E *userid*: Device *vdev* is not responding
- HCP1937E *userid*: Unable to {ATTACH | DETACH | DEFINE | LINK | COUPLE} device *vdev*. RC=*code*
- HCP1938I *userid*: Virtual machine's storage configuration was created using the DEFINE STORAGE CONFIG command
- HCP1939E Relocation of *userid* to *destination* is terminated for the following reason(s): (This message is issued once, followed by one or more messages showing all the reasons why the specified relocation was terminated before completion.)
- HCP1940E *userid* is not relocatable for the following reason(s): (This message is issued once, followed by one or more messages showing all the reasons why the specified virtual machine was not eligible for relocation.)
- HCP1941E VMRELOCATE MODIFY is valid only on the system where the relocation originates
- HCP1942E *userid*: A virtual machine cannot issue a VMRELOCATE command with itself as the target
- HCP1943I *userid*: Virtual machine has SET VMRELOCATE OFF
- HCP1944I *userid*: Architecture incompatibility
- HCP1945I *userid*: Virtual machine is still logging on or is being autologged on
- HCP1946I *userid*: Virtual machine is logging off or is being forced off the system
- HCP1947I *userid*: Virtual machine is in system hold state on the destination system
- HCP1948I *use rid*: Virtual machine system reset is in progress
- HCP1949I *userid*: Virtual machine is primary system operator
- HCP1950I *userid*: Virtual machine is not running disconnected
- HCP1951I *userid*: Virtual machine has CP traces set
- HCP1952I *userid*: Virtual machine is terminating
- HCP1953I *userid*: Virtual machine has dedicated crypto capability
- HCP1954I *userid*: Virtual machine device *vdev* is a logical device
- HCP1955I *userid*: Virtual machine is IPLing
- HCP1956I *userid*: Single path CHPID virtualization is not enabled
- HCP1957I *userid*: Virtual machine is a batch worker machine
- HCP1958I *userid*: Virtual machine is a Coupling Facility virtual machine
- HCP1959I *userid*: Virtual machine configuration includes access to a virtual Coupling Facility
- HCP1960I *userid*: Virtual machine is using, or is the subject of, system trace facilities
- HCP1961I *userid*: Virtual machine is in a resource pool and a compatible pool does not exist on the destination system
- HCP1963I *userid*: Virtual machine is using VMCF
- HCP1964I *userid*: Virtual machine is using CMS POSIX facilities
- HCP1965I *userid*: Virtual machine has an Adjunct started
- HCP1966I *userid*: The integrated ASCII console is attached to the virtual machine
- HCP1968I *userid*: Virtual machine used DIAGNOSE x'214' to establish a pending page release and those page releases have not yet been processed
- HCP1969I *userid*: Virtual machine device *vdev* is a TDISK
- HCP1970I *userid*: Virtual machine device *vdev* is a public VDISK

- HCP1971I *userid*: Virtual machine has directory authorization to use diagnose x'98'
- HCP1972I *userid*: Virtual machine has a CPU-type or VCONFIG setting conflict
- HCP1973I *userid*: Virtual machine is in XC mode or has access to an address space owned by another virtual machine
- HCP1974I *userid*: Virtual machine has connections to another virtual machine or to a system service that cannot be relocated
- HCP1975I *userid*: Error loading NSS or DCSS *ssname* on the destination system; error code = *code*
- HCP1976I *userid*: Virtual machine is defined as multiconfiguration virtual machine
- HCP1977I *userid*: Virtual machine *vdev* has an open, non-console, SPOOL file
- HCP1978I *userid*: Virtual machine has an SPXTAPE operation in progress
- HCP1979I *userid*: Virtual machine is using DCSS that is a segment space or a member of a segment space - *ssname*
- HCP1980I *userid*: Identical NSS or DCSS *ssname* does not exist on the destination system
- HCP1980I *userid*: NSS or DCSS *ssname* on the source system does not have a checksum value
- HCP1980I *userid*: NSS or DCSS *ssname* on the destination system does not have a checksum value
- HCP1981I *userid*: Source system virtual device *vaddr* on real device *raddr* cannot be created on the destination system because the equivalent real device *raddr* is offline
- HCP1981I *userid*: Source system dedicated virtual device *vaddr* on real device *raddr* cannot be created on the destination system because the equivalent real device *raddr* is not free
- HCP1981I *userid*: Source system minidisk *vaddr* on real device *raddr* cannot be created on the destination system because the equivalent real device *raddr* is not system attached
- HCP1981I *userid*: Source system virtual device *vaddr* on real PAV device *raddr* cannot be created on the destination system because the equivalent real device *raddr* is not in the same PAV mode
- HCP1981I *userid*: Source system DEVNO defined minidisk *vaddr* on real device *raddr* cannot be created on the destination system because the equivalent real device *raddr* is neither a DEVNO defined minidisk nor free
- HCP1982I *userid*: Source system network device *vaddr* is coupled to a Guest LAN
- HCP1982I *userid*: Source system real network device *raddr* requires an EQID to be assigned
- HCP1982I *userid*: Source system network device *vaddr* is a simulated NIC coupled to a VSWITCH without external connectivity
- HCP1982I *userid*: Source system simulated network device *vaddr* is coupled to a VSWITCH without an assigned EQID
- HCP1982I *userid*: Source system simulated network device *vaddr* is coupled to a VSWITCH without external connectivity
- HCP1982I *userid*: Destination system VSWITCH *vswitch name* for simulated network device *vaddr* does not have external connectivity at this time
- HCP1982I *userid*: EQID of the destination system's VSWITCH *vswitch name* external OSA ports for the simulated network device *vaddr* does not match the source system's VSWITCH external OSA port EQID
- HCP1982I *userid*: Destination system VSWITCH *vswitch name* for simulated network device *vaddr* is not configured to have external connectivity or does not exist
- HCP1982I *userid*: Source system network device *vdev* is coupled to a VSWITCH but the virtual NIC has too many devices assigned
- HCP1982I *userid*: *nnn* consecutive free network devices with EQID *eqid* cannot be found on the destination system to relocate virtual device *vdev*
- HCP1982I *userid*: Destination system VSWITCH *swname* is not configured as IP for simulated NIC *vdevno*.
- HCP1982I *userid*: Destination system VSWITCH *swname* is not configured as ETHERNET for simulated NIC *vdevno*.

- HCP1982I *userid*: Destination system VSWITCH *swname* is not configured as USERBASED for simulated NIC *vdevno*.
- HCP1982I *userid*: Destination system VSWITCH *swname* is not configured as PORTBASED for simulated NIC *vdevno*.
- HCP1982I *userid*: Destination system VSWITCH *swname* is not configured with NATIVE VLAN *vid* for simulated NIC *vdevno*.
- HCP1982I *userid*: Destination system VSWITCH *swname* is not configured with TYPE QDIO for simulated NIC *vdevno*.
- HCP1982I *userid*: Destination system VSWITCH *swname* is not configured with ISOLATION ON for simulated NIC *vdevno*.
- HCP1982I *userid*: Destination system VSWITCH *swname* is not configured with ISOLATION OFF for simulated NIC *vdevno*.
- HCP1982I *userid*: Destination system VSWITCH *swname* is not configured with VEPA ON for simulated NIC *vdevno*.
- HCP1982I *userid*: Destination system VSWITCH *swname* is not configured with VEPA OFF for simulated NIC *vdevno*.
- HCP1982I *userid*: Source system network device *vdevno* is coupled to a VSWITCH with VEPA ON. Destination system does not support VEPA.
- HCP1982I *userid*: Source system network device *vdevno* is coupled to a PORTBASED VSWITCH. Destination system does not accept PORTBASED relocations.
- HCP1982I *userid*: Source system network device *vdevno* is coupled with a PORTNUMBER outside the range supported by the destination system.
- HCP1982I *userid*: Source system network device *vdevno* is coupled to a VSWITCH with multiple network connections with different attributes. Destination system does not accept this configuration.
- HCP1982I *userid*: Destination system VSWITCH *vswitch name* for simulated network device *vaddr* does not support PRIQUEUEING. Change PQUPLINKTX setting to NORMAL.
- HCP1983I *userid*: Virtual machine's maximum storage size of *size* exceeds destination hardware maximum of *maxsize*.
- HCP1984I *userid*: Virtual machine's total VDISK space exceeds the VDISK system or user limit on the destination system.
- HCP1985I *userid*: The maximum number of users allowed is already logged on the destination system.
- HCP1986I *userid*: A list-directed IPL or dump is in progress
- HCP1989I *userid*: Virtual machine is hosting a logical device
- HCP1990I Relocation of *userid* has reset the virtual machine's SET RESERVED setting of *rrrrrrrr* to zero
- HCP1990I Relocation of *userid* will reset the virtual machine's SET RESERVED setting of *rrrrrrrr* to zero
- HCP1991I *userid*: *nnnnnnnn* guest pages locked to real storage frames have been unlocked during relocation
- HCP1991I *userid*: *nnnnnnnn* guest pages locked to host logical storage pages have been unlocked during relocation
- HCP1992I *userid*: A customizable field in a CP control block appears to be in use
- HCP1992I *userid*: Virtual machine device *vdev* has an associated CP control block that contains a customizable field in use
- HCP1993I *userid*: Virtual machine is relocating another virtual machine
- HCP1994I *userid*: Virtual machine has 370ACCOM set on
- HCP1995I *userid*: Virtual machine device *vdev* is an unsupported device
- HCP1995I *userid*: Virtual machine device *vdev* is an attached real terminal
- HCP1995I *userid*: Virtual machine device *vdev* is a dialed GRAF
- HCP1995I *userid*: Virtual machine device *vdevis* is a dialed in LINE

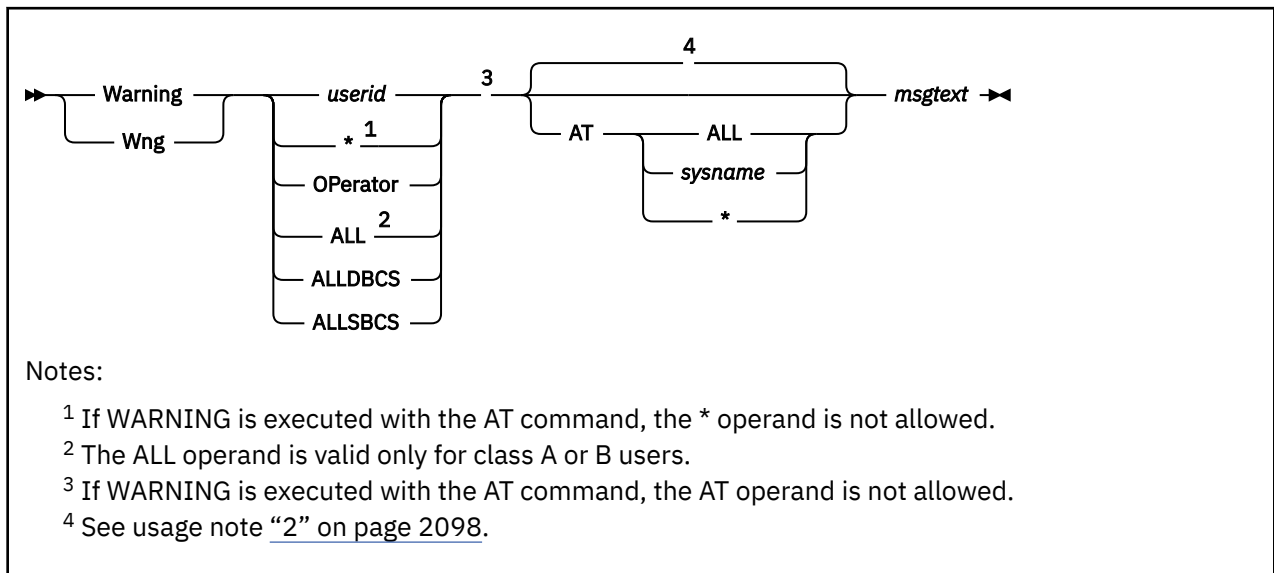

- HCP1995I *userid*: Virtual machine device *vdev* is a simulated CTCA that is coupled
- HCP1995I *userid*: Device *vdev* is coupled to a Coupling Facility virtual machine
- HCP1995I *userid*: Virtual machine device *vdev* is a dedicated SWITCH
- HCP1996I *userid*: Virtual machine device *vdev* is associated with a minidisk that was created with the DEFINE MDISK command
- HCP1996I *userid*: Virtual machine device *vdev* is a link to a private minidisk
- HCP1996I *userid*: Virtual machine device *vdev* is associated with a non-fullpack minidisk that was created with mode suffix V on the MDISK directory statement
- HCP1996I *userid*: Virtual machine device *vdev* is associated with a minidisk that is currently using virtual working allegiance simulation
- HCP1996I *userid*: Virtual machine device *vdev* is associated with a minidisk that is currently quiesced for HyperSwap
- HCP1996I *userid*: Virtual machine device *vdev* is an FBA DASD associated with real device *rdev* for which the reserve state is unknown
- HCP1996I *userid*: *userid*: Virtual machine device *vdev* is a full-pack overlay minidisk
- HCP1997I *userid*: Virtual machine device *vdev* is associated with real device *rdev* that has no EQID assigned to it
- HCP1997I *userid*: Source system virtual device *vaddr* on real device *raddr* cannot be created on the destination system because the real device does not exist there
- HCP1997I *userid*: Source system virtual device *vaddr* on real device *raddr* cannot be created on the destination system because an eligible equivalent real device cannot be found
- HCP1997I *userid*: Source system virtual device *vaddr* on real device *raddr* cannot be created on the destination system because its equivalent real device *rdev* is defined with a different device class and/or device type
- HCP1998I *userid*: Virtual machine device *vdev* has an outstanding delayed response message
- HCP1998I *userid*: Virtual machine device *vdev* is a single-user TAPE that is currently assigned
- HCP1998I *userid*: Virtual machine device *vdev* is a multi-user TAPE and the virtual machine currently owns the assign
- HCP1998I *userid*: Source system multi-user tape virtual device *vaddr* on real device *raddr* cannot be created on the destination system because the equivalent real device *raddr* is neither defined as a multi-user tape device nor free
- HCP1998I *userid*: Source system tape virtual device *vdev* on real device *rdev* is associated with an encryption key and cannot be created on the destination system because the equivalent real device *rdev* is associated with a different encryption key or one cannot be established for it
- HCP1998I *userid*: Virtual machine has directory authorization to use DIAGNOSE X'254' to control a Tape Library Dataserver
- HCP1998I *userid*: Source system tape virtual device *vdev* is a single-user TAPE for which assign status could not be determined
- HCP1998I *userid*: Virtual machine device *vdev* on real device *rdev* is not associated with an encryption key and cannot be created on the destination system because the equivalent real device *rdev* is associated with a key
- HCP2765E CP Exit *exit number* has returned unsupported return code *rc*
- HCP2779E CP Exit *exit number* has rejected the request
- HCP3150I *userid*: Destination system VSWITCH *swname* is reconfigured to GRANT *userid* for simulated NIC *vdevno*.
- HCP3150I *userid*: Destination system VSWITCH *swname* is reconfigured with PORTTYPE ACCESS for simulated NIC *vdevno*.
- HCP3150I *userid*: Destination system VSWITCH *swname* is reconfigured with PORTTYPE TRUNK for simulated NIC *vdevno*.

## VMRELOCATE

- HCP3150I *userid*: Destination system VSWITCH *swname* is reconfigured with PROMISCUOUS for simulated NIC *vdevno*.
- HCP3150I *userid*: Destination system VSWITCH *swname* is reconfigured with the source VLAN set for simulated NIC *vdevno*.

## WARNING

### Authorization

Privilege Class: A, B, C

### Purpose

Use WARNING to transmit a high-priority message to all or specified users.

#### Note:

1. WARNING does not wait for terminal input operations to complete. It breaks in on the line being displayed and sends the message immediately.
2. The SET WNG OFF command overrides this process.

### Operands

**userid**

\*

**OPERator**

**ALL**

identifies the user to whom you are sending the warning. To send a warning to yourself, specify an asterisk (\*).

Specify OPERATOR if you want to send a warning to the primary system operator, regardless of the operator's user ID. If you specify ALL, you broadcast the warning to all users receiving messages.

**ALLDBCS**

transmits the warning to all users logged on to DBCS (double-byte character set) terminals.

**ALLSBCS**

transmits the warning to all users logged on to SBCS (single-byte character set) terminals.

**AT ALL**

transmits the warning to all systems in the SSI cluster to which this system belongs. The lowest return code is returned to the command issuer.

**AT sysname**

transmits the warning to a specific system in the SSI cluster to which this system belongs. The return code is sent to the command issuer.

## WARNING

### AT \*

transmits the warning only to the system where the command is issued. This is the default if the system is not a member of an SSI cluster.

### *msgtext*

is the text of the warning message you are sending. The length of the message is limited by the number of characters remaining on the input line after the command and appropriate operand are entered. DBCS text is supported as message text.

## Usage Notes

1. If a warning is issued from a CMS environment, the command and the message text cannot be longer than 240 characters.  
If a warning is issued from a CP environment, the command and message length is limited by the input area of the terminal.
2. If the AT operand is not specified:
  - If WARNING is not executed with the AT command:
    - If the sender's system is not a member of an SSI cluster, the default is AT \*.
    - If the sender's system is a member of an SSI cluster, the default is AT ALL, except in the following cases, when the default is AT \*:
      - If the specified user ID is OPERATOR.
      - If the specified user ID is logged on to the same system as the sender.
      - If the specified user ID or the sender is defined by a multiconfiguration virtual machine definition.
      - If ALL, ALLDBCS, or ALLSBCS is specified, and a potential recipient user ID is defined by a multiconfiguration virtual machine definition, the default is AT \* for that user ID.
  - If WARNING is executed with the AT command, the AT operand function is bypassed (there is no default), and the message is sent to the system specified on the AT command.
3. The WARNING command routes the message to the secondary user of a disconnected virtual machine. If the secondary user is connected or the secondary user is disconnected but has a valid path to a \*MSG or \*MSGALL CP system service, the secondary user receives the message.  
If the secondary user is disconnected and there is no valid path to a \*MSG or \*MSGALL CP system service, the message *userid not receiving; disconnected* is returned to the command issuer.
4. If you receive a warning on a virtual console with the alarm feature, the alarm sounds.
5. If an external security manager (ESM) is installed on your system, you may not be authorized to enter this command. However, messages sent to or from the system operator and messages sent with the ALL option are not subject to authorization checking by the ESM. For additional information, contact your security administrator.

## Responses

Response 1:

```
hh:mm:ss * WNG FROM userid: msgtext
```

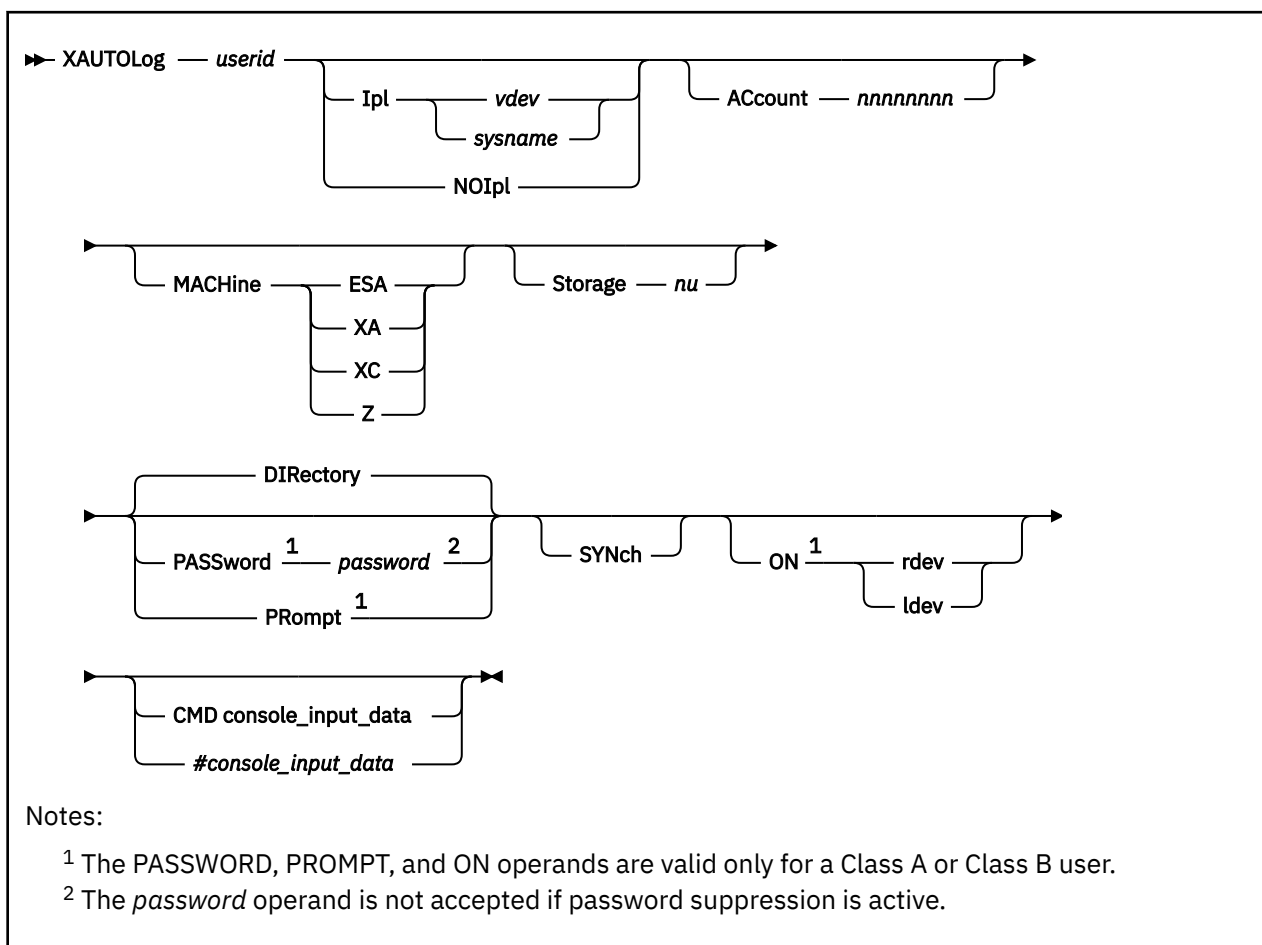

is the warning received by the specified users. The value *hh:mm:ss* represents the time the message was sent to the user.

## Messages

- HCP003E Invalid option - {*option*|command contains extra option(s) starting with *option*}
- HCP020E Userid missing or invalid
- HCP026E Operand missing or invalid

- HCP045E *userid* not logged on
- HCP057I *userid* not receiving; *text*
- HCP1142E The AT option is not allowed when this command is executed remotely with the AT command.
- HCP2970E The SSI cluster member name is missing or invalid.
- HCP2971I Specified SSI cluster member is not joined.
- HCP6600E An error was detected by installation-wide {*CP module name*|exit point 1210} - return code *nnnn*

# XAUTOLOG

## Authorization

Privilege Class: A, B, G

## Purpose

Use XAUTOLOG to log on another user virtual machine automatically.

**Note:** If you have Class G privileges only, the other user must have the appropriate XAUTOLOG statement in their system directory. If you have Class A or Class B privileges, and are not specifying a password, you are automatically authorized to log that virtual machine on.

## Operands

### *userid*

identifies the virtual machine you are logging on.

### **Ipl** *vdev*

### **Ipl** *sysname*

specifies the virtual device number or named saved system that you want IPLed after logon processing. This option overrides the IPL (if any) specified in the user's entry in the system directory.

If SYNCH is not specified, the IPL command processor determines whether the IPL operand is valid after the logon is completed; it is not verified as part of LOGON or XAUTOLOG processing.

If SYNCH is specified with IPL, the IPL operand is checked for validity before control returns to the XAUTOLOG command issuer.

The IPL command processor determines whether the IPL operand is valid after the logon is completed; it is not verified as part of logon processing.

### **NOIpl**

means that the IPL device specified in the user's entry in the system directory should not be used for an automatic IPL.

### **ACcount nnnnnnnn**

specifies an alternate account number to be assigned to the user's virtual machine at logon. This account number must be valid in order for the logon to complete successfully. If you do not specify this option, the primary (or first) account number specified in the user's entry in the system directory is used.

### **MACHine ESA**

### **MACHine XA**

### **MACHine XC**

### **MACHine Z**

specifies the mode (architecture) of the virtual machine. This option overrides the machine statement (if any) specified in the user's entry in the system directory. For further information on the [MACHINE](#) directory statement, see *z/VM: CP Planning and Administration*.

ESA designates ESA/390 (31-bit) architecture. A guest operating system can switch between ESA/390 and z/Architecture (64-bit) mode. XA is supported for compatibility and is functionally equivalent to ESA. XC designates ESA/XC architecture. A guest operating system can switch between ESA/XC and z/XC mode. Z designates a machine that executes only in z/Architecture mode.

See usage note “21” on page 2104.

### **Storage nu**

specifies an alternate storage size to be assigned to the virtual machine. The storage size is specified in the form *nu*, where *n* is a 1- to 8-digit decimal number and *u* is the 1-character storage unit suffix:

<i>Table 49. Maximum Input Values for Storage Units</i>	
<b>Storage unit suffix(u)</b>	<b>Maximum input value(n)</b>
K - kilobytes	99999999
M - megabytes	99999999
G - gigabytes	99999999
T - terabytes	16777216
P - petabytes	16384
E - exabytes	16

### **Notes:**

1. A K specification is rounded up to a MB value.
2. The maximum input value of 99999999 for the K, M, or G suffix is not a size limit but the physical limit of the operand (8 digits plus suffix). If the maximum input value for one of these suffixes does not allow you to define the amount of storage you want, you need to use a larger storage unit.
3. The value you specify for this option must be valid in order for the logon to be completed successfully. If you do not specify a value, the storage size defined in the user directory entry for the virtual machine is used. The maximum allowed value is the maximum storage size defined in the user directory entry for the virtual machine. The maximum cannot exceed a processor-specific limit imposed at run time.

**PASSword password**

is *userid*'s logon password. The ability to specify the password is available only to Class A or Class B users. Class A or Class B users are authorized to automatically log on any virtual machine without specifying a password, but this PASSWORD option is available when password verification is desired.

To determine whether password suppression is active for this command, use the QUERY PASSWORD XAUTOLOG command. If password suppression is active, you cannot specify a password on the command line. If you want to specify a password for the XAUTOLOG operation, use the PROMPT operand.

**PRompt**

specifies that you should be prompted for the password at the terminal. If password suppression is active for this command, you must specify PROMPT in order to use password authorization when entering the command at the terminal. The ability to specify PROMPT is available only to Class A or Class B users.

**DIRectory**

indicates that the user's entry in the system directory must contain an XAUTOLOG statement to authorize you to log on the virtual machine if you do not have Class A or Class B privileges.

**SYNch**

indicates that the command is to be run synchronously. CP returns control to the issuer of the XAUTOLOG command when the target user ID is logged on and IPL command is validated (if an automatic IPL is performed). Unless NOIPL is specified, there must be an IPL statement in the target user ID's directory entry or the IPL parameter must be specified on the XAUTOLOG command. (Note: If NOIPL is specified, CP returns control when the target user ID is logged on.)

If SYNCH is not specified, the XAUTOLOG command runs asynchronously, and CP returns control after a logon is scheduled. The XAUTOLOG command issuer receives a message when the target user is logged on. For asynchronous execution, no IPL statement or parameter is required.

**ON rdev**

specifies the real device number of a local 3270 device that is to be used as the console of the virtual machine. The ON option is available only to Class A or Class B users.

**ON ldev**

specifies the logical device number of the device that is to be used as the console of the virtual machine. Specify a logical device number as an "L" followed by up to four hexadecimal digits. Leading zeros may be omitted. The ON option is available only to Class A or Class B users.

**CMD console\_input\_data**

specifies the data that you want used as virtual console input in response to the first read issued by the user's virtual machine. You may use the remainder of the command line to enter console data.

**Note:** This option differs from *#console\_input\_data* in that logical line-end characters are not honored. Because of this, only one command can be sent. This option is intended to be used when the XAUTOLOG command is issued with the AT command to a remote member of the SSI cluster. It can also be used if the user being logged on is on the same system, with or without the AT command.

***#console\_input\_data***

is data that you want used as virtual console input in response to the first read issued by the user's virtual machine. You may use the remainder of the command line to enter console data; the entire line including any logical line-end characters (#) is passed to the virtual machine.

**Note:** # refers to the whatever logical line-end character is currently in effect for the virtual machine in which the XAUTOLOG command is being used.

If you are using CMS and you specify *#console\_input\_data* with the logical line-end character (#) on the command line, CMS truncates the XAUTOLOG command at the first logical line-end character. To prevent this, enter a logical escape character before the logical line-end character, or enter #CP, where # is your logical line-end character, before the XAUTOLOG command itself.

## Usage Notes

1. XAUTOLOG was a synonym for the AUTOLOG command. It was provided to ease future migration for those who wanted to use the extended options of the z/VM XAUTOLOG command.
2. A virtual machine is allowed to be logged on with XAUTOLOG even though the number of users already logged on is equal to or greater than the maximum allowed by the MAXUSERS operand of the FEATURES system configuration statement or by the SET MAXUSERS command if the user directory for the virtual machine was created using the IGNMAXU operand of the OPTION directory statement.
3. If neither IPL nor NOIPL is specified, the virtual machine that you log on using the XAUTOLOG command must have an IPL statement in its system directory entry unless it is a CF Service Machine (has OPTION CFVM in the directory).  
  
Unless NOIPL is specified, an automatic IPL is scheduled. If the IPL statement is not valid, you receive a message and *userid* is forced off the system.
4. Authorization to log on a user through the XAUTOLOG command is granted:
  - If you have Class A or Class B command privileges and you specify or default to the DIRECTORY option
  - If you have Class A or Class B command privileges and you specify a correct password in response to a prompt or through the PASSWORD option
  - If you have Class G (and not Class A or Class B) command privileges and your user ID appears in the XAUTOLOG directory statement belonging to the virtual machine that you want to XAUTOLOG.
5. Users with a password of NOLOG in their directory entries cannot be logged on by the XAUTOLOG command. For a complete description of the [XAUTOLOG directory statement](#), see *z/VM: CP Planning and Administration*.
6. If you do not specify the ON option, the virtual machine that you log on using the XAUTOLOG command operates in disconnect mode. The same restraints that apply to any disconnected machine also apply to virtual machines that are logged on with the XAUTOLOG command.
7. If you are using CMS and specify *#console\_input\_data* on the XAUTOLOG command line, CMS interprets the input line as two separate commands because of the logical line-end character (#). You can avoid this situation by turning off line editing, by preceding the logical line-end character with a logical escape character, or by preceding the XAUTOLOG command line with *#CP*, where *#* is your logical line-end character.
8. If the user ID you specify has a secondary user ID specified on the CONSOLE statement in its directory entry, messages from CP (and from the virtual machine if automatic IPL takes place) are routed to the secondary user if that user is logged on and not disconnected. If your user ID (XAUTOLOG issuer) is the designated secondary user ID and you are not running in disconnect mode, you receive messages resulting from the LOGON of the target user.
9. If your installation is using the password suppression facility for this command (controlled by the PASSWORDS\_ON\_CMDs operand of the FEATURES system configuration statement or by the SET PASSWORD command) and you want to use password authorization, you should enter the PROMPT parameter on the XAUTOLOG command line. Wait for the ENTER PASSWORD prompt before you type in the password. For system security, the password is automatically masked.
10. CP disables the XAUTOLOG and AUTOLOG commands for the rest of a user's log on session if a user enters excessive incorrect passwords to logon another user ID automatically. The initial system limit depends on how the JOURNALING system configuration statement is coded. Use the QUERY CMDLIMIT command to see the system limit value set by your installation. See *z/VM: CP Programming Services* for special considerations when issuing XAUTOLOG through the simulated virtual console interface (DIAGNOSE X'08').
11. If SYNCH is specified and an automatic IPL is scheduled but IPL processing is unsuccessful, you receive a message and the user ID is forced off the system.
12. If an external security manager (ESM) is installed on your system, you might not be authorized to use this command or you might not be authorized to use the ON operand for this command. For additional information, contact your security administrator.

13. There is no password authorization for an XAUTOLOG of a *userid* defined with the NOPASS operand, unless an ESM is installed. When an ESM is installed, password authorization may be required despite the NOPASS operand. Refer to documentation provided by your ESM for more information.
14. CP typically presents *console\_input\_data* to CMS through an interruption sequence before a CMS program has requested a console read. CMS places the *#console\_input\_data* into its terminal input queue in anticipation of some subsequent request to read from the console. This subsequent request is usually the PARSE EXTERNAL instruction in the SYSPROF EXEC, unless the SYSPROF EXEC is bypassed or the AUTOOCR parameter was used at IPL time. The EXTERNALS() VM REXX built-in function can be used to test for the existence of *console\_input\_data* before the PARSE EXTERNAL is issued.
15. Users defined with the LBYONLY operand in the password field of their USER or IDENTITY statement in the system directory may be restricted from performing functions that require password validation. When an ESM is not installed, users defined with the LBYONLY operand cannot be logged on by the XAUTOLOG command if password validation is required. When an ESM is installed, refer to the documentation provided by your ESM for more information.  
  
Refer to the [USER Directory Statement](#) or [IDENTITY Directory Statement](#) in *z/VM: CP Planning and Administration* for more details on the LBYONLY operand.
16. CP does not support System/370 architecture (370 mode) virtual machines. If a LOGON is attempted for a virtual machine whose directory entry specifies 370 mode, the XAUTOLOG command will be completed, but the virtual machine will be set to XA mode instead of 370 mode. Message HCP1512E is issued to inform the user.
17. If an XAUTOLOG is attempted for a virtual machine whose directory entry specifies z/Architecture-only mode, but the relocation domain does not support that mode, the XAUTOLOG command is completed, the virtual machine is set to ESA mode instead, and message HCP1512E is issued to inform the user.
18. If the ON option is specified, the designated real or logical device must exist and must be enabled.
19. If the ON option is specified and the virtual machine is already logged on, it will be reconnected on the designated device if it is disconnected or it will be disconnected from its current console device and reconnected on the designated device.
20. If the AT command is used to issue XAUTOLOG on a remote member of an SSI cluster, the PROMPT option is not allowed. If it is specified in this case, message HCP1516E is issued and the command is rejected.
21. An ESA (or XA) virtual machine will be put into either full ESA/390 mode or ESA/390 compatibility mode, depending on the level of ESA/390 capability available in the machine where the virtual machine is logged on or in the virtual machine's relocation domain. ESA/390 compatibility mode allows a subset of ESA/390 functionality sufficient for CMS and GCS, but lacks advanced functions like dynamic address translation (DAT). For details on ESA/390 compatibility mode, see [z/Architecture Principles of Operation](#).

## Responses

Response 1:

```
ENTER PASSWORD:
```

is the response to the PROMPT parameter. Enter the password of the user ID you want to XAUTOLOG.

Response 2:

```
Command accepted
```

indicates that the command syntax is correct.

This response appears if SYNCH is not specified and the command line syntax is accepted. This response means that the logon has been scheduled and VM has returned control to you. More information about the logon and IPL arrives later.

If the SYNCH parameter is specified, the COMMAND ACCEPTED response does not appear. All processing concerning the automatic logon is completed before VM returns control to you.

If an error occurs in trying to autolog the specified user, you receive an error message.

Response 3:

```
AUTO LOGON ***      userid USERS = nnnnn
```

is the response XAUTOLOG sends to the issuer of the command when that person is not the system operator. This response is generated by successful command completion.

\*\*\*

indicates there is no assigned line address for the virtual console.

**userid**

identifies the virtual machine initiated by XAUTOLOG.

**USERS = nnnnn**

is the number of logged-on users.

Response 4:

```
hh:mm:ss AUTO LOGON ***      userid USERS = nnnnn BY {SYSTEM }
                                     {userid2}
```

is the response XAUTOLOG sends to the system operator when the command completes successfully.

\*\*\*

indicates there is no assigned line address for the virtual console.

**userid**

identifies the virtual machine initiated by XAUTOLOG.

**USERS = nnnnn**

is the number of logged-on users.

**SYSTEM**

indicates that the XAUTOLOG process has occurred as part of VM system initialization. Typically, your primary system operator's virtual machine is logged on as part of the system initialization process.

**userid2**

identifies the user issuing the XAUTOLOG command.

Response 5:

```
hh:mm:ss USER DSC LOGOFF AS userid USERS = nnnnn FORCED
```

is the response to the system operator upon failure of the IPL for the user specified on the XAUTOLOG command. The system operator receives this response only if SYNCH is specified and an automatic IPL was scheduled for the *userid*.

**DSC**

indicates that the user you autologged is operating in disconnect mode.

**userid**

identifies the virtual machine initiated by the XAUTOLOG command.

**USERS = nnnnn**

is the number of logged-on users.

Response 6:

```
USER DSC LOGOFF AS userid USERS = nnnnn FORCED
```

is the response to the system operator if a not valid IPL statement is processed for the user specified in the XAUTOLOG command. The system operator receives this response only if an automatic IPL was scheduled for the user ID.

**userid**

identifies the virtual machine initiated by XAUTOLOG.

**USERS = nnnnn**

is the number of logged-on users.

Response 7:

```
AUTO LOGON type {rdev} userid USERS = nnnnn  
                {ldev}
```

is the response to the issuer of the command when that person is not the system operator and when the ON option of the XAUTOLOG command is specified.

**type**

is the display type.

**rdev****ldev**

is the real or logical device number where the user was logged on or reconnected.

**userid**

identifies the virtual machine initiated by XAUTOLOG.

**USERS = nnnnn**

is the number of logged-on users.

Response 8:

```
hh:mm:ss type {rdev} {AUTOLOGON} userid USERS = nnnnn BY userid2  
              {ldev} {RECONNECT}
```

is the response to the system operator when an XAUTOLOG command with the ON option specified completes successfully.

**type**

is the display type.

**rdev****ldev**

is the real or logical device number where the user was logged on or reconnected.

**userid**

identifies the virtual machine initiated by XAUTOLOG.

**USERS = nnnnn**

is the number of logged-on users.

**userid2**

identifies the user issuing the XAUTOLOG command.

## Messages

- HCP1509E You are not authorized to issue XAUTOLOG with the PASSWORD, PROMPT, or ON options.
- HCP1512E The System/370 machine mode was requested, but CP does not support System/370 mode virtual machines; the machine mode will be set to XA instead.
- HCP1512E The z/Architecture-only machine mode was requested, but is not supported in this relocation domain. The machine mode will be set to ESA instead.
- HCP1513E [XAUTOLOG failed for *userid*:] A logon is already in progress [on {*type rdev*|*type idev*|*liuname*|SYSC}]
- HCP1516E XAUTOLOG failed: The PROMPT option cannot be specified with the AT command.
- HCP6050E Your *userid* is not authorized to automatically logon *userid* *userid*
- HCP6052E XAUTOLOG command rejected; command format not valid.
- HCP6054E XAUTOLOG failed for *userid*: Explanatory message to follow.
- HCP6525E External Security Manager is unavailable.
- HCP6056I XAUTOLOG information for *userid*: The IPL command is verified by the IPL command processor.
- HCP6525E Authorization request failed.

## XLINK

---

### Authorization

Privilege Class: A, B

### Purpose

Use the XLINK family of commands to perform the following cross-system link functions:

#### XLINK CHECK

Use XLINK CHECK to determine whether one or more volumes are under cross-system link control.

#### XLINK FINDTAB

Use XLINK FINDTAB to attempt to verify that the CSE/SSI system table matches the date and time stamp in the CP table.

#### XLINK RESET

Use XLINK RESET to free links held by a failed system.

If a system is defined as a member of an SSI cluster, none of the XLINK commands are allowed.

### Usage Notes

1. The cross system extensions (CSE) environment is not supported. However, the cross-system link (XLINK) function that was included in CSE is still supported for non-SSI systems, and "CSE" is still used in some function and object names, command responses, and messages related to XLINK.
2. The following CP utilities provide additional XLINK functions:

#### XLINK DISPLAY

Use XLINK DISPLAY to display link indicators in the map records of all systems on a particular device. For more information, see [“XLINK DISPLAY” on page 2257](#).

#### XLINK FORMAT

Use XLINK FORMAT to prepare DASD for sharing by initializing the CSE area on the specified DASD volume. For more information, see [“XLINK FORMAT” on page 2260](#).

3. The following responses and messages can be issued for XLINK CHECK, XLINK FINDTAB, or XLINK RESET.

### Responses

```
HCP2883I  Volume volidn is not controlled by CSE LINK.
HCP2884I  Volume volidn is controlled by CSE LINK.
HCP2886D  Are you ready for XLINK RESET of
           system sysname, volume volidn?
           Enter YES or NO:
HCP2887I  XLINK RESET complete.
HCP2888I  XLINK RESET ignored.
HCP2892I  WARNING! XLINK RESET must be used with
           extreme caution. Improper use will cause
           loss of minidisk data.
```

### Messages

- HCP0023E Volid missing or invalid
- HCP0026E Operand missing or invalid

- HCP1667E THE XLINK COMMAND IS NOT ALLOWED BECAUSE THE SYSTEM IS A MEMBER OF AN SSI CLUSTER.
- HCP2881E XLINK RESET is not allowed. There is no CSE LINK control on this system.
- HCP2882E XLINK RESET is not allowed. There is no CSE LINK control on system *sysname*.
- HCP2885E Volume *validn* is offline.
- HCP2889E XLINK RESET on your own system is not allowed.

## XLINK CHECK

---

### Authorization

Privilege Class: A, B

### Purpose

Use XLINK CHECK to determine whether one or more volumes are under cross-system link control. If a system is defined as a member of an SSI cluster, XLINK CHECK is not allowed.

### Operands

#### *valid*

is the 1- to 6-character name of a volume to be checked.

### Usage Notes

1. The cross system extensions (CSE) environment is not supported. However, the cross-system link (XLINK) function that was included in CSE is still supported for non-SSI systems, and "CSE" is still used in some function and object names, command responses, and messages related to XLINK.
2. The volume does not have to be mounted before you enter XLINK CHECK.

## XLINK FINDTAB

---

► XLINK — Findtab ◄

### Authorization

Privilege Class: A, B

### Purpose

Use XLINK FINDTAB to attempt to verify that the CSE/SSI system table matches the date and time stamp in the CP table.

If a system is defined as a member of an SSI cluster, XLINK FINDTAB is not allowed.

### Usage Notes

1. The cross system extensions (CSE) environment is not supported. However, the cross-system link (XLINK) function that was included in CSE is still supported for non-SSI systems, and "CSE" is still used in some function and object names, command responses, and messages related to XLINK.
2. This function is performed during the XLINK FORMAT process. Under normal circumstances, you should not need to enter this command.

## XLINK RESET

### Authorization

Privilege Class: A, B

### Purpose

Use XLINK RESET only when you want to free cross-system links held by a failed system.

**Attention:** Issuing XLINK RESET when the specified system is not really down or is in the process of coming up destroys minidisk data—not directly, but by disrupting cross-system link operation.

If XLINK RESET *sysname* is issued and users have write access to one of the minidisks on a volume just reset, all link indicators are cleared. This condition can allow another user to get write access to the same minidisk, possibly causing a loss of minidisk data.

If a system is defined as a member of an SSI cluster, XLINK RESET is not allowed.

### Operands

#### *sysname*

identifies the name of the system whose map records are to be RESET. This system must *not* be in operation.

#### **ALL**

specifies that all volumes on XLINK\_VOLUME\_INCLUDE configuration statements for the system *sysname* are to be cleared.

#### *valid*

identifies the serial number or label of the volume to be cleared.

#### **NOPROMPT**

specifies that the RESET should be performed WITHOUT a system prompt to the user requesting that the user verify if the RESET should really be done.

### Usage Notes

1. The cross system extensions (CSE) environment is not supported. However, the cross-system link (XLINK) function that was included in CSE is still supported for non-SSI systems, and "CSE" is still used in some function and object names, command responses, and messages related to XLINK.
2. The system specified as *sysname* should not be considered down unless it is powered off or unless its storage has been cleared to binary zeros.
3. To avoid losing user data, enter the SYSTEM RESET and SYSTEM CLEAR commands for the system that is down. Do this before issuing the XLINK RESET command from another system.
4. This command clears the record of existing links held by the failed system, allowing users on the other systems identified on XLINK\_SYSTEM\_INCLUDE configuration statements to establish links to those minidisks.
5. The XLINK RESET command is not necessary for shutdown because the link indicators are automatically cleared.
6. To avoid problems, confirm that the suspect system is not operating before you enter this command.
7. You cannot enter the XLINK RESET command for the system you are logged onto.

---

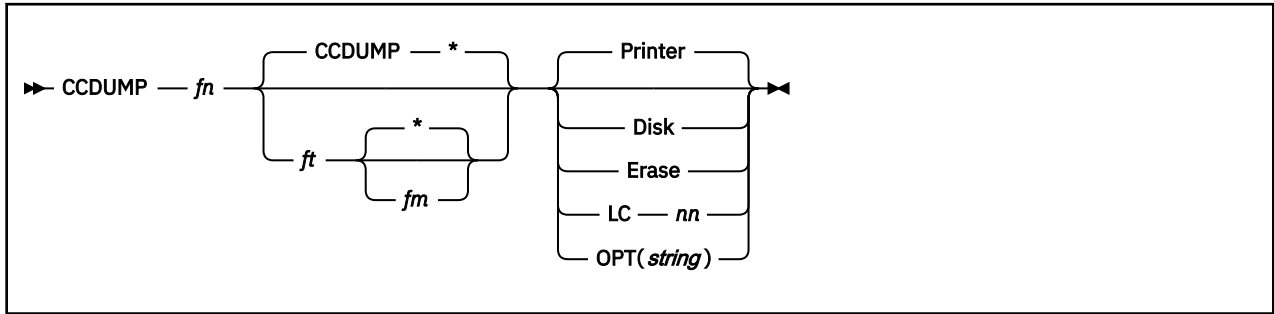

## Chapter 3. CP Utilities

This section contains reference information on the CP utilities. These utilities operate in the CMS environment. The utilities are listed in alphabetical order.

Each utility description is presented in the following format (some sections might not be included):

- **Name:** Identifies the name of the utility.
- **Format:** Shows the syntax of the utility with all the possible operands and options you can use.
- **Purpose:** States what the utility is used for.
- **Operands and Options:** Defines the function of each operand and option and any values you can include.
- **Usage Notes:** Identifies and describes special situations and other considerations that may affect your use of the utility.
- **Examples:** Provides one or more examples to show how the utility is commonly used.
- **Responses:** Describes the responses you might receive from the utility on your display device. Responses are normal operational output; they tell you about the execution and effect of the utility. Unlike system messages, utility responses are not prefixed with an identifying number and are not contained in *z/VM: CP Messages and Codes*.
- **Messages:** Lists the messages issued by the utility. Messages not unique to the utility might also be issued. Each message is prefixed with an identifying number. For more information on the messages, including suggested actions, see *z/VM: CP Messages and Codes*.

## CCDUMP

### Purpose

Use the CCDUMP utility to format and print a communications controller dump file produced by the CCLOAD command.

### Operands

#### *fn ft fm*

identifies the file containing a dump produced by the SSP utility IFLREAD, invoked directly or invoked by the CCLOAD command. The file type default is CCDUMP. The file mode default is asterisk (\*), indicating any disk. If a file name is not specified, CCDUMP processes the DUMP $nn$  file with the highest number  $nn$  on the specified disk, or all accessed disks if the filemode is specified with an asterisk (\*).

### Options

#### Printer

#### Disk

specifies the destination of the formatted dump output. Specifying PRINTER requires no A-disk space for the output file. Specifying DISK saves the formatted output on disk. The output file is always named *inputfn* LISTING A, where *inputfn* is the file name of the unformatted input file. The default is PRINTER.

#### Erase

specifies that the input dump file is to be erased after it is successfully printed.

#### LC $nn$

specifies the linecount parameter (the number of print lines per page) for the SSP utility IFLDUMP.

#### OPT *string*

specifies the optional formatting parameters to be passed to IFLDUMP in the SYSIN file. See the documentation for your communications controller for the allowable parameters. The string should not include the DUMP keyword, which is required and is generated automatically by CCDUMP. If a parameter string is not specified, the control statement contains just DUMP.

### Usage Notes

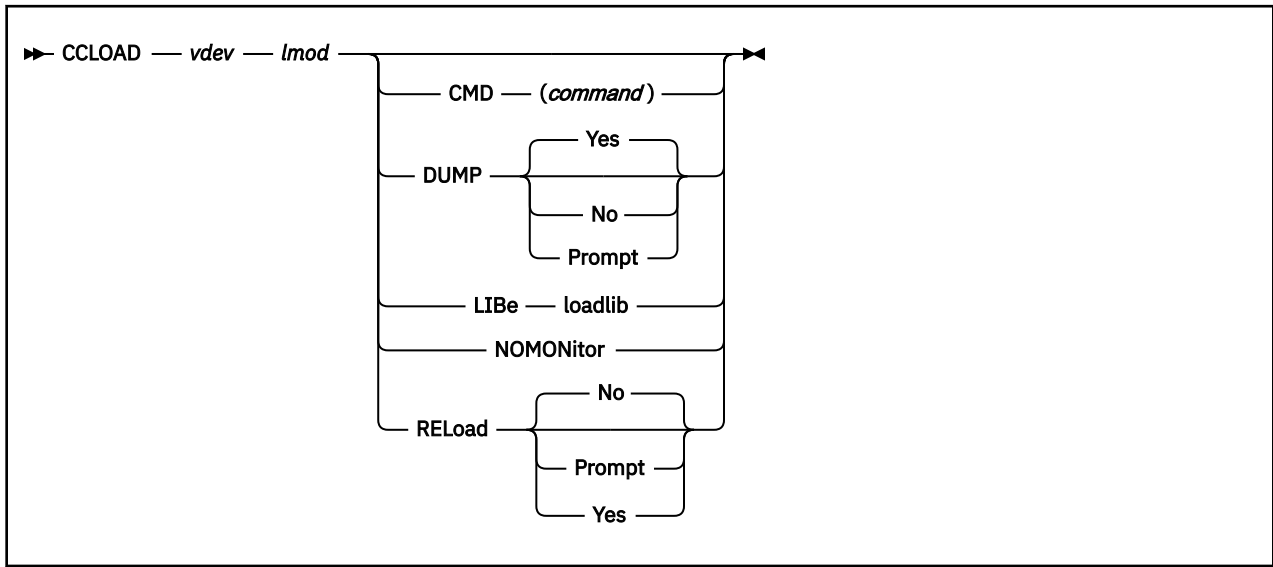

1. CCDUMP requires access to a R/W A-disk, even if PRINTER is specified.
2. If you specify DISK, you must have sufficient space on your A-disk for the formatted output file. Refer to the documentation for your communications controller for information on space requirements.
3. When you format the dump on the printer (PRINTER), messages produced by IFLDUMP do not appear on your console but are included in the SYSPRINT file. If you specify DISK, messages included in the SYSPRINT file are displayed on the console.

4. In order to erase the input dump file, you must have write access to the disk on which it resides. Do not specify the ERASE option if you are sharing access to files on another user's A-disk; for example, those generated by the CCLOAD EXEC on a disconnected service machine.

## Messages

## CCLOAD

### Purpose

Use the CCLOAD utility to provide support for loading and dumping a communication controller manually, or from a service virtual machine.

### Operands

#### *vdev*

identifies the virtual device to which the base subchannel for loading and dumping the communication controller is dedicated or attached.

#### *lmod*

identifies the member of the emulation program (EP) load module to be loaded from the OS format LOADLIB created by the generation process.

### Options

#### **CMD *command***

specifies a command to be processed when the controller is loaded and ready for use. For example, you can notify the VM/Pass-Through Facility (PVM) to start its remote line drivers by specifying `cmd(cp smsg pvm exec ep01)` where EP01 PVM is a file containing PVM start commands.

#### **DUMP Yes**

#### **DUMP No**

#### **DUMP Prompt**

specifies whether the controller is automatically dumped when an EP control program failure is detected. If PROMPT is specified, the user is asked to decide whether to take the dump. If NOMONITOR is specified, the DUMP operand is ignored.

#### **LIBe *loadlib***

specifies the file name of the file type LOADLIB that contains the load module. If not specified, *lmod* is assumed.

#### **NOMONitor**

specifies that the command is to load the controller only, then end without monitoring controller and console interrupts. If not specified, the command monitors the controller and console for interrupts. A console attention interrupt results in prompting for a user decision on whether to dump and/or reload the controller, end the command, or ignore the attention.

**RELoad No****RELoad Yes****RELoad Prompt**

specifies the action taken when the controller is found to be already loaded. NO is the default and means that the controller is not reloaded. YES means that the controller is unconditionally reloaded. Prompt means that the user is prompted to decide whether to reload.

**Usage Notes**

1. CCLOAD requires access to a R/W A-disk. Loading requires space for SYSIN and SYSPRINT files. If CCLOAD is used for dumping the communication controller either automatically or at user request, it requires enough disk space for the dump files created by IFLREAD. For DASD requirements, refer to the Network Program Products publications.
2. Use the CCDUMP command to format and print the dump files produced by CCLOAD. If you provide another user with shared access to the A-disk of the user ID running CCLOAD, controller dump files can be printed off-line while the service virtual machine monitors the controller.
3. PROMPT should be specified on a disconnected machine only if you use the Single Console Image Facility to provide console support.
4. If NOMONITOR is specified, the DUMP operand is meaningless.

**Messages**

## CPEREPXA

### Purpose

Use the CPEREPXA utility to access the Environmental Record Editing and Printing (EREP) program. This utility reads EREP records from a disk or a tape and produces printed output reports. The input records come from a CMS file that belongs to the error recording virtual machine or from a history tape. The content of the output report depends upon the specified or defaulted EREP keyword parameters and control statements and upon the EREP input records.

Because the EREP program is not used exclusively with z/VM, be sure that you have the latest publications that describe EREP before you attempt to invoke the program. See [Environmental Record Editing and Printing Program \(EREP\): User's Guide](#).

**Note:** The CPEREPXA utility produces error messages prefixed with the letters *HCP*. Messages issued from the EREP program are prefixed with the letters *IFC*. For descriptions of the HCP-prefixed messages, see [z/VM: CP Messages and Codes](#). For descriptions of the IFC-prefixed messages, see [Environmental Record Editing and Printing Program \(EREP\): Reference](#).

For information on [Setting Up Virtual Machines to Collect EREP Records](#), and an example of a procedure using the CPEREPXA utility to process EREP records, see [z/VM: CP Planning and Administration](#).

### Operands

#### *fn ft fm*

\*

is a control file containing EREP keyword parameters and control statements. (The keyword parameters and control statements are described in "EREP Keyword Parameters" below.) You can specify an asterisk (\*) in place of the file mode to indicate that the standard CMS search order is to be used to find the file.

If you do not enter the file name and file type of a control file, you are prompted to enter the keyword parameters and control statements from your display station.

#### EREP Keyword Parameters

You can enter the following list of EREP keyword parameters in your CPEREPXA control file or enter at your display station in response to the prompts issued by the CPEREPXA utility. This list contains only EREP keyword parameters. All control statements are passed to the EREP program without any recognition or action by CP.

This publication does not fully document the EREP program keyword parameters. It does not describe the precise meaning and use of the keyword parameter values that are required to be used with the keyword parameters. For complete details on EREP keyword parameters and control statements, including parameter-to-parameter relationships, refer to [Environmental Record Editing and Printing Program \(EREP\): User's Guide](#) and [Environmental Record Editing and Printing Program \(EREP\): Reference](#).

The EREP keyword parameters list contains two elements that are operands recognized by the CPEREPXA utility, CLEAR/CLEARF and TERMINAL. These operands are not operands for EREP, are unique to z/VM and are processed entirely by it. These operands are discussed only in this publication, and not in the [Environmental Record Editing and Printing \(EREP\) Program User's Guide and Reference](#).

*	MERGE
	MERGE=Y
	MERGE=N
ACC	
ACC=Y	
ACC=N	TERMINAL
	TERMINAL=Y
CLEAR	TERMINAL=N
CLEARF	
	THRESHOLD=(tempread,tempwrite)
ENDPARM	
	ZERO
HIST	ZERO=Y
HIST=Y	ZERO=N
HIST=N	

\*

in column 1 identifies a comment. Comments may appear anywhere in the input, regardless of whether it is entered from a control file or from your display station. EREP performs no processing; it simply places the contents of the comment in the TOURIST data set.

#### ACC=

indicates that selected error records are to be accumulated in an output data set. The particular error records selected and the source of these records (a CMS file, a history file, or both) depends on the other keyword parameters coded. The output accumulation data set is normally a tape mounted on tape drive 181, but this can be changed (see "CPEREPXA FILEDEFS" below). When output is accumulated on tape 181, the output is added as an extension of the existing file. The tape is rewound and spaced to the end of the first file before writing. Therefore, if you are using a tape for the first time, you should write a tape mark at the beginning of the tape before invoking CPEREPXA (the CMS TAPE command can do this). When output is accumulated on a tape, mount and ready the tape, and attach it to your virtual machine as tape 181 before invoking CPEREPXA. Note that for most types of reports, ACC=Y is the default.

**Note:** There are two CMS error record files: one for machine checks and one for other records.

#### CLEAR

#### CLEARF

This operand pair is exclusive to z/VM.

CLEAR requests z/VM to erase all error records from the error recording files, but not service record file (SRF) frame records. The CLEARF operand requests z/VM to erase all error records from the error recording files. Since z/VM does not record SRF frame records, these two operands are equivalent.

The CLEAR or CLEARF operand cannot be started along with keyword parameters; you must start each one in a stand-alone manner.

Because these operands cause error data to be erased from the input files, do not enter them within a sequence of keyword parameters or control statements that request error records as output. You should obtain all desired error data *before* issuing one of these operands.

#### ENDPARM

denotes the end of parameter specifications if you have used any keyword parameter statements. The ENDPARM keyword parameter is required if there are any control statements to enter, even if there are no keyword parameters to enter.

#### HIST=

indicates that the source of the error records for this run is to be a history data set rather than a CMS error record file. A history data set is a data set that was created as an accumulation (ACC) data set during an earlier session. Usually, the history data set is a tape mounted on tape drive 182, but this can be changed (see "CPEREPXA FILEDEFS" below). When input is from a history tape, mount and ready the tape and attach it to your virtual machine as tape 182 before invoking CPEREPXA.

**Note:** There are two CMS error record files: one for machine checks and one for other records.

**MERGE=**

indicates that the source of the error records for this run is to be both a history data set and a CMS error record file. The history data set is as described earlier for the HIST operand.

**Note:** There are two CMS error record files: one for machine checks and one for other records.

**TERMINAL=**

This operand is exclusive to z/VM.

When CPEREPXA encounters this operand while reading keyword parameters or control statements from a control file, CPEREPXA stops reading records from the file and begins to prompt for keyword parameters at your display station instead. All keyword parameters or control statements that are read from the control file before the TERMINAL operand is encountered are processed before CPEREPXA begins to prompt at your display station. Any subsequent records in the control file, however, are ignored. If CPEREPXA encounters this operand while reading from the display station, it is ignored. Control cannot be transferred back to the control file.

**THRESHOLD=**

Use the THRESHOLD keyword parameter to request a threshold report for the specified threshold values. The fields are not checked for syntax by CP. When CP recognizes the THRESHOLD keyword parameter, it changes the default value of the ACC keyword parameter to N.

**ZERO=**

Use the ZERO keyword parameter to tell EREP to clear the error recording files after generating the requested reports.

## Output Reports

For a complete description of the output reports that you can generate using CPEREPXA and the EREP program, see [Environmental Record Editing and Printing Program \(EREP\): User's Guide](#).

## Entering EREP Keyword Parameters and Control Statements

You must have IPLed CMS in your virtual machine in order to start the CPEREPXA utility. You can supply EREP keyword parameters or control statements to CPEREPXA by means of a console prompting technique, by a previously generated control file that contains the instructions required to produce the desired EREP record output, or by a combination of these two methods.

The sequence for invoking CPEREPXA is as follows:

1. Log onto the error recording service virtual machine. (Alternatively, log onto another virtual machine, link to the service virtual machine's minidisk that contains error records, and access that disk.)
2. IPL CMS.
3. Have the system operator attach any required tape devices to your virtual machine to serve for input and/or output data set use. (See the descriptions of the HIST and ACC operands).
4. Enter EREP keyword parameters or control statements through the file entry method or by the prompting method.

**Note:** The typical method of entering commands and operands on the same input line, as is done for other CP and CMS commands, is not valid. The reason that such action is disallowed is that many functions of EREP can exceed the maximum input line length the control program allows.

## Prompting Method

Type the CPEREPXA command at your display station and press the ENTER key. The system responds with this prompt: ENTER.

You may then enter EREP keyword parameters. If your needs exceed one line of input (limited by terminal line length), type a few keyword parameters and then press the ENTER key again. The system responds with the ENTER: prompt message again. You may then enter more keyword parameters. Repeat this process until no more keyword parameters are required. When this occurs, enter the ENDPARM keyword parameter to signal to the system that no more keyword parameters are to be entered.

Now you may enter control statements, but unlike the keyword parameters, they may be entered only one control statement for each line of input. Each time you press the ENTER key, the system responds with the ENTER: prompt message again. Repeat this process until no more control statements are required. When this occurs, press the ENTER key with no input. The null line signifies the end of the input.

When entering keyword parameters and control statements, observe the following rules:

- Separate keyword parameters and their associated values from the following keyword parameter by a blank (space), by multiple blanks, or by a comma.
- Enter embedded commas, periods, and parentheses that define the extent of variable keyword parameters as indicated in the CPEREPXA command format structure described earlier.
- Maintain the following sequence when entering input:
  1. Enter keyword parameters (if any).
  2. Enter the ENDPARM keyword parameter.
  3. Enter control statements (if any).

A comment card (\*) may appear anywhere in the sequence above. The TERMINAL operand is ignored if you enter it while using the prompting method.

- When you specify a keyword whose allowed values are Y and N, and you select the value Y, you may enter the keyword parameter without specifying a value. This form of the keyword parameter is always interpreted as a Y specification, regardless of the normal default value.
- To begin CPEREPXA with system default values, respond to the first ENTER: prompt message with the ENDPARM keyword parameter. When the second ENTER: prompt message appears, respond to it by pressing the ENTER key without any input; the null line signals to the system that there is no more input.

#### File Entry Method

The CPEREPXA command is entered followed by the file name, file type, and file mode of a file that contains a "package" of EREP keyword parameters and control statements arranged in the format as described in "Prompting Method" above. The same rules regarding blanks, commas, and parentheses apply; in addition, card images are truncated at column 71.

In practice, an installation probably has multiple files containing various operand mixes to satisfy the installation CPEREPXA report needs. To create and generate the necessary CPEREPXA files for this method of entry, use the CMS XEDIT command. File generation using the [CMS XEDIT command](#) is described in *z/VM: XEDIT User's Guide*.

#### Mixed Method

The CPEREPXA command is entered followed by the file name, file type, and file mode of a file that contains EREP keyword parameters and control statements, one of which is the TERMINAL operand of CPEREPXA. This operand may appear anywhere in the file, and keyword parameters (if any) and control statements (if any) are read until it is encountered. At this point, no further input is read from the file. Prompting begins at the display station, where additional EREP keyword parameters and control statements may be entered. When the system responds to the TERMINAL operand by transferring control from the control file to the display station, it expects input to proceed from the beginning of the sequence as it is described in "Prompting Method" above.

#### CPEREPXA FILEDEFS

CPEREPXA issues the FILEDEFS listed below before invoking EREP. These allow CMS to simulate the corresponding EREP files.

Where a mode letter of *x* is shown, *x* represents the read/write disk that has the most free space when CPEREPXA is invoked. At the end of the run, the FILEDEFS listed below are cleared with the exception of:

- EREPPT
- ACCIN
- ACCDEV.

These FILEDEFS are left intact because you can sometimes supply them yourself.

For those FILEDEFs where NOCHANGE is an option, you can supply an overriding FILEDEF before invoking CPEREPXA. The NOCHANGE option in CPEREPXA's FILEDEF means that it cannot change your previous FILEDEF.

```
filedef ereppt printer ( nochange blksize 133
filedef sysin disk sysin erepwork x3
filedef serlog disk serlog erepwork ( block 4096
filedef tourist terminal ( blksize 133
filedef directwk disk directwk erepwork x4
filedef accdev tap1 ( nochange recfm vb blksize 12000
filedef accin tap2 ( nochange recfm vb blksize 12000
```

### EREPPT

is EREP's printer file to which the report output is sent. You can override this FILEDEF with your own FILEDEF, which you can enter before invoking CPEREPXA.

### SYSIN

is a workfile built by CPEREPXA and read by EREP. You need not be concerned with it because it contains very few records. It is placed on the read/write disk having the most available space. It is erased automatically at the end of the run because its file mode number is 3. In those runs where there is no data to go into SYSIN, CPEREPXA issues FILEDEF SYSIN DUMMY for it, rather than the FILEDEF shown.

### SERLOG

represents the SYS1.LOGREC data set. The SYS1.LOGREC does not exist for z/VM; EREP's I/O to the SYS1.LOGREC is trapped by HCPIFC. Nevertheless, the FILEDEF is required to satisfy the needs of the OPEN and CLOSE commands issued by EREP because these are not trapped. Although a FILEDEF is defined, no corresponding file ever exists on any disk.

### TOURIST

is the message data set directed to your display station. EREP writes messages and diagnostics to this file with printer control characters. These characters may appear as data on the display station. A line of unknown characters may be printed before the EREP INFORMATIONAL MESSAGES heading.

### DIRECTWK

is a workfile built and read by EREP. It is not always created; whether it is created depends upon the particular report and whether the input comes from a history tape. This file may be quite large because it contains all input error records. The file is placed on the read/write disk having the most available space and is erased at the end of the run.

### ACCDEV

is the accumulation file. Normally, it is a tape on tape drive 181. This file is used if ACC=Y is specified either explicitly or implicitly. If ACC=Y is specified, tape 181 is rewound and spaced forward over the existing file and then backspaced over the tape mark before any writing is done. In this way, the tape is positioned to write new records at the end of the accumulation file.

**For standard label tapes only:** You must enter your own FILEDEF for ACCDEV before invoking CPEREPXA, so that the header labels are read correctly as *filedef accdev tapel sl (recfm vb blksize 12000*

In addition, if you want to update the standard label tape file, you should include the DISP MOD option.

**Note:** By issuing your own FILEDEF for ACCDEV before invoking CPEREPXA, you can override CPEREPXA's FILEDEF. In this way, you can accumulate data to another tape drive or to a disk file. However, the positioning of tape 181 is independent of your FILEDEF. This causes the following problems:

- Regardless of your FILEDEF, CPEREPXA attempts to position tape 181 as long as there is a tape 181 attached to the virtual machine (provided that ACC=Y).
  - If tape 181 is attached and ready, it is positioned.
  - If it is attached but not ready, the operator is notified, and CPEREPXA waits for the user to make it ready. The solution is to detach tape 181 before running CPEREPXA.

- CPEREPXA does not automatically position the user-defined file before writing into it, as it does when the file is tape 181.
  - If you define the file to another tape drive, the solution is to enter appropriate CMS TAPE commands to position the tape before invoking CPEREPXA.
  - If you define the file to a disk, the solution is to specify the DISP MOD option in your FILEDEF in order to add records at the end of an existing disk file.

You must always specify both RECFM and BLKSIZE. The record format must be either V or VB.

### ACCIN

is the history file. Normally, it is a tape on tape drive 182. This file is used if either MERGE=Y or HIST=Y is specified explicitly or implicitly. (HIST=Y is implied when certain reports are requested.) If either MERGE=Y or HIST=Y is specified, tape 182 is rewound before any reading is done.

**For standard label tapes only:** You must enter your own FILEDEF for ACCIN before invoking CPEREPXA, so that the header labels are read correctly.

**Note:** By issuing your own FILEDEF for ACCIN before invoking CPEREPXA, you can override CPEREPXA's FILEDEF. In that way, you can read history data from another tape drive or from a disk file. However, the rewinding of tape 182 is independent of your FILEDEF and can cause the following problems:

- Regardless of the your FILEDEF, CPEREPXA attempts to rewind tape 182 as long as there is a tape 182 attached to the virtual machine (provided that MERGE=Y or HIST=Y).
  - If 182 is attached and ready, it is rewound.
  - If it is attached but not ready, the operator is notified and CPEREPXA waits for the user to make it ready. The solution is to detach tape 182 before running CPEREPXA.
- CPEREPXA does not automatically rewind the user-defined file (if it is another tape drive) before reading from it as it does for tape 182. The solution is to enter a CMS TAPE command to rewind the tape before invoking CPEREPXA.

You must specify both RECFM and BLKSIZE if the history file is on a tape. The record format must be either V or VB.

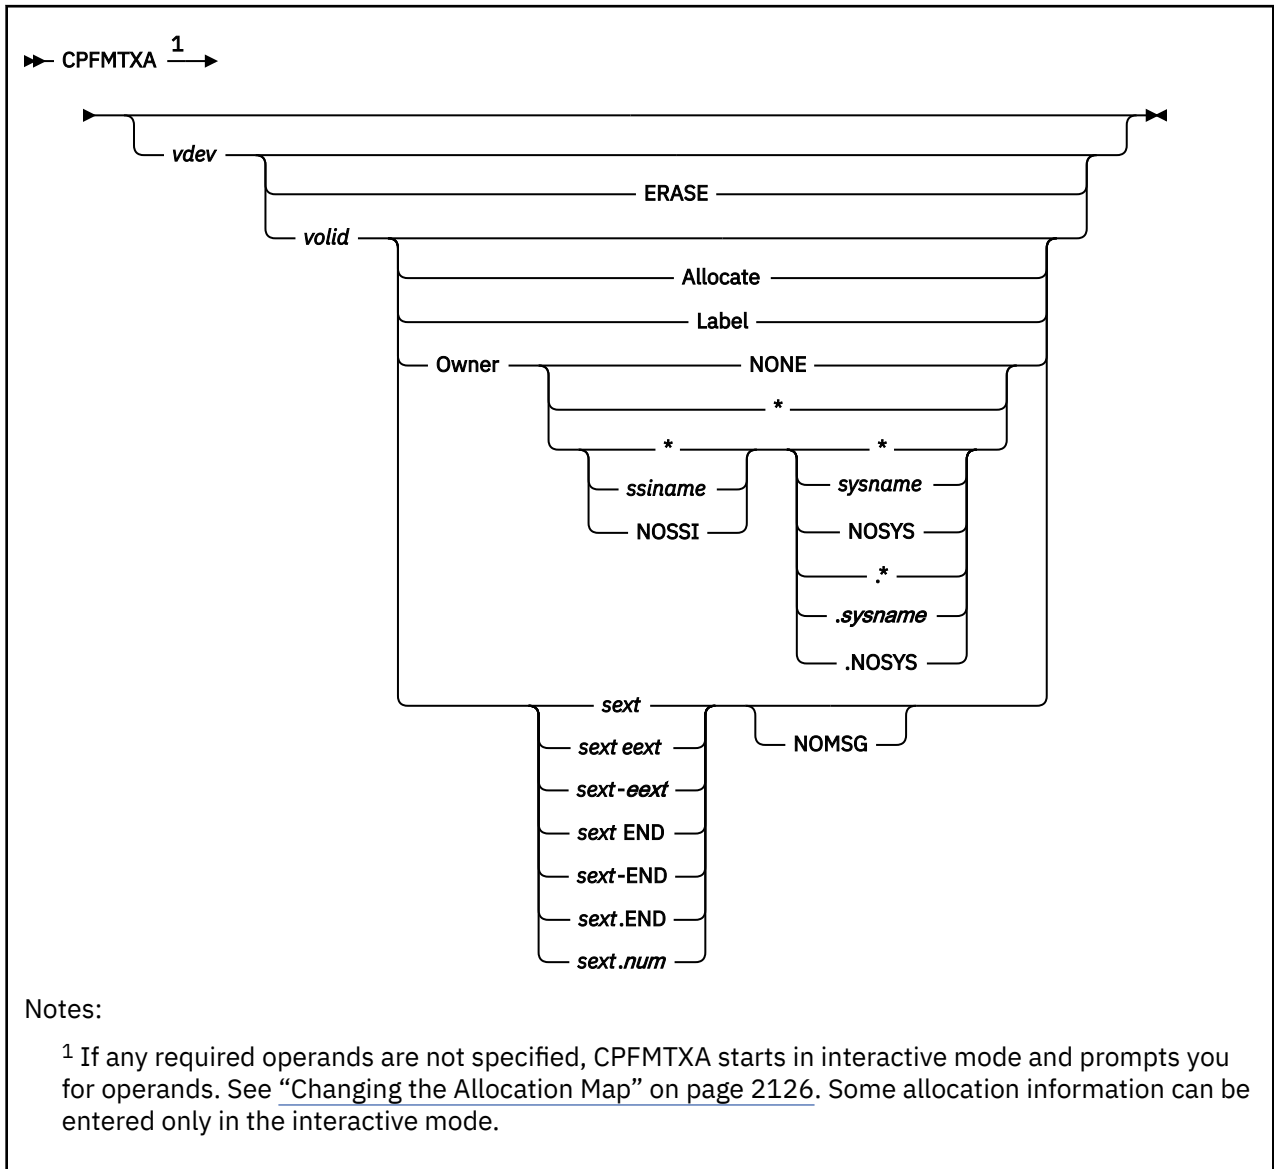

### Usage Notes

1. The CPEREPXA utility can invoke one or more CP commands that require a user privilege class other than G.

# CPFMTXA

**Notes:**

<sup>1</sup> If any required operands are not specified, CPFMTXA starts in interactive mode and prompts you for operands. See [“Changing the Allocation Map” on page 2126](#). Some allocation information can be entered only in the interactive mode.

## Purpose

Use the CPFMTXA utility to format, label, and allocate DASD volumes for CP uses such as paging, spooling, temporary disk, directory, and minidisk space. CPFMTXA can be used for both FBA and ECKD DASD. CPFMTXA requires ICKDSF, which is the standard method to format, label, and allocate DASD volumes for CP use. If ICKDSF is not available, no volumes are processed (see [Response 2](#)).

For information about using ICKDSF to format, label, and allocate DASD volumes, see [Device Support Facilities \(ICKDSF\): User's Guide and Reference](#).

## Operands

**vdev**

is the virtual device number of the DASD to be formatted, labeled, or allocated. It is specified as a 1- to 4-character hexadecimal number. The device type that is associated with this vdev must be supported as a CP-owned volume, and you must have write access to the device.

**ERASE**

indicates that you want to erase a volume. This option is not valid for FBA devices.

***valid***

is the volume identification label of the virtual device to be formatted, labeled, or allocated. *valid* is specified as a 1- to 6-character name. (The characters are not required to be alphanumeric.) Embedded blanks are not allowed. The volume ID is written on the disk if *sext* is 0 or if you specify the LABEL option. Otherwise, *valid* on the virtual device is read and compared to what you specify on the command line.

**Allocate**

indicates that you want only to reallocate a previously formatted volume.

**Label**

indicates that you want only to change the volume identification label. The volume must already be formatted. Only the volume identifier is changed; other information on the label record of the DASD remains unchanged.

**Owner**

indicates that you would like to specify or modify the ownership information for a CP-formatted device. Ownership information consists of an SSI cluster name and a system name.

**NONE**

indicates that the ownership information, if it exists, must be removed from the device.

**\***

***ssiname***

is the name of the SSI cluster that owns the device. Specifying an asterisk (\*) uses the name of the SSI cluster in which the current system is a member. If the current system is not a member of an SSI cluster, NOSSI is assumed.

The *ssiname* can be any 1- to 8-character alphanumeric string. However, OWNER *ssiname* \* and OWNER *ssiname*.\* are valid only when *ssiname* is the name of the SSI cluster in which the current system is a member.

Specifying OWNER \* is equivalent to specifying OWNER \*\* or OWNER \*.\*.

**NOSSI**

indicates that a null must be recorded for the SSI cluster name. OWNER NOSSI \* and OWNER NOSSI.\* are valid only when the current system is not a member of an SSI cluster.

**\***

**.\***

***sysname******.sysname***

is the system name of the system that owns the device. Specifying an asterisk (\*) uses the system name of the current system.

The *sysname* can be any 1- to 8-character alphanumeric string.

**NOSYS**

indicates that a null must be recorded for the system name.

***sext***

specifies the starting point of the extent to be formatted. The starting point is expressed as a cylinder number for ECKD DASD or a page number for a fixed-block device. The number is a 1- to 7-digit decimal integer (1- to 9-digit decimal integer for fixed-block devices) and must be within the size of the virtual device.

When *sext* is specified with no other range operand, only that cylinder or page is formatted.

*sext* can be specified with another range operand in any of the following formats:

***sext eext******sext-eext***

*eext* specifies the last cylinder (ECKD devices) or page (fixed-block devices) of the allocation. The *eext* cylinder number or page number has the following restrictions:

- *eext* is a 1- to 7-digit decimal integer (1- to 9-digit decimal integer for fixed-block devices).
- *eext* is equal to or greater than *sext*.
- *eext* must be within the size of the virtual device.

*sext* and *eext* can be separated by a dash or one or more blank spaces.

***sext* END**

***sext*-END**

***sext*.END**

END specifies that all remaining cylinders or pages of the volume are allocated.

*sext* and END can be separated by a dash, a period, or one or more blank spaces.

***sext.num***

*num* specifies a number of cylinders (ECKD devices) or pages (fixed-block devices) to be allocated. The allocation begins at *sext* and extends for *num* cylinders or pages. The *num* cylinder number or page number has the following restrictions:

- *num* is a 1- to 7-digit decimal integer (1- to 9-digit decimal integer for fixed-block devices).
- *num* is not 0.
- The sum of *sext* and *num* must not exceed the size of the virtual device.

*sext* and *num* must be separated by a period.

**NOMSG**

indicates that the ICKDSF cylinder progress messages are suppressed during formatting. Only the starting and ending cylinder message is displayed.

**Notes:**

- If you do not specify *sext*, LABEL, or ALLOCATE, then 0-END is assumed.
- If you do not specify any of the ALLOCATE, LABEL, OWNER, or *sext* options, the default is to format, allocate, and label the entire device.

**Changing the Allocation Map**

Whenever you format a disk or specify the ALLOCATE option, the current allocation of the disk is displayed as in the following example for an ECKD device:

```

CYLINDER ALLOCATION CURRENTLY IS AS FOLLOWS:
TYPE      START      END      TOTAL
-----
type      nnnnn      nnnnn      nnnnn
:
type      nnnnn      nnnnn      nnnnn
    
```

For fixed-block devices, the current allocation is displayed as in the following example:

```

PAGE ALLOCATION CURRENTLY IS AS FOLLOWS:
TYPE      START      END      TOTAL
-----
type      nnnnnnnnnn  nnnnnnnnnn  nnnnnnnnnn
:
type      nnnnnnnnnn  nnnnnnnnnn  nnnnnnnnnn
    
```

The fields are described:

**type**

is normally DRCT, PAGE, PARM, PERM, SPOL, or TDSK.

**BAD**

indicates that the disk was not formatted by CPFMTXA. You can consider reformatting the entire disk by using CPFMTXA.

**nnnnnnnnnn**

is the cylinder or page range and total number of cylinders or pages that are allocated for each corresponding type.

You are then prompted to update the allocation map as in the following prompt for an ECKD device:

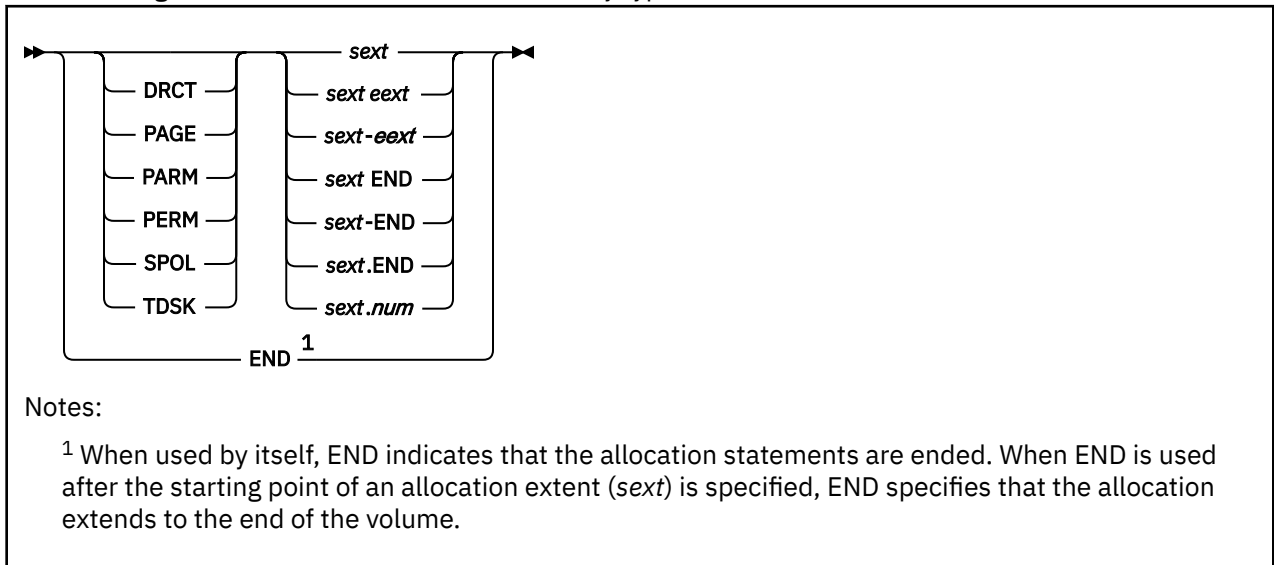

```
ENTER ALLOCATION DATA
TYPE CYLINDERS
.....
```

The following prompt is for a fixed-block device:

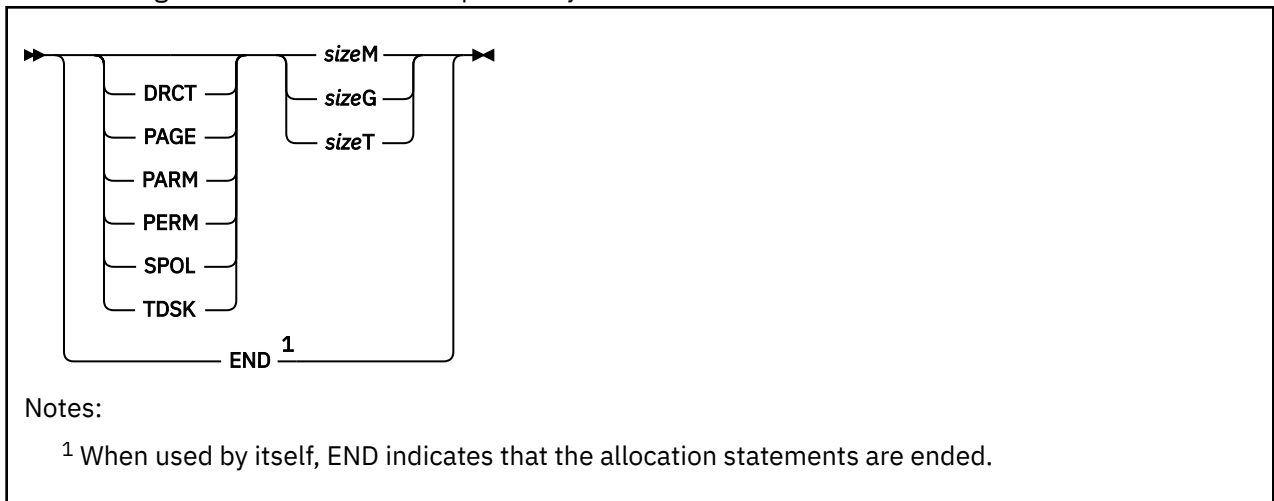

```
ENTER ALLOCATION DATA
TYPE PAGES
.....
```

Enter one line of data for each allocation.

The following allocation format can be used for any type of device:

The following allocation format is an option only for fixed-block devices:

The data elements are described:

**DRCT**

indicates allocation for directory files.

**PAGE**

indicates allocation solely for system paging activity.

**PARM**

indicates allocation that specifies the location of a CMS-formatted minidisk that contains the System Configuration files.

**PERM**

indicates allocation for CP user minidisks, checkpoint, warm start, and other static space.

**SPOL**

indicates allocation for spooling, dump space, or overflow paging activity.

**TDSK**

indicates allocation for temporary disk space, which becomes available to users after they log on to the system. Cylinder 0 cannot be allocated as TDSK.

**sext**

specifies the starting point of the allocation. The starting point is expressed as a cylinder number or page number. The number is a 1- to 7-digit decimal integer (1- to 9-digit decimal integer for fixed-block devices) and must be within the size of the real device where *vdev* is located.

When *sext* is specified with no other range operand, only that cylinder or page is allocated.

*sext* can be specified with another range operand in any of the following formats:

***sext eext******sext-eext***

*eext* specifies the last cylinder or page of the allocation. The *eext* cylinder number or page number has the following restrictions:

- *eext* is a 1- to 7-digit decimal integer (1- to 9-digit decimal integer for fixed-block devices).
- *eext* is equal to or greater than *sext*.
- *eext* must be within the size of the real device where *vdev* is located.

*sext* and *eext* can be separated by a dash or one or more blank spaces.

***sext END******sext-END******sext.END***

END specifies that all remaining cylinders or pages of the volume are allocated.

*sext* and END can be separated by a dash, a period, or one or more blank spaces.

***sext.num***

*num* specifies a number of cylinders or pages to be allocated. The allocation begins at *sext* and extends for *num* cylinders or pages. The *num* cylinder number or page number has the following restrictions:

- *num* is a 1- to 7-digit decimal integer (1- to 9-digit decimal integer for fixed-block devices).
- *num* is not 0.
- The sum of *sext* and *num* must not exceed the size of the virtual device.

*sext* and *num* must be separated by a period.

The following allocation examples are valid and yield the same allocation (2097120 pages of PERM) on a volume with an 8 GB (2,097,152 pages) capacity:

```
perm 32 2097151
perm 32-2097151
perm 32 END
perm 32-END
perm 32.END
perm 32.2097120
```

**sizeM****sizeG****sizeT**

is the size of the area to be allocated, in megabytes (M), gigabytes (G), or terabytes (T). The *size* operand is specified as a positive integer and must be immediately followed by M, G, or T.

An allocation that is expressed in this format is contiguous with the preceding allocation. If the first allocation is in this format, then 'PERM 0-31' is automatically included and the specified allocation starts at page 32.

Requested allocations are automatically reduced in some situations:

- The maximum extent for spool space is page 16,777,214 (64 GB). If you request a SPOL allocation that extends above page 16,777,214, then the allocation is automatically reduced in size so that the allocation extent ends at page 16,777,214 or the last page of the volume (whichever is less).
- If you request an allocation that extends beyond the volume capacity, then the allocation is automatically reduced in size so that the allocation extent ends at the last page of the volume.

**END**

When used by itself, END indicates that the allocation statements are ended.

**Interactions with ICKDSF**

If you enter CPFMTXA without operands and ICKDSF is available, you are prompted to enter formatting information. The following screens show examples of prompts, user input (in italic text) and responses.

**Example 1: Format and allocate an ECKD device by specifying the allocation ranges**

Allocations are requested by using the range format. This example is accurate for a count-key device (ECKD). For a fixed-block device, the prompts and responses would indicate allocation space in page units instead of cylinder units.

**Example 2: Format and allocate an FBA device by specifying allocation sizes. Request less space than the volume capacity.**

The following example formats and allocates spool and page space on an FBA volume. The FBA volume can be a VDISK, EDEVICE, or real FBA device. 20 MB of SPOL space and 20 MB of PAGE space is requested on a volume with roughly 48.8 MB capacity. CPFMTXA allocates PERM space for the remainder of the volume.

The first step formats the volume. Because FBA devices use fixed-block architecture, their records do not need to be formatted. However, some formatting is required because the formatting process writes the label and default allocation map. Depending on how you plan to use the space, it might be prudent to use the format function to erase the disk contents. If you plan to use the disk for spool or page space, erasing the disk contents is unnecessary. The following example formats the first 256 pages of a larger 12,500-page FBA volume.

CPFMTXA generates some input for ICKDSF. In the example screens, user input is in italic text.

ENTER INPUT COMMAND:
  END

```

The initial allocation of the device is PERM. Pages 0-3 cannot be allocated because they are reserved for the Control Program. The remaining 12,496 pages on the volume are allocated as PERM and correspond to blocks 32–99,999. The range of PERM blocks is calculated as follows:

- There are eight 512-byte blocks per 4096-byte page.
- The initial four pages occupy 32 blocks (4 pages × 8 blocks/page), which are block numbers 0-31. Hence, the first PERM block is at block number 32.
- The device contains a total of 100,000 blocks (12,500 pages × 8 blocks/page), which are block numbers 0-99,999. The last PERM block is 99,999.

The second step allocates space on the volume. In this example, 20 megabytes are allocated for type SPOL and 20 megabytes are allocated for type PAGE on the device that was previously formatted. 20

megabytes is 5,120 pages (40,960 blocks). Space can be allocated by specifying the starting page number and number of pages, but in this example only the amount of space to allocate for each type is specified.

The PAGE ALLOCATION table shows the following results:

- From the formatting step, the first four pages (0-3) are reserved for the system.
- From the allocation step:
  1. Pages 4-31 are reserved as PERM and can be used for the Stand-Alone Program Loader.
  2. SPOL space occupies pages 32-5,151 (blocks 256-41,215).
  3. PAGE space is next to SPOL space and occupies pages 5,152-10,271 (blocks 41,216-82,175).
  4. The remaining space (pages 10,272-12,499) is allocated as PERM.

**Note:** Pages, blocks, and bytes are related in the following ways:

- A page contains eight blocks.
- A block contains 512 bytes.
- A page contains 4,096 bytes.

- The first block of page N is block number  $(8 \times N)$ . For example, the first block of page 5,151 is  $(8 \times 5,151) = 42,208$ .
- The last block of page N is block number  $(8 \times N + 7)$ . For example, the last block of page 5,151 is  $(8 \times 5,151 + 7) = 42,215$ .
- A graphic example of page 0:

Page 0							
Block 0	Block 1	Block 2	Block 3	Block 4	Block 5	Block 6	Block 7
Bytes 0 - 511	Bytes 512 - 1023	Bytes 1024 - 1535	Bytes 1536 - 2047	Bytes 2048 - 2559	Bytes 2560 - 3071	Bytes 3072 - 3583	Bytes 3584 - 4095

**Example 3: Format and allocate an FBA device by specifying allocation sizes. Request more space than the volume capacity.**

The following example formats and allocates PAGE space on a 1021.82 GB FBA volume. The FBA volume can be a VDISK, EDEVICE, or real FBA device. Although the requested space is greater than the volume's capacity, CPFMTXA adjusts and allocates to the volume's limit.

CPFMTXA generates some input for ICKDSF. In the example screens, user input is in italic text.

```

The PAGE ALLOCATION table shows the following results:

- From the formatting step, the first four pages (0-3) are reserved for the system.
- From the allocation step:
  - Pages 4-31 are reserved as PERM and can be used for the Stand-Alone Program Loader.
  - PAGE space occupies pages 32-267,864,355. The total PAGE space is 267,864,324 pages, which is roughly 1021.82 GB. Although 1024 GB of PAGE space was requested, the volume capacity limited the allocation. CPFMTXA extended the PAGE space to the end of the volume. The same space would be allocated if the user requested 1 TB or a larger value.
- All space definitions combine for a total of 267,864,356 pages (2,142,914,848 blocks) on the volume:
  - Reserved for the system (four pages)
  - Reserved as PERM, perhaps for the Stand-Alone Program Loader (28 pages)
  - PAGE space (267,864,324 pages)
- The 267,864,356 pages contain 2,142,914,848 blocks (267,864,356 pages × 8 blocks/page).

The QUERY EDEVICE command shows the following details for the FBA volume:

**q edev f000 details**

```

EDEV F000 TYPE FBA ATTRIBUTES NVMe
VENDOR: KCM61RUL PRODUCT: 30T7 REVISION:
BLOCKSIZE: 512 NUMBER OF BLOCKS: 2142914848
SEGMENT: 01/28
HYPERPAV POOL: 0
PCIFUNCTION: 00000072
EQID: 8CE38E00F00000000000000000000000F0F0000000007FBA4923
SERIAL NUMBER: Z1N0A004T2K8

```

**Usage Notes**

1. By default, the CPFMTXA utility is on the cross-release utilities disk (PMAINT 551). This disk must be accessed to run the CPFMTXA utility.
2. If ICKDSF is available to the user, it is started to process the function designated by the CPFMTXA parameters. The message INVOKING ICKDSF . is issued to the console. If ICKDSF is not on an accessed disk, no formatting, allocating, or labeling occurs. See [Response 2](#).

Using ICKDSF is the recommended way to format, label, and allocate DASD volumes for CP use. For information about using ICKDSF, see [Device Support Facilities \(ICKDSF\): User's Guide and Reference](#).

3. You can interrupt CPFMTXA processing by pressing the PA1 key.
4. If you do not format an ECKD volume before you use the ALLOCATE option, then a permanent I/O error message is displayed.

When reallocating cylinders or pages from TDSK, PERM, or PARM to PAGE, SPOL, or DRCT, you must reformat these cylinders or pages first. For ECKD devices, for SPOOL and DIRECTORY volume types, extents are limited to cylinders 0-65519, and for PAGE volume types extents are limited to cylinders 0-1182005. TDSK and PARM disks can be located anywhere on the volume, but the PARM disk size is limited to 65520 cylinders. PERM space allocation is allowed anywhere on the volume.

5. If the starting cylinder is 0, CPFMTXA helps to prevent you from accidentally erasing a disk. CPFMTXA indicates the cylinders or pages that are to be formatted, and prompts you to continue. If the cylinders or pages are incorrect, you can reply NO, and the disk remains unchanged. If they are correct, you can reply YES, and processing continues.

If the starting cylinder is not 0, CPFMTXA first verifies the DASD and then prompts you with the cylinder range to be formatted. When formatting a portion of a DASD (anything other than cylinder 0) you must specify the existing label for that DASD. You cannot change the label during the formatting of a DASD unless cylinder 0 is included in the range of cylinders to format.

6. If you enter the CPFMTXA command without the LABEL or ALLOCATE options, it is assumed that you want to format the entire DASD.

For example, suppose you enter `CPFMTXA 192 TEST1`

CPFMTXA assumes that you want to format the entire device. All cylinders or pages are formatted, and all cylinders or pages are initially allocated as PERM space. Then, you are prompted to update the DASD allocation, and the volume on 192 is labeled TEST1.

However, suppose that you enter `cpfmtxa 192 test2 0.3`

CPFMTXA formats cylinders or pages 0, 1, and 2. Since you formatted cylinder or page 0, all cylinders or pages are to be initially allocated as PERM space. Then, you are prompted to update the DASD allocation, and the volume on 192 is labeled TEST2.

If you enter `cpfmtxa 192 test3 1-3`, then CPFMTXA first checks to see whether the volume ID on 192 is TEST3. If it is not, you receive an error message that indicates what the correct label is, and CPFMTXA processing ends. If *valid* is TEST3, CPFMTXA formats cylinders or pages 1, 2, and 3, and you are prompted to update the DASD allocation. Since you did not format cylinder or page 0, the label is not written, and the cylinders or pages are not initially allocated as PERM.

7. DRCT, PAGE, PARM, PERM, SPOL, and TDSK are allocation types. You can use these entries in any order. Each entry in turn overlays the allocation record, and any space that is not reallocated remains the same.

**Note:** Special care must be exercised in this area, especially when cylinder 0 or pages 0-3 are reformatted. For example, if new directory cylinders or pages are allocated, then the allocation record is overwritten, effectively destroying any pointers to the active directory and rendering it inaccessible. If an allocation entry overlays a previous cylinder or page allotment, the previous cylinder or page space allotment is truncated to the beginning of the next cylinder or page allotment. For example, assume that the following example is the current allocation of a vdev:

CYLINDER ALLOCATION CURRENTLY IS AS FOLLOWS:			
TYPE	START	END	TOTAL
PERM	0	0	1
PARM	1	29	29
PERM	30	554	525

Assume that you enter the following allocation data:

```
parm 20-49
tdsk 50-100
drct 100-200
spol 150-500
page 400.50
```

The actual output follows:

CYLINDER ALLOCATION CURRENTLY IS AS FOLLOWS:			
TYPE	START	END	TOTAL
PERM	0	0	1
????	1	19	19
PARM	20	49	30
TDSK	50	99	50
DRCT	100	149	50
SPOL	150	399	250
PAGE	400	449	50
SPOL	450	500	51
PERM	501	554	54

**Note:** A PARM range must be entirely reallocated when a change is made. If the PARM range is not entirely reallocated, the ranges that are not reallocated are set to indicate that undefined allocation types exist.

- Space for system dumps and system data files must be allocated as SPOL. For a CKD/ECKD device, you must not allocate cylinder 0 as TDSK. For an FBA device that is formatted for z/VM, ICKDSF reserves pages 0-3 (blocks 0-31) for system use.

If the SALIPL utility is then used to install Stand-Alone Program Loader (SAPL) onto an FBA device, then pages 0-25 (blocks 0-207) are reserved for system use. These reserved FBA pages must be allocated only as PERM and must not later be provisioned as user minidisks.

- These types of allocations cannot reside above page 16,777,214:
  - DRCT allocations on FBA devices and EDEVICES
  - SPOL allocations on FBA devices and EDEVICES
  - PAGE allocations on FBA devices and EDEVICES, except for NVMe EDEVICES

For PAGE allocations on NVMe EDEVICES, the maximum block number is limited only by the device size.

All other FBA allocations (PERM, PARM, TDSK) can reside above page 16,777,214.

Message HCP381E is issued if allocation is attempted of a higher page than is allowed.

- For ECKD devices, for SPOOL, PARM, and DIRECTORY volume types, extents are limited to cylinders 0-65519, and for PAGE volume types extents are limited to cylinders 0-1182005. TEMP and PARM disks can be located anywhere on the volume, but the PARM disk size is limited to 65520 cylinders. PERM space allocation is allowed anywhere on the volume. Message HCP138E or HCP139E is issued if you attempt to define a user volume of type other than PERM above 65519 cylinders.

11. If you do not format a volume before you use the OWNER option, a permanent I/O error message is displayed.

When a volume is initially formatted, the ownership information is set to NOSSI and NOSYS. You must then issue CPFMTXA with the OWNER option to set the appropriate ownership information.

12. Ownership information is written to cylinder 0 and must be assigned only to a volume that is CP-formatted. Reformatting cylinder 0 destroys any ownership information that is recorded there.
13. For information about how DASD ownership information is used when the CP-owned list is processed, see [How the CP-Owned List Is Processed](#) in *z/VM: CP Planning and Administration*.

## Responses

Response 1:

```
INVOKING ICKDSF.
```

This response is issued to alert the user that ICKDSF is used instead of CPFMTXA to format, label, and allocate DASD volumes.

Response 2:

```
DEVICE SUPPORT FACILITIES (5684-042) IS NECESSARY FOR
CP VOLUME MAINTENANCE. FILE ICKDSF MODULE CANNOT BE
FOUND ON ANY ACCESSED DISK; CPFMTXA PROCESSING ENDED.
```

This response is issued to alert the user to access ICKDSF. CPFMTXA translates user input only to input that is acceptable to ICKDSF.

For information on using ICKDSF to format, label, and allocate DASD volumes, see [Device Support Facilities \(ICKDSF\): User's Guide and Reference](#).

Response 3:

```
ENTER FORMAT, ALLOCATE, LABEL, OWNER OR QUIT:
```

This prompt is issued if you do not supply both *vdev* and *valid* on the command line when CPFMTXA is started and you want to change ownership of the CP-formatted device.

### FORMAT

indicates that you want to format the disk. If you format the disk from cylinder or page 0, you are prompted for a volume label to be written on the disk. If you are not formatting cylinder or page 0, the volume label you enter is verified with the existing volume label of the disk. After the disk is formatted, you are prompted to enter the disk allocations.

### ALLOCATE

indicates that you want to change only the present allocations. The ALLOCATE option requires that the disk is already formatted.

### LABEL

indicates that you want to change only the volume label on the disk.

### OWNER

indicates that you want to change the ownership information. Ownership information consists of an SSI cluster name and a system name.

### QUIT

indicates that you want to end CPFMTXA.

Any truncation of FORMAT, ALLOCATE, LABEL, OWNER, or QUIT is acceptable. For example, you can enter FORMAT as F, FO, FOR, FORM, FORMA, or FORMAT.

Response 4:

```
ENTER THE VDEV TO BE PROCESSED OR QUIT:
```

This prompt is issued when *vdev* is not entered on the command line when you start CPFMTXA.

**VDEV**

is the virtual device number of the disk to be formatted, allocated, or labeled. Any truncation of QUIT is acceptable (Q, QU, QUI, or QUIT).

Response 5:

```
ENTER THE {CYLINDER|PAGE} RANGE TO BE
FORMATTED ON DISK vdev OR QUIT:
```

This prompt is issued when FORMAT is selected in Response 3.

**vdev**

is the virtual device number that was either specified on the command line or entered in response to a prompt.

Response 6:

```
ENTER THE VOLUME LABEL FOR DISK vdev:
```

**vdev**

is the virtual device number that was either specified on the command line or entered in response to a prompt. This prompt is issued when *valid* is not entered on the command with which you start CPFMTXA.

Response 7:

```
FORMAT WILL ERASE {CYLINDERS|PAGES} range ON DISK vdev
DO YOU WANT TO CONTINUE? (YES | NO)
```

This prompt is issued whenever you format a disk. If you reply YES, ICKDSF is started and the format function continues. If you reply NO, CPFMTXA processing ends.

**range**

is inclusive, and specifies the numbers of the cylinders or pages to be formatted.

**vdev**

is the virtual DASD to be formatted.

Response 8:

```
ENTER ALLOCATION DATA
TYPE {CYLINDERS|PAGES}
.....
```

This response is issued whenever you update the allocation map. The response prompts you to update the allocation map. Enter your allocation data from the console; this data must contain both (1) the allocation type, and (2) the cylinders or pages to be allocated as that type. When you enter END, the updated allocation map is displayed on your console, by using the CURRENT ALLOCATION response. For more information, see [Changing the Allocation Map](#).

**type**

can be DRCT, PAGE, PARM, PERM, SPOL, or TDSK.

**nnnnnn-nnnnnn**

is the cylinder or page range for the corresponding type.

Response 9:

```
REENTER: TYPE AND {CYLINDERS|PAGES} OR 'END'
```

This prompt is issued whenever you enter erroneous allocation data. An error message that explains the error precedes this prompt. You are prompted to correct and reenter the line of allocation data that contained the error.

Response 10:

```
ERASE WILL DESTROY THE CONTENTS OF DISK vdev ON MDISK ownerid ovdev
DO YOU WANT TO CONTINUE? (YES | NO)
```

This prompt is issued whenever you erase a disk by using the fast erase function. If you reply YES, processing continues and the following information is displayed:

```
Erasing vdev with      NNNNN cylinders at HH:MM:SS
Erased   AAAA cylinders at: HH:MM:SS
Erased   BBBB cylinders at: HH:MM:SS
```

If you reply NO, CPFMTXA processing ends.

***vdev***

the virtual device number of the DASD to be erased.

***ownerid***

the user ID of the owner of the virtual device number of the DASD to be erased.

***ovdev***

the owner's virtual device number of the DASD to be erased.

***NNNNN***

is the number of cylinders to be erased on the virtual device.

***HH:MM:SS***

is the time at which the erase function was completed.

***AAAA***

***BBBB***

is the number of cylinders that are deleted since the ERASE command started.

## Messages

**Note:** The messages that are returned by the CPFMTXA utility are CP messages.

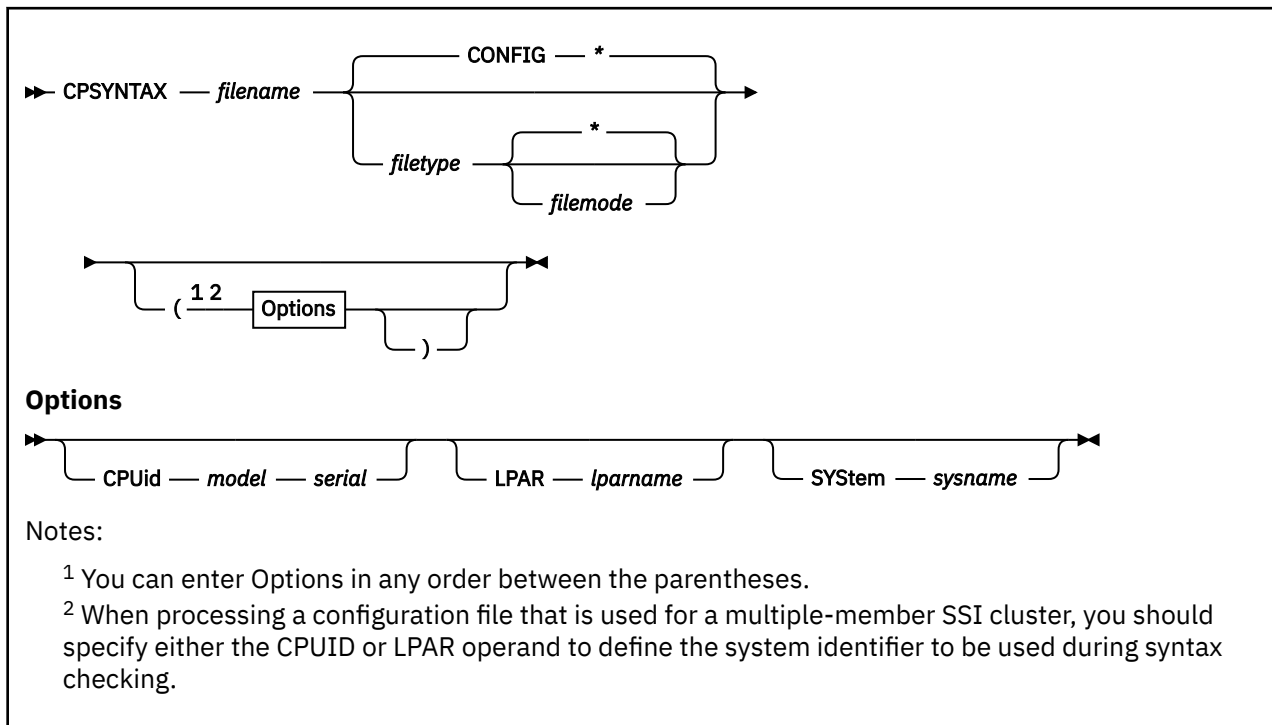

Messages:

For information about ICKDSF messages and responses, see [Device Support Facilities \(ICKDSF\): User's Guide and Reference](#).

## CPSYNTAX

### Purpose

Use the CPSYNTAX utility to check the syntax of the system configuration file.

CPSYNTAX catches incorrect and unrecognized statements in the system configuration file. It does not attempt to identify problems arising between statements or valid but duplicate operands on a single statement. CPSYNTAX does not guarantee that it will find all configuration file changes that will lead to a problem during system IPL.

During system IPL, configuration file postprocessing routines do further checking of the data specified in the configuration file. IPLing a second-level system to check the configuration file is recommended for a more thorough test and might find problems that CPSYNTAX does not. However, second-level IPL does not eliminate environmental factors of the real production environment and still might not find all problems related to the system configuration file.

Some items that CPSYNTAX does not address:

- Ensuring that some CP-owned volume remains STARTed for PAGE (DRAIN data).
- Ensuring that some operator console remains available (OFFLINE\_AT\_IPL).
- Inappropriate positioning of SYSTEM\_IDENTIFIER statements.
- Inappropriate ordering of DRAIN/CP\_OWNED statements or of TIMEZONE\_DEFINITION/TIMEZONE\_BOUNDARY statements.

### Operands

#### **filename**

is the file name of the configuration file you want to be syntax checked.

#### **filetype**

is the file type of the configuration file you want to be syntax checked. The default file type is CONFIG.

#### **filemode**

is the file mode of the configuration file you want to be syntax checked. The default file mode is \*.

## Options

### CPUI*d model serial*

where *model* is the CPU model, such as 2097, and *serial* is the CPU serial number, up to six hexadecimal digits, of the processor on which you eventually want the file to be processed. The CPUID option can be used to pass environmental data to CPSYNTAX to cause SYSTEM\_IDENTIFIER statements to match.

### LPAR *lparname*

where *lparname* is the 1- to 8-character logical partition name on which you eventually want the file to be processed. The LPAR option can be used to pass environmental data to CPSYNTAX to cause SYSTEM\_IDENTIFIER statements to match.

### SYStem *sysname*

where *sysname* is the 1- to 8-character string that will be used as the default system identifier. The SYSTEM option causes SYSTEM\_IDENTIFIER\_DEFAULT statements to be ignored. If a matching SYSTEM\_IDENTIFIER statement is found, the *sysname* specified on the matching statement becomes the new system identifier.

## Usage Notes

1. Imbedded files are processed by CPSYNTAX, but all imbedded files must reside on the same minidisk as the base configuration file.
2. By default, the CPSYNTAX utility is located on the system tools disk (MAINT 193). The utility consists of an exec called CPSYNTAX and a module called CPSYNCHK. The CPSYNTAX EXEC is a REXX exec that can be compiled by the REXX compiler.
3. The CPUID and LPAR options can be used to pass environmental data to CPSYNTAX to cause SYSTEM\_IDENTIFIER statements to match. The options CPUID, LPAR, and SYSTEM can be specified on the same CPSYNTAX invocation.
4. If your configuration file has a statement that contains the string &LPARNAME, or a SYSTEM\_IDENTIFIER statement that specifies the LPAR operand, you must use the CPSYNTAX LPAR option. If you do not, those statements will be flagged as an error, because the LPAR name cannot be determined.

## Messages

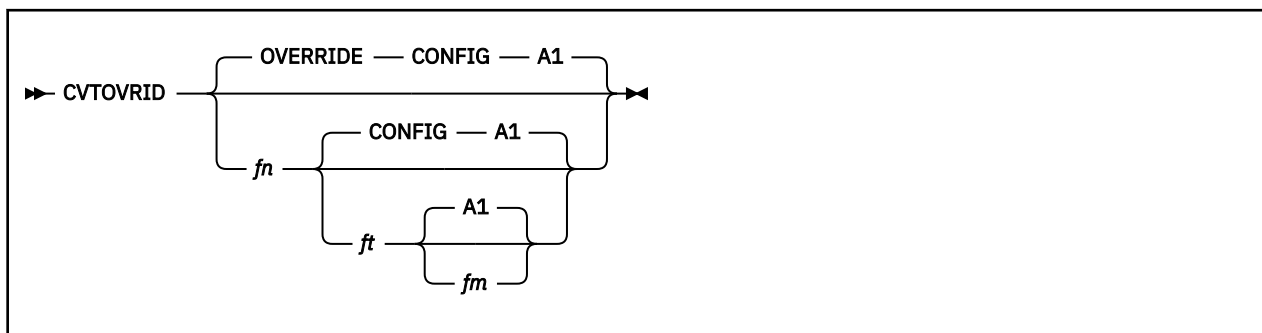

- HCP002E Invalid operand - *operand*
- HCP003E Invalid option - {command|statement} contains extra option(s) starting with *option*
- HCP003E Invalid option - *option*
- HCP013E Conflicting option - *option*
- HCP1001E An operand is missing for *option*.
- HCP1646E Too many qualifiers specified on BEGIN or END statement. No more than 64 qualifiers may be specified.
- HCP1647E Unexpected END statement found. BEGIN and corresponding END statement must be in the same file.
- HCP1671E This system is not a member of the SSI cluster.
- HCP1672E SSI statement encountered but system identifier has not been defined
- HCP1672E The system ID was changed by a SYSTEM\_IDENTIFIER statement after the SSI statement was processed.
- HCP1673E The system identifier *sysname* is not the same as the gateway identifier *gateid*. They must be the same because this system is a member of an SSI cluster.
- HCP1675E Missing qualifier on BEGIN statement
- HCP1676E No END statement found for BEGIN statement on line *nnnnnnnn* of file *fn ft*. BEGIN and corresponding END statement must be in same file.

- HCP1677E Unexpected END statement because no BEGIN statement is in effect.
- HCP1678E BEGIN statement encountered while another BEGIN statement is in effect.
- HCP1679E Specified qualifier(s) do not match qualifiers that are in effect.
- HCP1680E Record qualifiers not allowed because BEGIN statement is in effect.
- HCP1681E SSI statement already processed - statement ignored
- HCP1683E *statement* statement on line *number* of file *fn ft fm* must not be specified with SSI statement.
- HCP1685E The same system ID appears more than once on the SSI statement.
- HCP1687E The statement failed because the LPAR name is unknown. Specify the LPAR option of CPSYNTAX.
- HCP1687E &LPARNAME cannot be resolved. Specify the LPAR option of CPSYNTAX.
- HCP1689W An error was found related to a BEGIN or END statement. System IPL will fail unless this error is corrected.
- HCP2149E A variable name starting with reserved prefix "CP." cannot be set.
- HCP2585E Reconfigurable storage size of *stgsize* exceeds the maximum allowed reconfigurable storage size of *maxsize*. Reconfigurable storage is restricted to a maximum of *xx%* of all online storage.
- HCP2768E Missing variable name
- HCP6700E File *fn ft*, [*nnnnnnnn* through] *nnnnnnnn*:
- HCP6701E Invalid {logo|system} configuration file statement - *operand*
- HCP6702E Error encountered while attempting to read records from *fn ft [fm]*
- HCP6703E File *fn ft fm* not found.
- HCP6704E Missing {CPU model number | CPU serial number | system ID | lparname | token} at end of line.
- HCP6705E Comment starting on line *nnnnnnnn* in *fn ft* was never completed.
- HCP6705E Statement starting on line *nnnnnnnn* in *fn ft* was continued past end of file.
- HCP6706E Invalid CPU model number - *string*
- HCP6706E Invalid CPU serial number - *string*
- HCP6706E Invalid file name - *string*
- HCP6706E Invalid file type - *string*
- HCP6706E Invalid identifier - *string*
- HCP6706E Invalid variable name - *name*
- HCP6706E Invalid variable range - *range*
- HCP6707E Statement exceeded maximum length of 4000 on record *nnnnnnnn* in file *fn ft*.
- HCP6709E Too many items specified - *token*
- HCP6710E File *fn ft* does not exist and cannot be imbedded.
- HCP6710E Imbedding file *fn ft* would cause an embed loop -- statement ignored.
- HCP6710E System cannot be resolved because system ID is undefined -- file *fn ft* cannot be imbedded.
- HCP6711E Duplicate volume identifier *nnnnnn* specified -- statement ignored.
- HCP6711E Slot *nnn* already contains [system|volume] *nnnnnn* -- statement ignored.
- HCP6716E Already [not] tolerating configuration file errors -- statement ignored.
- HCP6725E XLINK system ID *sysID* is a duplicate -- statement ignored.
- HCP6820E Required file name has been omitted.
- HCP6821E Invalid quoted string encountered -- statement ignored.
- HCP6822E Statement contained only qualifiers.
- HCP6823E *fn* MODULE was not found.

- HCP6824E Unexpected return code *rc* received from module *fn*.
- HCP6825E Unknown conversion type encountered -- may need a different version of *fn* module.
- HCP6826E One or more errors were encountered in processing sections of the system configuration file that were marked not to tolerate errors.
- HCP6827E XLINK systems were specified and *sysname* was in neither the XLINK system inclusion nor the exclusion list. Failure to correct this error may lead to loss of user data.
- HCP6828E No {CP owned volumes|system residence area| operator consoles} defined in the configuration file.
- HCP6829W Configuration file processing complete -- no errors encountered.

## CVTOVRID

### Purpose

Use the CVTOVRID utility to convert a CMS class override file (formerly processed by the CP OVERRIDE utility) into a series of MODIFY statements to imbed into a system configuration file.

**Note:** CVTOVRID is an XEDIT MACRO, so you must be editing (XEDITing) the file that you want to convert when you invoke this utility.

### Operands

#### *fn*

is the file name of the output file that will contain the MODIFY configuration file statements. If omitted, the default file name is OVERRIDE.

#### *ft*

is the file type of the output file that will contain the MODIFY configuration file statements. If omitted, the default file type is CONFIG.

#### *fm*

is the file mode of the output file that will contain the MODIFY configuration file statements. You must have a link that allows you to write to the disk (or SFS directory) accessed at the specified file mode. If omitted, the default file mode is A1.

### Usage Notes

1. By default, the CVTOVRID utility is located on the system tools disk (MAINT 193).
2. After creating the file of MODIFY statements, you must:
  - a. Add an IMBED statement to your system configuration file to pull in the new file (or move the MODIFY statements from the new file to your system configuration file)
  - b. Make sure that the new file (or your system configuration file) is on the parm disk.
3. CP maintains some of the QUERY subcommand control blocks off of a virtual subcommand chain. These blocks are for QUERY VIRTUAL subcommands and generic subcommands for which there is no specific operand that identifies them. For example, QUERY 0003 for a class B user is identified by the generic QUERY subcommand block because the second operand, which would be used to identify it, is a device address of which there is no single keyword that indicates that a real device is being queried. If no keyword is found, then the entry point for the generic QUERY subcommand is used, provided that the user has the correct privilege class.

CVTOVRID creates MODIFY CMD commands for the virtual QUERY subcommand chain when it determines that the UCR file (that would have been created under User Class Restructure, which is no longer supported) would have affected the subcommand blocks on that chain. This occurs for CP privilege class B and G subcommands.

## Responses

Response 1:

To convert a CMS class override file into a file of MODIFY statements for your system configuration file, enter the following on the command line of your XEDIT screen:

```
====> cvtovrid newstmts config a
```

This causes XEDIT to create a file called NEWSTMTS CONFIG that you can file on your A-disk (or SFS directory). You can then imbed this file in your system configuration file or place the statements in NEWSTMTS CONFIG directly in your system configuration file.

## DDR

### Purpose

Use the DASD Dump Restore (DDR) utility to dump, copy, or print data which resides on z/VM user minidisks or dedicated DASDs. The utility may also be used to restore or copy DASD data which resides on z/VM user tapes. There are two versions — a CMS command (DDR) and an IPLable stand-alone program.

To run the DDR utility as a stand-alone program under CP, you need to use IPL DDRXA. See [z/VM: System Operation](#) for examples.

The DDR utility has five functions:

1. Dumping part or all of the data from a DASD to tape.
2. Transferring data from tapes created by the DDR dump function to a direct access device. The direct access device must be the same type as that which originally contained the data.
3. Copying data from one device to another of the same type. Data may be reordered by cylinder or block when copying it from disk to disk. In order for one tape to be copied to another, the original tape must have been created by either the DDR command or the DDRXA stand-alone utility DUMP function.
4. Printing selected parts of DASD and tape records in hexadecimal and EBCDIC on the virtual printer.
5. Displaying selected parts of DASD and tape records in hexadecimal and EBCDIC on the terminal.

### Operands

*fn ft fm*

\*

the file containing the control statements for the DDR utility. If no file identification is provided, the DDR utility attempts to obtain control statements from the console. The file mode defaults to asterisk (\*) if a value is not provided.

### Usage Notes

1. In the CMS environment, all output is directed (by default) to the CMS printer 00E, unless you specify the SYSPRINT CONS option. Any other SYSPRINT devno option specification is ignored.
2. When you start DDR in CMS in a virtual machine environment, the I/O operation is performed by CP. CP has better error recovery facilities.
3. When performing the DUMP or COPY functions, the stand-alone DDR utility does not support cylinder faults for mass storage subsystem (MSS) virtual volumes.
4. DDR copies mode zero (private) files from a CMS disk, regardless of whether the disk is linked R/O or R/W.
5. Results are unpredictable if you use DDR to copy data from one minidisk to another minidisk unequal in size (for example, the output disk contains fewer cylinders or blocks than the input disk).
6. If the DDR stand-alone utility is IPLed from tape with a LOADPARAM of AUTOxxxx, it automatically restores the tape to the DASD with device address xxxx. No output is produced on the console. Command completion is indicated by loading a disabled wait PSW. A wait code of zero in this PSW

indicates a successful restore; a non-zero wait code signals an unsuccessful restore. See *z/VM: CP Messages and Codes* for PSW wait state details.

7. DDR writes its own tape marks after a dump. It reads past any tape marks found between dumps during a restore.
8. In an emergency that requires data to be restored to a SCSI device in order for recovery to be performed, do the following:
  - IPL the initial install DVD.
  - Define the appropriate EDEVICES.
  - Run DDR under CMS in the MAINT virtual machine.

For more information, see the *z/VM: Installation Guide*.

9. To use DDR as a PIPE stage, the DRPC MODULE must first be run to install the DDR PIPE stage. This installation of the PIPE stage will last until CMS is re-IPLed.

#### DDR Control Statements

DDR control statements describe the intended processing and the needed I/O devices. Specify I/O definition statements first.

All control statements may be entered from either the console or the card reader. The program inspects only columns 1 to 71. It ignores all data after the last operand in a statement. Since the output tape must have the DASD cylinder header records in ascending sequences, you must enter extents in sequence by DASD location (that is, in sequence by cylinder number if this is a count-key-data device). You may specify only one type of function to be performed in one execution. Choose from:

- Dump
- Restore
- Copy

You may enter up to 300 statements describing cylinder or block extents.

The function statements are delimited by an INPUT or OUTPUT statement, or by a null line if the console is used for input. If additional functions are to be performed, the sequence of control cards must be repeated. If you do not use INPUT or OUTPUT control statements to separate the functions you specify, an error message (HCP702E) is displayed when the input is read from a card reader or CMS file. The remainder of the input stream is checked for proper syntax, but no further DDR operations are performed. Only those statements needed to redefine the I/O devices are necessary for subsequent steps. All other I/O definitions remain the same.

**To return to CMS**, enter a null line (carriage return) in response to the prompting message (ENTER:). **To return directly to CP**, enter #CP.

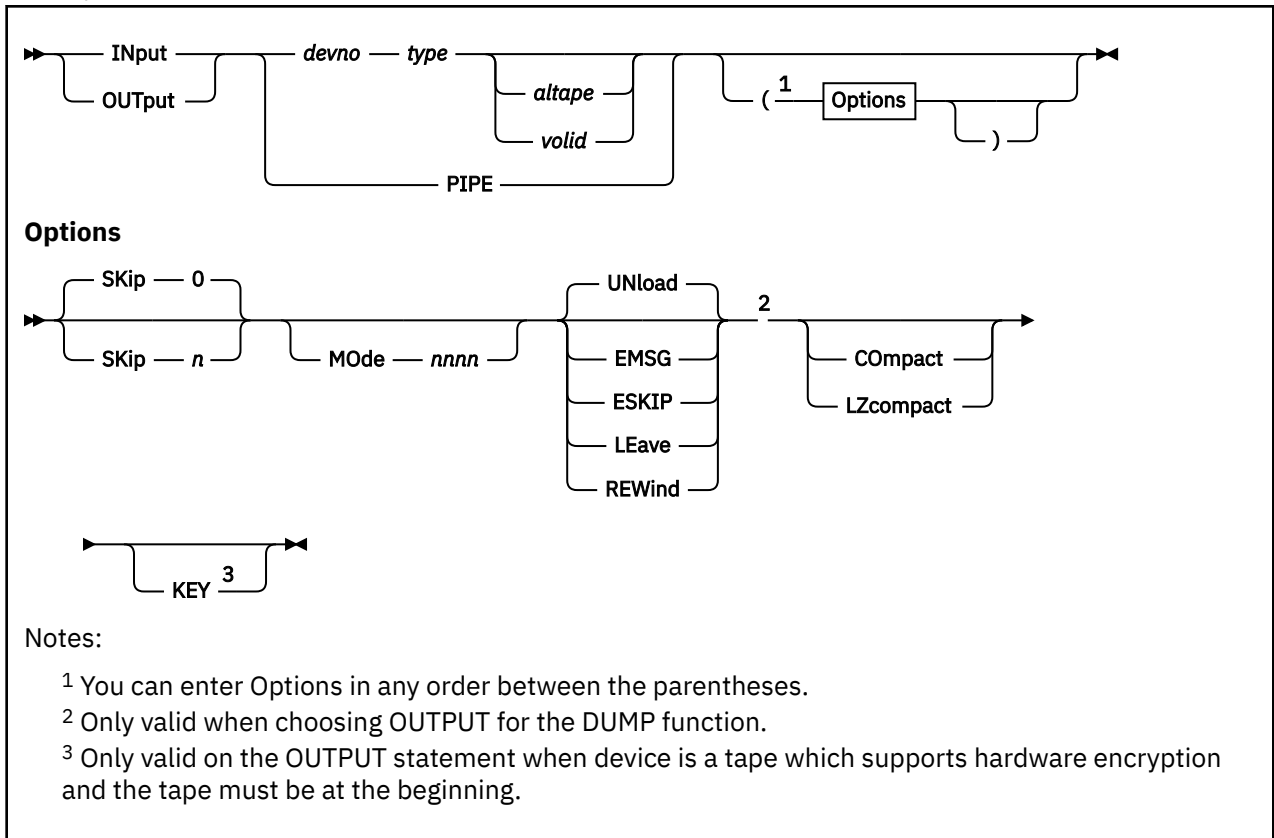

Two logical line editing symbols are recognized and handled by the DDR command. The first is the logical character-delete symbol (@) that allows deletion of one or more of the previous characters entered. The second is the logical-line delete symbol (¢) that deletes the entire previous physical line. Most often, the default values for these two symbols are defined for each virtual machine at system generation. When you use the CP TERMINAL command to redefine the CHARDEL and LINEDEL characters, the redefinitions have no effect on DDR line editing. DDR continues to recognize the at sign (@) and the cent sign (¢) as valid CHARDEL and LINEDEL symbols, respectively.

The PRINT and TYPE statements work differently from other DDR control statements in that they operate on only one data extent at a time. If the input is from a tape created by the dump function, it must be positioned at the header record for each step. The PRINT and TYPE statements have an implied output of either the console (TYPE) or system printer (PRINT). Therefore, PRINT and TYPE statements need not be delimited by an INPUT or OUTPUT statement.

#### I/O Definition Control Statements

The I/O definition statements describe the tape, DASD, and printer devices used while the DASD Dump Restore utility is running.

INPUT/OUTPUT Control Statement

An INPUT or OUTPUT statement describes each tape and DASD unit used.

**INput**

the device described is an input device.

**OUTput**

the device described is an output device.

**Note:** If the output device is a DASD and DDR is running under CMS, the device is released using the CMS RELEASE command function, unless the device is the CMS system disk.

**devno**

the device number of the input or output device.

**type**

the device type. The valid device types are:

DASD	Tape
3380	3422
9336	3480
3390	3480
FB-512	3490
DASD	3590
	Tape

**Notes:**

1. DDR does not provide 7-track support for any tape devices.

2. Specify 3380 for a 3390 that is in 3380 track compatibility mode. Specify 3390 for any 3390 operating in native mode.
3. Any fixed-block device may generically be specified by typing "FB-512" (minimum abbreviation is "FB").
4. The DDR utility, executing in a virtual machine, uses I/O DIAGNOSE X'A8' to perform I/O operations on tape and DASD. DDR under CMS requires that the device type entered agree with the device type of the real device as recognized by z/VM. If there is a conflict with device types, the following message is issued:

```
HCP708E INVALID INPUT OR OUTPUT DEFINITION
```

5. If you enter a specific device type on the INPUT or OUTPUT statement that does not match the actual type of the device that the statement is identifying, then DDR issues the following message:

```
HCP708E INVALID INPUT OR OUTPUT DEFINITION
```

### **valid**

the volume identifier of the disk originally dumped to tape. If the keyword SCRATCH is specified instead of the volume identifier, no label verification is performed.

### **altape**

the address of an alternate tape drive. The alternate tape address is only used when a DUMP command reaches the end of the tape, or a read operation reaches the END-OF-VOLUME marker placed at the end of the tape during a DUMP operation.

**Note:** If multiple reels of tape are required and *altape* is not specified, DDR types the following at the end of the reel:

```
END OF VOLUME CYL xxxxxxxx HD xx, MOUNT NEXT TAPE
```

or

```
END OF VOLUME BLOCK xxxxxx, MOUNT NEXT TAPE
```

After the new tape is mounted, DDR continues automatically.

### **PIPE**

specifies that rather than a device, DDR will use CMS PIPES for input and output. This operand is meant to be used when invoking DDR as a PIPE stage. Note that the DRPC MODULE must first be executed to install the DDR PIPE stage.

*Example 1: Dumping a disk to a CMS file via PIPES*

```
Control Statement File DUMP191 DDR L:
INPUT 191 DASD
OUTPUT PIPE ( LZ
PROMPTS OFF
DUMP ALL

PIPE DDR DUMP191 DDR L | > 191 DUMP L
```

The result will be a file 191 DUMP L that contains the contents of the 191 disk.

*Example 2: Restoring a previously dumped disk via PIPES*

```
Control Statement File RES191 DDR L:
INPUT PIPE ( LZ
OUTPUT 191 DASD
PROMPTS OFF
RESTORE ALL

PIPE < 191 DUMP L | DDR RES191 DDR L
```

This will result in the contents of the file 191 DUMP L being written to the 191 disk.

**SKip *n*****SKip 0**

forward spaces *n* files on the tape, *n* is any number up to 65535. (See note “6” on page 2153.) The SKIP option is reset to zero after the tape has been positioned. The zero value is the default.

**MOde *nnnn***

selects the recording format in which data will be written on the tape. On 3422 tape devices, you can specify the recording format (the MODE) only at the beginning of a tape volume. No changes in the format can be made after this initial designation. On 3480 and 3490 (including 3490Es), you can change the recording format (the MODE) each time you choose to write to a tape volume. On 3590 tape devices you can only change device independent mode option values each time you choose to write to a tape volume, while device dependent mode option values can only be specified at the beginning of a tape volume (see note “8” on page 2153. After you write to a volume, the MODE value returns to the default value for that particular tape device. If you wish to write to the tape in a different recording format next time, you must again specify the MODE value.

The table below specifies the valid and default mode option values for supported tape devices:

Device Type	Valid Device-Dependent (MODE <i>nnnn</i> ) Option Values	Valid Device-Independent (MODE <i>nnnn</i> ) Option Values	Device (MODE <i>nnnn</i> ) Default Value
3422	1600, 6250	n/a	1600
3480	38K	NOCOMP	38K
3480 w/IDRC	XF, 38K	COMP, NOCOMP	38K
3490	3490C, 3490B	COMP, NOCOMP	3490C
3590	EFMT1, EFMT2, EFMT3, EFMT4	COMP, NOCOMP	COMP

**Notes:**

1. If you specify a density mode that the tape cannot handle, the control unit may not return an error condition. In this case, the mode setting is ignored, and the default control unit setting is used.
2. The 3490 tape devices, models A01, A02, B02, B04, D31, and D32, should be treated as type 3480 devices. All other 3490 device models should be treated as type 3490 devices. For a complete breakdown of 3480 and 3490 device types by model number, see [Defining I/O Devices in z/VM: CP Planning and Administration](#).
3. COMP and NOCOMP are device-independent MODE options for compaction and non-compaction, respectively, for use with either 3480, 3490, or 3590 tape subsystems.
4. On 3480 tape drives only, if you specify both hardware (MODE XF or COMP) and software (COMPACT) compaction options, the hardware support takes precedence.  
  
For 3490s, where hardware compaction is the default (MODE 3490C or MODE COMP), software compaction will take precedence, if specified.  
  
It is recommended that both software compaction and hardware compaction not be specified for any tape device.
5. Data is always translated into non-compacted form when read from tape.
6. All other tape related commands view a file as a CMS file located on a minidisk. However, DDR's definition of a file is anything that is dumped, restored, or copied by one DDR command. There could be hundreds of CMS files in just one DDR file.
7. By specifying an EFMTx mode explicitly, the device default COMP value is also active.
8. For specifying an EFMTx mode, the tape must be at the beginning. If data has already been written to the tape using a specific mode and/or the tape is not at the beginning (for example, SKIP option), any further data dumped to the tape will also use the already, formerly used mode.

**REWind**

rewinds the tape when a function completes.

**UNload**

rewinds and unloads the tape when a function completes. This is the default.

**LEave**

leaves the tape positioned at the end of the file when a function completes.

**EMSG**

allows the user to determine whether to continue after an I/O error on the INPUT device. The user must respond to the prompt 'DO YOU WISH TO CONTINUE? RESPOND YES OR NO:' which will be issued with messages HCP705D and HCP714D. This option may only be specified on the INPUT statement.

**ESKIP**

allows the user to continue automatically after an I/O error on the INPUT device without having to supply a 'YES' to the prompt 'DO YOU WISH TO CONTINUE? RESPOND YES OR NO:'. This option may only be specified on the INPUT statement.

**COmpact**

causes the output tape to be in a compact format. Output in compact format uses less tape space than output in standard format. DDR stores data in a compact format by compressing strings of duplicate data into a smaller amount of space, thus reducing the amount of space necessary to represent the characters in the data.

This option is valid only on the OUTPUT control statement for the DUMP function. Tapes in the compact format may be used as input to the RESTORE, COPY, PRINT, and TYPE functions without any changes. Refer to the following sections on function statements for more information.

You cannot use tapes created with the COMPACT option as input to earlier levels of DDR or IPL DDRXA that do not support the compaction function.

**LZcompact**

causes the output tape to be in a compact format. Output in a compact format uses less tape space than output in standard format. DDR stores data in a compact format by using the processor's compression call instruction to compress the data before writing it out to tape.

This option is valid only on the OUTPUT control statement for the DUMP function. Tapes in the compact format may be used as input to the RESTORE, COPY, PRINT, and TYPE functions without any changes. Refer to the following sections on function statements for more information.

You cannot use tapes created with the LZCOMPACT option as input to earlier levels of DDR or IPL DDRXA that do not support the LZcompact function.

**KEY**

causes encryption to be used for the output type. If the LABEL/HASH control statement is also specified, the label value specified will be the key label used for tape encryption. Otherwise, default key encryption will be used.

**Notes:**

1. When the wrong input tape is mounted, the message HCP709E is displayed, and the tape rewinds and unloads, regardless of whether the options REWIND, UNLOAD, or LEAVE are specified.
2. If DDR is processed from CMS, failure to attach the tape drive or the disk device (or both) to your virtual machine before invoking the input/output statement causes the following response to be displayed:

```
HCP708E INVALID INPUT OR OUTPUT DEFINITION
```

3. The EMSG and ESKIP options are ignored when executing the stand-alone version of DDR in a real machine to dump or restore FBA data.
4. Options EMSG and ESKIP are mutually exclusive. The last option entered will be the one in effect.

5. If LEAVE was specified and an End-Of-Tape condition is encountered while performing End-Of-Job processing, the tape will be rewound and unloaded and message HCP8102I will be issued.
6. Tape hardware compaction is the default on 3490 and later tape drives. Hardware compaction may give better compression than software compaction. On 3480 tape drives, if both the dumping and restoring tape drive have XF capability, then MODE XF may be used to turn on tape hardware compaction. Compact or LZcompact may be used for 3480 tape drives that do not have XF support and will automatically turn off tape hardware compaction on any tape drive.
7. When the KEY option is used for tape encryption, the tape must be at the beginning. If encrypted data has already been written to the tape and the tape is not at the beginning, any further data dumped to the tape without using the KEY option will also be encrypted.

#### LABEL/HASH Control Statement for Encryption Keylabels

Up to two key labels may be specified for tape encryption. LABEL1/LABEL2 indicates the label value should be used as is. HASH1/HASH2 indicates the key label encoding mechanism is a hashed value of the associated public key, to better share data accessed through different key managers. Label values are up to 64 characters. The first character of the key label must be alphabetic or a national character (#, \$, @). The remaining characters may be alphabetic, numeric, national, or a period. Imbedded blanks are allowed.

#### SYSPRINT Control Statement

The SYSPRINT control statement describes the device to which output is to be sent. If you specify the SYSPRINT CONS option, the output is directed to the console.

In the CMS environment, all output is directed (by default) to CMS printer 00E, unless you specify the SYSPRINT CONS option. Specifying SYSPRINT CONS will direct all output to the console. Any other SYSPRINT option specification is ignored.

#### 00E

the device number of the printer to be used for printed output. This is the default.

#### CONS

the console as the output device.

**Note:** If the SYSPRINT control statement is issued with anything other than 00E or CONS and the option is not omitted, the statement is ignored and you will receive the message:

```
HCP701I SYSPRINT NOT 00E OR CONS--IGNORED
```

#### PROMPTS Processing Control Statement

The PROMPTS processing control statement provides a user with the option to bypass the prompts that are normally issued with messages 711, 716, 717, and 725. PROMPTS ON (the default) will cause DDR to solicit a response to any of the above mentioned messages from the user before any further processing will be done. The action that DDR will take depends on the response entered by the user. PROMPTS OFF will cause DDR to act as if every prompt encountered has been answered with "YES". Although the prompting messages will no longer be issued when PROMPTS OFF is in effect, other messages similar in content to the original messages will be issued. These other messages, numbered 696-699, are the PROMPTS OFF equivalents of messages 711, 716, 717, and 725, respectively.

**Attention:** Although the default is to prompt the user with messages 711, 716, 717, and 725 when unexpected circumstances arise, these prompts when turned off will remain off for the rest of that session unless the user turns them back on by entering PROMPTS ON. DDR users considering the use of PROMPTS OFF should carefully examine the conditions under which the prompting messages are issued and then determine whether any adverse effects would result by allowing the DDR function to continue.

Function Statements

The function statements tell the DDR utility the action to perform. The function commands also describe the extents to be dumped, copied, or restored.

**Note:** The FTR, FTR32k, and OLDFORM options are valid only with the DUMP control statement.

**DUmp**

requests that the utility move data from a direct access volume onto a magnetic tape or tapes. After the data is dumped, if the COMPACT or LZCOMPACT option was specified on the OUTPUT control statement, you receive the following messages:

```
'BYTES IN _____ BYTES OUT _____'
'TRACKS NOT COMPACTED ON THE TAPE - _____'
```

or, for an FBA DASD:

```
'BYTES IN _____ BYTES OUT _____'
'BLOCKS NOT COMPACTED ON THE TAPE - _____'
```

where

- “BYTES IN” is the total number of bytes that were read in from the input device.
- “BYTES OUT” is the total number of bytes that written out to the output (tape) device.
- “TRACKS or BLOCKS NOT COMPACTED ON THE TAPE” is the number of Tracks or Blocks read in from DASD that were not reduced in size by software compaction, and therefore were written out exactly as they were read in.

If you know the density of the output tape, you can use the value for “BYTES OUT” to calculate the approximate number of feet of tape used. The density is dependent on the tape device and may be modified with the value for MODE on the OUTPUT control statement.

The format of the tape depends on the type of the direct access volume.

Once the dump is complete, DDR writes a tape mark.

### **FTr**

requests an output tape format of variable unblocked records with a maximum size of 65535. Specifying FTR will reduce the number of read I/O operations initiated on the device by reading many records (a full-track) for each operation. In addition, the tape record format (variable length and unblocked) will result in less tape used. The size of the records and the number of records on each track written to the tape depends on the density of the tape. The option can be used for those devices supporting the full-track-read feature (FTR): 3380, 3390 and for FBA devices. FTR is the default for the 3380 and 3390 and therefore need not be specified.

If FTR is specified on the DUMP control statement for a count-key-data (CKD) DASD but the control unit does not support the feature, a message is written, and the operation proceeds with data written, in the old format.

For a count-key-data DASD, the data is moved cylinder by cylinder. Any number of cylinders can be moved. The format of the resulting tape is:

- *Non-FTR and Non-Compact Format:*

*Record 1:* a volume header record, consisting of data describing the volumes.

*Record 2:* a track header record, consisting of a list of count fields to restore the track, and the number of data records written on tape. After the last count field, the record contains key and data records to fill the 4 KB buffer.

*Record 3:* track data records, consisting of key and data records packed into 4 KB blocks, with the last record truncated.

*Record 4:* either the end-of-volume (EOV) or end-of-job (EOJ) trailer label. The end-of-volume label contains the same information as the next volume header record, except that the ID field contains EOJ. The end-of-job trailer label contains the same information as record 1, except that the cylinder number field contains the disk address of the last record on tape and the ID field contains EOJ.

- *FTR or Compact Format:*

*Record 1 and Record 4* are the same as described for the non-FTR format.

*Record 2:* a track header record, consisting of fields containing the length of the track, the density of the tape, and the number of count fields in the track followed by the track contents.

*Record 3:* track data records, consisting of count-key-data records in 8 KB, 12 KB, or 48 KB blocks for 800, 1600, or 6250 BPI respectively. The last block in all cases is a short block.

For FBA devices, the data is moved in sets of blocks. Each set is arbitrarily called a track (there is no relation to device geometry in this terminology). Any number of blocks can be moved with one DUMP statement. The format of the resulting tape depends on whether the FTR option is used or not, and also on the recording format of the tape.

- *FBA Tape Format:*

*Record 1:* a volume header record, consisting of data describing the volume

*Record 2:* a track header record. This consists of data that describes the set of blocks that follow (such as block numbers and the number of tape records required to hold these FB-512 blocks).

Following the control data are the actual FB-512 blocks filling out the tape record. When possible, DDR will use a 480K data buffer to store the FBA data (959 FBA blocks maximum). If storage for this buffer cannot be obtained or if the OLDFORM option was specified, then a smaller, 64K buffer will be used (127 FBA blocks maximum).

*Record 3:* FB-512 data records. These contain the rest of the blocks making up the set. The record lengths of records 2 and 3 are 4K when FTR is not specified. When FTR is specified, these tape records are 8K, 12K, or 48K depending on the recording format of the tape.

*Record 4:* either the end-of-volume (EOV) or end-of-job (EOJ). The end-of-volume label contains the same information as the next volume header record, except that the ID field contains EOV. The end-of-job trailer label contains the same information as record 1, except that the ID field contains EOJ.

**Note:** When dumping with FTR to a 3490E or subsequent tape device, tape records may vary in length (depending on the size of each track header record) up to a maximum record length of 64K–1.

### **FTR32k**

requests an output tape format of variable unblocked records with a maximum size of 32654 bytes. Using this option instead of FTR will possibly result in more I/O to the output device and is generally recommended only when an output tape will be read by applications that cannot handle larger blocks. Generally FTR (which is the default for many devices) is a better choice. See FTR for a complete description of this option.

### **OLDFORM**

indicates that the FBA data should be dumped using the smaller buffer (64K) rather than the larger buffer (480K) to remain compatible with older versions of DDR. The large buffer was implemented to enhance the performance of dumping FBA data to a streaming tape drive in a virtual machine environment. Using the OLDFORM option in this situation may degrade performance. This option is ignored when dumping from a CKD/ECKD DASD.

### **COPY**

requests that the utility copy data from one device to another device of the same or equivalent type. Data may be recorded on a cylinder basis from input device to output device. A tape-to-tape copy can be accomplished only with data dumped by this program. A tape in compact format may be used as input. For a tape-to-tape copy, the output is in the same format (compact, LZcompact, or standard) as the input tape. The COMPACT or LZCOMPACT option on the OUTPUT control statement is not valid for the COPY function. If it is specified, a message stating COMPACT OPTION IGNORED FOR COPY OPERATIONS is displayed.

### **REstore**

requests that the utility return data that has been dumped by this program. Data can be restored only to a DASD volume of the same or equivalent device type from which it was dumped. It is possible to dump from a real disk and restore to a minidisk as long as the device types are the same. A tape in a compact format may be used as input. DDR checks to see if the input is in compact format, and expands the data back to standard format, if needed. You do not need to specify anything to the program about the tape format. After data is restored, you receive the following message:

```
'BYTES RESTORED _____'
```

### **Notes:**

1. When restoring DDR-compacted tapes which were created with a release of DDR prior to release 2.0, the number of bytes indicated by the 'BYTES RESTORED' response will be larger than the number of bytes originally indicated by the 'BYTES IN' response following the dump function. This discrepancy is because DDR now uses a larger track header record format. The current track header record is 4 bytes longer than that used in release prior to release 2.0, thus the 'BYTES RESTORED' value will be larger than the 'BYTES IN' value by 4 bytes per track header record. This does not compromise the integrity of the data restored.
2. DDR reads past any tape marks found between dumps during a restore.

**cyl1 To cyl2 Reorder To cyl3**

Only those cylinders specified are moved, starting with the first track of the first cylinder (*cyl1*), and ending with the last track of the second cylinder (*cyl2*). The REORDER operand causes the output to be reordered, that is, moved to different cylinders, starting at the specified cylinder (*cyl3*) or at the starting cylinder (*cyl1*) if *cyl3* is not specified. The REORDER operand must not be specified unless specified limits are defined for the operation; the starting and, if required, ending cylinders (*cyl1* and *cyl2*) must be specified. Note that if the input device cylinder extents exceed the number of cylinders specified on the output device, an error message results.

**block1 To block2 Reorder To block3**

Only the specified blocks are moved, starting with the first block (*block1*), up to and including the last block (*block2*). The REORDER operand causes the data to be moved to a different DASD location. The REORDER operand must not be specified unless limits are defined for the operation. If *block1* or *block2* exceeds the capacity of the input drive, an error message will result. Similarly, if the reorder block, *block3*, exceeds the capacity of the output device, an error message will be issued. When the output device is a tape, the device capacity is considered to be the same as the capacity of the input FBA DASD or of the FBA volume residing on the input tape.

**CPvol**

specifies that cylinder 0, or blocks 0-31 (for FBA devices) and all permanent, parameter, and active directory space is dumped or copied as indicated by the z/VM allocation record from the input device. In the case of a tape input function specifying CPVOL, all the data is restored or copied.

**ALL**

specifies that the operation is to be performed on the entire DASD volume (all cylinders or all blocks).

**Note:** The occurrence of message HCP705E (issued upon completion of the copy, restore, or dump operation) indicates that an attempt was made to copy, restore, or dump the contents of DASD locations beyond the extents of the designated minidisk.

**Restrictions**

- Each track must contain a valid home address, containing the real cylinder and track location.
- Record zero must not contain more than eight key and data characters.
- Flagged tracks are treated just as any other track for all 2314 and 2319 devices—that is, no attempt is made to substitute the alternate track data when a defective primary track is read. In addition, tracks are not inspected to determine whether they were previously flagged when written. Therefore, volumes containing flagged tracks should be restored to the same cylinders of the volume from which they were dumped. The message HCP715E occurs each time a defective track is dumped, copied, or restored, and the operation continues.
- A minidisk that has extended into the alternate track cylinder must be moved either to another area of the disk, or to another disk entirely. Use the REORDER option to copy or restore a minidisk to another area.
- The FTR option can be used with the COMPACT option; however, DDR ignores the FTR option. This happens because when data compaction is requested, DDR defaults to using full-track-read if possible, and the tape record formats for the default are the same as those generated by FTR.
- For DASDs other than the 3380 and 3390 that support the full track read (FTR) processing, the option must be specified. Otherwise, the tape is produced in the current DDR format of 4096 blocks.
- Tapes created by the DDR DUMP function in compact or LZcompact format cannot be used as input to earlier levels of DDR that do not support the same format.
- If performing a DDR COPY from a device with a cylinder-based allocation record to a device with an extent-based allocation record, or vice versa, and if you plan on attaching the output DASD to the system as a CP volume, the output DASD should be reallocated by issuing the ICKDSF CPVOLUME ALLOCATE command. If the output DASD contains a cylinder-based allocation map when it should contain an extent-based allocation map, ICKDSF will convert the cylinder-based map into an extent-based map during the reallocation. Likewise, if the output DASD contains an extent-based allocation map when it should have a cylinder-based allocation map, ICKDSF will convert the extent-based map into a cylinder-based map during the reallocation.

*Example 1*

```
input 191 3390 sysres
output 180 3490 181dump all
input 130 3390 mini01
dump 1 to 50 reorder 51
dump 60 70 101
```

This example dumps all data from the volume labeled SYSRES onto the tape mounted on unit 180. If the program runs out of space on the first tape, it continues dumping onto the alternate device (181). A map of the dumped cylinders is printed on unit 00E while the program is dumping. When the first function is complete, the volume labeled MINI01 is dumped onto a new tape. Its cylinder header records are labeled 51 to 100. A map of the dumped cylinders is printed on unit 00E. Next, cylinders 60 to 70 are dumped and labeled 101 to 111. This extent is added to the cylinder map on unit 00E. When the DDR processing is complete, the tapes are unloaded, and the program stops.

*Example 2*

```
input 182 3490
output 250 fb-512 systst
restore 10 to 20 reorder 30
```

This example restores data previously dumped from an FBA device to another FBA device with device number 250. Blocks 10 through 20 stored on the tape are restored to the DASD on blocks 30 through 40.

If cylinder or block extents are being defined from the console, the user need only enter DUMP, COPY or RESTORE on the command line. The following is displayed:

```
ENTER CYLINDER EXTENTS
ENTER:
```

or

```
ENTER BLOCK EXTENTS
ENTER:
```

For any extent after the first extent, the following message is displayed.

```
ENTER NEXT EXTENT OR NULL LINE
ENTER:
```

You may then enter additional extents to be dumped, restored, or copied. A null line causes the job step to start.

**Notes:**

1. When a cylinder map is printed on the virtual printer (00F as in the previous example) a heading precedes the map information. DDR displays the disk, time and zone in the heading.
2. Attempts to restore cylinders or blocks beyond the capacity that were recorded on the tape produces a successful EOJ, but the printout only indicates the last cylinder or block found on the tape.

PRINT/TYPE Function Statement

Use the PRINT and TYPE function statement to print or type (display) a hexadecimal and EBCDIC translation of each record or block specified. The output is directed to the system console for the TYPE function, or to the SYSPRINT device for the PRINT function. (This does not cause redefinition of the output unit definition.)

A tape in a compact format may be used as input to the PRINT or TYPE function. The printed or displayed output is not affected by the input format. You do not need to specify anything to the program about the format of the input tape.

#### **cyl1**

the starting cylinder. Up to an 8-digit cylinder value is accepted.

#### **hh1**

the starting track. If present, it must follow *cyl1*. The default is track zero.

#### **rr1**

the starting record. If present, it must follow *hh1*. The default is home address and record zero.

#### **TO cyl2**

the ending cylinder. If more than one cylinder is to be printed or typed, TO *cyl2* must be specified.

#### **hh2**

the ending track. If present, it must follow *cyl2*. The default is the last track on the ending cylinder.

#### **rr2**

the last record to print. The default is the last record on the ending track.

#### **block1**

identifies the first FBA device block that is to be printed or typed.

#### **To block2**

identifies the last FBA device block that is to be printed or typed. If more than one block is to be printed or typed, To *block2* must be specified.

#### **Hex**

prints or displays a hexadecimal representation of each record specified.

#### **Graphic**

prints or displays an EBCDIC translation of each record specified.

#### **Count**

prints or displays only the count field for each record specified. The COUNT option is ignored for FBA data.

#### *Usage Notes*

1. If the TYPE statement follows the occurrence of error message HCP705E and specifies the same cylinder, track, and record, or block extents indicated in the error message, the contents of the printed record or block must be interpreted in the context of the I/O error information given in the initial message.

**Examples**

```
print 0 to 3
```

prints all of the records from cylinders 0, 1, 2, and 3.

```
print  
0 1 3
```

prints only one record, from cylinder 0, track 1, record 3.

```
print  
1 10 3 to 1 15 4
```

prints all records starting with cylinder 1, track 10, record 3, and ending with cylinder 1, track 15, record 4.

The example in [Figure 1 on page 2163](#) shows the information displayed at the console (TYPE function) or system printer (PRINT function) by the DDR utility. The listing is annotated to describe some of the data fields.

Figure 1. An Annotated Sample of Output from the TYPE and PRINT Functions of the DDR Program

For FBA device data, the utility first prints or types a heading that indicates the block number and then prints or types the 512 bytes of data residing in that block. This output will look as follows:

```

ENTER:
type 1
BLOCK 00000001
  
```

```

## Responses

**Note:** If PROMPTS OFF was specified by the user, messages 696-699 will replace messages 711, 716, 717, and 725, respectively. Please see the PROMPTS control statement description for more details. See also the list of DDR-issued messages at the end of this utility description.

```

VOLID READ IS valid2 [NOT valid1]
DO YOU WISH TO CONTINUE? RESPOND YES NO OR REREAD:

```

### **valid2**

the volume identifier from the VOL1 label on the DASD unit.

### **valid1**

the volume identifier from the INPUT or OUTPUT control card.

The volume identifier read from the device at *devno* is not the same as that specified on the INPUT or OUTPUT control card.

```

NO VOL1 LABEL FOUND FOR valid
DO YOU WISH TO CONTINUE? RESPOND YES NO OR REREAD:

```

### **valid**

the volume identifier of the DASD device from the INPUT or the OUTPUT control card.

The DASD at *devno* contains no volume identifier.

```

DATA DUMPED FROM valid1 TO BE RESTORED TO valid2
DO YOU WISH TO CONTINUE? RESPOND YES NO OR REREAD:

```

### **valid1**

the volume identifier from the input tape header record (volume dumped).

### **valid2**

the volume identifier from the output DASD.

This message is printed to verify the input parameters.

```

ENTER CYLINDER EXTENTS
ENTER:

```

or

```

ENTER BLOCK EXTENTS
ENTER:

```

This message is received only if you are entering input from your terminal.

```

END OF VOLUME CYL xxxxxxxx HD xx, MOUNT NEXT TAPE

```

or

```

END OF VOLUME BLOCK xxxxxx, MOUNT NEXT TAPE

```

DDR continues processing after the next tape is mounted.

```
RESTORING valid
```

**valid**

the volume identifier of the disk dumped.

The RESTORE operation has begun.

```
COPYING valid
```

The COPY operation has begun.

```
DUMPING valid
```

The DUMP operation has begun.

```
PRINTING valid
```

The PRINT operation has begun.

```
END OF DUMP
```

The DUMP operation has ended.

```
END OF RESTORE
```

The RESTORE operation has ended.

```
END OF COPY
```

The COPY operation has ended.

```
END OF PRINT
```

The PRINT operation has ended.

```
END OF JOB
```

All specified operations have completed.

```
ENTER:
```

Prompts for input from the terminal. A null line—that is, pressing the Enter key or equivalent—returns control to CMS.

```
ORIGINAL INPUT DEVICE WAS(IS) LARGER THAN OUTPUT  
DEVICE. DO YOU WISH TO CONTINUE?  
RESPONSE YES OR NO:
```

**Explanation:** RESTORE function—The number of cylinders or blocks on the original DASD input unit is compared with the number on the output device.

COPY function—The input device contains more cylinders or blocks than the output device.

**Note:** This response is issued only if the ALL operand was specified on the RESTORE or COPY function statement.

**Operator Action:** The operator must determine if the COPY or RESTORE function is to continue. The response is either yes or no.

A progress response will be issued to the user's console if the enter key is pressed while performing a dump, copy, or restore of data using the stand-alone version of the DDR utility (IPL DDRXA). The progress

response indicates the last block or the last cylinder and head successfully transferred to the output device at the time when the enter key was pressed.

The FBA format of the progress response is:

```
LAST BLOCK - xxxxxxxx
```

The CKD format of the progress response is:

```
LAST ADDRESS - CYL xxxxxxxx HD xx
```

#### Code

#### Meaning

- 1**  
Invalid file name or file not found
- 2**  
Error running the program
- 3**  
Flagged DASD track
- 4**  
Permanent tape or DASD I/O error
- 1xx**  
Error in printing a line (PRINTL routine)
- 2xx**  
Error in reading from the terminal (LINERD routine)
- 3xx**  
Error in reading a file (FSREAD routine)
- 4xx**  
Error in writing to the terminal (LINEWRT routine)
- 20**  
Error in the decoding routine.

**Note:** xx is the return code from the CMS routine.

## DIRECTXA

### Purpose

Use the DIRECTXA utility to create a user directory.

### Operands

*fn*

identifies the file name of the source directory. If it is not specified, the default file name is USER.

*ft*

identifies the file type of the source directory. If it is not specified, the default file type is DIRECT.

*fm*

\*

identifies the file mode of the source directory. If it is not specified, the default file mode is asterisk (\*). (The utility searches all accessed disks for the file name and file type).

### Options

#### EDIT

lets you enter the DIRECTXA command without updating the directory on disk. With this option, you can check the syntax of directory statements.

#### SYSAFNID *sysafnid*

identifies a 1- to 8-character alphanumeric value that must correspond to a system affinity ID specified on one of the DIRECTORY statements in the source directory named in the DIRECTXA command. A maximum of 56 system affinity ids can be specified. This option can be used only with the EDIT option, and it specifies that the DIRECTXA utility is to compile the source directory as if it were executing on the system identified by *sysafnid*.

This option is not allowed when processing an SSI-ready or SSI-enabled source directory. For more information about SSI-ready and SSI-enabled source directories, see [Source Directory Types](#) in *z/VM: CP Planning and Administration*.

### **&SYSRES valid**

is a one to six-character value that is used to represent the volume serial number of the system residence volume for minidisks defined using the symbolic value &SYSRES. This value is used in responses to the VMUDQ LSTMDISK function. It need not be the actual system residence volume serial number. If this option is omitted, a value of +VMRES is used.

If SSI is specified on the DIRECTORY directory statement in the source directory, then the &SYSRES option is not allowed, and &SYSRES and +VMRES are not allowed on MDISK directory statements. If this rule is violated for an SSI-enabled source directory, then an error message occurs and the object directory is not written. For an SSI-ready source directory, a warning message is issued explaining that &SYSRES or +VMRES are not allowed once the SSI option is added.

For more information about SSI-ready and SSI-enabled source directories, see [Source Directory Types](#) in *z/VM: CP Planning and Administration*.

### **MIXED**

specifies that DIRECTXA is to validate, but not process, statements and options encountered in the source directory that are unique to other releases of VM, such as VM/XA SP™ 2.1, VM/SP HPO release 5, and VM/ESA. This lets you use a source directory from one of those systems without having to edit out those unique values. If the MIXMSG option is in effect, DIRECTXA prints informational messages for each statement or option not processed.

### **MIXMSG**

#### **NOMIXMSG**

specifies whether to enter a message indicating that a directory statement or an option of a directory statement applies to other releases of VM, such as VM/XA SP 2.1, VM/SP HPO release 5, and VM/ESA. The default is MIXMSG, which causes informational messages to be issued for each statement or option not processed; see the description of MIXED above.

### **DELTA**

specifies that a mini-directory representing a set of changes from the existing base directory is to be created. This option causes the following:

- No attempt is made to bring the new directory online to CP
- The volume allocation map is not updated
- The volume label is not updated
- A password of DELETEUSER is allowed on the USER statement and marks the associated user deleted in the directory userid index.

The DELTA option is not allowed if the source directory contains IDENTITY or SUBCONFIG statements.

### How the Directory Program Works

The DIRECTXA utility performs the following VM steps during execution:

1. The program looks for the file you specify on the DIRECTXA command line. If you do not specify a file name or a file type, the program looks for a file that has the file name of USER and a file type of DIRECT.

The source directory found must be compatible with the system on which DIRECTXA is running (a system with no SSI cluster defined, a single-member SSI cluster, or a multiple-member SSI cluster), else the object directory is not brought online. For more information, see [Source Directory Types](#) in *z/VM: CP Planning and Administration*.

2. If the program does not find the source directory or an error occurs during processing, the program does not create a directory, and the old directory remains online. The program continues to check the syntax of all directory statements before ending.
3. DIRECTXA looks for the RPWLIST DATA file, which contains a list of restricted passwords. The RPWLIST DATA file is supplied on your system. You can edit this file to add your own restricted

passwords. If the RPWLIST DATA file is not found, DIRECTXA issues a warning message but continues processing. If the RPWLIST DATA file is found, DIRECTXA checks all the passwords in the directory against it and changes any restricted passwords (except the password of the user issuing the DIRECTXA command) to NOLOG. Any user whose password is changed to NOLOG cannot log on. If the password of the virtual machine issuing the DIRECTXA command is restricted, it is not changed to NOLOG. DIRECTXA issues an error message and does not update the directory.

4. If DIRECTXA runs out of DASD space, the utility issues an error message, and the directory is not processed. To continue, you must allocate more cylinders or blocks for the user directory and reissue the DIRECTXA command.

If DIRECTXA runs out of virtual storage, the utility issues an error message, and the directory is not processed. To continue, you must define more virtual storage (DEFINE STORAGE command), re-IPL CMS, and reissue the DIRECTXA command. Using the following formula, calculate the size of virtual storage you need:

```
vstor = 200 KB + (600 bytes * (users + totgrents))
          + (110 bytes * (device statements))
          + (250 bytes * (NAMESAVE + CPU statements))
          + (125 bytes * (IUCV + APPC statements))
          + length of SCPDATA specified on LOADDEV statements
          + length of commands specified on COMMAND statements
```

This is an estimate for the size of the directory. It is not an exact calculation.

**vstor**

the amount of virtual storage in the program area that DIRECTXA requires.

**userid**

identifies the total number of virtual machines and subconfigs defined in the directory control file. This is the sum of all USER, IDENTITY, and SUBCONFIG statements plus the number of users defined by POOL statements.

**totgrents**

identifies the total number of POSIXGROUP statements, plus all groups listed in all POSIXGLIST statements, plus all groups specified in all POSIXINFO statements, plus 1.

5. If no errors occur, and EDIT is not specified, the program writes the directory on DASD and the DASD address of the new directory on the volume label for that device. If the program is updating an active system directory, the program makes the new directory immediately available for the system.

**Usage Notes**

1. On a system where different release levels of z/VM can be IPLed, DIRECTXA is required to be at the highest release level of z/VM that can run on the system. When migrating to a higher release level of z/VM, run the highest release level of DIRECTXA to update the object directory prior to IPLing the higher release level of z/VM. An object directory created using the highest release level of DIRECTXA is compatible with all supported release levels of z/VM. Running a higher release level of z/VM with an object directory created using a lower release level of DIRECTXA is not supported.
2. By default, the DIRECTXA utility is located on the cross release utilities disk (PMAINT 551). This disk must be accessed to run the DIRECTXA utility.
3. You must have CP privilege class A, B, or C to update the system user directory.
4. A complete description of the directory program, including a description of directory statements, is contained in [Creating and Updating a User Directory in z/VM: CP Planning and Administration](#).
5. When writing a user directory, DIRECTXA does not overwrite the current directory, but does write an alternate user directory. The directory pointer in the volume label is then changed to refer to this new directory.
6. You should be careful to target a different physical pack when using the DIRECTXA utility from a new version of z/VM to create a user directory for that new version of the system, by running it under the old system.

7. If the directory specified on the DIRECTXA command is not the current directory, the directory that is created by this utility is not brought online.
8. The MIXED, MIXMSG, NOMIXMSG, EDIT and SYSAFNID options are not positional and can be entered in any order. However, if the SYSAFNID option is specified, the EDIT option also must be specified. If the MIXMSG or NOMIXMSG option is specified, the MIXED option also must be specified.

## Examples

To compile the USER DIRECT source directory and apply it to the system if successful, enter:

```
directxa user direct *
```

To do a test compile of a USER DIRECT source directory from a VM/SP HPO 5 system to see which control statements are HPO-only or contain HPO-only options, enter:

```
directxa user direct * (edit mixed
```

To do a test compile of a USER DIRECT source directory for a specific system named SYSVMA in a mixed complex of systems sharing the source directory, enter:

```
directxa user direct * (edit mixed mixmsg sysafnid sysvma
```

To do a test compile of a USER DIRECT source directory for a specific system named SYSVMA in a z/VM-only complex of systems sharing the source directory, enter:

```
directxa user direct * (edit sysafnid sysvma
```

To compile a USER DIRECT source directory for this system and to suppress the compatibility error messages, enter:

```
directxa user direct * (mixed nomixmsg
```

## Responses

Response 1:

When you enter the DIRECTXA command, you receive the following response:

```
z/VM USER DIRECTORY CREATION PROGRAM - VERSION n RELEASE n.n
```

You then receive Response 2, 3, or 4.

Response 2:

If the directory is updated and CP places the new directory in use, you receive the following response:

```
EOJ DIRECTORY UPDATED AND ON LINE
```

Response 3:

If the directory is written to a CP-formatted DASD that is not the CP-owned volume containing the online object directory, you receive the following response:

```
EOJ DIRECTORY UPDATED
```

Response 4:

You receive the following response if one or more of the following is true:

- You issued DIRECTXA with the EDIT option.
- Your virtual machine does not have the necessary privilege class to change the directory that is in use.
- You attempted to write a directory to the online object directory volume that is not valid in the current system configuration.

- Errors prevented the directory from being updated.

E0J DIRECTORY NOT UPDATED

## Return codes

The DIRECTXA utility issues the following (RC) return codes:

### RC

#### Possible Causes

**0**

DIRECTXA processed successfully. The real user directory has been updated (unless the EDIT option was specified).

**1**

A directory source file was not found on an accessed disk.

**2**

An error was encountered while processing a directory source file.

**3**

A invalid option was specified on the DIRECTXA command line.

**4**

No errors were encountered while processing a directory source file, but one or more of the following conditions exists:

- You do not have the proper privilege class to update the real user directory. To determine if your virtual machine has the proper privilege class to update the real user directory, issue the following CP command and look for the string "DIAG3C" in the response:

```
cp query commands
```

- You have attempted to update the real user directory with an SSI-enabled source directory, which is not valid in the current system configuration.

- You have attempted to update the real user directory with a directory that is not SSI-enabled, which is not valid in the current system configuration.

**5**

Condition code 1 was received from DIAGNOSE X'3C', which means a class A, B, or C user updated a virtual directory.

**6**

Condition code 2 was received from DIAGNOSE X'3C', which means a invalid directory pointer was found in the volume label.

**7**

Condition code 3 was received from DIAGNOSE X'3C', which means a fatal I/O error occurred.

**9**

The directory has been rewritten, but warning messages have been issued.

**> 100**

Return codes greater than 100 may be returned accompanied by message 764—except for code 333, which will not be accompanied by message 764. See the explanation for message 764 for details on these return codes.

**333**

DIRECTXA was run in EDIT mode, and at least one password was changed to NOLOG.

## DISKMAP

### Purpose

Use the DISKMAP utility to summarize the MDISK statements in the user directory. The output produced by DISKMAP shows gaps and overlaps between minidisk assignments.

DISKMAP does NOT replace the EDIT function of the DIRECTXA command. You should use both to check your directory after changes.

Also see the [DIRMAP utility](#) in *z/VM: CMS Commands and Utilities Reference*.

### Operands

#### *fn*

is the file name of the directory to be mapped.

#### *ft*

is the file type of the directory to be mapped. The default is DIRECT.

#### *fm*

is the file mode of the directory to be mapped. The default is an asterisk (\*).

#### DOENDS

causes MDISK statements that had "END" specified for the ending cylinder/block in the directory being mapped to be included in the DISKMAP output file.

### Responses

The output from DISKMAP is a file sent to your A-disk. The file name of the output is the same as that of the target directory. The file type of the output is DISKMAP. The file contains information on MDISK statements found in the directory. The files are in order by volume in the output file. Gaps between minidisks and overlapping minidisks are flagged.

### Usage Notes

1. By default, the DISKMAP utility is located on the cross release utilities disk (PMAINT 551). This disk must be accessed to run the DISKMAP utility.
2. Because some DASD types come in several sizes, DISKMAP does not list gaps found after all minidisks. You need to know the maximum cylinder/block value for your DASD type.
3. DISKMAP creates the map on your A-disk. If your directory is very large and your A-disk is almost filled, you may need to find some extra disk space in order to run DISKMAP.
4. You may choose to include some overlaps in the directory. DISKMAP flags *all* overlaps; you must understand your layout to determine if a particular overlap is expected or in error.
5. If the directory contains MDISK statements with "END" specified as the ending cylinder/block, DISKMAP ignores these MDISK statements and issues a warning message. In order to have these MDISK statements appear in the DISKMAP output file, you need to invoke DISKMAP with the "DOENDS" option.
6. DISKMAP does not allow an asterisk (\*) as an input parameter for a file type.

7. If DEVNO is specified as a starting cylinder for a minidisk statement, the statement will be ignored and a single message for all statements will be issued explaining this. If T-DISK or V-DISK is specified as a starting cylinder, those statements will not be included and no message will be issued.
8. From an authorization perspective, the USERID value specifies the user ID to which the MDISK belongs. For multiconfiguration virtual machine instances, the MDISKS can be defined within either the identity or subconfiguration entries. In both cases the USERID value specifies the name from the IDENTITY statement. If the SUBCONFIG statement is not referenced by any BUILD statement, the USERID value contains a value of \*NOUSER!.
9. The SUBCONFIG value in the output is blank unless the MDISK was defined within a subconfiguration entry.
10. The MEMBER value in the output is \* unless the MDISK was defined within a subconfiguration entry, in which case the value displayed is the system identifier from the BUILD statement. If there is no corresponding BUILD statement, this value is blank.
11. DISKMAP does not perform stringent directory verification. It is assumed that all input directories are verified using DIRECTXA to be valid directories.

## Examples

If the directory contains the following statements:

```

DIRECTORY SSI 123 3390 M01RES M02RES M03RES
*
*****
*
USER $DIRECT$ NOLOG
  MDISK A01 3390 001 020 M01RES R
  MDISK A02 3390 001 020 M02RES R
*
*****
*
*
IDENTITY MAINT      MAINT      128M 1000M ABCDEFG
  BUILD ON TAPE1 USING SUBCONFIG MAINT-1
  BUILD ON TAPE2 USING SUBCONFIG MAINT-2

SUBCONFIG MAINT-1
  MDISK CF1 3390 039 120 M01RES RR READ      WRITE      MULTIPLE
  MDISK CFD 3390 159 001 M01RES RR READ      WRITE      MULTIPLE
* END OF MAINT-1

SUBCONFIG MAINT-2
  MDISK CF1 3390 039 120 M02RES RR READ      WRITE      MULTIPLE
  MDISK CFD 3390 159 001 M02RES RR READ      WRITE      MULTIPLE
* END OF MAINT-2

```

DISKMAP will provide the following minidisk summary in the output file:

```

-----
VOLUME  USERID      CUU  DEVTYPE  START      END      SIZE      GAP  SUBCONFIG  MEMBER
M01RES  $DIRECT$      A01   3390    00001      00020    00020    GAP
                MAINT         CF1   3390    00039      00158    00120    GAP  MAINT-1    TAPE1
                MAINT         CFD   3390    00159      00159    00001    MAINT-1    TAPE1
-----

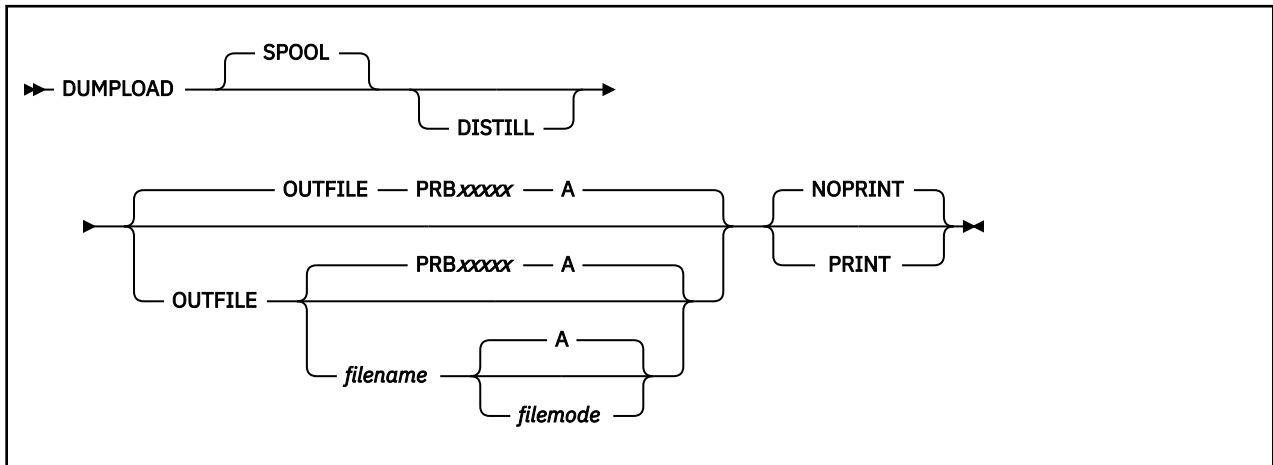

```

```

-----
VOLUME  USERID      CUU  DEVTYPE  START      END      SIZE      GAP  SUBCONFIG  MEMBER
M02RES  $DIRECT$      A02   3390    00001      00020    00020    GAP
                MAINT         CF1   3390    00039      00158    00120    GAP  MAINT-2    TAPE2
                MAINT         CFD   3390    00159      00159    00001    MAINT-2    TAPE2
-----

```

## DUMpload

### Purpose

Use the DUMpload utility to process system abend dumps, stand-alone dumps, and virtual machine dumps. Issue DUMpload to:

- Load a system abend dump from a reader spool file or a reader system data file into a CMS dump file.
- Load a virtual machine dump from a reader system data file into a CMS dump file.

### Operands

#### SPool

indicates the dump to be processed is in a reader spool file or reader system data file. SPOOL is the default.

Before issuing DUMpload, be sure that your reader is at address X'00C', and it is spooled for the correct class for the type of dump you want to process. System abend dumps are class D and virtual machine dumps are class V. Also, be sure that the dump you want to process is in HOLD NONE status. Use the ALL option of the QUERY READER command to display the HOLD status of your reader files as well as other information about dump files in your reader. Also, the ORDER READER command can be used to place the dump you want processed as the first file in the reader queue.

Also make sure that your user ID has the correct privilege class to load a CP dump. To read a CP system abend dump, you need class C or class E authorization. For a virtual machine dump, you need class G authorization. If a dump file exists under a different user ID, ask your operator to transfer that file to your user ID so that your virtual reader can access it.

Each invocation of DUMpload will process only one dump. DUMpload will read the first available reader file that is a dump, matches the specified spool class, and is not in HOLD status. If that dump is of the same release as DUMpload, DUMpload asks you if you want DUMpload to process it. If you answer "NO", DUMpload will terminate without processing the file. If you answer "YES", DUMpload will process the file and then terminate. In either case, the reader file that DUMpload read will now be in USER HOLD status and must be changed to HOLD NONE if you wish DUMpload to process it again.

If the reader is spooled class \*, DUMpload will attempt to find the first available class D system abend dump. If no available class D file is found, DUMpload will attempt to find the first available class V virtual machine dump.

#### DISTILL

extracts an abridged dump from a hard abend dump or a snap dump on a spool file. This option is ignored if the input dump is not a hard abend or a snap dump. An abridged dump is typically much smaller and easier to transmit to IBM support personnel for diagnosis. If the input dump contains a

frame table, this operand causes a correlation table to be created from the frame table and stored in the loaded dump. For both frame table dumps and correlation table dumps, pageable PGMBK pages are omitted if the original dump was taken by using the PGMBKS ALL option. If the original dump was taken by using the PGMBKS FAILUSER option, those PGMBK pages are retained.

The original dump remains on the spool file, and if necessary, the DUMPLD2 utility, or the DUMpload utility without the DISTILL option, can be used later to load the complete dump for transmission to IBM.

### OUTFILE

is a keyword for specifying the file name and file mode of the CMS dump file to be created. You can specify only one CMS dump file on the command line.

### PRBxxxxx

is the default file name of the CMS dump file, where xxxxx is a five-character numeric from 00000 to 99999. The dump is given a file type of DUMP nnnn, where nnnn is 0001 through 9999.

### filename

is the file name of the CMS dump file to be created. It can be any valid CMS file name, but cannot be the same as a DUMpload operand.

### filemode

is any file mode to which you have write access. The default is file mode A.

### PRINT

### NOPRINT

are allowed for compatibility. The PRINT function formerly used to print VMDUMP command dumps of ESA/390 guests is now in the PRTDUMP command of the Dump Viewing Facility. For any other dumps, use the VM Dump Tool to create a DUMPLOG file that can then be printed. See Usage Note [“5” on page 2181](#).

## Usage Notes

1. You can use the CMS dump files you create with the DUMpload command as input for the Dump Viewing Facility or the VM Dump Tool.
2. If you use DUMpload to read a system abend dump or virtual machine dump from a reader spool file or system data file, the system saves the file upon completion of the command processing. In addition the reader is also closed at the beginning as well as at the end of the command processing.
3. All the CMS dump files created from a single virtual machine dump have the same file name. The file type of the first is *DUMP0001*, the second *DUMP0002*, and so on. When several CMS files are created for a virtual machine dump, the file names of related files are put into the CMS dump files. Therefore, you should not rename those files except as a group. Instead, use the OUTFILE option on the DUMpload command to give the set of files the file name you prefer.
4. If DUMpload runs out of space on your disk or file space during the processing of a virtual machine dump for several address spaces, DUMpload stops but does not erase the dump files it has created, including an incomplete one. You can use the Dump Viewing Facility to view the files you do have, or obtain more space and reissue the DUMpload command. It will start from the beginning and recreate all files as if it had never been run. If you do not erase the files you do have, you must specify another file name on the DUMpload command.
5. Even though the printing function formerly in the DUMpload command is now in the PRTDUMP command, the PRINT and NOPRINT options are still allowed for compatibility. If PRINT is specified, DUMpload issues a message informing you that the dump should be printed using the PRTDUMP command. DUMpload ignores NOPRINT.
6. Before you enter the DUMpload command, be sure that you have sufficient space at a read/write file mode or enough SFS file space to hold the CMS dump. Forty-two hundred 4K blocks of SFS file space are needed for each 16 MB of dumped storage. The following chart indicates how many cylinders for CKD/ECKD or blocks for FBA devices of free DASD space you will need for each 16 MB of dumped storage, based upon the device type and the block size of the formatted minidisk. For dumps of less than 16 MB, the number of cylinders or blocks is proportional.

## DUMpload

BLKSIZE	3380	3390	FB-512
512	34	36	52,700
1024	36	34	48,960
2048	31	27	38,880
4096	28	23	33,120

The DASD space requirement shown assumes the dump was produced using a single invocation of VMDUMP. The CMS blocks listed is also the number of free CMS blocks of each size (512, 1024, etc.). When VMDUMP operates in continuous output mode, and page ranges are not dumped in strict ascending sequence, DUMpload must allocate additional DASD space for one or more work files, named xxxxxxxx \$DUMPLD\$, in order to create a merged output file.

Be sure the space allocated for the dump file allows for discontinuous saved segments, if they were requested with the dump. If the dumped address ranges include unreferenced (never used) storage, those pages are excluded, decreasing the storage requirement. Use the number of records in the VMDUMP spool file, which you can obtain using the QUERY RDR command, to estimate the amount of storage actually dumped. The size of VMDUMP spool file records is 4 KB.

7. Use the DUMPLD2 utility as an alternative to DUMpload, to segment a dump into multiple files in order to load or transmit it, especially for larger dumps. The utility will handle all dump types currently supported by DUMpload, except for multiple address space dumps.

You can receive CP or CMS error messages other than those indicated here. Any CMS errors that occur during DUMPLOAD processing are reported by CMS through CMS messages or CMS macro return codes. All prompts and CP error indications are reported through CP messages.

You can find a description of the message you receive in [\*z/VM: CP Messages and Codes\*](#).

## DUMPLD2

### Purpose

Use the DUMPLD2 utility as an alternative to DUMpload, to segment a dump into multiple files in order to load or transmit it. The utility will handle all dump types currently supported by DUMpload, except for multiple address space dumps. Hard Abend, Soft Abend, SNAPDUMP, and VMDUMP will be handled. Stand-alone dumps will also be handled.

### Operands

#### SP00L

indicates dump to be processed is in spool. This is the default.

#### FILE

indicates the dump to be processed is a single CMS file on disk. If you specify FILE, you must enter the file name of the dump and file mode where it can be found. The file type is assumed to be 'DUMP0001'.

#### DASD

indicates the dump to be processed is on DASD and was written by stand-alone dump. You will be prompted to enter the virtual device number of the first device containing the dump. DUMPLD2 will read data from that device and display information about which devices contain the dump. All of those devices need to be defined, attached, or linked, as appropriate, before DUMPLD2 will process the dump.

The DUMPLD2 utility requires all of the real devices that are part of the stand-alone dump configuration to be attached at the same virtual device numbers that were used when SDINST formatted them. If this is not the case, error messages are displayed and the dump is not loaded. To help you set up the devices correctly, the DUMPLD2 utility displays a device table which has a DUMPLD2 VDEV column that shows the virtual device at which the real device must be attached. You can use the CP DEFINE command to change the virtual device number if the device is attached at the wrong number.

If the dump was written to SCSI DASD, you must respond with the virtual device number of the first emulated device (EDEV). Additional dump DASD must be defined at sequential virtual device numbers starting after the first number specified by the user.

#### AUTomatic

indicates that the record count of each output file will be determined by the sizes of the disks specified by the user. The record count will be calculated based on the disk space available on the

specified file modes and virtual device addresses. File modes and virtual device addresses that have less than 65,536 (the 'small' record count) available will be ignored. The smallest available space on any of the remaining file modes or virtual device addresses will be compared to the "small" "medium" or "large" values. The largest of these 3 sizes to fit in that space will be chosen as the record count for each of the CMS files created. This is the default if the record count parameter is omitted.

**SMALL**

indicates the record count of each file will be:

65,536 records, which is approximately .25 G, or 365 cylinders on a 3390 disk.

**MEDium**

indicates the record count of each file will be:

262,144 records, which is approximately 1 G, or 1460 cylinders on a 3390 disk.

**LARge**

indicates the record count of each file will be:

1,048,576 records, which is approximately 4 G, or 5825 cylinders on a 3390 disk.

**OUTfile *fn***

is a keyword for specifying the file name for the CMS files (of file type MDMPxxxx) to be created. If *fn* is omitted, the utility will produce an error message and exit.

**Note:** If 'OUTFILE' is omitted, the multiple dump files will have a file name of format "PRBxxxxx", where "xxxxx" is an unused number from 00000 to 99999, chosen by the utility.

**TO**

is a keyword indicating the disks on which the CMS files should be created (of file type MDMPxxxx). The user may specify file modes or virtual device addresses, or a combination in any order. If the user does not specify any file modes or virtual device addresses after 'TO', the utility will display an error message and exit.

**Note:** If 'TO' is omitted, the MDMPxxxx files will be written to the A disk.

***fmlist***

indicates the set of file modes on which to create the CMS files (MDMPxxxx). Accepted inputs include:

- a blank delimited list: "A D E F"
- a range: "A-F", indicating all R/W file modes in that range are to be used.

If a specified file mode is not accessed or is not R/W, it will be ignored and not used.

***vdevlist***

indicates the set of virtual devices on which to create the CMS files. Accepted inputs will include:

- a blank delimited list of 3 or 4-digit hex values: "0122 125 0121"
- a range: "0121-012E" (3 or 4 digit hex values are accepted)

If a specified virtual device is not attached as a CMS DASD, or is not R/W, it is ignored and not used.

**Note:** The user must have at least one free file mode available so that a virtual device may be accessed if it is not currently accessed.

**\***

indicates that the utility will search for available R/W file modes and use them in order of search sequence.

**Usage Notes**

1. You can use the CMS files you create with DUMPLD2 as input for the VM Dump Tool.
2. If you use DUMPLD2 to read a dump from a reader spool file, the system changes the file to User 'HOLD' status and does not purge it upon completion of the command processing.

3. If DUMPLD2 runs out of file modes or virtual devices during the processing of a dump, DUMPLD2 stops but does not erase the CMS files it has created, including a possibly incomplete one. You can use the VM Dump Tool to view the files you do have, or you can obtain more space and reissue the DUMPLD2 command. It will start from the beginning and recreate all files as if it had never been run – the existing files will be overwritten. If you wish to keep the old files, specify another file name when re-invoking DUMPLD2.
4. After the 'TO' operand, a combination of *fmlist*, *vdevlist* and '\*' may be intermixed in any order.  
For example, "D 0120-012F A-C \*" is valid.
5. You can specify *fmlist* or *vdevlist* for as many file modes or VDEVs as you have – duplicate values will be ignored.
6. Every CMS file that DUMPLD2 produces will have the file type of "MDMPxxxx".
7. If you are processing a Hard Abend dump, the frame table must not span over the first two different unaccessed virtual device addresses.
  - If the first disk specified is an unaccessed VDEV, the frame table must be contained within the multiple files on that VDEV.
  - If the first few disks specified are file modes, the frame table must be contained within the multiple files on these file modes and must not span to an unaccessed VDEV.
8. If one of the file modes specified is an SFS directory, multiple dump files are loaded up to the space limits for that directory. The utility will not calculate in advance how many files will be written or if there will be sufficient space to load the entire dump.
9. 'VMLINK' is used to temporarily access virtual device addresses. The file modes used to temporarily access virtual device addresses are chosen according to the default settings in 'VMLINK'.
10. The order in which file modes, virtual device addresses, or SFS directories are specified after the 'TO' operand is the order to which they are written.

# FORMSSI

## Purpose

Use the FORMSSI utility to create, update, unlock, or display a persistent data record (PDR) on cylinder zero of a disk.

## Operands

### CREATE

specifies that a PDR is to be created. Any existing PDR that does not appear to be in use is overwritten.

### *vdev1*

specifies the virtual device number representing the dedicated volume, full-pack minidisk, or regular minidisk on which the PDR is to be created or modified. The disk must be a 3390 or on a 3390 DASD.

### *ssiname*

specifies the name of the single system image (SSI) cluster. The name can be up to eight characters long and can contain the following characters:

- A-Z
- 0-9

### UPGRADE

specifies that an existing PDR is to be upgraded (for example, when a new release of z/VM is to be installed).

### UNLOCK

specifies that an existing PDR that was left locked by a previous unsuccessful invocation of the FORMSSI utility is to be unlocked.

### DISPLAY

specifies that an existing PDR SSI cluster name and state are to be displayed.

## Options

### FORCE

specifies that a PDR is to be created even if the target device contains a PDR that might be in use.

## Usage Notes

1. By default, the FORMSSI utility is located on the cross release utilities disk (PMAINT 551). This disk must be accessed to run the FORMSSI utility.
2. No special privileges are required to run the FORMSSI utility. However, the utility issuer must have read/write access to the volume on which the PDR resides when using any operand other than DISPLAY. The issuer must have read access to the volume on which the PDR resides when using DISPLAY.
3. The PDR structure allows complete forward and backward compatibility among different releases of z/VM. This compatibility allows the sizes of record structures to increase over time using the

UPGRADE function. However, the UPGRADE function does not accommodate decreasing these structure sizes, and produces an error message if such a change is attempted. z/VM will upgrade the PDR automatically during IPL if the system being IPLed determines that the record structure supported by the system is larger than the record structure in the PDR on disk.

4. The PDR resides on cylinder zero and its location is compatible with the CP allocation record and other data that might also reside on cylinder zero.
5. The PDR must reside on a volume that has been allocated for CP use (through CPFMTXA) and cylinder zero must be allocated as PERM.
6. During system installation, a full-pack minidisk is defined for the DASD volume where the PDR is created. That minidisk address is 141 and is owned by user PMAINT.
7. The "last change:" field in the FORMSSI DISPLAY output will equal a constant of \$LCLSYS\$ when a member is attempting to join the SSI cluster. When set to \$LCLSYS\$, the last change to the current slot was made by the member in that slot.

## Examples

Example 1:

Querying an active PDR on virtual device EFE0 displays the following information:

```
formssi display efe0
HCPPDF6618I Persistent Data Record on device EFE0 (label VMCOM1) is for CLUSTERA
HCPPDF6619I PDR state: Unlocked
HCPPDF6619I time stamp: 04/11/15 21:22:03
HCPPDF6619I cross-system timeouts: Enabled
HCPPDF6619I replacement: None
HCPPDF6619I PDR slot 1 system: VMSYS01
HCPPDF6619I state: Joined
HCPPDF6619I time stamp: 04/11/15 21:22:00
HCPPDF6619I last change: VMSYS01
HCPPDF6619I PDR slot 2 system: VMSYS02
HCPPDF6619I state: Joined
HCPPDF6619I time stamp: 04/11/15 21:21:40
HCPPDF6619I last change: VMSYS02
HCPPDF6619I PDR slot 3 system: VMSYS03
HCPPDF6619I state: Joining
HCPPDF6619I time stamp: 04/11/15 21:21:57
HCPPDF6619I last change: VMSYS03
HCPPDF6619I PDR slot 4 system: VMSYS04
HCPPDF6619I state: Down
HCPPDF6619I time stamp: 04/02/15 17:02:25
HCPPDF6619I last change: VMSYS02
```

Example 2:

Querying an obsolete PDR on virtual device EFEF displays the following information:

```
formssi display efef
HCPPDF6618I Persistent Data Record on device EFEF (label VMCOM1) is for CLUSTERA
HCPPDF6619I PDR state: Obsolete
HCPPDF6619I time stamp: 04/11/15 21:22:03
HCPPDF6619I replacement: EFE0
```

# GENIMAGE

## Purpose

Use the GENIMAGE utility to create text decks containing the following:

- Forms control buffer (FCB) images
- Copy modifications
- Character arrangement tables (CATs)
- Graphic character modifications
- Library character sets.

## Operands

**fn**

identifies the file name of the CMS input control file. The name may be up to eight alphanumeric characters long. If a name is not specified, the default file name is SYSIN.

**ft**

identifies the file type of the CMS input control file. The file type may be up to eight alphanumeric characters long. If a file type is not specified, the default file type is FILE.

**fm**

**\***

identifies the file mode of the CMS input control file. The file mode may be up to two alphanumeric characters long. If a file mode is not specified, the default file mode is \*.

**sfn**

identifies the file name of the file into which GENIMAGE places the message listing. If a name is not specified, the default file name is SYSPRINT.

**sft**

identifies the file type of the file into which GENIMAGE places the message listing. If a type is not specified, the default file type is LISTING.

**sfm**

identifies the file mode of the file into which GENIMAGE places the message listing. If a file mode is not specified, the default file mode is A1.

Below are listed the “starter set” of character sets supplied by IBM for both the 3800 Model 1 and Model 3 printers. They are supplied with VM, and they all have names of the form XTB1xxxx TEXT. They are built during the system generation process.

AN	FM12	GU10	ODA	RN
AOA	FM15	GU12	ONA	SN
AOD	GF10	GU15	ONB	TN
AON	GF12	G11	PCAN	TU10
A11	GF15	HN	PCHN	T11
BOA	GN	H11	PN	XN
BON	GS10	KN1	P11	YN
DUMP	GS12	OAA	QN	2773
FM10	GS15	OAB	QNC	2774

Below are listed the starter set of character sets supplied by IBM for the 3800 Model 3 printer only. They are supplied as both text and source files on the S-disk, and they all have names of the form XTB1xxxx TEST S. They are built during the system generation process.

AE10	EITR	GP12	LR12	SB12
BITR	ESTR	GR10	OB10	SI10
BRTR	GB10	GSC	OR10	SI12
CE10	GB12	GT10	PB12	SO12
CE12	GF10	GT12	PI12	SR12
CO10	GF12	GT15	PR10	ST10
CR10	GF15	GUC	PR12	ST12
DOTR	GFC	LB12	RT10	ST15
EBTE	GI12			

These fonts are described in the *IBM 3800 Printing Subsystem Programmer's Guide*.

The GENIMAGE utility produces two groups of output files. The first is the listing file (*fileid sfn sft sfm* as above) that contains the messages from the GENIMAGE utility. The second is a TEXT deck for each NAME statement in the input file. Below are listed the meanings of the file names of these TEXT decks.

**XTB1xxxx**

For a character arrangement table

**FCB3xxxx**

For a forms control buffer

**MOD1xxxx**

For a copy modification module

## GENIMAGE

### **GRAFxxxx**

For a graphic character modification module

### **LCS1xxxx**

For an image library character set module

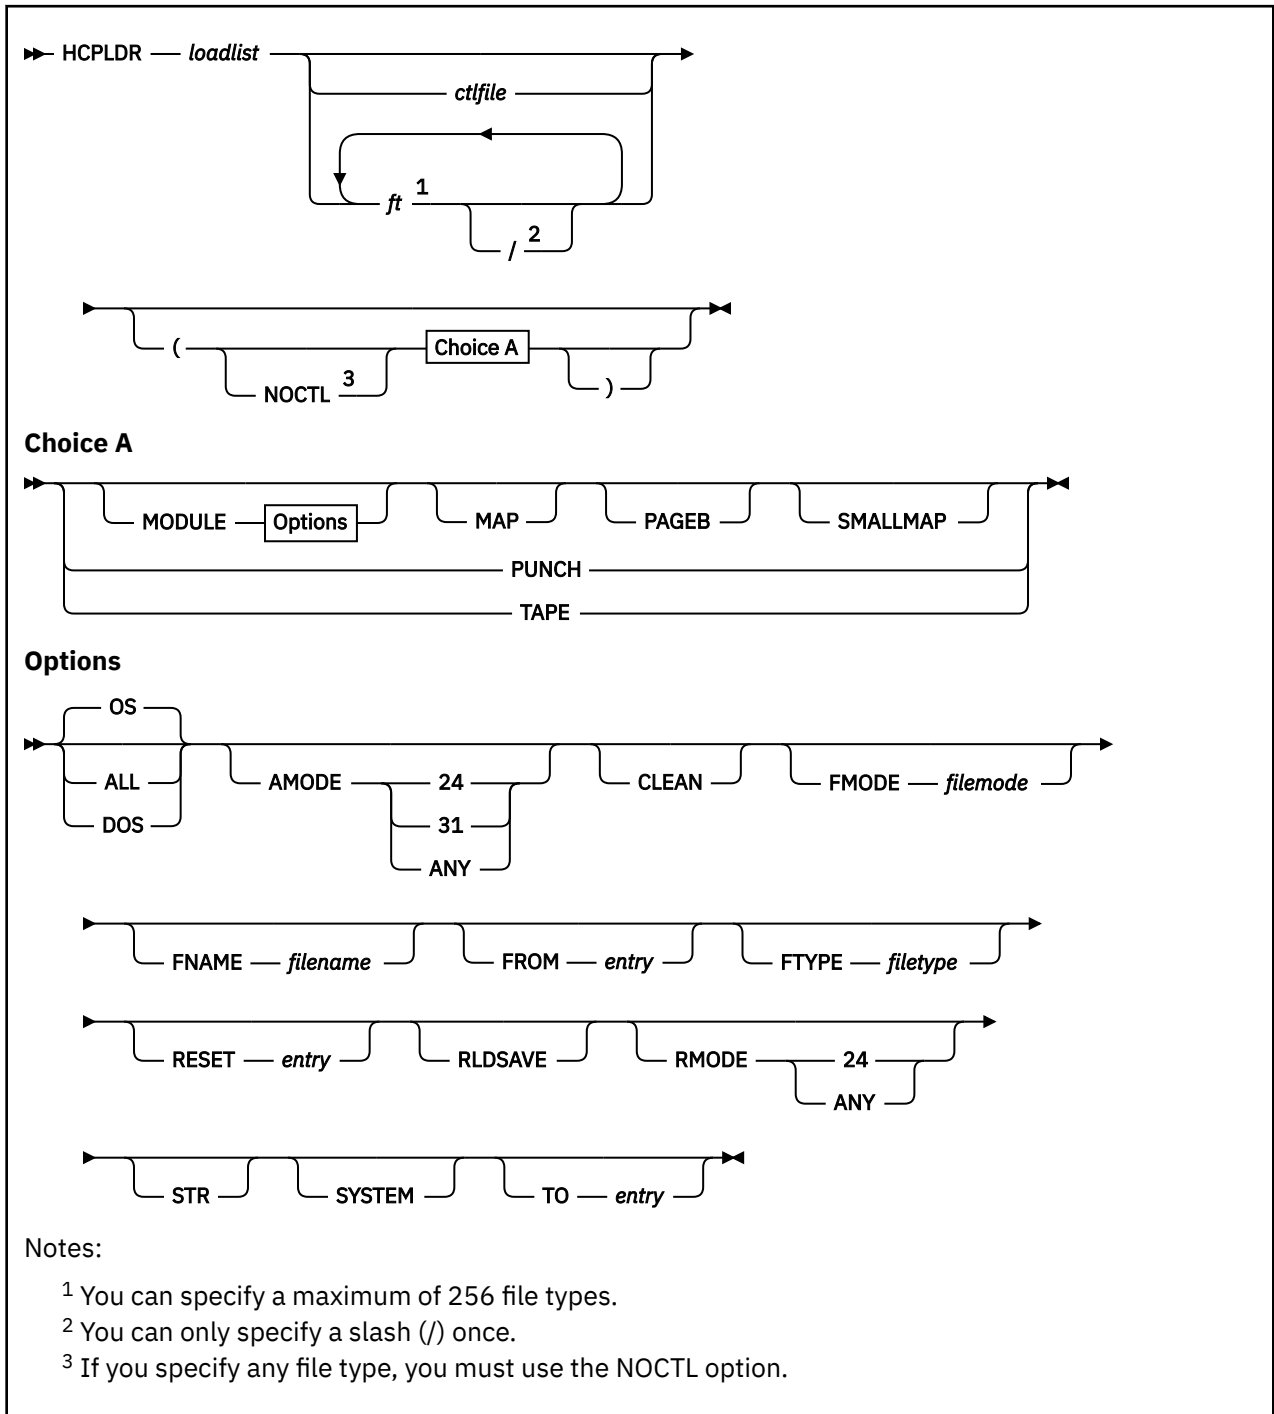

## **Usage Notes**

1. To produce image libraries, you must use the IMAGELIB utility to process the text decks that GENIMAGE creates.

## **Messages**

For information about the messages and return codes from this command, see the *IBM 3800 Printing Subsystem Programmer's Guide*.

# HCPLDR

## Purpose

Use the HCPLDR utility to call and control the system loader to perform one of two possible functions:

- If you enter the HCPLDR command without the PUNCH option or the TAPE option, the loader generates a system (directly under CMS). This means the system loader link-edits all object files and passes control to the program (HCPGEN) that writes the system on the system residence device.

- If you enter the HCPLDR command with either the TAPE option or the PUNCH option, the loader creates a continuous card deck beginning with a three-card loader, continuing with a stand-alone version of the system loader, and ending with the object files belonging to the system to be generated. When you enter HCPLDR with the TAPE or PUNCH option to generate CP, the loader does not link-edit object modules and does not pass control to HCPGEN to write the system on the system residence device.

Issue the HCPLDR command under CMS.

**Attention:** You should use the VMFBLD EXEC to build nuclei. If you use the HCPLDR command, it does not load any serviced text decks contained in the nucleus. The HCPLDR command does not support loading text decks by PTF number.

## Operands

### *loadlist*

is the file name of the load list EXEC file. It contains the names of the object files in the order in which they are to be loaded. The load list may look like this.

```
&CONTROL OFF
&1 &2 &3 HCPLDR LOADER
&1 &2 &3 fn [ft]
&1 &2 &3 fn [ft]
⋮
```

*fn* and *ft* are the file name and file type of an object file. The *ft* is optional. If *ft* is omitted, HCPLDR searches the control file or an explicit list of file types to determine the file type.

HCPLDR LOADER must always be the first file. HCPLDR loads each object module in order from the top of the load list to the bottom.

You can place most loader control statements in the load list EXEC file. You cannot place VERIFY, REPLACE, or INCLUDE CONTROL SECTION statements in the EXEC file. A loader control statement begins with a 12-2-9 punch (X'02'). Whenever HCPLDR encounters X'02' in the first column of a record, it interprets that record as a control statement. For more information see Appendix D in [z/VM: CP Commands and Utilities Reference](#).

### *ctlfile*

is the file name of the control file.

HCPLDR uses the update level identifiers in the control file to determine the file type for those object modules listed in the load list without file types. The command skips the MACS record in the control file and searches for update level identifiers from the top of the control file down. If HCPLDR finds an update level identifier other than TEXT, the command appends the identifier to TXT to create a file type, then searches for the file (*fn* TXTxxxx). If HCPLDR cannot find an object file that has the first update level identifier, the command finds the next identifier and continues the search. As a last resort, when HCPLDR cannot find the object file according to update level identifiers, the command searches for *fn* TEXT. For example, if the control file is:

```
TEXT MACS HCPGPI HCPSI HCPOM1 HCPOM2 DMSGPI DMSOM OSMACRO
SPEC AUX1111
IBM1 AUXVM
```

HCPLDR follows this search order:

```
fn TTXSPEC
fn TTXIBM1
fn TEXT (last resort)
```

If an asterisk (\*) or a period appears in the first column of a control file record, HCPLDR ignores the record. The command also ignores update level identifiers of PTF.

### *ft* [./] [...*ft*]

is a list of file types (up to 256) that you want HCPLDR to use in lieu of a control file. HCPLDR establishes a search order from left to right. The list of file types can be null, in which case a file type must be specified for each object module in the load list EXEC.

If you place a slash (/) anywhere in the file type list, HCPLDR notifies you when it loads an object module that has the same file type as the one that is to the left of the slash.

You must use the NOCTL option if you specify file types directly on the HCPLDR command line.

For example, assume you want to establish the following search order for HCPLDR:

```
fn TXT1
fn TXT2
fn TXT3
```

You also want to be notified when HCPLDR uses file type TXT1 or TXT2. You are using the load list CPLOAD EXEC. You would enter the following command:

```
hcpldr cpload txt1 txt2 / txt3 (noctl
```

When you enter a list of file types on the command line, HCPLDR does not automatically look for *fn* TEXT.

## Options

### NOCTL

allows you to specify a list of file types to be used in the search in place of using a control file.

### MODULE

requests that the object files be linked together as a module and be written to disk. The file name of the module will default to the name of the loadlist, the file type will default to MODULE and the file mode will default to A. The default file name, file type, and file mode may be overridden by using the FNAME, FTYPE, and FMODE options.

### MAP

requests the production of a load map during the loading process. This map is written in the file *loadlist* MAP A1. It is a variable length file with ASA carriage control and a maximum record length of 133 characters.

### PAGEB

requests the unconditional page boundary be initialized to 4 KB. The lower three hexadecimal digits of the address are the same as the assembled address for any single CSECT assembly. Use PAGEB only for systems that you are testing.

### SMALLMAP

requests the production of a smaller version of the standard load map (MAP option) during the loading process. The smallmap is written in the file *loadlist* SMALLMAP A1. It is a variable-length file and contains one line for each csect that was included. Both MAP and SMALLMAP can be specified at the same time. SMALLMAP cannot be used with the PUNCH or TAPE option.

### PUNCH

requests the object files be punched on the punch at virtual address 00D. A CP CLOSE command is issued when all of the object files have been punched.

### TAPE

requests the output of object files be placed on a tape drive at virtual address 182.

### OS

indicates the program may contain OS macros and therefore should be run only when CMS/DOS is not active. OS is the default.

### ALL

indicates that one or more of the following are true about the program:

- It contains CMS macros and must be capable of running regardless of whether CMS/DOS is active
- It contains no VSE or OS macros
- It preserves the value of the DOS flag on entry into the CMS nucleus, and, if it modifies that value, resets it on exit
- It does its own setting of the DOS flags.

**Note:** The ALL option is primarily for use by CMS system programmers. CMS system routines know which environment is active and preserve and reset the DOS flag in the CMS nucleus.

**DOS**

indicates the program contains VSE macros; CMS/DOS must be active (that is, SET DOS ON must have been previously invoked) for this program to run.

**AMODE**

specifies the addressing mode in which the program will be entered. The AMODE defined by this option is placed in the header record of the MODULE file being created.

If you specify RMODE but do not specify AMODE, the AMODE for the MODULE is determined from the following default criteria:

- If you specify RMODE ANY, the AMODE specification defaults to AMODE 31.
- If you specify RMODE 24, the AMODE defaults to the AMODE of the entry point determined by the LOAD process.

If you specify neither AMODE nor RMODE, the AMODE for the module defaults to 31.

The valid AMODE values and their meanings are as follows:

**24**

This entry point is to receive control in 24-bit addressing mode.

**31**

This entry point is to receive control in 31-bit addressing mode.

**ANY**

tells HCPLDR that the specified entry point is capable of operating in either 24-bit or 31-bit addressing mode. It will receive control in the addressing mode of its caller. If the module is run by name from the command line or from an exec, it will receive control in 31-bit addressing mode.

**CLEAN**

tells CMS to erase the module from storage at the end of its execution. This option will work only for modules running under CMS. CLEAN is the default for relocatable modules.

**Note:** You cannot specify the CLEAN option for nonrelocatable modules.

**FMODE *filemode***

specifies the file mode of the module being generated. If omitted, *filemode* defaults to A.

**FNAME *filename***

specifies the file name of the module being generated. If omitted, *filename* defaults to the name of the load list.

**FROM *entry***

specifies an entry point or a control section name that represents the starting virtual storage location from which a nonrelocatable MODULE is generated.

**FTYPE *filetype***

specifies the file type of the module being generated. If omitted, *filetype* defaults to MODULE.

**RESET *entry***

sets the starting location for the module. The operand *entry* must be an external name (for example, CSECT control section or ENTRY) in the module. If RESET is not specified, the default entry point is used.

**Note:** You should not use the RESET option when creating a module from text files created by any of the following OS/VS language processors under CMS:

- OS Code and Go FORTRAN
- OS FORTRAN IV (G1)
- OS FORTRAN IV (H) Extended
- OS/VS COBOL Compiler and Library
- OS Full American National Standard COBOL Version 4 Compiler and Library.

**RLDSAVE**

instructs HCPLDR to save the relocation information from the text files and to create a relocatable module.

**RMODE**

specifies the location in virtual machine storage where the loaded MODULE is to reside.

If you specify AMODE but do not specify RMODE, the RMODE for the module defaults to 24.

If you specify neither AMODE nor RMODE, the RMODE for the module defaults to ANY.

The valid RMODE values and their meanings are as follows:

**24**

The load must reside below the 16 MB line, overriding the RMODE determined by the LOAD process. A definition of RMODE 24 would be reflected in the MODULE header record.

**ANY**

The load may reside above or below the 16 MB line, overriding the RMODE determined by the LOAD process. A definition of RMODE ANY would be reflected in the MODULE header record.

**STR**

deletes previously loaded non-OS programs when used in conjunction with the NOPRES option on the CMS LOADMOD command.

**SYSTEM**

indicates that when the MODULE file is subsequently loaded, it is to have a storage protect key of zero.

**TO entry**

specifies an entry point or a control section name that represents the ending virtual storage location from which a nonrelocatable MODULE is generated.

**Usage Notes**

1. When you use the system loader as a system generator, your virtual machine must have sufficient storage to contain CMS **plus** the entire system you are generating. If the system is too large to generate directly, use the stand-alone version of the system loader.
2. Using the PAGEB option improves the debugging task because it eliminates needless arithmetic (the lower three hexadecimal digits of the load address is the same as the assemble address). Note, however, that PAGEB should only be used for testing purposes because the option wastes storage.
3. After the new nucleus or module resides on the system residence device, you can shut down your present system (with the SHUTDOWN command) and perform a hardware load of the new system.
4. The following response will appear if you create the CP module with the MAP option but without the PAGEB option:

```
CSECT'S WITH SIZE GREATER THAN CONDITIONAL PAGE BOUNDARY
@MAPSTRT xxxxxxx
```

This response is for information only and is no cause for concern unless other CSECTs are listed. If other CSECTs are listed, notify the IBM Support Center.

5. Although the RLDSAVE operand is accepted when generating the CP module, it has no effect on CP. CP will always relocate itself back to X'2000'.

# IMAGELIB

▶ IMAGELIB — *libname* ◀

## Purpose

Use the IMAGELIB utility to create or replace an image library with images in text decks. The output image library can then be referenced by a printer by issuing the START command with the IMAGE option for the printer.

## Operands

### *libname*

identifies in one to eight characters the image library that you want to create or replace. This name is also the name of the new or replacement library. The control file that lists the members that you want to create or replace also must have this name as its file name (see Usage Note “2.b” on page 2201).

## Usage Notes

1. The IMAGELIB utility can invoke one or more CP commands that require a user privilege class other than G.
2. Before you enter the IMAGELIB command, you must do two things:
  - a. First, follow the procedure that applies to your type of printer.
    - For 3800 images, enter the GENIMAGE utility to create the text decks that contain the images for the new library.
    - For impact printer images, code the appropriate FCB or UCS macro in an ASSEMBLE file. Assemble this file to create the TEXT deck for each image.
  - b. Create a control file whose file name is the same as the IMAGELIB you want to build, and whose filetype is CNTRL. The format of this file is one statement per TEXT deck you want to include, with the names of the decks in columns 1 through 8.
3. You may use the IMAGELIB utility with these printers:
  - 1403
  - 3203
  - 3262
  - 3800
  - 4245
4. Using VMRELOCATE for a virtual machine that might be using this function is not recommended and may have undesired results. If a virtual machine reads an IMAGELIB and is then relocated to another system, any subsequent save of that IMAGELIB will be written out to a different system, not the one from which it was read.

## Messages

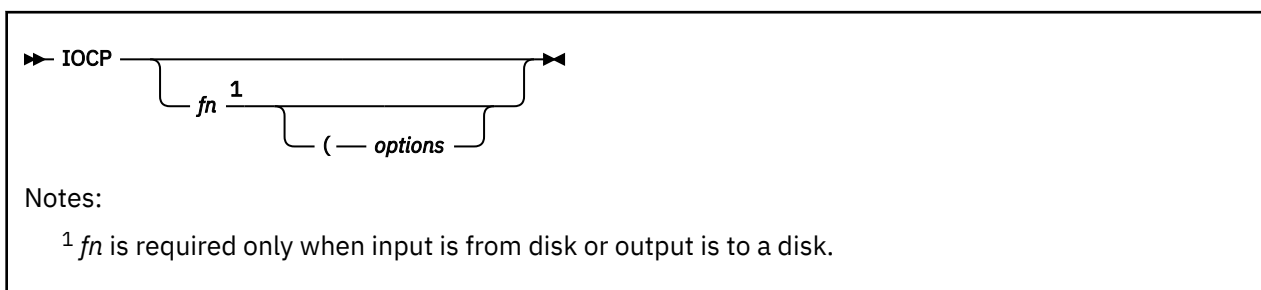

- HCP247I NAMED IMAGE *imagename* CREATED
- HCP248E SPECIFIED IMAGE *imagename* NON-EXISTENT
- HCP249E ERROR LOADING IMAGE *imagename*
- HCP253E RESIDUAL BYTE COUNT = *nnnnnnnn* (HEX)
- HCP254E ERROR SAVING *imagelib*

## IMAGELIB

- HCP759E INSUFFICIENT VIRTUAL STORAGE

**Note:** If the control file discussed in Usage Note [“2.b” on page 2201](#) does not exist or is not valid, IMAGELIB issues a return code of 4 in register 15, but does not enter an error message.

## IOCP

### Purpose

Use the IOCP utility to call the input/output configuration program for the following reasons:

- To generate a new input/output configuration data set (IOCDS) from a file containing source IOCP statement
- To produce configuration reports from an existing IOCDS

### Operands

#### *fn*

is the name of the file that contains the source IOCP statement or of the output listing file, depending on the options you specify. *filetype* must be IOCP.

#### *options*

are the options passed to the IOCP utility. The IOCP utility consists of a front-end IOCP exec that examines and possibly alters the IOCP input file before giving control to the IOCP program. The options that are listed here are only used and interpreted by the front-end IOCP exec. They are not passed on to the IOCP program. The options for the IOCP program are not described here. For a complete description of the IOCP program options, see the *IBM Z: Input/Output Configuration Program User's Guide for ICP IOCP*.

#### **DYN**

is an outdated option. Specifying DYN or NODYN no longer has any effect on the operation. Doing so only triggers a warning message. The issuer's privilege class now determines whether dynamic changes are allowed to their I/O configuration, not DYN and NODYN. See Usage Note "3" on page 2204 for more details.

#### **NODYN**

is an outdated option. See the description of the DYN parameter for more details.

#### **DESC1 string**

indicates that you want the specified string to be stored in the first descriptor field of the hardware configuration token. The string can be up to eight characters and cannot contain blanks.

#### **DESC2 string**

indicates that you want the specified string to be stored in the second descriptor field of the hardware configuration token. The string can be up to eight characters and cannot contain blanks.

### Usage Notes

1. For more information about using the IOCP utility and making dynamic changes to your I/O configuration, see *z/VM: CP Planning and Administration*. For additional information about the IOCP program, see *IBM Z: Input/Output Configuration Program User's Guide for ICP IOCP*.
2. If the IOCP front-end exec terminates without invoking the IOCP program, an error return code of the format (1000+nnn) is generated. The nnn value provides additional information about the problem that was encountered:

**nnn****Description****sss**

Changes to the IOCP file could not be saved. This value is the error return code received from the XEDIT SAVE command. See *z/VM: Enterprise Systems Architecture/Extended Configuration Principles of Operation* for additional information as to the nature of the problem.

The IOCP program will also generate return codes. For details on the return codes, see *IBM Z: Input/Output Configuration Program User's Guide for ICP IOCP*.

3. If you want to create an IOCDs that will allow dynamic changes to your I/O configuration, you must have privilege class B so that the CP QUERY TOKEN command can be used. The front-end IOCP exec examines and changes the IOCP file to ensure a valid hardware configuration token is present in the IOCP file before invoking the IOCP program. The IOCP file must be on a read/write disk so that the change to the IOCP file can be saved. If the change cannot be saved, the front-end IOCP exec will terminate without invoking the IOCP program.

If you do not have the correct privilege class to make dynamic changes to your I/O configuration, the IOCP file will be examined; and if the IOCP file contains a hardware configuration token, it will be removed before invoking the IOCP program. If the IOCP file contains a hardware configuration token that must be removed, then the IOCP file must be on a read/write disk so that the change can be saved. If the change cannot be saved, the front-end IOCP exec will terminate without invoking the IOCP program.

## IOEXPLOR

### Purpose

Use the IOEXPLOR utility to obtain device information. For IBM devices, this utility formats device characteristics obtained from the CP QUERY EDEVICE and QUERY DASD commands. For non-IBM devices, data which is not vendor specific will be formatted.

### Operands

**rdev**

**rdev1-rdev2**

Specifies the devices for which you want information to be displayed. A device in the active configuration can be entered as a 4-digit hexadecimal device number between X'0000' and X'FFFF'. For a device in the active or standby configuration, the device can be a 5-digit hexadecimal number between X'00000' and X'3FFFF' with the leading digit specifying the subchannel set. A range of devices cannot span subchannel sets.

### Options

#### CHARacteristics

Returns characteristic data for a device.

- For a connected EDEVICE, this data is selected from standard inquiry data, unit serial number page (80), device identification page (83), and Read Device Characteristics data. For IBM devices, the data is formatted to the console. For non-IBM devices, data which is not vendor specific will be formatted to the console. Control will be given to a vendor format routine if one exists.
- For a FICON-connected device, output from Read Device Characteristics and Read Configuration Data is formatted to the console.

#### PAGE *page*

Use the PAGE option to specify a vital product data page (*page*) to have that data returned for a connected emulated device. The *page* value must be a hexadecimal number between X'00' and X'FF'. The data returned is a hexadecimal data block unless a format routine exists. Format routines can be written for each device manufacturer, one per manufacturer, to format the output from the QUERY EDEVICE command for specific vital product data pages.

#### DEBUG

displays general and diagnostic information during program execution. Results of this option are subject to change.

### Format Routine

IOEXPLOR calls a format routine if the PAGE option is specified. This routine could format the hexadecimal output from the QUERY EDEVICE command with the INQUIRE option specified. The routine has a file name that consists of the manufacturer's name concatenated with "DEVF". If the name consists of more than four characters, only the first four characters will be used. The file type must be EXEC.

For IBM devices, the data from the serial number page (80) and the device identification page (83) is formatted by the IOEXPLOR utility.

IOEXPLOR will call the routine with the specified page number and the hexadecimal data returned from the QUERY EDEVICE command. The output is obtained from the data returned by the SCSI INQUIRY command. Parts of the response are vendor-specific and could vary from one vendor to another. Consult your vendor documentation if you plan to supply a custom formatting routine. IOEXPLOR will format the data that is not vendor specific.

It is expected that the routine will format the data as desired and display it on the console.

## Usage Notes

1. This utility issues the QUERY EDEVICE command and the QUERY DASD command, which require class B privilege.
2. The maximum length of the inquiry response data display is 255 bytes.
3. When the CHARACTERISTICS option and the PAGE option are both specified, the PAGE option is ignored for FICON-connected devices.
4. When a range of devices is specified, information about each device is displayed.
  - a. All emulated devices will have the requested CHARACTERISTICS data and PAGE information. If a device in the range does not support the requested page, an error message will be displayed for that device.
  - b. All FICON-connected devices will have the requested CHARACTERISTICS data returned. If the PAGE option was specified, it will be ignored. If only PAGE data was requested, an error message will be displayed for each device.
  - c. If a device in the range does not exist, an error message is displayed for that device.

## Responses

Response 1:

The following is a flash system example.

```
IOEXPLOR 0125 or IOEXPLOR 0125 CHAR

-Begin: Characteristics Data for device 0125
Serial Number _____ 052a62e2052a-0000-0027-000029
      Standard Inquiry Data
Peripheral Qualifier/Peripheral Device Type __ 000b/00h
Vendor Identification _____ IBM

-End: Characteristics Data for device 550A

```

## Response 5:

The following is an example of using the PAGE option with an XIV device. PAGE 83 is formatted by IOEXPLOR.

```
IOEXPLOR 0500 PAGE 83

-Begin: Characteristics Data for device 500
      Device Identification
Peripheral Qualifier/Peripheral Device Type _____ 000b/00h
Extended Unique Identifier _____ 0017380030BB03A7
Company Identification _____ IBM
Model Type _____ 2810XIV
Plant of Manufacture _____ 78
Machine's Serial Number _____ 030BB
Volume Identification _____ 03A7
-End: Characteristics Data for device 500
```

## Response 6:

The following is an example of using the PAGE option with a Flash device. In this case, page 00 is not formatted by IOEXPLOR because it is not one of the supported pages. The hexadecimal data from the QUERY EDEVICE command is displayed.

```
IOEXPLOR 0125 PAGE 00

- Begin - EDEV 0125 - Vital Product Data Page 00 -
00000006 00808386 B0B1
- End - EDEV 0125 - Vital Product Data Page 00 -
```

## Response 7:

Some variations in the returned information, where 019A is a FICON-connected device.

## 1. IOEXPLOR 019A PAGE 00

Returns: HCP972I The PAGE option is not valid for device 19A

## 2. IOEXPLOR 019A CHAR PAGE 00

Returns the CHARACTERISTICS data for 019A and ignores the PAGE option.

## Response 8:

Some variations in the returned information, where 019A is a FICON-connected device, 019B is an emulated device, and 019C does not exist.

## 1. IOEXPLOR 019A-019C CHAR

- Returns CHARACTERISTICS data for 19A and 19B
- Returns: HCP040E Device 019C does not exist

## 2. IOEXPLOR 019A-19C CHAR PAGE 00

Returns similar results as the previous example and the emulated device 019B would also display the hex data for page 00.

## Messages

- HCP040E Device *rdev* does not exist
- HCP970E Invalid range specified
- HCP971E Missing operand(s)
- HCP972I The PAGE option is not valid for device *rdev*
- HCP974E *option* is not a valid command line option

## IPWIZARD

---

▶ IPWIZARD ◀

### Purpose

Use the IPWIZARD utility to create a minimal TCP/IP configuration that establishes basic connectivity to your IP network. The command displays a panel requesting network information. After you fill out the panel, the information is processed and the TCP/IP SYSTEM DTCPARMS, TCPIP DATA, and PROFILE TCPIP files are created.

### Usage Notes

1. IPWIZARD requires access to the MAINT 193 and 2CC minidisks. This utility is intended to be used only as part of a z/VM system installation procedure.

### Messages

- HCP8300E FILE *filename filetype* NOT FOUND
- HCP8312E ERROR DISPLAYING HELPFIELD *name*
- HCP8330E DEVICE ADDRESS MUST BE BETWEEN *addr1* AND *addr2*

Refer to [IPWIZARD Messages](#) in *z/VM: TCP/IP Messages and Codes* for information about the DTCIPW messages you may receive.

## MIGR51D

►► MIGR51D ◄◄

### Purpose

Use the MIGR51D utility to update the System Software Inventory files for this z/VM release from the inventory files of your previous z/VM release. MIGR51D displays panels that allow you to select which products and segments to migrate and not to migrate.

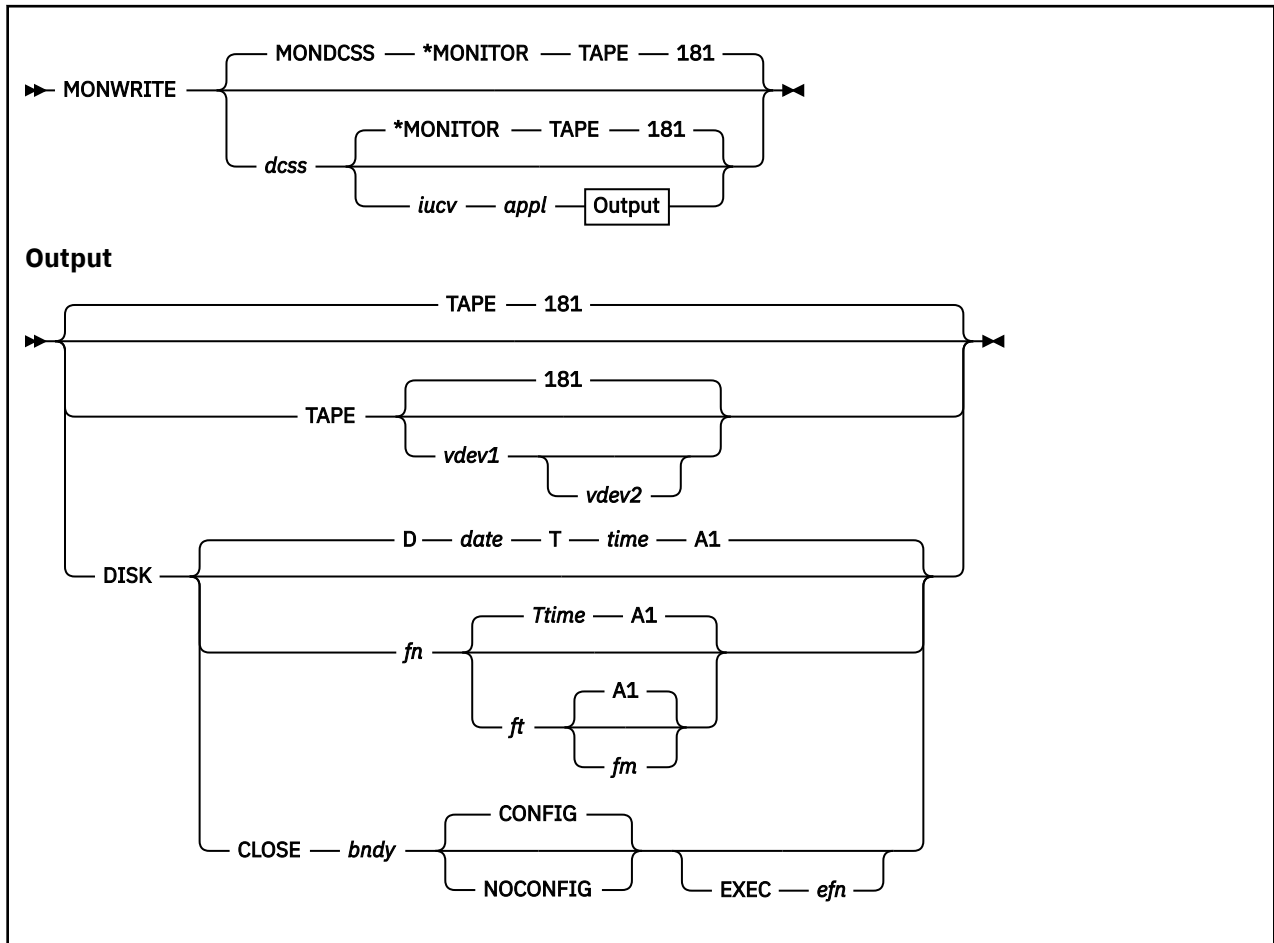

### Usage Notes

1. By default, the MIGR51D utility is located on the system tools disk (MAINT 193). MIGR51D requires write access to the MAINTvrm 51D minidisk. This utility is intended to be used only as part of a z/VM system installation procedure.
2. The MIGR51D utility logs issued messages and commentary about its principal actions (file copy, rename, or updates) in a MIGR51D MSGLOG file.
3. If errors arise during MIGR51D program execution, review the MIGR51D MSGLOG file for detailed information about files that might need to be renamed to allow for a successive MIGR51D command to complete successfully.

### Messages

- IUG8992E *command* processing completed unsuccessfully (RC=*rc*)

## MONWRITE

### Purpose

Use the MONWRITE utility to retrieve monitor records from the monitor saved segment and store them in a CMS file or on a tape.

To stop the MONWRITE utility, use the MONWSTOP command. See “MONWSTOP” on page 2216 for more information.

### Operands

#### *dcss*

identifies the saved segment defined and saved for monitor. MONDCSS is the default name.

#### *iucv*

identifies the IUCV server that notifies the monitor writer about data in the saved segment. \*MONITOR is the default server.

#### *appl*

identifies the IUCV application program running in the virtual machine specified by *iucv*. This option is required if you specify *iucv* and is not allowed if you specify \*MONITOR.

#### TAPE

specifies that the output will be written on a tape. TAPE is the default.

#### *vdev1*

specifies the virtual device number of the first tape on which the output will be written. The default virtual device number is 181.

If *vdev2* is not specified (that is, only one tape is to be used), and *vdev1* becomes full, it rewinds and unloads from the tape drive and MONWRITE waits for a new tape to be mounted.

**vdev2**

specifies the virtual device number of the second tape on which the output will be written when the first tape, *vdev1*, becomes full. When *vdev2* becomes full, MONWRITE reuses the first tape, *vdev1*.

**DISK**

specifies that the output will be written to a CMS file.

**Ddate Ttime**

specifies the default date and time used for the file name and type of the monitor data file.

The format for the file name is *Dmmdyy*, where *mm* is the month (1-12), *dd* is the day (1-31), and *yy* is the last two digits of the year when the file was created.

The format for the file type is *Thhmmss*, where *hh* is the hour (00-23), *mm* is the minute (0-59), and *ss* is the second (0-59) when the file was created.

**fn ft fm**

identifies the file name, type, and mode of the CMS file to which the output will be written. The default is *Ddate Ttime A1*, where *date* and *time* are the date and time, respectively, when the file was created.

**CLOSE**

specifies that the output file containing the monitor records will be closed and a new file is created at interval *bdy*.

**bdy**

specifies an interval, in minutes, between 15 and 1440. Starting at midnight, at each such interval, the next time CP emits monitor sample records, MONWRITE closes the file and starts a new one.

**CONFIG**

specifies that each file created contains monitor configuration data. The connection to monitor is severed and reestablished upon each close and open.

**NOCONFIG**

specifies that only the first file created will contain monitor configuration data. The connection to monitor will not be severed between closing the old file and creating the new.

**EXEC**

indicates that a user exit EXEC will be executed.

When a user exit is invoked, the following parameters are passed:

- The file name and file type of the file closed just prior to the call of the user exit.

**efn**

specifies the user exit that will be executed. *efn* must be a CMS EXEC file with file name *efn* and file type EXEC. The default CMS file search order is used to determine where the EXEC file is located.

**Usage Notes**

1. To use the MONWRITE utility, the IUCV server (\*MONITOR, for example) must be specified on an IUCV statement in your directory entry.
2. MONWRITE connects to \*MONITOR in shared mode. It writes event data as long as it is active.
3. If other users are connected to \*MONITOR in shared mode, the name of the saved segment specified on the MONWRITE utility must be the same saved segment. (Issue QUERY MONITOR to determine the current saved segment.)
4. If another user is already connected in exclusive mode, the MONWRITE utility fails and a message is issued indicating that \*MONITOR severed the connection.
5. When the DISK operand is specified, the file name of the output file cannot be CLOSE.
6. The following considerations apply to the use of the CLOSE operand:
  - DISK must be specified. If TAPE is specified, an error message is issued and processing of the MONWRITE utility halts.

## MONWRITE

- The default date *Ddate* and time *Ttime* will be used for the file name and file type of the monitor data files.
  - The digits representing seconds in the time stamp, which make up the file type, are not significant and could vary from 0 to 59.
  - When a time zone change occurs, the current file is closed and a new file is opened. The time stamp of the new file is set according to the new time zone.
  - The *bdy* interval you specify is honored at only a moment when CP emits sample records. For example, suppose you enter CP MONITOR START at 15:35 and you specify a monitor sample interval of 30 minutes. This means monitor sample records arrive at *hh:35* and *hh:05*. Now suppose you enter MONWRITE CLOSE 60. Because the monitor sample interval occurs at *hh:05*, the MONWRITE file will be closed at *hh:05*.
7. The format of the MONWRITE output is described in *z/VM: Performance*; see [The MONWRITE Program](#) for more information.
  8. For tape output devices, MONWRITE uses the mode setting that exists for the device before you start the command. To obtain the proper mode setting, enter the TAPE MODESET command, specifying the TRACK and DENSITY parameters you want, for each device MONWRITE uses before using the MONWRITE utility.

When writing across multiple tape reels, it is possible for MONWRITE to miss data as it waits for a new tape to be mounted. It is recommended that two tape drives be mounted so that MONWRITE does not lose any data.
  9. CMS recognizes symbolic names for certain virtual devices, so you can use a symbolic name as the virtual device. For example, TAP1 is equivalent to 181.

### Examples

1. To collect data and send it to tape 181, enter:

```
monwrite
```

**Note:** This form of the command provides the easiest operation for the IBM 3480 tape drive with the cartridge stacker loader, which handles end-of-tape conditions automatically.

2. To collect data and send it to a disk file with a file ID that contains the date and time, enter:

```
monwrite mondcss *monitor disk
```

3. To collect data on tape using addresses 181 and 185, enter:

```
monwrite mondcss *monitor tape 181 185
```

4. In this example, you want to collect data from a monitor DCSS called CPMON.

- The IUCV server is running in the USERVM virtual machine.
- The name of the application program, as specified in the HNDIUCV SET macro, is WALKMON.
- Output goes to the file ID SPECIAL MONFILE C0. If this file already exists, MONWRITE appends the data to the end of the file.

Be sure to access your C-disk, then enter:

```
monwrite cpmo uservm walkmon disk special monfile c0
```

## MONWSTOP

---

► MONWSTOP ◄

### Purpose

Use the MONWSTOP command to cause the MONWRITE program to stop processing, close the output file, and exit normally.

### Usage Notes

1. To use the MONWSTOP command, the IUCV server (for example, \*MONITOR) must be specified on an IUCV statement in your directory entry.
2. MONWSTOP is a CMS immediate command.
3. You can also stop MONWRITE from processing by issuing the following CP command to cause an external interrupt:

```
#cp external
```

4. If the IUCV server specified on the MONWRITE command is the CP monitor system service, \*MONITOR, and no other users are connected, data collection goes to a pending state.
5. For normal system termination, issue the MONWSTOP command before you shut down the system. You should receive message HCP6265A indicating that MONWRITE has successfully connected to IUCV. If not, use the #CP EXTERNAL command to stop MONWRITE, because MONWRITE may not be ready to recognize the MONWSTOP command. If the MONWSTOP command is processed when MONWRITE is not ready to recognize it, it is ignored by MONWRITE. It is stacked by CMS for future processing—that is, it remains in the program stack until MONWRITE is successfully stopped by other means. If MONWRITE is not ready to recognize the #CP EXTERNAL command as well, CP passes the external interrupt to CMS for processing. See [“EXTERNAL” on page 469](#) for more information.
6. You may use the CMS HX immediate command to stop MONWRITE, but the output file is left in an unpredictable state.

### Messages

## MOVE2SFS

### Purpose

Use the MOVE2SFS utility to move data from minidisks to the Shared File System servers (SFS) and optionally reclaim the minidisk space. MOVE2SFS creates the subdirectories on the VMSYS file pool that each component needs and then copies the data from the minidisks to the correct subdirectories. The System-Level Software Inventory tables VM SYSRECS and VM SYSAPPS are updated.

### Operands

#### VM

If VM is chosen, all nine components of VM will be copied from minidisks to SFS.

#### RSCS

If RSCS is chosen, the data for RSCS will be copied from minidisks to SFS.

#### TCPIP

If TCPIP is chosen, the data for TCPIP will be copied from minidisks to SFS.

#### ICKDSF

If ICKDSF is chosen, the data for ICKDSF will be copied from minidisks to SFS.

#### DIRM

If DIRM is chosen, the data for DirMaint will be copied from minidisks to SFS.

#### RACF

If RACF is chosen, then the data for RACF will be copied from minidisks to SFS.

#### PERF TK

If PERF TK is chosen, the data for Performance Toolkit for z/VM will be copied.

#### VMHCD

If VMHCD is chosen, the data for VMHCD will be copied from minidisks to SFS.

### Options

#### RECLAIM

reclaims minidisks of moved items by commenting out their entries in the directory specified, bringing the directory online, and detaching the minidisks.

#### *userdir*

is the file name of the directory file. USER is the DEFAULT.

### Usage Notes

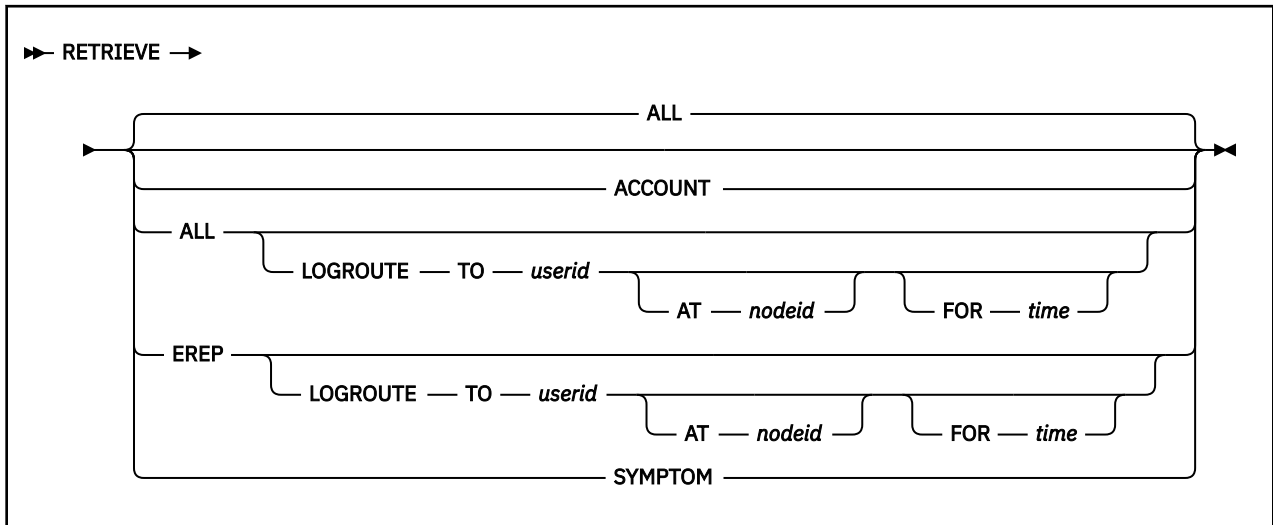

1. The MAINT 193 minidisk must be accessed.

2. You must access the 2CC and the 4CC minidisk in R/W mode.
3. The Software Inventory minidisk (default is the MAINTvrm 51D) must be accessed as the file mode defined in VMFINS DEFAULT and it must be accessed in R/W mode. By default, the Software Inventory minidisk is the MAINTvrm 51D disk and is accessed as file mode D.
4. The VMSYS and VMPSFS file pools must be active.
5. MOVE2SFS will only work if the system is not a member of an SSI cluster or has only one member in the SSI cluster. If there are two or more members in the SSI cluster, the command will not move any products or components.

# RETRIEVE

## Purpose

Use the RETRIEVE utility to collect accounting, I/O error (EREP), and symptom records and to place them in the proper file for later processing and analysis.

## Operands

**ACCOUNT**

**EREP**

**SYMPTOM**

**ALL**

indicates the type of records that you want to collect. Specify ACCOUNT if you want to collect only accounting records; specify EREP if you want to collect only EREP records; and specify SYMPTOM if you want to collect only SYMPTOM records. Specify ALL if you want to collect all of the record types. This is the default.

### LOGROUTE TO *userid*

indicates the user ID to which error records will be routed. LOGROUTE is valid only when EREP or ALL is also specified. If EREP or ALL is specified and LOGROUTE is omitted, the error records are accumulated in CMS files on file mode A. They are not routed to another user ID.

### AT *nodeid*

indicates the node ID to which error records will be routed. If AT is omitted, RETRIEVE processing assumes the LOGROUTE user ID is on the same system.

### FOR *time*

indicates the time interval at which error records will be collected and sent to the specified user. For *time*, specify a whole number from 1 to 1440 indicating the time interval, in minutes. If this parameter omitted, the default is 30 minutes.

## Usage Notes

1. The user issuing the RETRIEVE utility must have a directory entry containing an IUCV directory statement authorizing the virtual machine to connect to the CP system service which supports the type of record being collected. \*ACCOUNT must be specified for ACCOUNT records, \*LOGREC for EREP records, and \*SYMPTOM for SYMPTOM records. Successful completion of this command will cause this user ID to be known to CP (for recording purposes) until a cold start of the system is performed.

## RETRIEVE

2. You can interrupt RETRIEVE processing by entering the EXTERNAL command. You can then decide to stop processing altogether or request a summary of the records collected so far and resume processing by responding to a prompting message issued by the RETRIEVE utility.
3. As records are collected, they are placed in one or more CMS files based upon their type.

**System accounting records** are placed in a file named ACCOUNT \$Ammddy where *mddy* indicates the month, day, and year on which the files were collected.

**Error recording records** are added either to the file XAEREPIO RECORD for outboard type records, or the file XAEREPMC RECORD for inboard type records. The CPEREPA utility needs these files for its processing. Error recording records are also placed in XAEREPSD RECORD when LOGROUTE is specified. For an example of a procedure using the CPEREPA utility to process the collected EREP records, see [Setting Up Virtual Machines to Collect EREP Records in z/VM: CP Planning and Administration](#).

**Note:** Short object recording (OBR) records are not useful for configuration and error management and are not routed by the LOGROUTE parameter.

**Each symptom record** is placed in a separate CMS file whose name is based on the time the symptom record was processed by CP. All symptom record files have the characters SYM as the last three characters of the file type. You can use the CMS VIEWSYM command to select symptom records for viewing based on user-specified criteria. If a symptom record is received that contains unformatted dump-related data supplied by a virtual machine, the portion of the symptom record containing the dump data is not formatted by the VIEWSYM command; it is presented as raw hexadecimal data. The maximum size symptom record supported by z/VM is 4K bytes.

4. At least eight 800-byte CMS disk records must be available on your A-disk and your virtual machine storage size must be at least 512K bytes in size in order to use this command.
5. When LOGROUTE is specified, the user ID and node ID can be either a VM or TSO system.
6. When LOGROUTE is specified, RETRIEVE utility processing accumulates certain error records in a CMS file named XAEREPSD RECORD A. The records collected are ones which should be handled as soon as possible. The records include: long outboard type records for permanent errors on 3380 models D, E, J, and K; long outboard type records for serial switches (9033 and 9032); temporary outboard type records with a fault symptom code of 9F9F; service alert records (type A3); and serial incident records (type A2).

The file is routed to the specified user ID every time the indicated time interval elapses. It is also routed when a service alert or serial incident record is received, even if the time interval has not yet elapsed. After the file is sent, it is erased.

If you used a CP EXTERNAL command to halt RETRIEVE processing, any accumulated records will be routed to the user ID.

7. The RETRIEVE utility does not support recording retrieval to SFS directories.
8. The RETRIEVE utility attempts to periodically close the files which it creates and updates. The committing of the close can be delayed if there are other files on the disk which are open. This can occur when RETRIEVE has been invoked by an EXEC and files were opened but not closed prior to invoking RETRIEVE. It is recommended that all files be closed on the target disk prior to invoking RETRIEVE so that the closes performed by RETRIEVE are not delayed.

## Responses

Response 1:

```
RECORDING RETRIEVAL DISK IS FULL
```

is issued when disk space is no longer available to add records to the various files.

Response 2:

```
RECORDING RETRIEVAL DISK nn% FULL
```

is sent when your disk passes either the 75% or 90% full status. The message is sent only once per threshold.

Response 3:

```
ENTER END OR SUMMARY
```

is the prompting message that you receive in response to an external interrupt.

Response 4:

```
nnnn EREP RECORDS PROCESSED
```

is the response displayed if you are retrieving error records and request a summary. The variable *nnnn* indicates the number of error records that were processed.

Response 5:

```
nnnn ACCOUNTING RECORDS PROCESSED
```

is the response displayed if you are retrieving accounting records and request a summary. The variable *nnnn* indicates the number of accounting records that were processed.

Response 6:

```
nnnn SYMPTOM RECORDS PROCESSED
```

is the response displayed if you are retrieving symptom records and request a summary. The variable *nnnn* indicates the number of symptom records that were processed.

**Note:** If you are retrieving more than one type of record when you request the SUMMARY, one message is issued for each type of record you are retrieving.

Response 7:

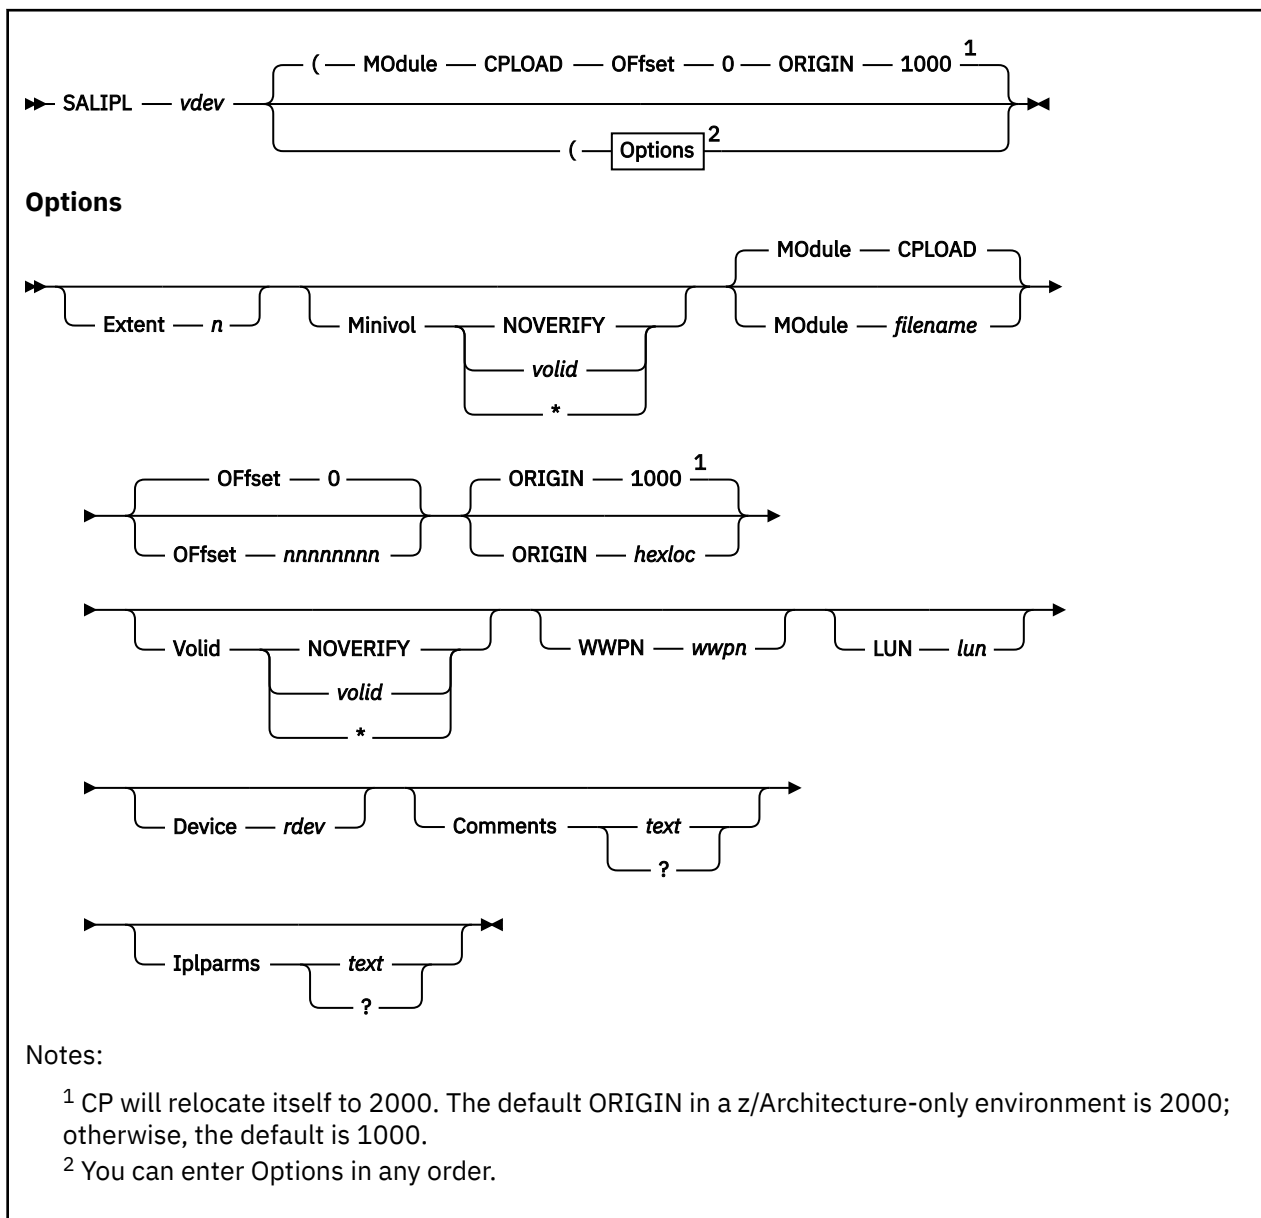

```
RECORDING RETRIEVAL TERMINATED
```

is sent when RETRIEVE ends processing, either upon your request, or because of an error condition.

## SALIPL

## Purpose

Use the SALIPL utility to install a copy of the Stand-Alone Program Loader (SAPL) in cylinder zero or, in the case of FBA DASD, in blocks 5 to 207 of a disk.

The SALIPL utility can run under CMS or it can be loaded by SAPL to run stand-alone. There is also a version of SALIPL that can be IPLed stand-alone from tape or card readers. For information on [Running the Stand-Alone Program Loader Creation Utility \(SALIPL\)](#) refer to *z/VM: System Operation*.

When SALIPL writes SAPL to the IPL volume, defaults for the following attributes that SAPL uses are established:

- The location of the CMS minidisk where modules can be found
- The name of the module that is to be loaded by SAPL
- The location in storage at which the module will be loaded, if it is relocatable

- The IPL parameters that are passed to the program being loaded
- Operator instructions that are displayed on the SAPL screen.

## Operands

### *vdev*

specifies the virtual device number (*vdev*) representing the dedicated volume, full-pack minidisk, or regular minidisk on which SAPL is to be installed. The virtual device may be located on an emulated device.

If SAPL is installed on a regular minidisk, it cannot be IPLed in stand-alone mode. This type of SAPL installation is typically used for initializing second level systems and utilities that need to run stand-alone in a virtual machine.

The *vdev* operand may specify an FCP device. If this is done, the WWPN and LUN options must be specified.

## Options

### Extent *n*

specifies which minidisk extent on a CP-formatted volume contains the module to be loaded. *n* is a single decimal number from 1 to 9. 1 refers to the first extent formatted as 'PARM', while 9 refers to the ninth such extent.

**Note:** If you specify EXTENT, you cannot specify OFFSET.

### Minivol

specifies whether SALIPL should check the label of the CMS formatted minidisk from which SAPL will load the module. If MINIVOL is not specified, SALIPL skips the check but displays the minidisk label when installing SAPL.

### NOVERIFY

specifies that SALIPL is not to check for a matching minidisk label and the label of the minidisk should not be displayed in response to the SALIPL invocation.

### *valid*

is a 1- to 6- character minidisk label. If the minidisk identified by OFFSET does not have a matching label, SALIPL issues an error message and no new loader is installed on the target *vdev*. If the minidisk does have a matching label or if *valid* is specified as an asterisk (\*), no minidisk label is displayed in response to the SALIPL invocation.

### Module

specifies the file name of the module that SAPL is to load.

### CPLOAD

is the default module name.

### *filename*

is the file name of the module that SAPL is to load. The file type of the module must be MODULE.

### Offset *nnnnnnnn*

specifies the offset from the beginning of the disk (identified by *vdev*) at which the CMS-formatted minidisk containing the module resides. You can specify up to 10 digits for OFFSET. For CKD and ECKD DASD, the offset is specified as the number of cylinders from the beginning of the disk. For FBA DASD, the offset is specified as the number of blocks from the beginning of the disk.

If you do not specify OFFSET or EXTENT, the default is OFFSET 0.

**Note:** If you specify OFFSET, you cannot specify EXTENT.

### ORIGIN

specifies the address at which SAPL should load the module.

This option is ignored by SAPL if the module that is being loaded has not been generated with the RLDSAVE option. In this case, the module is loaded into storage at the location at which the module was generated.

The entire module, including its required CP data structures, must fit below the 2G line.

When loading CP, the ORIGIN option is accepted, but CP will relocate itself to location X'2000'.

**X'1000'**

is the default address except when SAPL runs in a z/Architecture-only environment, and then the default is 2000.

**hexloc**

is the address at which to load the module.

**WWPN *wwpn***

specifies the world wide port name for a specific path to a SCSI device. The *wwpn* must be a 16-digit hexadecimal number between X'00000000 00000000' and X'FFFFFFFF FFFFFFFF'. WWPN is only valid if the *vdev* operand refers to an FCP device.

**LUN *lun***

specifies the logical unit number for a specific path to a SCSI device. The *lun* must be a 16-digit hexadecimal number between X'00000000 00000000' and X'FFFFFFFF FFFFFFFF'. LUN is only valid if the *vdev* operand refers to an FCP device. Note that the number of digits recognized by the SCSI device may vary by manufacturer, type and model. You must be careful to specify all 16 digits, using *trailing* zeros, as explained in the note below.

**Attention:**

1. *lun* and *wwpn* must be specified as 16 hexadecimal digits. This can be accomplished by specifying two 8-digit tokens, or by specifying one 16-digit token. CMS command invocation may truncate any token to 8 characters, with no warning. For safest operation, specify these arguments as two 8-digit tokens. However, if you know that the CMS command invocation technique uses extended plist (which is done for commands entered at the console or in a REXX EXEC), you can safely specify the value as a single 16-digit token.
2. Because SALIPL cannot know how many digits your device recognizes, you must enter *all 16 digits*. If your SCSI device is identified by fewer than 16 digits, you should use *trailing* zeros to fill out the 16-digit *lun*. Note that if you enter non-zero digits following the digits identifying the SCSI device, those extra digits may be ignored by your device. (For example, if your device recognizes a four-digit *lun*, 5A51888811221122 and 5A51999933443344 would both represent the same device.) This could lead to unintended device sharing and hence might introduce data-integrity exposures.

**Note:** Always identify your SCSI device by its actual *lun* unit number as defined in your storage-area network, padded on the right with zeros.

**Valid**

specifies whether SALIPL should check the volume serial identifier of the CP or CMS-formatted volume on which SAPL is being installed. If VALID is not specified, SALIPL skips the check but displays the volume serial identifier when installing SAPL.

**NOVERIFY**

specifies that SALIPL is to perform no check for a matching volume serial identifier and the volume serial identifier of the *vdev* should not be displayed in response to the SALIPL invocation.

***valid***

is a 1- to 6-character volume serial identifier. If the volume identified by *vdev* does not have a matching *valid*, SALIPL issues an error message and no new loader is installed on the *vdev*. If the volume does have a matching *valid* or if *valid* is specified as an asterisk (\*), no volume serial identifier is displayed in response to the SALIPL invocation.

**Device *rdev***

specifies the address of the device where the minidisk containing the module to be loaded resides. This can be a 5-digit device address, in which case the leading digit specifies the subchannel set

number where the device is located. This subchannel set will be used by z/VM to determine which devices belong in the active configuration. If the multiple subchannel set facility is not installed, the leading digit is truncated and subchannel set zero is used. If this operand is not specified, the minidisk is assumed to be located on the IPL device.

### Comments

specifies up to 320 characters of text information that is to be displayed to the operator if SAPL is given a console address in the load parm when it is IPLed.

#### **text**

is the text to be displayed to the operator.

#### **?**

causes SALIPL to prompt the operator for exactly 4 lines of data to be read from the console. Each line is either truncated to 80 characters or padded with blanks out to 80 characters.

**Note:** When you enter *text* on the command line, COMMENTS must be the last option you specify.

### Iplparms

specifies information that is to be passed to the loaded program by SAPL.

#### **text**

specifies up to 240 characters of text information that is to be passed on to the loaded program by SAPL.

**Note:** When you enter *text* on the command line, IPLPARMS must be the last option you specify.

The format of the IPL parameters depends entirely on the options supported by the loaded program. For a list of IPL parameters supported by CP, see [Passing IPL Parameters in z/VM: System Operation](#).

#### **?**

causes SALIPL to prompt the operator for exactly 3 lines of data to be read from the console. Each line is either truncated to 80 characters or padded with blanks out to 80 characters.

### Usage Notes

1. No special privilege classes are required to run the SALIPL utility. The command issuer must, however, have write access to the volume on which SAPL is to be installed.
2. If you are running SALIPL from an exec, it is suggested that you provide SALIPL with both the label of the volume on which SAPL is to be installed and the label of the CMS-formatted minidisk from which the module is to be loaded. This information is used by SALIPL to ensure that SAL is being installed on the correct volume and is pointing to the correct minidisk on that volume.
3. If both IPLPARMS and COMMENTS are specified with a single '?' as parameters, the user is prompted to enter the text for the options in the same order as they were specified on the command line.
4. If you are IPLing CP from an FCP device (SCSI disk), PDVOL=*raddr* must be specified as an IPL parameter. Any device address that is not in the I/O configuration of the system to be IPLed can be specified for *raddr*. CP requires this parameter in order to build the EDEVICE control block for the SYSRES / PARM disk device during CP initialization.
5.  **Attention:** The number of blocks on FBA DASD (SCSI or not) that SALIPL uses for SAPL has increased. SALIPL writes to blocks 5-207 on CP-formatted DASD. In previous releases, SALIPL wrote to blocks 5-31. You must ensure that no other functions, such as CP directory, warmstart, checkpoint, paging, spooling, or minidisks, are using the area to which SALIPL writes.

On a CMS minidisk with a RECOMP area, SALIPL writes SAPL to blocks 5-207 of the RECOMP area. In previous releases, blocks 5-31 of the RECOMP area were used. In order to accommodate the larger size of SAPL, you may need to increase the size of the RECOMP area on the CMS minidisk.

The following data is in the blocks that SALIPL writes out:

Blocks 5-196

SAPL program

Blocks 197-199	Reserved for IBM Use
Blocks 200-207	SCSI boot records

## Responses

If you want to install SAPL on device 0400, a full-pack minidisk to which you have R/W access, and you want SAPL to use the CMS-formatted minidisk that is 210 cylinders into the full-pack minidisk as the disk from which it will read a module, you enter this command, and see the responses:

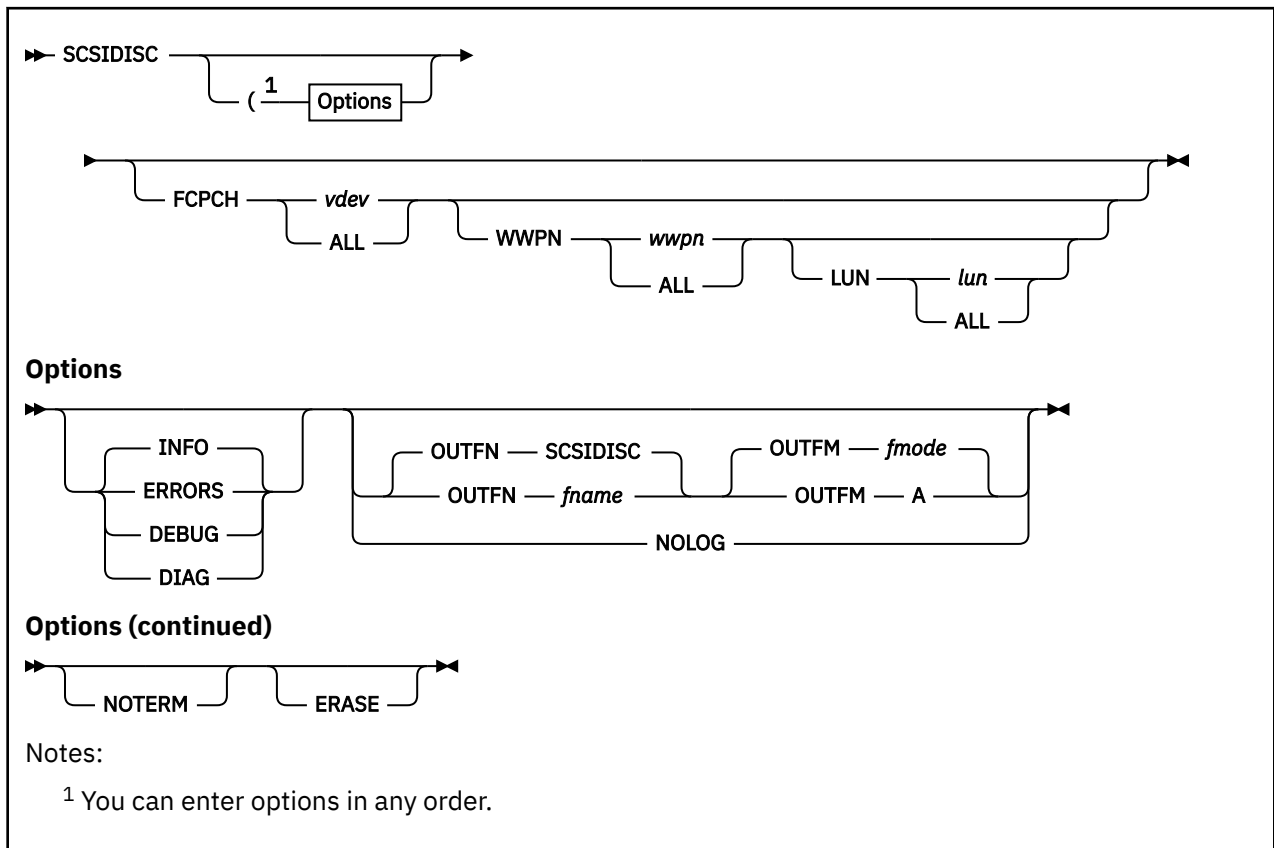

```
salipl 0400 (offset 210 module cpnew iplparms fn=sysnew
VOLUME ID IS ESARES
MINIDISK VOLID AT OFFSET 210 IS PARMD1
Ready;
```

## SCSIDISC

### Purpose

Use SCSIDISC to return information regarding LUNs that are accessible through virtual FCP devices.

### Operands

#### FCPCH

identifies the virtual FCP device to use. This requires 8 hexadecimal digits to be included to identify the FCP device (generally, 4 zeros and a virtual device number).

#### WWPN

identifies the worldwide port number of a DASD subsystem to use. This requires 16 hexadecimal digits to be included as input. WWPN is valid only when FCPCH is valid.

#### LUN

identifies the logical unit within a DASD subsystem to use. This requires 16 hexadecimal digits to be included as input. LUN is valid only when FCPCH and WWPN are valid.

### Options

#### INFO

displays general information during the program's execution. This is the default level of verbosity.

#### ERRORS

displays the same level of information as the INFO option, with the addition of information displayed by the DEBUG option when a WWPN/LUN produces an error.

**DEBUG**

displays general and diagnostic information during the program's execution. Results of this option are not documented and are subject to change.

**DIAG**

displays diagnostic output that includes the level of information displayed by the DEBUG option, as well as a trace of SCSI function calls. Results of this option are not documented and are subject to change.

**OUTFN**

is the file name of the Outfile and the Logfile. The default is SCSIDISC. File types are fixed as OUT and LOG, respectively. This option is mutually exclusive with NOLOG.

**OUTFM**

is the one-character alphabetic file mode of both the Outfile and Logfile. The default is A. This option is mutually exclusive with NOLOG.

**NOLOG**

suppresses disk output. NOLOG is an alternative to the OUTFN and OUTFM file specifications. This option is mutually exclusive with OUTFN, OUTFM, and NOTERM.

**NOTERM**

suppresses terminal log output. NOTERM can be specified with OUTFN and OUTFM. This option is mutually exclusive with NOLOG.

**ERASE**

deletes any existing output and log files if they previously exist. This program will prompt for user intervention if the files exist and this option is not specified.

**Usage Notes**

1. Although the SCSIDISC utility can be executed by a user of any privilege class, there is no guarantee that the virtual machine will have a virtual FCP device available.
2. You can enter options in any order.
3. The DEBUG option implicitly enables the INFO level of information.
4. The INFO, ERRORS, DEBUG, and DIAG options are all mutually exclusive. INFO is the default. More than one of these options can be specified, but only the most verbose takes priority. The order of increasing verbosity is: INFO, ERRORS, DEBUG, DIAG.
5. Given the potential for producing large volumes of console data, using SCSIDISC with CMS pipelines is not recommended. Output from SCSIDISC is captured on disk in the LOG and OUT files, which can be used as input to customize for further analysis. If console output suppression is desired, use the NOTERM option (rather than PIPE COMMAND EXEC SCSIDISC with no follow-on stage).
6. If SCSIDISC is executed from a pipe, interface text will not be visible. To prevent this scenario, it is recommended that the FCPCH, WWPN, and LUN parameters are all provided when executing from a pipe. This will avoid being prompted by SCSIDISC.

**Responses**

The SCSIDISC utility has the following responses:

Response 1:

If the SCSIDISC OUT file already exists and the ERASE option was not specified, the following response will be issued:

```
Outfile SCSIDISC OUT A already exists. Erase? (Y/N):
```

Note: "SCSIDISC OUT A" may be replaced by the user defined Outfile.

Response 2:

If the SCSIDISC LOG file already exists and the ERASE option was not specified, the following response will be issued:

```
Logfile SCSIDISC LOG A already exists. Erase? (Y/N):
```

Note: "SCSIDISC LOG A" may be replaced by the user defined Logfile.

Response 3:

If no virtual FCP device is specified with the FCPCH operand, the following response will be issued:

```
Please choose a number corresponding to an FCP device, "ALL" to select all
FCP devices or "QUIT"
```

Note: This will be followed by a numbered list of virtual FCP devices that are accessible to the virtual machine.

Response 4:

If no worldwide port number is specified with the WWPEN operand, the following response will be issued once for each virtual FCP device specified:

```
Please choose a number corresponding to a WWPEN, "ALL" to select all WWPENs
or "QUIT"
```

Note: This will be followed by a numbered list of worldwide port numbers that are accessible through the provided virtual FCP devices.

Response 5:

If no logical unit number is specified with the LUN operand, the following response will be issued once for each WWPEN specified:

```
Please choose a number corresponding to a LUN, "ALL" to select all LUNs or
"QUIT"
```

Note: This will be followed by a numbered list of logical unit numbers that are accessible through the provided virtual FCP devices and associated WWPENs.

Response 6:

Once SCSIDISC execution has completed, the following response will be issued:

```
Storage area network analysis complete
```

Response 7:

If the INFO option was specified and all virtual FCP devices were selected, the following response will be issued:

```
Chosen virtual FCP devices=ALL DEVICES
```

Response 8:

If the INFO option was specified and a single virtual FCP device was selected, the following response will be issued:

```
Chosen virtual FCP device=vdev
```

Response 9:

If the INFO option was specified, the following response will indicate the number of WWPENs accessible through some virtual FCP device:

```
For virtual FCP device=vdev number_of_wwpens WWPENs were found
```

Note: "*number\_of\_wwpns* WWPNS were found" will be replaced with "a point-to-point connection was found" if a point-to-point connection is being utilized.

Response 10:

If the INFO option was specified and all WWPNS were selected, the following response will be issued:

```
For virtual FCP device=vdev chosen WWPNS=ALL WWPNS
```

Response 11:

If the INFO option was specified and a single WWPNS was selected, the following response will be issued:

```
For virtual FCP device=vdev chosen WWPNS=wwpn
```

Response 12:

If the INFO option was specified, the following response will indicate the number of LUNs accessible through some virtual FCP device, WWPNS pair:

```
For virtual FCP device & WWPNS wwpn number_of_luns LUNs were found
```

Note: "WWPNS *wwpn*" will be replaced with "point-to-point destination WWPNS *wwpn*" if a point-to-point connection is being utilized

Response 13:

If the INFO option was specified and all LUNs were selected, the following response will be issued:

```
For virtual FCP device vdev & WWPNS wwpn chosen LUNs=ALL LUNs
```

Note: "WWPNS *wwpn*" will be replaced with "point-to-point destination WWPNS *wwpn*" if a point-to-point connection is being utilized.

Response 14:

If the INFO option was specified and a single LUN was selected, the following response will be issued:

```
For virtual FCP device vdev & WWPNS wwpn chosen LUN=lun
```

Note: "WWPNS *wwpn*" will be replaced with "point-to-point destination WWPNS *wwpn*" if a point-to-point connection is being utilized.

Response 15:

If the INFO option was specified, the following response will be issued when a virtual FCP device is reset:

```
Virtual FCP device vdev reset
```

Response 16:

If the INFO option was specified, the following response will be the number of virtual FCP devices found:

```
Number of virtual FCP devices found=number_of_virtual_fcp_devices
```

Response 17:

If the INFO option was specified, the following response will be issued when a virtual FCP device is initialized:

```
Virtual FCP device vdev initialized
```

Response 18:

If the INFO option was specified, the following response will be issued when a virtual FCP device is reinitialized:

```
Virtual FCP device vdev reinitialized
```

**Response 19:**

If the INFO option was specified, the following response will be issued when a WWPN is opened:

```
For virtual FCP device vdev, WWPN wwpn opened
```

Note: "WWPN *wwpn*" will be replaced with "point-to-point destination WWPN *wwpn*" if a point-to-point connection is being utilized.

**Response 20:**

If the INFO option was specified, the following response will be issued when the utility LUN for a WWPN is opened:

```
For virtual FCP device vdev, utility LUN on WWPN wwpn opened
```

Note: "WWPN *wwpn*" will be replaced with "point-to-point destination WWPN *wwpn*" if a point-to-point connection is being utilized.

**Response 21:**

If the INFO option was specified, the following response will be issued when the utility LUN for a WWPN is closed:

```
For virtual FCP device vdev, utility LUN on WWPN wwpn closed
```

Note: "WWPN *wwpn*" will be replaced with "point-to-point destination WWPN *wwpn*" if a point-to-point connection is being utilized.

**Response 22:**

If the INFO option was specified, the following response will be issued when a WWPN is closed:

```
For virtual FCP device vdev, WWPN wwpn closed
```

Note: "WWPN *wwpn*" will be replaced with "point-to-point destination WWPN *wwpn*" if a point-to-point connection is being utilized.

**Response 23:**

If SCSIDISC exits with an error before attempting to open the log file or output file, then no new log file or output file will be created and any previously existing log file or output file will remain. In this event, the following response will be issued after the error message:

```
Logfile and Outfile not updated
```

**Output Files**

Execution of the SCSIDISC utility will result in two files. The first line of both files will indicate the level of SCSIDISC used to generate them. The format of this line is as follows:

```
SCSIDISC LEVEL 0002
```

This level number will start at 0002 and increase with every version of SCSIDISC. Level 0001 is considered to be the SCSIDISC sample utility. The level should increase any time a change is made to the layout of the Outfile or Logfile.

**1. The Outfile**

The Outfile will contain a list of every path available to the set of virtual FCP devices provided. Each entry also includes additional information regarding the LUN accessible through that path.

If a failure occurs on some portion of the path, an entry will be added to the Outfile with any information that was obtained about that path. All remaining fields in the entry will contain repeated dashes (-) for the entire width of that field.

Prior to the first entry in the file, there will be a header labeling all information to follow. The format of the header will be displayed on a single line. It is displayed here on three lines due to formatting restraints.

```
_FCP_CH_      _WWPN_      _LUN_ID_      _UUID_
_VENDOR_ _PROD MODL _SERIAL_ _CODE _BLK_SIZE_ _DISKBLKS_ _LUN_SIZE_
(bytes) _
```

Each label corresponds to the data below it as follows:

<b>Heading</b>	<b>Meaning</b>
FCP_CH	Virtual FCP device composing this path
WWPN	Worldwide port number composing this path
LUN_ID	Logical unit number composing this path
UUID	Universally unique identifier of the referenced LUN
VENDOR	Vendor of the product associated with this LUN
PROD	Product composing this LUN
MODL	Model of the referenced product
SERIAL	Serial number of the storage server
CODE	Product revision level (code level) of the storage server
BLK_SIZE	Number of bytes in each block
DISKBLKS	Total number of blocks residing on the LUN
LUN_SIZE_(bytes)	Total number of bytes residing on the LUN

## 2. The Logfile

The Logfile will contain a list of all the informational messages issued during SCSIDISC execution.

### Messages

- HCP973E No virtual FCP devices are available

- HCP979I Disk write failure, EXECIO\_RC=*return code*

# SDINST

► SDINST ◄

## Purpose

Use the SDINST utility to build a configuration file used for a stand-alone dump containing device addresses for dump IPL DASD as well as additional dump output devices.

## Usage Notes

1. The user must have a R/W minidisk at device number 191 and accessed as file mode A. The configuration file is written there.
2. The SDINST utility creates a file called SDINST DUMPCONF on the user's A-disk. If the file is found at runtime, the user can choose to continue to install stand-alone dump using the existing file, or continue normal configuration and create a new file.  
  
SDINST also creates a dump status file called SDINST CMSUT1 on the user's A-disk. The file contains information for SDINST's DASD formatting routine. This file is recreated each time SDINST is run and can be erased by the user if desired.
3. ECKD or SCSI DASD can be used as dump devices, however devices must be all ECKD or all SCSI.
4. There is a maximum of 30 DASD, including the IPL DASD.
5. The SDINST utility expects a virtual reader device at virtual device number 00C and a virtual punch device at virtual device number 00D.
6. The SDINST utility requires at least 512 MB of virtual storage in order to load its DASD formatting program.
7. The SDINST utility requires that your virtual machine does not have any existing class N reader files.
8. The SDINST utility requires the following files, all of which have a filetype of IMAGE: SADU $nn$ , SSPI $nn$ , SSPK $nn$ , and SSPP $nn$ . The  $nn$  is a version number that SDINST supplies and with which it is compatible. In a standard z/VM installation, the MAINT 400 disk contains these files and should be accessed before running SDINST. The SDINST utility also looks for these files on the 191 disk before the 400 disk, so that service can be tested before it is installed. Files with matching names on other accessed disks are ignored.
9. The first dump device is formatted to contain the stand-alone dump program and is made IPLable. It is required to be large enough to hold the program plus some minimal space for a dump. For dumping a first-level system (LPAR), each dump device is an entire 3390 or SCSI LUN. Currently, a 3390 used by stand-alone dump is limited 65520 cylinders when allocated on an IBM TotalStorage DASD subsystem. That is approximately 45 GB of data. The maximum SCSI device support is limited to about 1 TB because VM's EDEVICE support is used when loading the dump.  
  
When using the stand-alone dump program to dump a second-level system, minidisks may be used. The minidisk used for the IPL device must be at least 75 cylinders. Minidisks for additional dump devices could be as small as 1 cylinder but that is not a reasonable size for dump devices. The minimum SCSI LUN sizes are equivalent: 53 MB for the IPL device and 0.7 MB for additional dump devices.
10. For additional instructions on creating a stand-alone dump utility on ECKD and SCSI devices, taking a stand-alone dump, and processing a stand-alone dump, see Chapter 12, "The Stand-Alone Dump Utility", in *z/VM: CP Planning and Administration*.

## Examples

Typical use of the SDINST utility with no pre-existing configuration file using one 3390 DASD:

```

>>> SDINST
HCPSDI8682I STAND-ALONE DUMP INSTALLER Vd.r
ENTER 'QUIT' AT ANY PROMPT TO TERMINATE EXECUTION.
HCPSDI8654A PLEASE ENTER THE VIRTUAL DEVICE ADDRESS OF THE IPL DASD
555
HCPSDI8655A PLEASE ENTER THE REAL DEVICE ADDRESS FOR THIS DASD
OR ENTER Y TO USE 0555
y
HCPSDI8674A DASD HAS EXISTING VOLID DSD555.
DO YOU WISH TO CONTINUE? (Y/N)
y
HCPSDI8658A ARE THERE ANY ADDITIONAL DUMP DASD TO SPECIFY? (Y/N)
n
SSPK73 IMAGE F1 F 80 113581 1738 yyyy-mm-dd hh:mm:ss

- HCP8675E SDINST failed because no file modes are available.
- HCP8676E Existing file *file* is not a valid stand-alone dump configuration file.
- HCP8677E Existing file *file* was created with an older version of the SDINST utility and is no longer compatible.
- HCP8678E Existing file *file* was created with a newer version of the *sdinst* utility. Please use the newest version of SDINST.
- HCP8679E There was a problem with the DASD specified starting on line *line*.
- HCP8680E Parsing failed on line *line*. Check previous error message.
- HCP8681E There can be only one IPLDASD statement in a stand-alone dump configuration file.
- HCP8682I Stand-alone Dump Installer *Vversion* enter 'QUIT' at any prompt to terminate execution.
- HCP8683E VDEV must be 1 to 4 digits - *vdev*.
- HCP8684E Size of the SCSI device *devno* can not be larger than 2,147,483,640 512-byte blocks.
- HCP8684E Size of the 3390 device *devno* can not be larger than 65520 cylinders.
- HCP8685E *operand* value missing.
- HCP8686E RDEV value not valid - *operand*. It must be a 1 to 4 digit hex number.
- HCP8687E WWPN must be 16 digits - *operand*
- HCP8688E WWPN must be a hex value - *operand*
- HCP8689E LUN must be 16 digits - *operand*

## SDINST

- HCP8690E LUN must be a hex value - *operand*
- HCP8691E VDEV *vdev* cannot be accessed at file mode A.
- HCP8692E *operand* was already specified.
- HCP8693E IPLDASD statement must be the first configuration statement in file *file*.
- HCP8694E The stand-alone dump DASD formatting module is incompatible with this version of the SDINST utility.
- HCP8695E Could not read configuration data from 191 disk.
- HCP8696E An unexpected error has occurred and stand-alone dump installation has been aborted. You may re-IPL CMS.
- HCP8697E The stand-alone dump DASD formatting module encountered invalid configuration data.
- HCP8698E *keyword* keyword on line *line* is not valid when device type is *devtype*.
- HCP8699E Found second occurrence of *keyword* keyword on line *curr* for statement starting on line *line*.

## SECTABLE

### Purpose

Use the SECTABLE utility to associate a line of installation-defined text with a RACF-defined security label (SECLABEL). When a system printer is started with a particular security label, the associated line of text will be printed on the header and trailer page of each file printed on that printer. Security labels are assigned only when multilevel security (MLS) is active.

### Operands

#### STORE

alters the human-readable text associated with each SECLABEL listed in the file SECTABLE FILE. The first copy of SECTABLE FILE found in the CMS file search order will be used.

To use the STORE operand, you must have READ access to the DIAG0A0.HRTSTORE profile in the VMCMD class. If protection for DIAGNOSE X'A0' has been turned off, then you must have class A or B privilege.

If you omit the STORE operand, no special privileges are required as the file will only be checked for correct syntax.

### Usage Notes

1. By default, the SECTABLE utility is located on the system tools disk (MAINT 193).
2. SECTABLE FILE is a variable-format (RECFM V) file with a logical record length between 10 and 141 bytes. The size of the file cannot exceed 65,536 bytes (64 KB). The format of SECTABLE FILE is:

Column	Content
1 - 8	SECLABEL character string
9	Required blank space
10 - 141	Human-readable label (1 to 132 characters long)

Ensure that only authorized administrators have write access to the minidisk containing SECTABLE FILE.

3. SECTABLE STORE must be run each time the system is IPLed. Alter the PROFILE EXEC for AUTOLOG2 to issue the SECTABLE STORE command *before* any other service machines or system printers are started.
4. A system printer has a default security label of NONE and will not print until SECTABLE STORE has been issued and a valid SECLABEL has been specified on the CP START command. The SECLABEL must be listed in SECTABLE FILE.
5. For more information on RACF authorization for DIAG0A0.HRTSTORE, see [Protecting the DIAGNOSE X'A0' Subcodes](#) in *z/VM: RACF Security Server Security Administrator's Guide*.

### Messages

- HCP8601I All SECTABLE file records were found to be valid.

## SECTABLE

- HCP8602I SECLABEL/HRL correlation table has been successfully stored. [RC=0]
- HCP8603E Invalid operand specification on SECTABLE invocation. [RC=2]
- HCP8604E Error from CMS *macro* macro with return code *retcode*. [RC=4]
- HCP8605E SECTABLE FILE must have LRECL not < 10, LRECL not > 141, and RECFM = V. [RC=6]
- HCP8606E SECTABLE FILE is too large - CP virtual buffer will be > 64K bytes. [RC=8]
- HCP8607E Record *n* causes CP virtual buffer to overflow 64K bytes.
- HCP8608E The following represent invalid SECTABLE FILE records:
- HCP8609E A total of *n* records were found to be invalid. [RC=10]
- HCP8610E Condition code of *condcode* upon return from DIAGNOSE X'A0' subcode X'34' processing. [RC=12]
- HCP8611E Severe error occurred during DIAGNOSE X'A0' subcode X'34' processing.

To find the description of a message, see [z/VM: CP Messages and Codes](#).

## SFCOUNTR

### Authorization

Privilege Class: D

### Purpose

Use the SFCOUNTR utility to create a list of all of the users who own more than a specified number of spool files.

This utility is specifically designed for single-configuration virtual machines (USERS), not multiconfiguration virtual machines (IDENTITY users), in a single system image (SSI) cluster. This utility is needed because USERS are limited to fewer than the maximum 9,999 per user files created on and owned by each SSI cluster member. The limit depends on the number of members for which the cluster is enabled. If the installation is increasing the maximum number of members (from 4 to 8, for example), the spool file limit per user per member decreases.

The main use of this utility is during a change of an SSI cluster from having 4 members to having up to 8 members. When this change is made on the SPOOL\_MEMBERS operand of the SSI\_CONTROLS statement in the system configuration file and the system is restarted, users can have a maximum of 1,249 spool files created on and owned by each member. This utility can be used to determine ahead of time if there might be any users with more than the new maximum. For more information, see usage note “2” on page 2241.

### Operands

#### *filethresh*

is the threshold number of spool files owned by a user above which the user will be included in the list. This operand can be specified as any integer from 1 to 9999. The default is 1124, which is 90% of the maximum number of files a user can have in an SSI cluster that is enabled for 8 members.

### Usage Notes

1. This utility ignores logged-on multiconfiguration virtual machines (MCVMs). If an MCVM is not logged onto this member, SFCOUNTR will not recognize it as such and will include it in the report. However, it can be ignored, because MCVMs are always allowed to have the full 9,999 files.
2. A spool file is owned by a cluster member if it was created on that system. The creating system assigns a spool ID and allocates spool space for the file on its CP-owned devices. This utility returns the number of spool files owned by a user. For a user logged onto this member, the number includes files created on other cluster members. Only the files owned by this member are relevant to the question of whether a user will have too many files when the SPOOL\_MEMBERS statement is changed. However, if the reported number is below 1,249 for all users, this member can safely be switched to the SPOOL\_MEMBERS 8 setting.
3. This utility must be run from a privileged user, that is, with certain CP command privileges along with class G. The privileged commands issued and their IBM privilege classes are:

+ QUERY MAXSPOOL SYSTEM	Class D
+ QUERY RDR SYSTEM ALL	Class D
+ QUERY PRT SYSTEM ALL	Class D
+ QUERY PUN SYSTEM ALL	Class D

```

+ QUERY TRF SYSTEM|userid ALL Class A, C, D, or E
+ QUERY FILES SYSTEM|userid Class D
+ LOCATE userid Class C or E
+ DISPLAY Host Class C or E

```

## Responses

The output from SFCOUNTR is a file sent to your A-disk. The file is called *mmddhhmm* SFCOUNTR. The file type is always SFCOUNTR. The file name is an indication of when the utility was run and is of the form *mmddhhmm*, where:

### **mm**

is the month

### **dd**

is which day of the month

### **hh**

is the hour

### **mm**

is the minute

If the utility is run more than once in the same minute, the earlier output files are replaced and only the latest output file from that minute is retained.

The output file will look something like the example below if there are users whose spool file count is over the limit.

The users are listed in descending order by number of files owned.

Note that the second line of the output contains the time and date the utility was run in the user's DATEFORMAT setting. The following example shows the line when the user's DATEFORMAT is set to SHORTDATE.

```

SFCOUNTR data collected by OPERATOR AT VM1
TIME IS 11:32:58 EDT TUESDAY 07/13/22
Threshold was set to 1124 files.
USER FILES
=====
USERABC 2304
USERXYZ 1518
WHOEVER1 1125

```

The output file will look something like the example below if there are no users whose spool file count is over the limit. The last line shows the number owned by the user with the most spool files.

Note that the second line of the output contains the time and date the utility was run in the user's DATEFORMAT setting. The following example shows the line when the user's DATEFORMAT is set to FULLDATE.

```

SFCOUNTR data collected by OPERATOR AT VM1
TIME IS 13:31:11 EDT TUESDAY 07/13/2022
Threshold was set to 1124 files.
No users had more than 518 spool files.

```

## Messages

- HCP002E Invalid operand - *operand*

- HCP8250E SFCOUNTR REQUIRES A R/W A-DISK

# SPORDER

---

► SPORDER ◄

## Purpose

Use the SPORDER utility to put your virtual reader files in chronological order.

## Responses

SPORDER has no normal response; successful completion results in return code 0.

Response 1:

```
No RDR files to order
```

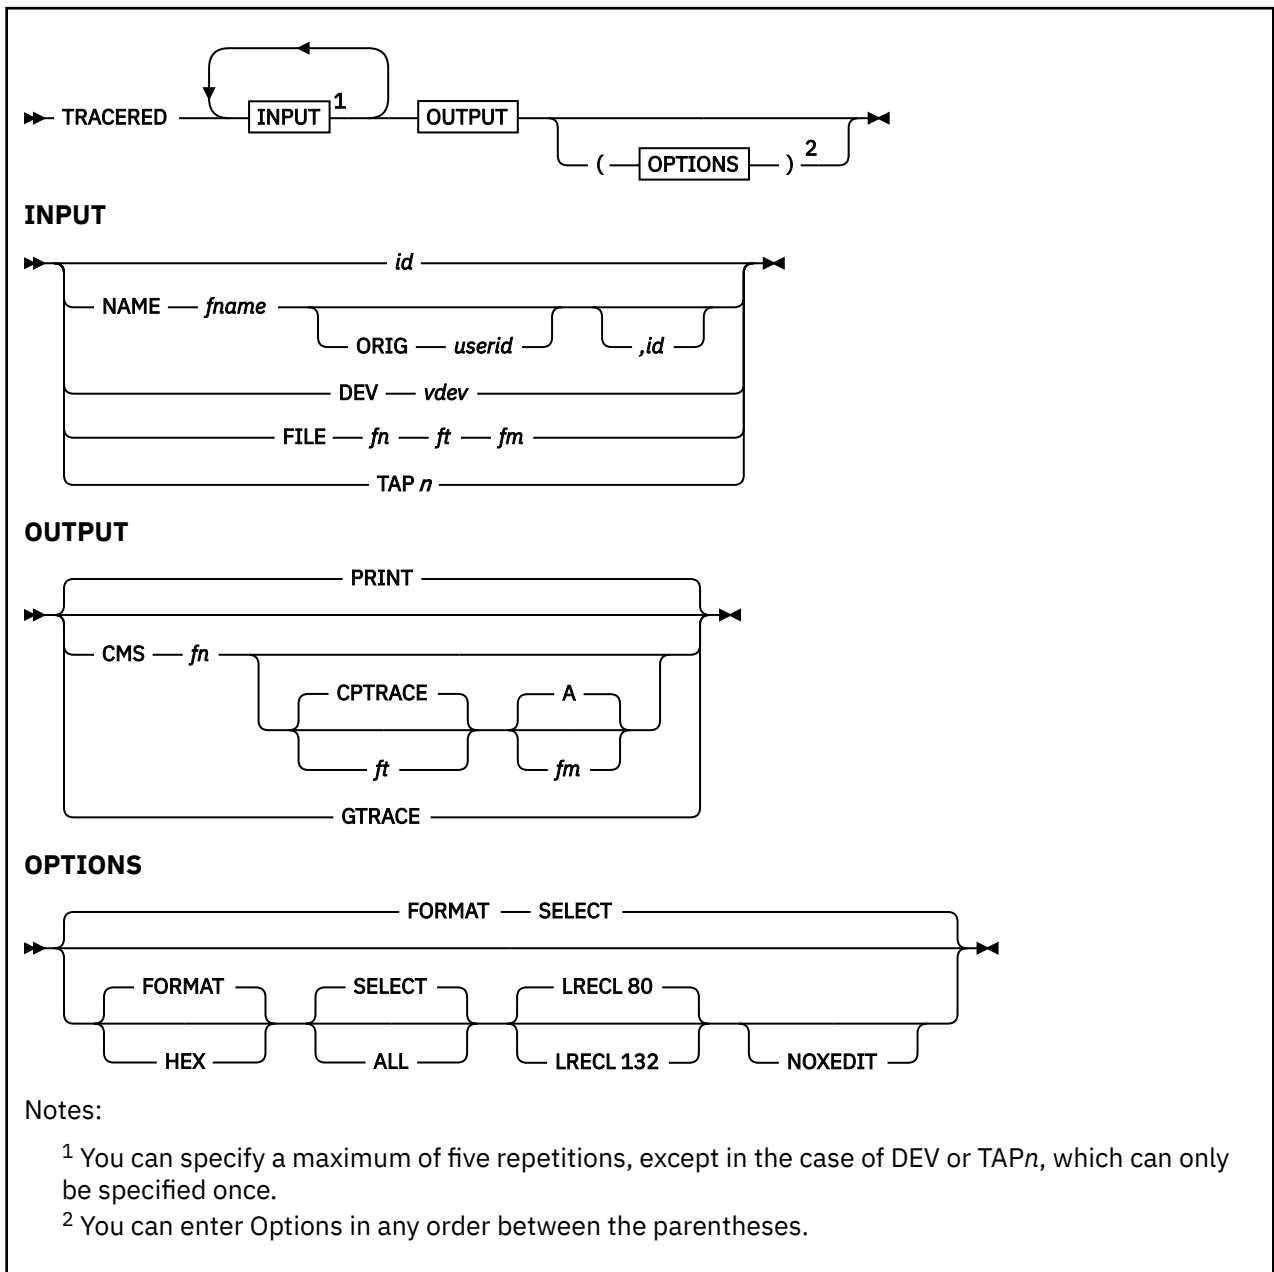

is the response sent if the originator of SPORDER has no files in their virtual reader (the return code is 4).

Response 2:

```
Return code nn from CP Q FILES
```

is the response sent to the originator if an error occurs when SPORDER issues the CP Q FILES command (the return code is 98).

# TRACERED

## Purpose

Use the TRACERED utility to process trace data recorded by the TRSOURCE command or to process CP trace data. CP trace data includes system trace files, data captured in a CMS file by the TRSAVE subcommand, and system trace table records contained on tape or in system trace files. The TRSOURCE command data can be merged with existing CP or TRSOURCE data as follows:

- TRSOURCE data can be merged with CP data, or other TRSOURCE DATA, to generate CP data.
- TRSOURCE data can be merged with other TRSOURCE data to generate a consolidated output file in chronological sequence. Refer to [“TRSOURCE” on page 2018](#) for further information on TRSOURCE, as well as creating trace files.

## Operands

### *id*

specifies the primary input to TRACERED as a system trace file containing CPTRACE or TRSOURCE data. The *id* operand is a spool ID, a decimal number from 1 to 9999.

### NAME

specifies the primary input to TRACERED from one or more files containing trace data collected using SET CPTRACE or TRSOURCE commands. You may identify files by file name, origin ID, and spool ID. Trace file names are assigned by the TRSOURCE and TRSAVE commands. Within a set of traces, you may select trace data for a particular virtual machine by specifying an origin user ID. Further selectivity is allowed by selecting individual trace files by spool ID. The *fn* operand specifies the file name assigned by the TRSAVE or TRSOURCE command. The ORIG *userid* operand identifies, for guest type traces, files containing an individual virtual machine's trace data. This enables an individual member of a VMGROUP trace to be specified on the TRACERED command line. The *id* operand identifies an individual system trace file created with file name *fn*, and it is specified as a spool ID, a decimal number from 1 to 9999.

A total of five system trace files, CMS files, or both can be merged including only one CP TRACE data file. The output is merged by time-of-day and formatted as it is written to a CMS file or the virtual printer as designated by this command.

### DEV *vdev*

specifies the primary input to TRACERED as a tape containing CP trace table data at virtual device address *vdev*.

### FILE *fn ft fm*

specifies a file containing data (for example, TRSOURCE data extracted from a dump with the TRSAVE command) to be processed by TRACERED.

### TAP*n*

specifies the primary input to TRACERED as a tape containing CP trace table data at symbolic tape address TAP*n*. See the FILEDEF command in *z/VM: CMS Commands and Utilities Reference* for a list of supported TAP*n* values.

### PRINT

designates that the output of the TRACERED command goes to your virtual printer. This is the system default.

### CMS

indicates that the output of the TRACERED command should be directed to a CMS file of the file name, file type, and file mode you specify. If you do not specify a file type, the default is CPTRACE. If you do not specify a file mode, the default is A. If you specify this keyword, you will be put into XEDIT when the command completes successfully.

### GTRACE

specifies that the output will be in the form of an OS QSAM file. Only guest virtual machine recorded trace events created by TRSOURCE in either BLOCK mode or EVENT mode are output to this file.

## Options

### FORMAT

specifies that each selected trace entry should appear in a long format. Three lines per trace entry are formatted for CP trace table entries. The number of lines of output for TRSOURCE recorded entries is determined by a formatting routine based on the length of the trace record and the output LRECL value. When the formatting routine is not supplied, the data is in hexadecimal form. The difference between HEX and FORMAT processing is left to the exit routine to define. FORMAT is the default value. Some products may provide only one format, that being either a short (HEX) or long (FORMAT) format for their guest trace data.

The following records are supported for the format option:

- CP trace table records
- CP records of type DATA, IO, and LAN

## TRACERED

- Guest trace records providing a formatting routine that is accessible by TRACERED.

Other guest trace records will be formatted in hex output.

### HEX

stipulates that the hexadecimal (or short) format should be used for the selected entries. CP trace table data output is one line per trace entry. The mixture of hexadecimal and interpreted output is determined by the exit routine for guest trace data. Some products may provide only one format, either a short (HEX) or a long (FORMAT) format for their guest trace data. You may want to use this option when you want output to go to a CMS file and limited DASD space precludes the use of the FORMAT option.

The following records are supported for the format option:

- CP trace table records
- CP records of type DATA, I/O, and LAN
- Guest trace records providing a formatting routine that is accessible by TRACERED.

Other Guest trace records will be formatted in hex output.

### SELECT

signifies that you want selection criteria to be applied to the trace entries. You will be prompted for the selection criteria you want. This is the system default.

### ALL

indicates that all trace entries from the specified input tape or system trace file are to be selected for output. You will not be prompted for selection criteria.

### LRECL 80

### LRECL 132

specifies the record length maximum for the output file. When not specified, CMS files default to 80 bytes and print files default to 132 bytes.

### NOXEDIT

avoids entering an XEDIT session when the CMS keyword is specified on TRACERED. This option may be useful if the CMS output file created is too large to XEDIT.

**Selection Criteria for the SELECT:** If you choose or let the system default to the SELECT option for the TRACERED command, you receive the following prompt:

```
ENTER TRACE ENTRY SELECTION CRITERIA, NULL LINE TO END  
SELECTION, OR QUIT TO END TRACERED COMMAND
```

If you enter a null line, **no** selection criteria are applied. As a result, everything will be traced.

If you enter selection criteria, you will continue to receive this prompt until you enter a null line, thus indicating that entry of selection criteria is complete. Acceptable replies to the prompt are:

1. Any combination of the following keywords and values:

- **CODE xxxx xxxx . . .**

You may enter up to 16 four-digit hexadecimal values representing the trace table codes to be selected during data reduction of the input tape or system trace file. Leading zeros are required. The last two digits of any code may be specified as the character string \*\* or \*. This indicates that you want a range of trace table codes. For instance, 15\*\* or 15\* would select all trace table entries beginning with the hexadecimal digits 15. CODE is valid for CP trace table data only.

- **VMDBK xxxxxxxx xxxxxxxx . . .**

You may enter up to 16 hexadecimal values that represent the VMDBK addresses to be used during data reduction of the input tape or system trace file. Leading zeros are not required. Each address specified must be in the range of X'0' to X'7FFFF000' and on a page (4 KB) boundary. VMDBK is valid only for CP trace table data.

- **RDEV xxxx xxxx . . .**

You may specify up to 16 hexadecimal values that represent the RDEV numbers to be used during data reduction of the input tape or system trace file. Leading zeros are not required. Each device number specified must be in the range of X'0' to X'FFFF'. RDEV is valid only for CP trace table data.

- **VDEV xxxx xxxx . . .**

You may specify up to 16 hexadecimal values that represent the VDEV numbers to be used during data reduction of the input tape or system trace file. Leading zeros are not required. Each device number specified must be in the range of X'0' to X'FFFF'. VDEV is valid only for CP trace table data.

- **CPU xxxx xxxx . . .**

You may specify up to 16 hexadecimal values that represent the processor addresses to be used during data reduction of the input tape or system trace file. Leading zeros are not required. Each processor address specified must be in the range of X'0000' to X'004F'. CPU is valid only for CP trace table data.

- **TIME mm/dd/yy hh:mm:ss mm/dd/yy hh:mm:ss**

You may designate a start/stop date/time for the data reduction of the input trace entries. If this option is selected, only trace entries created within the designated date and time range will be processed. You may select only one date/time range. All the TIME parameters may be input on the same line.

**Note: TIME** is the only valid selection criteria if TRSOURCE entries are being processed.

2. CMS – To enter the CMS subset mode.
3. HELP – To invoke the help panel for the TRACERED command.
4. QUIT – To end the TRACERED command.
5. A null line – To indicate that you are done entering selection criteria and want to end prompting.

If your immediate response to the prompt is a null line, then all trace entries are selected.

## Usage Notes

1. The *filename* of the NAME operand designates a set of system trace files created by one invocation of the CP TRSAVE command. Multiple system trace files may exist with the same file name. If you specify a file name as NAME *fn*, TRACERED processes all system trace files with that file name, beginning with the oldest. If you specify NAME *fn1 ,id1*, TRACERED processes all system trace files with that file name beginning with the spool ID *id1*. If you specify the *id* operand, TRACERED will process that system trace file.
2. Avoid using TRACERED keywords for file names and file types as part of the file id specified with the "FILE" operand.
3. TRACERED uses the first 2 bytes of each TRSOURCE created entry record as the length of that entry.
4. When more than one tape created by the same TRSAVE command is to be mounted and processed, they must be processed in chronological order.
5. Use the QUERY TRFILES command to display information about system trace files you own, including spool ID, file name, and the time of creation.
6. A total of five system trace files, CMS files, or both can be merged. However, only one CP trace table file or tape may be included. Therefore, you may specify one of the following:
  - One CP trace table file with up to four TRSOURCE trace files
  - One tape with CP Trace table and up to four TRSOURCE trace files
  - Up to five TRSOURCE trace files.

You cannot merge a CP tape or tapes with a CP trace table file.

7. The following guidelines apply to your responses to the prompt for selection criteria when **CP trace table data** is processed:
  - Each time the prompt appears, you may specify any or all of the six selection types: CODE, VMDBK, RDEV, VDEV, CPU, and TIME.

- You do not have to enter these values on one line (with the exception of TIME), as the prompt for selection criteria will reappear until you enter a null line or QUIT.
- You cannot specify more than a total of 16 values per selection type in all of your response lines combined, with the exception of TIME.
- An individual trace entry may or may not contain a field of the same type specified in your reply to the prompt for selection criteria. All trace entries have a trace code, CPU address, and time-of-day field; not all trace entries have a VMDBK address, real device number, or virtual device number. As a result, there are two main rules that apply to TRACERED data reduction:

- If you specify just one selection type in response to the prompt — CODE, VMDBK, RDEV, VDEV, CPU, or TIME — then the trace entries chosen for output will have a field for the selection type you indicated **and** a value in the field that matches the value you indicated in your response.

For instance, your response to the selection criteria prompt may have been the following:

```
code 0c32 1000 0100
```

In this case, all trace entries with the code 0C32, 1000, or 0100 are selected.

- If you specify more than one selection type in response to the prompt — some combination of CODE, VMDBK, RDEV, VDEV, CPU, and TIME — then the trace entries chosen for output depend on the selection type fields a given trace entry contains. Trace entries that contain fields for only some of the selection types you indicated, but whose values in those fields match the values you designated, are chosen for output. A trace entry does not have to have all the selection types you specified in order to be chosen for output.

For example, your response to the selection criteria prompt may be the following:

```
code 0c32 rdev 399 vdev 191 code 1000 0100
```

In this case, trace entries to be selected for output depend on the following:

- Trace entries with code 0C32 contain both an RDEV and VDEV value. Therefore, a trace entry of 0C32 must have an RDEV field value of 399 and a VDEV field value of 191 in order to be selected for output.
- Trace entries with code 1000 contain only an RDEV value. The VDEV selection value does not apply in this situation. Therefore, all trace entries of code 1000 with an RDEV field value of 399 are chosen for output.
- Trace entries with code 0100 have neither an RDEV nor VDEV value. Therefore, all trace entries of code 0100 are output.

8. The following guidelines apply to your responses to the prompt for selection criteria when **CP and TRSOURCE data** is requested:

- If you immediately enter a null line when prompted for the selection criteria, this indicates that no data reduction is requested. As a result, all trace entries are selected.
  - You can specify a time range only once.
9. If you own more than one set of files with different originators, you must specify NAME *fn, id* for the file you want.
  10. All files being processed must have been created under a z/VM environment.
  11. When a new system trace file or tape is being processed, a message will be issued to the screen indicating which file or tape is being processed.
  12. When you indicate VMDBK in your response, data reduction takes place by VMDBK address. Should you want to trace a specific user or users, you need to find out the VMDBK address for the user in question **before** invoking the TRACERED command.
  13. For TIME selection criteria, the handling of a two-digit year will be interpreted within a window of 100 years centered on the current date.

For example, if the year is 1997, the 100-year window spans from 1947 to 2046. Any two-digit year in the range 47-99 will be interpreted as 1947-1999, and any two-digit year in the range 00-46 will be interpreted as 2000-2046. Likewise, if the year is 2003, the 100-year window spans from 1953-2052. Any two-digit year in the range 53-99 will be interpreted as 1953-1999, and any two-digit year in the range 00-52 will be interpreted as 2000-2052.

14. When the output is directed to a CMS file, the XEDIT command will be invoked automatically. You can then scroll back and forth through the merged data.
15. When processing system trace files that contain GCS trace entries, it is advisable to use the LRECL 132 option for formatted CMS output.
16. A file of fixed length records is created when the TRSAVE subcommand extracts CP trace data. A file of variable length records is created when the TRSAVE subcommand extracts TRSOURCE trace data. These files need to remain in their original fixed or variable length format for proper input to TRACERED.
17. To further process CP records of type LAN, see [Using IPFORMAT Packet Trace Formatting Tool in z/VM: TCP/IP Diagnosis Guide](#). Note that you can convert LAN traces to the PCAP format using IPFORMAT.

## Examples

- **tracered 190 cms trace1 tables a**

TRACERED is invoked for a system trace file with spool ID 190. The user is prompted to enter selection criteria. The fully formatted output is put into CMS file TRACE1 TABLES A. XEDIT is invoked for the output file.

- **tracered 183 194 172**

TRACERED is invoked for three system trace files with spool IDs 183, 194, and 172. All defaults are taken. That is, the user is prompted to enter selection criteria, and the output is fully formatted and goes to the virtual printer.

- **tracered 0183 name pvmttrace 194 cms trace2 output a (all noxedit)**

TRACERED is invoked to merge system trace files 183 and 194 and all system trace files with file name PVMTRACE. All records are formatted and put into CMS file TRACE2 OUTPUT A. XEDIT is not invoked for the output file.

- **tracered file prb00002 trapA file prb00002 trapB A cms trace3 output a (all format)**

TRACERED is invoked to merge two CMS files created from a CP dump by the TRSAVE subcommand of DUMPSCAN. All records are formatted and put into CMS file TRACE3 OUTPUT A. XEDIT is invoked for the output file.

- **tracered name rscsprb4 orig rscsv2 ,17 cms rscs4 trace (lrecl 132)**

TRACERED is invoked for system trace files with file name RSCSPRB4 and origin ID RSCSV2, starting with spool ID 17. Output is fully formatted in 132-byte records and put in CMS file RSCS4 TRACE A.

- **tracered dev 182 name tsaf 194 (hex)**

TRACERED is invoked to merge CP trace table data on tape 182 with all system trace files with file name TSAF and with another system trace file with spool ID 194. Output is in short (hex) format and directed to the printer.

- **tracered name gcstrc orig vtam1 gtrace (all)**

TRACERED is invoked to prepare a file containing input for the ACF/TAP (Trace Analysis Program). It will contain all of the GTRACE type GCS records found in the system data files with file name GCSTRC recorded with origin ID VTAM1.

**TRACERED Output:** There are four types of output you may generate from the TRACERED command: a formatted CMS file, a formatted print file, an unformatted CMS file, or an unformatted print file.

**Note:** You may encounter storage constraints if you select a CMS file for the output. The more trace entries that meet the selection criteria, the larger the storage requirements.

One way to alleviate storage constraints is to designate more stringent selection criteria.

**Formatted CMS File:** When you select the FORMAT option (the default) and designate a CMS file in the TRACERED command, the default setting of the output to the CMS file consists of 80-character fixed-length records. You can reset the default record using the LRECL option.

**CP Trace Table Output:** Each CP trace entry selected comprises three output lines:

- The first line contains the trace code, the CPU address, a description of the type of entry, and the time the entry was created.
- The second and third lines describe the trace entry data contents, which vary according to the type of entry.

```
0600 CPU 0000 OBTAIN FREE STORAGE (FREE)      TIME 19:26:31.000000
      BLOCK ID  DOUBLE WORDS   BLOCK ADDR  VMDBK ADDR  RETURN ADDR
      <IOR      00000020      00FC5EA8   00FB1000   004CF922
```

Figure 2. Formatted CP Trace Entry

Each time TRACERED encounters a missing CP data record, the following line appears in the CMS file:

```
CPU xxxx - TRACE DATA HAS BEEN LOST
```

A blank line precedes and follows the lost data line in the CMS file. Processing continues with the next available trace entry.

Processing Input Tapes:

Each time a new input tape is processed, a header record is written that contains the volume sequence number and creation date and time of the TRSAVE tape. Also at the time a new input tape is processed, that same information is displayed at your terminal screen. Informational message O30I indicates the volume sequence number of the current TRSAVE input trace tape and the date the tape was created.

**Guest Trace Event Output:** An example of formatted GCS Event output follows:

```
3D 0E NET    VM/GCS USER REQUESTED GTRACE
      TIME OF DAY CLOCK = 9A6266195A8E2C00
      LENGTH OF GTF HEADER AND TRACE DATA =0017
      FORMAT ROUTINE ID = FD
      EVENT IDENTIFICATION = EFE1
```

Figure 3. Guest Trace Data of Type GCS in Event Mode

**Guest Trace Block Output:** An example of formatted TSAF Block output follows:

```
----- 12/15/89 14:55:20.852228 -----
10A0 GOT INTERNAL TRACE BLOCK                                TSAF
      CLOCK = A15CE563 4C704301      MODULE = ATSCTL
      TIME = 14:55:20.852228 GMT 12/15/1989  LENGTH = 0000
```

Figure 4. Formatted Guest Trace Data of Type TSAF in Block mode

**I/O Trace Entry Output:** TRACERED recognizes I/O data trace information. An example of a formatted I/O data trace entry follows:

```

TRACE TYPE IO, CPU 0000                TIME 01:00:00.000000
TRACEID - I01, TRACESET = IO, IODATA = 0
USER = OPERATOR, I/O OLD PSW = 07064000 80000000 00000000 00000000
DEVICE = 0191, SCSW = 00C04007 0FA59610 0C000000
                ESW = 00800017

-> CCW(2) = 4B600016 0FA38520, CCW ADDRESS = 0FA38540
-> CCW(3) = 92400008 0FA38008, CCW ADDRESS = 0FA38548
-> CCW(4) = 86411000 0FA38290, CCW ADDRESS = 0FA38550 ** MIDA **
-> MIDAW(1) = 00000000_0E4D1000

```

Figure 5. I/O Data Formatted by TRACERED

**LAN Trace Entry Output:** TRACERED recognizes LAN data trace information.

LAN data trace information is formatted by TRACERED as:

- TOD of when entry was created.
- Contents of the trace entry in hexadecimal (up to 20 bytes per line).
- The string SPID followed by a decimal number. This identifies the system trace file from which the entry was obtained.

**Data Trace Entry Output:** TRACERED recognizes CP data trace information.

An example of a CP data trace entry output formatted by TRACERED is shown in [Figure 6 on page 2251](#).

```

```

Figure 6. Data Trace Entry Output Formatted by TRACERED

**Formatted Print File:** TRACERED formatted print output is identical with formatted CMS file output except that the default record length is 132 bytes. The TRACERED output is directed to your virtual printer rather than to a CMS file.

**Unformatted CMS File:** When you select the HEX option and designate a CMS file in the TRACERED command, the default setting of the output to the CMS file consists of 80-character fixed-length records. You can reset the default record using the LRECL option.

**CP Trace Table Output:** Each CP trace entry selected comprises one line. The line contains the CPU address, the time the entry was created, the trace code, and the trace entry data contents. These are in hexadecimal format.

```

CPU   SECONDS   CODE ***** TRACE ENTRY CONTENTS *****
      05/31/88 11:51:21.123456
0000  21.123456 3310  E4C34040 00000001 00FAC000 00FFBA80 005311E0 SPID 0003
    
```

Figure 7. CP Trace Table Output

**Guest Trace Block Output:** When HEX option is entered for a Block mode Guest Trace the Guest's formatting routine is invoked and its HEX output is given.

An example of HEX TSAF Block output follows:

```

----- 12/15/89 18:00:28.000000 -----
TSAF      A15C0FF4 F4BA5C01 C3E3D3 10A0 0000      GOT INTERNAL TRACE BLOCK
    
```

Figure 8. Hex Guest Trace Data of Type TSAF in Block Mode

**Other Trace Types:** TRACERED processes other traces (I/O, CP data, LAN, and guest traces when the formatting routines are not available) and produces the following information per trace record:

- TOD of when entry was created
- Contents of the trace entry in hexadecimal (up to 20 bytes per line)
- The string SPID followed by a decimal number. This identifies the system trace file from which the entry was obtained.

An example of unformatted trace data output follows:

```

----- 12/15/89 18:01:52.123456 -----
18:01:52.123456      A15C1044 BB7F8901 C3E3D310 A00000E0 0E      SPID 0086
    
```

Figure 9. Unformatted Guest Trace Output

**Unformatted Print File:** TRACERED hex print output is identical with hexadecimal CMS file output except the default record length is 132 bytes. The TRACERED output is directed to your virtual printer rather than to a CMS file.

**TRACERED Exit Descriptions:** Following are the exit descriptions.

**TRACERED Merge and Selection Exit:** TRACERED provides an interface between itself and GCS GTRACE trace data formatting routines. When you use the GCS GTRACE macro and specify the FID option (to define data to be recorded in the GCS trace table) you must provide to TRACERED a matching format routine to make your trace data suitable for printing. The name for the formatting routine must be as described in z/VM: Group Control System under the GTRACE macro.

The GTRACE macro provides you with complete control over the trace record layout, including the location of a TOD clock field. Therefore, TRACERED requires the assistance of your selection routine to obtain the TOD value for each record it processes.

**Merge/Selection Exit Interface:** When TRACERED reads a trace record in a guest trace block, it calls the exit, if it exists, to determine the TOD value or set the selection return code indicator.

*Registers at entry:*

```

R1      address of parameter list
R13     address of 72 byte save area for caller's registers
R14     return address
R15     entry point address of exit routine
    
```

*Parameter list format:*

```

x'0 '  Parameter list length
x'2 '  Flag byte
      1... .... GTRACE records requested
      .111 1111 Reserved
x'3 '  Reserved
x'4 '  Address of the trace record
x'8 '  Address of an eight byte output area for
      the TOD value supplied by the exit routine.

```

*Registers at exit:*

```

R0-R14  unchanged
R15     return code
      0      = record selected
      4      = no TOD value available
      8      = record not selected

```

The merge and selection exit returns an 8-byte time stamp for the individual record and indicates whether the record should be selected for further processing.

TRACERED selects either CP or guest trace entries by time. If the timestamp of an entry is identical to that of the previous entry, as can occur when the Store-Clock-Fast Facility is installed and enabled during tracing, an '=' sign is displayed immediately following the timestamp, signifying that the order of occurrence of those entries is unpredictable. If the timestamp of a guest record is not returned by the exit routine, the record cannot be selected by time.

The GCS merge and selection exit should select only GTRACE records when requested by TRACERED.

A return code 4 to TRACERED results in the record being skipped if the record is to be merged with others. If TRACERED is not merging multiple input files and if the records are not being selected by time, however, the record will be processed for output.

A return code of 8 indicates that the record should not be selected.

**TRACERED Formatting Exit:**

The TRACERED program supports user specified trace formatting exits for guest trace records recorded in system data files using the FID option of the GCS GTRACE macro and the TRSOURCE command (BLOCK mode).

TRACERED reads blocks of data from system trace or CMS files, separates the individual records, and passes each to the formatting exit which is identified in the block descriptor record.

Make sure that the CMS loader can access the TRACERED exit routine.

**Formatting Exit Interface:** When TRACERED processes a trace record in a system trace file block, or a CMS trace file block, it passes it to the user-supplied formatting exit if available:

*Registers at entry:*

```

R1     address of parameter list
R13    address of 72 byte save area for caller's registers
R14    return address
R15    entry point address of exit routine

```

*Parameter list format:*

```

x'0 '  Address of the trace record
x'4 '  Address of the trace record data portion
x'8 '  Length of the trace record
x'C '  Length of the trace record data portion
x'10'  Reserved, set to zero
x'14'  Address of the output buffer, into which the exit
      will build a line of formatted output.
      It is initially blank.
x'18'  Reserved, set to zero
x'1C'  Address of the output routine (in the
      TRACERED program).
x'20'  Communications Flags
      1... .... Output should be formatted in 80 byte records

```

```

                                for display. This is set when TRACERED is invoked
                                with the CMS operand, or when the output length is
                                overridden by the LRECL 80 option.
.1.. .... Output should be formatted in 132 byte records
                                for printing. This is set when TRACERED is invoked
                                with the PRINT operand, or when the output length is
                                overridden by the LRECL 132 option.
..1. .... Reserved, set to zero
...1 .... Long output format wanted. The FORMAT option
                                was specified (or defaulted) on the command.
                                This bit is zero if the HEX option was specified.
.... 1111 Reserved, set to zero

```

**Output Routine Interface:** When the user formatting exit calls the Dump Viewing Facility output routine, it will use standard linkage conventions and pass the address of the parameter list with which it was entered.

This routine uses standard exit linkage with the return code (register 15) containing an unconditional value of zero.

## Messages

When the trace reduction process is complete, the TRACERED utility issues one of the following codes:

### **Code**

#### **Meaning**

<b>0</b>	Successful completion
<b>4</b>	No trace entries meet the selection criteria
<b>20</b>	Invalid character in output file ID
<b>24</b>	Command syntax error
<b>28</b>	Tape not attached or output file already exists or system trace file is not found
<b>36</b>	Disk not accessed
<b>41</b>	Insufficient virtual storage
<b>100</b>	I/O error

## UTILITY

### Purpose

Use the UTILITY utility to provide occasionally-used installation utility functions:

- Issuing DIAGNOSE code X'24' and X'210' for a virtual device
- Creating a stand-alone service utility tape for either or both ICKDSF and DDRXA.

### Operands

#### **DTYPE** *devno*

issues a DIAGNOSE code X'24' and X'210' for the specified virtual address, uses the returned information to look up the DASD type in the \$DASD\$ CONSTS file, and returns that information to the terminal (if UTILITY DTYPE is issued from the terminal) or to the program stack (if UTILITY DTYPE is called by an exec).

The information returned is a single line consisting of three fields:

- DASD type, model, or both
- The capacity of the device in cylinders
- The proper representation of the given DASD model to the CPFMTXA program.

If the virtual device address is incorrect, nonexistent, or addresses an unsupported device type, a nonzero return code is displayed.

The UTILITY DTYPE function is intended primarily for use by installation-related utilities.

#### **UTILTAPE**

creates a tape containing either or both of the following stand-alone utility programs:

##### **DSF:**

Device Support Facility (ICKSADSF COREIMAG)

##### **DDRXA:**

DASD Dump/Restore program (IPL DDRXA)

on a tape drive at virtual address 181.

The version of DDRXA or ICKSADSF that occurs first in the minidisk search order is the version placed on tape.

If ALL is specified, both IPLable programs are written to the same tape file, with ICKSADSF being written first. After the last program, two tape marks are written. When ALL is specified, to IPL the DDRXA program from the tape, you must IPL twice to bypass ICKSADSF.

If you do not have a R/W A-disk the tape write operation will complete but no \$MSGLOG will be created.

## UTILITY

### **VTYPE *devtype***

locates the DASD type, *devtype*, in the \$DASD\$ CONSTS file, and returns the device information to the terminal (if UTILITY VTYPE is issued from the terminal) or to the program stack (if UTILITY VTYPE is called by an exec).

The information returned is a single line consisting of three fields:

- DASD type, model, or both
- The capacity of the device in cylinders
- The proper representation of the given DASD model to the CPFMTXA program.

If *devtype* is not an acceptable device type, a nonzero return code is displayed.

The UTILITY VTYPE function is intended primarily for use by installation-related utilities.

Acceptable values of *devtype* are:

<b><u>Device Type</u></b>	<b><u>devtype</u></b>
Single-density 3380	3380
Double-density 3380	3380-E4
Triple-density 3380	3380-K4
Single-density 3390	3390-1
Double-density 3390	3390-2
Triple-density 3390	3390-3
Double-density Model-20	9336-20

### **Usage Notes**

1. By default, the UTILITY utility is located on the system tools disk (MAINT 193). This utility is intended to be used only as part of a z/VM system installation procedure.

### **Messages**

- DMSOPN037E Filemode A is accessed as read/only.
- DMSEIO632E I/O error in EXECIO; rc=12 from FSOPEN command.
- HCP8300E File *filename filetype* not found.
- HCP8302E Parameter missing after *value*.
- HCP8304E Invalid parameter *parameter*.
- HCP8305E Invalid address *devno*.
- HCP8317I Moving *filename filetype* to tape.
- HCP8318I The *filename filetype* program is on tape file number *n*.

## XLINK DISPLAY

### Purpose

Use the XLINK DISPLAY utility to display link indicators in the map records of all systems on a particular device.

If a system is defined as a member of an SSI cluster, XLINK DISPLAY is not allowed.

### Operands

#### **vaddr**

specifies the virtual address of the device. This can be one of the following:

- A full-pack minidisk that defines the entire real volume
- The real volume attached to you at address *vaddr*
- A minidisk defining the cylinder on the volume that contains the CSE area.

#### **NOHeader**

keeps the descriptive column header information from being put on the CMS stack.

#### **STACK**

#### **FIFO**

#### **LIFO**

puts the information in the CMS program stack (for use by an EXEC or other program) instead of displaying it at the terminal. The information is stacked either FIFO (first in first out) or LIFO (last in first out). The options STACK and FIFO are equivalent.

#### **CYL(nnnnn)**

limits the display to the information for one minidisk starting on a specific cylinder.

### Usage Notes

1. The cross system extensions (CSE) environment is not supported. However, the cross-system link (XLINK) function that was included in CSE is still supported for non-SSI systems, and "CSE" is still used in some function and object names, command responses, and messages related to XLINK.
2. By default, the XLINK DISPLAY utility is located on the system tools disk (MAINT 193).
3. This utility requires read access to the device listed as *vaddr*.

### Responses

Response 1:

## XLINK DISPLAY

The normal response to the XLINK DISPLAY utility is:

```
HCPXXL2867I VOLSER valid NOT IN INCLUDE LIST, DEVTYPE CSE
           DEFAULTS WILL BE USED.

HCPXXL2876I VOLUME valid WAS FORMATTED FOR CSE ON
           mm/dd/yy AT hh:mm:ss
           BY USER userid AT SYSTEM sysname

           -CYL- READ/WRITE FLAGS ON valid (CYL=c TRK=t
           RECL=l RECS=r SYSTEMS=s)

           cccc   mode       sysname2   . . .   . . .   . . .
           . . .   . . .       . . .       . . .   . . .   . . .
           . . .   . . .       . . .       . . .   . . .   . . .
```

- or -

```
----- NO LINK FLAGS ON THIS VOLUME
```

### ***valid***

identifies the volume identifier of the specified device.

### ***userid***

identifies the user who formatted the CSE area on volume *valid*.

### ***sysname***

identifies the system from which the CSE area for this volume was formatted.

### ***c***

identifies the cylinder number where the CSE area was formatted.

### ***t***

identifies the track number of the CSE area.

### ***l***

identifies the number of cylinders made available for XLINK use. For CKD devices it is also the length of the XLINK map records.

### ***r***

identifies the number of XLINK records written on the CSE area.

### ***s***

identifies the number of systems that can share this DASD volume.

### ***cccc***

identifies the starting cylinder of an MDISK on volume *vvvvv* that has link flags outstanding by one or more systems.

### ***mode***

identifies the link mode, currently in effect for this MDISK by system *sysname2*. The possible mode values are:

#### **Read on**

Read-only access

#### **Write on**

Read and write access

#### **SRead on**

Read-only access and negates all write access requests.

#### **SWrite on**

Read and write access and negates all write access requests.

#### **ERead on**

Read-only access and negates all other access requests.

#### **EWrite on**

Read and write access and negates all other access requests.

**sysname2**

identifies the name of the system that has a read or write link to the MDISK that begins on cylinder *cccc*.

**Messages**

- HCP1667E THE XLINK UTILITY IS NOT ALLOWED BECAUSE THE SYSTEM IS A MEMBER OF AN SSI CLUSTER.
- HCP2861E MISSING OR INVALID FUNCTION: *subcommand*
- HCP2862E VOLSER *valid* IS NOT A CP FORMATTED VOLUME
- HCP2863E DIAG-A8 I/O ERROR, CC=*n* R15=hhhhhhh SCSW=hhhhhhh SENSE=hhhhhhh
- HCP2864E DEVICE ADDRESS *ccuu* IS INVALID OR NOT OPERATIONAL
- HCP2870E ERROR *nnn* ON CMSSTOR CALL
- HCP2871E INVALID OPTION: *option*
- HCP2872E COMMAND LINE TOO LONG FOR CP. CP CAN ACCEPT NO MORE THAN 240 CHARACTERS - YOUR COMMAND WAS *nnn* CHARACTERS IN LENGTH
- HCP2873E MISSING OR INVALID PARAMETER OR OPTION
- HCP2874E DEVICE *vdev* IS NOT A CKD OR ECKD DASD DEVICE.
- HCP2877E EITHER NOT A CSE VOLUME, OR CSE DATA IS NOT ON CYL *cccc* TRK *tt*

## XLINK FORMAT

```
▶▶ XLINK — FOrmat — vaddr — valid ▶▶
```

### Purpose

Use the XLINK FORMAT utility to prepare a DASD for sharing under cross-system link protection. The utility initializes the CSE area on the specified DASD volume.

If a system is defined as a member of an SSI cluster, XLINK FORMAT is not allowed.

### Operands

#### *vaddr*

specifies the virtual address of the device. This can be one of the following:

- A full-pack minidisk that defines the entire real volume
- The real volume attached to you at address *vaddr*
- A minidisk defining the cylinder on the volume that contains the CSE area.

#### *valid*

specifies the volume identifier that must match the one on the device.

### Usage Notes

1. The cross system extensions (CSE) environment is not supported. However, the cross-system link (XLINK) function that was included in CSE is still supported for non-SSI systems, and "CSE" is still used in some function and object names, command responses, and messages related to XLINK.
2. By default, the XLINK FORMAT utility is located on the system tools disk (MAINT 193).
3. The volume label on the disk is checked and must match the *valid* you enter with the utility.
4. You must have write access to device *vaddr*.
5. If the volume is CP-owned, you should allocate it as PERM space with the CPFMTXA utility. Even if the volume is not CP-owned, it is recommended that you allocate the CSE area as PERM.
6. If any system that will share this volume is not at release VM/ESA 1.1 or later, the CSE area must be reformatted, and the XLINK FORMAT command must be issued from a release earlier than VM/ESA 1.1. Otherwise, CP LINK commands to minidisks on this volume might fail.
7. If the number of cylinders being mapped is large or the number of tracks per cylinder is small, then XLINK FORMAT will write the ECKD format of the CSE area on multiple cylinders. The user will be given the option of stopping XLINK FORMAT before any formatting occurs on multiple cylinders, in case there are minidisks whose location needs to be adjusted.

### Responses

Response 1:

The normal responses to the XLINK FORMAT utility are:

```
HCPXXL2860I  WARNING!
             IMPROPER USE OF THE XLINK FORMAT COMMAND
             WILL CAUSE LOSS OF MINIDISK DATA. BE SURE
             THAT VOLSER valid IS NOT ON-LINE
             TO ANY ASSOCIATED SYSTEMS.

             CONTINUE?  ENTER YES OR NO:

HCPXXL2865I  VOLSER READ IS valid, FORMAT NOT DONE.
```

```
HCPXXL2867I VOLSER valid NOT IN INCLUDE LIST,
DEVTYPE CSE DEFAULTS WILL BE USED.

## Appendix A. Restricted User IDs

Many keywords have a specific meaning to your z/VM when they are encountered in a command input line.

The command syntax of the z/VM CP commands often lets you enter one of these keywords or a user ID with equal frequency. If you have assigned one of these keywords as a user ID, an ambiguity results that may cause the system to improperly analyze the command line.

You can avoid this problem by not using any of the following words as a user ID:

## Restricted User IDs

• *	DUMP	OBSERVER	SRM
• ABEND	DUPlex	OFF	STGEXempt
• ACCount	D8ONECMD	PAGing	STGLimit
• ALL	EXTended	PASSWORD	STORAge
• ALLDBcs	FENCES	PATHS	STore
• ALLOC	Files	PAV	SVC76
• ALLSBcs	FORCE	PCH	SWCH
• ALTID	FRames	PCIFUNCT	SWitches
• BRKKEY	Gateway	PENDING	SYSOPER
• BYUSER	GRAF	PER	SYStem
• CACHE	Hold	PFnn	S370E
• CACHEFW	HOTIO	PINNED	TAG
• CCWtran	IMG	Printer	TApes
• CFLINK	IMSG	PRIORity	TDisk
• CHANNEL	IOAssist	PRIVCLASS	TDISKCLR
• CHPID	ISLink	PROcessors	TDSK
• CMDLIMit	JOUrnal	PROcessr	TERMinal
• COLlect	LDEVs	Prt	Time
• COMMands	Links	PUnch	TIMER
• CONCOPY	LKFAC	PVMSG	TIMEZONEs
• CONsole	LINEs	QDROP	TRace
• CONV	LINEDit	QUICKDSP	TRACEFRAMEs
• COPY	LOGLxxxx	Rdr	TRFiles
• CPAssist	LOGmsg	Reader	TRSAve
• CPCHECKing	LOGNxxxx	REAL	TRSource
• CPDisks	LOGVxxxx	RECORDing	TYPe
• CPLANGLIST	MACHine	REPLY	UCR
• CPLANGuage	MAXSPOOL	REServed	UNDIAL
• CPLEVEL	MAXUsers	RESourCe	UR
• CPLOAD	MDCache	RETrieve	USERID
• CPOWNed	MDisk	RSAW	Users
• CPTRace	MITime	RUN	'V=F'
• CPUs	MOD	SASSISt	'V=R'
• CPUID	MODEL	SCReen	VDISK
• CRYPto	MONData	SDF	VDSK
• CTCa	MONitor	SEClabel	Virtual
• CTRL	MSG	SECuser	VMDump
• DAsd	MSGPROC	Set	VMSave
• DASDFW	Names	SHARE	VMSG
• DCSS	NLS	SPaces	WNG
• DISPlay	NSS	SPECIFIC	WRKALleg
	NVS	SPMODE	XSTorage
		SPOOL	XSTore

**Note:** Uppercase letters in this table represent the minimum truncations that the system will accept for any of these keywords. Where a keyword is specified in both uppercase and lowercase letters, you should not assign a user ID that is exactly the same as any acceptable truncation of the keyword. For example:

STORage

is a reserved keyword. You should not assign any of the following as user IDs:

STOR  
STORA  
STORAG  
STORAGE

Users should not be given user IDs that match SNA device LUNAMES.

Userids starting with LOGNxxxx, LOGLxxxx, and LOGVxxxx are used by the system and are restricted. The xxxx can be any character, number, or symbol.

**Note:** A one-to-four digit spoolid may be treated as a userid if it is in the directory.

The characters that you may use for user IDs specified in system configuration file statements are restricted by the USERID\_CHARACTERS and by the USERID\_PATTERN translate test tables. These tables restrict legal user ID characters to these:

**alphabetic**

A through Z

**numerics**

0 through 9

**others**

@ # \$ \_ (underscore) - (hyphen)

It is recommended that you not use logical line editing symbols in userids. See [Appendix B, “Logical Line Editing Symbols,”](#) on page 2267.

If you must change these legal character restrictions, please refer to [CHARACTER\\_DEFAULTS Statement](#) in *z/VM: CP Planning and Administration*.

## Appendix B. Logical Line Editing Symbols

To aid you in entering command or data lines from your line mode or display terminal, z/VM provides a set of logical line editing symbols, which you can use to correct mistakes as you enter lines. Each symbol has been assigned a default character value. These normally are:

<b>Symbol</b>	<b>Character</b>
Logical character delete	@
Logical line end	#
Logical line delete	␣
Logical escape	"

### Logical Character Delete

The logical character delete symbol (@) lets you delete one or more of the previous characters entered. The @ deletes one character per @ entered, including the ␣ and # logical editing characters. For example,

```
ABC#@@    results in AB
ABC@D    results in ABD
␣@DEF    results in DEF
ABC@@@   deletes the entire string
```

### Logical Line End

The logical line end symbol (#) lets you enter more than one command on the same line, and thus minimizes the amount of time you have to wait between entering commands. You type the # at the end of each logical command line, and follow it with the next logical command line. z/VM stacks the commands and runs them in sequence. For example, the entry

```
query users#query time#query dasd
```

is run in the same way as the entries

```
query users
query time
query dasd
```

The logical line end symbol also has special significance for the #CP function. Beginning any physical line with #CP indicates that you are entering a command that is to be processed by z/VM immediately. If you have set a character other than # as your logical line end symbol, you should use that character instead of a #.

### Logical Line Delete

The logical line delete symbol (␣) deletes the entire previous physical line, or the last logical line back to (and including) the previous logical line end (#). You can use it to cancel a line containing many or serious errors. If a # immediately precedes the ␣ sign, only the # sign is deleted, because the # indicates the beginning of a new line, and the ␣ cancels the current line. For example:

- Logical Line Delete:

```
ABC#DEF␣    deletes the #DEF and results in ABC
ABC#␣       results in ABC
ABC#DEF␣#GHI results in ABC#GHI
ABC#DEF␣GHI results in ABCGHI
```

## Logical Line Editing Symbols

- Physical Line Delete:

```
ABC␣          deletes the whole line
```

**Note:** When you cancel a line by using the ␣ logical line delete symbol, you do not need to press a carriage return; you can continue entering data on the same line.

## Logical Escape

The logical escape symbol (") causes z/VM to consider the next character entered to be a data character, even if it is normally one of the logical line editing symbols (@, ␣, ", or #). For example,

```
ABC"␣D        results in ABC␣D
"ABC"         results in "ABC"
```

If you enter a single logical escape symbol (") as the last character on a line, or on a line by itself, it is ignored.

When you enter multiple logical escape characters in conjunction with other logical editing characters, the results may be difficult to predict. For example, the lines

```
ABC""@DEF
ABC""@@DEF
```

both result in the line ABCDEF.

## Defining Logical Line Editing Symbols

The logical line editing symbols are defined for each virtual machine in the virtual machine's CP directory entry. If your terminal's keyboard lacks any of these special characters, your installation can define other special characters for logical line editing. To find out the logical line editing symbols in effect for your virtual machine, enter the command

```
cp query terminal
```

The response might be

```
LINEND # , LINEDEL ␣ , CHARDEL @ , ESCAPE " , TABCHAR ON
LINESIZE 080 , ATTN OFF , APL ON , TEXT OFF , MODE VM , HILIGHT ON
CONMODE 3215 , BREAKIN IMMED , BRKKEY PA1 , SCRNSAVE OFF
AUTO CR ON
```

You can use the TERMINAL command to change the logical line editing characters for your virtual machine. For example, if you enter

```
terminal linend /
```

then, the line

```
input # line / input / #
```

is interpreted

```
input # line
input
#
```

The terminal characteristics listed in the response to the QUERY TERMINAL command are all controlled by operands of the TERMINAL command.

## Appendix C. ASCII Translation

z/VM supports ASCII devices using 37x5. This section describes enhancements to VM support of ASCII in connection with line mode support.

### Provision of Translate Tables

The `TERMINAL` command has as an operand, `ASCIITBL`, that can be used on TTY type terminals. `ASCIITBL` lets you select the translation tables you want to use from the following:

#### VM1

ASCII translate tables based on STD TTY ANSI X3.4 1977 translate tables. VM1 is the default.

#### VM2

ASCII translate tables based on STD TTY ANSI X3.26 1980 translate tables.

If you find translate table discrepancies because your application uses STD TTY ANSI X3.26 1980 translate tables, you can select these translate tables with the VM2 option. If not, you can continue to use the 1977 translate tables as the default or by selecting the VM1 option.

### ASCII to EBCDIC Differences

ASCII	VM1 EBCDIC	Graphic	VM2 EBCDIC	Graphic
21	5A	!	4F	
5B	AD	[	4A	¢
5D	BD	]	5A	!
7C	4F		6A	!

### EBCDIC to ASCII Differences

ASCII	VM1 EBCDIC	Graphic	VM2 EBCDIC	Graphic
4A	7F	DEL	5B	[
4F	7C		21	!
5A	21	!	5D	]

## Appendix D. HCPLDR Control Statements and Output

The section provides information about the loader control statements and the HCPLDR output for future diagnostic purposes.

### Loader Control Statements

The following general rules apply to loader control statements:

1. The first column of the loader control statement must be X'02'.
2. Columns 2–4 must contain the statement name.
3. Unless stated otherwise:
  - operands can appear anywhere between columns 5 and 72
  - operands must consist of arguments of no more than 8 characters.
4. Operands must be separated by blanks.

### Printer Control Statement

The printer control statement enables or disables printing of the cross-reference listings and load maps.

Format:

Column 1	Columns 2-4	Columns 5-72
X'02'	PRT	{ON   <i>rdevno</i>   OFF }

Where:

**X'02'**

must appear in column one.

**PRT**

is the printer control statement acronym.

**{ON | *rdevno* | OFF }**

ON and *rdevno* enable printing of cross-reference listings and the load map. If you specify ON, the printer is at 000E. If you specify *rdevno*, the printer is at that device number.

OFF disables printing. If you enter the HCPLDR command without the PUNCH or TAPE option, this operand is ignored.

**Note:** Only one operand may appear on the statement.

### Set Page Boundary Control Statement

The set page boundary control statement aligns the next CSECT according to the page size specified.

Format:

Column 1	Columns 2-4	Columns 5-72
X'02'	SPB	<i>nnnnn</i>

Where:

**X'02'**

must appear in column 1.

### SPB

is the set page boundary control statement acronym.

### *nnnnn*

is the page size in hexadecimal. The page size may be any power of 2 from 8 to 65536. If not specified, the page size is X'1000' (decimal 4096).

**Note:** Only one argument may appear on the statement.

## Unconditional Page Boundary Control Statement

The unconditional page boundary control statement aligns all subsequent CSECTs according to the page size specified.

Format:

Column 1	Columns 2-4	Columns 5-72
X'02'	UPB	<i>nnnnn</i>

Where:

### **X'02'**

must appear in column 1.

### **UPB**

is the unconditional page boundary control statement acronym.

### *nnnnn*

is the page size in hexadecimal. The page size may be any power of 2 from 8 to 65536. The initial value is 8. If not specified, the page size is X'1000' (decimal 4096).

**Note:** Only one argument may appear on the statement.

## Conditional Page Boundary Control Statement

The conditional page boundary control statement conditionally aligns all subsequent CSECTs according to the page size specified. If a CSECT will not fit within the remainder of the present page, the system loader will locate the CSECT on the next page boundary.

Format:

Column 1	Columns 2-4	Columns 5-72
X'02'	CPB	<i>nnnnn</i>

Where:

### **X'02'**

must appear in column 1.

### **CPB**

is the conditional page boundary control statement acronym.

### *nnnnn*

is the page size in hexadecimal. The page size may be any power of 2 from 8 to 65536. If not specified, the page size is X'1000' (decimal 4096).

**Note:** Only one argument may appear on the statement.

Usage Notes®:

1. The standard value for page sizes is X'1000' (decimal 4096).

## Set Location Counter Control Statement

The set location counter control statement sets the next CSECT at an absolute address.

Format:

Column 1	Columns 2-4	Columns 5-23	Columns 24-80
X'02'	SLC	<i>nnnnnnnn</i>	ignored

Where:

**X'02'**

must appear in column 1.

**SLC**

is the set location counter acronym.

***nnnnnnnn***

is the absolute address in hexadecimal.

**Note:** Only one argument may appear on the statement.

Usage Notes:

1. Module HCPSYS uses the set location counter control statement to set the base address of the CP nucleus.
2. CMS uses the set location counter control statement to set the transient and user areas.

## Padding Control Statement

The padding control statement fills all unspecified locations in a CSECT with a specified value.

Format:

Column 1	Columns 2-4	Columns 5-72
X'02'	PAD	<i>nn</i>

Where:

**X'02'**

must appear in column 1.

**PAD**

is the padding control statement acronym.

***nn***

is the fill character in hexadecimal. The initial value is 0.

**Note:** Only one argument may appear on the statement.

Usage Notes:

1. Padding helps in debugging a program. If a program references unspecified areas, you can detect such references by padding with a value of X'F0' or some similar value.

## Parameter Control Statement

The parameter control statement supplies a parameter string that a loaded system uses upon execution.

Format:

Column 1	Columns 2-4	Columns 5-72
X'02'	PRM	<i>parmstring</i>

Where:

**X'02'**

must appear in column 1.

### PRM

is the parameter control statement acronym.

### *parmstring*

is a parameter string having a 2-byte length field followed by the parameter. When the system begins execution, general purpose register one addresses this parameter string.

## Subsystem Control Statement

The subsystem control statement specifies a subsystem and the location within a virtual machine where the subsystem appears. Such a subsystem is a separately loaded system, having its own relocation, page boundaries, cross reference listings, and load maps. However, the system loader loads the subsystem as a part of the main system. Use such a "system loaded within a system" for stand-alone programs. You can load the programs as part of the CP nucleus.

Format:

Column 1	Columns 2-4	Columns 5-72
X'02'	SYS	<i>name</i> [ <i>loc</i> ]

Where:

### **X'02'**

must appear in column 1.

### **SYS**

is the subsystem control statement acronym.

### *name*

is the name of the subsystem.

### *loc*

is the location where the subsystem appears in the virtual machine. If omitted, the location is 0.

## Loader Termination Control Statement

The loader termination control statement terminates the current system or subsystem. Control is passed to the entry point specified on the loader termination control statement. Every subsystem control statement must have its corresponding loader termination control statement and there must be one loader termination statement for the base system.

Format:

Column 1	Columns 2-4	Columns 5-72
X'02'	LDT	<i>name</i>

Where:

### **X'02'**

must appear in column 1.

### **LDT**

is the loader termination control statement acronym.

### *name*

is the entry point name that receives control after the system nucleus is loaded into storage. This operand is ignored for subsystems.

## Replace Control Statement

The replace control statement replaces instructions and constants in virtual storage.

Format:

Column 1	Columns 2-4	Columns 5-6	Columns 7-12	Columns 13-14	Columns 15-16	Columns 17-70	Columns 71-72	Columns 73-80
X'02'	REP		<i>sadd</i>		<i>esdid</i>	<i>flds</i>		nu

Where:

**X'02'**

must appear in column 1.

**REP**

is the replace control statement acronym.

***sadd***

is the hexadecimal starting address of the area that will be replaced.

***esdid***

is the External Symbol Identification, a number assigned by the compiler or assembler to the CSECT in which the replacement occurs.

***flds***

can be up to eleven 4-digit hexadecimal fields, separated by commas, each replacing one halfword. A comma cannot follow the last field.

**nu**

means "not used" by the loader. The field may be left blank or contain program identification.

Usage Notes:

1. The replace control statement must be in hexadecimal code.
2. The data in columns 17–70 (excluding commas) on the replace statement replaces what already was loaded into virtual storage beginning at the address specified in columns 7–12.
3. A replace statement may appear immediately preceding the:
  - END statement of an object module, if the module does not contain relocatable data (such as address constants)
  - First relocatable dictionary statement, if the object module does contain relocatable data.
4. If additions made by the replace statements increase the length of a CSECT, an include control section control statement must appear preceding the object module.
5. If the most recent VER control statement for a CSECT failed, the replace operation for that CSECT does not occur.

## Verify Control Statement

The verify control statement verifies a corresponding replace control statement, that is, verify assures that the proper data is replaced.

Format:

Column 1	Columns 2-4	Columns 5-6	Columns 7-12	Columns 13-14	Columns 15-16	Columns 17-70	Columns 71-72	Columns 73-80
X'02'	VER		<i>sadd</i>		<i>esdid</i>	<i>flds</i>		nu

Where:

**X'02'**

must appear in column 1.

**VER**

is the verify control statement acronym.

***sadd***

is the hexadecimal starting address of the area to be verified.

## ***esdid***

is the External Symbol Identification, a number assigned by the compiler or assembler to the CSECT in which the verification occurs.

## ***flds***

is up to eleven 4-digit hexadecimal fields, separated by commas, each verifying previously loaded halfwords. A comma cannot follow the last field.

## ***nu***

means "not used" by the loader. This field may be blank or contain program identification.

Usage Notes:

1. The verify control statement must be in hexadecimal code.
2. The data in columns 17–70 (excluding commas) on the verify statement verifies what already was loaded into virtual storage beginning at the address specified in columns 7–12.
3. Place verify control statements immediately before corresponding replace control statements.
4. If the verify function fails:
  - The loaded system does not run.
  - All following REP control statements for that CSECT are ignored until the next successful VER control statement for that CSECT.

## **Include Control Section Control Statement**

The include control section statement changes the length of a CSECT. Use it only when replace control statements cause a control section to increase in length.

Format:

<b>Column 1</b>	<b>Columns 2-4</b>	<b>Columns 5-72</b>
X'02'	ICS	<i>name size</i>

Where:

### **X'02'**

must appear in column 1.

### **ICS**

is the include control section statement acronym.

### ***name***

is the name of the CSECT you wish to enlarge.

### ***size***

is the total size required for the CSECT. If size is smaller than the assembled size, the assembled size is used. The value is hexadecimal.

Usage Notes:

1. Both arguments in the include control section statement are required.
2. The include control section statement must appear before the first ESD statement of the CSECT.

## **Delete Control Statement**

The delete control statement deletes up to eight CSECTs.

Format:

<b>Column 1</b>	<b>Columns 2-4</b>	<b>Columns 5-72</b>
X'02'	DEL	<i>name1 [... name8]</i>

Where:

**X'02'**

must appear in column 1.

**DEL**

is the delete control section statement acronym.

**name1 [...name8]**

is up to eight CSECT names. These names must not be previously defined within the load. Subsequent attempts to define these names as part of the system or subsystem will result in those CSECTs being deleted.

## Output

HCPLDR output for the MAP option consists of a file that contains several cross-reference listings and load maps. These listings and load maps from HCPLDR contain information provided for future diagnostic purposes. HCPLDR output for the SMALLMAP option consists of a file that contains CSECT information. This information is provided for future diagnostic purposes.

## Text Deck Information

This section contains the following information about each text deck (object file) in the generated system:

- The name of the text deck and its history
- The CSECT name, location, and size
- The names of the entry points and their locations
- Any loader control statements included in the text deck.

A one record header precedes the text deck information section. This header prevents the loss of information when HCPLDR output is PEEKed or RECEIVED by CMS. The header card produced by HCPLDR looks like this:

```
:READ  HEADER  HCPLDR  A1 AAAAAA 00/00/00  00:00 PEEK/RECEIVE REMOVE THIS CARD
```

The format of the header card is defined in the description of the CMS PUNCH command. For more information, see [PUNCH command](#) in *z/VM: CMS Commands and Utilities Reference*.

## System Summary

This section shows the labels that mark the beginning and end of the system, and its size in hexadecimal. @MAPSTRT and @MAPEND are the beginning and ending addresses of the load map. The module size is the size of the CP load map in bytes. @LOADEND is the next highest page address after the end of the map. [Figure 10 on page 2277](#) shows an example of this information from a CP load map.

```
@MAPSTRT AT 004A7000  MODULE SIZE IS 013A60
@MAPEND  AT 004BAA60
@LOADEND AT 004BB000  MODULE SIZE IS 000000
```

*Figure 10. System Summary for CP*

## CSECTs with Size Greater than Conditional Page Boundary

This report lists the pageable modules whose size is greater than the conditional page boundary setting.

[Figure 11 on page 2278](#) shows an example of this report from a CP load map. Any modules other than @MAPSTART that appear in this report are in error.

```
CSECT'S WITH SIZE GREATER THAN CONDITIONAL PAGE BOUNDARY
@MAPSTART 026D00
```

Figure 18. Load Map Sorted by Name

Table 51 on page 2280 shows the contents of the report for modules and entry points.

Table 51. Load Map Contents		
Label	Contents for Modules (CSECTs)	Contents for Entry Points
NAME	The name of the module	The name of the entry point

*Table 51. Load Map Contents (continued)*

Label	Contents for Modules (CSECTs)	Contents for Entry Points
(Blank)	SD	A reference code: -- The entry point is unreferenced. ** The entry point is referenced by an EXTRN but not by any address constant. <b>(blank)</b> The entry point is referenced by an EXTRN with an address constant (most CP entry points fall into this category).
LOAD	The load address of the module	The load address of the entry point
ASM	The offset of the module name within the module (for CP, this is usually 0)	The offset of the entry point within the module
SIZE	The size of the module	(Blank)
(Blank)	Normally blank. ? if an attempt was made to define the symbol twice.	Normally blank. ? if an attempt was made to define the symbol twice.

### Load Map Sorted by Address

This report contains the same information as the Load Map Sorted by Name, but it is sorted by the load address of the module or entry point.

You can use this report to check the starting and ending addresses of your generated system and verify that modules were loaded in the correct order.

### Other Information

Figure 19 on page 2281 shows an example of the last report from a CP load map. It shows:

- The number of failures of any VERIFY loader control statements contained in the system.

Your system should not have any verify failures. Since VERIFY and REPLACE loader control statements are most often used to replace object code in a text deck, a verify failure probably indicates an error in the resulting code.

- The number of unreferenced CSECTs and their names.
- The relocation summary. The relocation summary shows the number of references by length (1, 2, 3, and 4 bytes).

For CP, all of the references are 4 bytes long (AL4s).

## SMALLMAP File Information

If the SMALLMAP option is used, HCPLDR will produce a file with the following characteristics. The example given is for a CP system and [Figure 20 on page 2282](#) shows an excerpt of its contents.

Filename	Filetype	Fm	Format	Lrecl	Records	Blocks	Date	Time
CPLoad	SMALLMAP	A1	V	39	1667	34	2/17/93	17:30:21
HCPABN	00032260	000CA8	01/29/93	20:22				
HCPABS	00032F10	000420	01/29/93	20:22				
HCPABW	00034000	009760	01/23/93	20:02				
HCPADP	0003D760	000000	01/29/93	21:31				
HCPADPTR	0003D760	000100	01/29/93	21:31				
HCPAEP	0003D860	000000	01/29/93	21:42				
HCPAEPKA	0003D860	0006E0	01/29/93	21:42				
HCPAEPKI	0003DF40	000140	01/29/93	21:42				
HCPAEPDA	0003E080	0001B8	01/29/93	21:42				
HCPAEPPI	0003E240	0001A8	01/29/93	21:42

HCPAEPQV	0003E550	0001A0	01/29/93	21:42				
HCPAEPRI	0003E6F0	0007B0	01/29/93	21:42				
HCPAER	0003EEA0	000298	01/29/93	20:22				
HCPAFF	0003F140	000B68	01/29/93	20:22				

*Figure 20. Contents of SMALLMAP option*

- first token = csect name
- second token = address
- third token = csect size
- fourth token = text file date
- fifth token = text file time

**Note:** Date/time refer to the date/time of the text file from which the csect was read.

## Notices

---

This information was developed for products and services offered in the US. This material might be available from IBM in other languages. However, you may be required to own a copy of the product or product version in that language in order to access it.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

## Terms and Conditions for Product Documentation

---

Permissions for the use of these publications are granted subject to the following terms and conditions.

### Applicability

These terms and conditions are in addition to any terms of use for the IBM website.

### Personal Use

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

## Commercial Use

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

## Rights

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the above instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

## IBM Online Privacy Statement

---

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user, or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth below.

This Software Offering does not use cookies or other technologies to collect personally identifiable information.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see:

DELETE PCIFUNCTION command [272](#)

DELETE RDEVICE command [274](#)

DELETE RESPOOL command [276](#)

DEST operand

- CLOSE command [70](#)
- SET RDEVICE command [1650](#)
- START UR command [1868](#)

DESTAGE command [277](#)

destination

- controlling CP output [1440](#)

detach

- local or remote devices [296](#)
- message processor [292](#)
- processors using DETACH CPU [284](#)
- virtual devices [304](#)

DETACH (real device) command [296](#)

DETACH (virtual device) command [304](#)

DETACH CFLINK [282](#)

DETACH command [279](#)

DETACH CPU command [284](#)

DETACH CRYPTO command [286](#)

DETACH LAN command [290](#)

DETACH MSGPROC [292](#)

DETACH NIC command [293](#)

detach pcifunction

- virtual machine [294](#)

DETACH PCIFUNCTION command [294](#)

DETACH SYSASCSII command [302](#)

detaching virtual switch segment [307](#)

DETAIL operand

- QUERY CONV command [811](#)

DETAILS operand

- QUERY DASD command [868](#)
- QUERY MDISK command [1004](#)
- QUERY TAPES command [1207](#)

determine

- CHPID virtualization directory setting [798](#), [1275](#)
- devices on channel path [791](#)
- logical status of channel path [791](#)
- MONITOR record data [1575](#)
- physical status of channel path [796](#)

determine (*continued*)

- status of channel path [791](#), [796](#), [798](#), [1275](#)
- tape file names [1857](#)
- volumes under cross-system link control [2110](#)

DEVCLASS operand

- SET RDEVICE command [1664](#)

DEVCTL operand

- ATTACH command [35](#)

device

- adding emulated [1504](#)
- adding real [168](#), [1627](#)
- block
  - real, locating [618](#)
  - system logical, locating [616](#)
- changing [693](#)
- changing emulated [1504](#)
- changing real [1627](#)
- characteristics of minidisks [1004](#)
- control block, deleting real [274](#)
- creating real [168](#)
- defining real [168](#)
- deleting emulated [268](#)
- deleting real [265](#)
- deleting real control block [274](#)
- displaying
  - emulated [898](#)
  - installed on channel path [791](#), [798](#), [1275](#)
  - storage available for adding [895](#)
  - whether CP initializes new [1033](#)
- initializing
  - after IOMCK [1581](#)
  - when added to the system [1581](#)
- new, displaying whether CP initializes [1033](#)
- path, displaying installed [1064](#)
- restarting drained spool [1867](#)

DEVICE operand

- SET CACHE command [1422](#)
- SET DASDFW command [1485](#)

Device Support Facilities (ICKDSF) [2129](#)

DIAGNOSE code

- creating new [122](#), [172](#)
- defining new [122](#), [172](#)
- displaying authorized [78](#), [802](#)
- redefining [697](#)
- X'08'
  - containing multiple CP commands [865](#), [1482](#)
  - issuing QUERY ALLOC commands through [774](#)
- X'274'
  - receiving time zone interrupt from [1738](#)

DIAL command [308](#)

direct access subsystem cache [277](#)

DIRECTORY operand

- QUERY MDISK command [1004](#)

DIRECTXA utility [2168](#)

disable

- cache fast write [1427](#)
- cache function [1422](#)
- channel path [2046](#)
- DASD fast write [1485](#)
- devices for host system access [311](#)
- exit [319](#)
- HCD [321](#)
- I/O throttling [1734](#)
- internal CP checking [1439](#)

disable (*continued*)

- logical connections to real devices [2053](#)
- path, channel [2046](#)
- products using SET PRODUCT [1619](#)
- products, displaying status of [1095](#)
- protected application environment [1434](#)
- pseudo-page-fault facility [1594](#)
- real device [2063](#)
- subchannel [2067](#)
- subchannel measuring [1685](#)
- trace for real machine events [1446](#)
- trace ID tracing [2022](#)
- DISABLE (device) command [311](#)
- DISABLE CMD command [313](#)
- DISABLE COMMAND command [313](#)
- DISABLE DIAGNOSE command [316](#)
- DISABLE EXITS command [319](#)
- DISABLE HCD command [321](#)
- DISASSOCIATE command [324](#)
- DISCARD PINNED command [327](#)
- disconnect
  - from host system [329](#)
  - terminal logically [2042](#)
  - user to MPLF configuration [1540](#)
- DISCONNECT command [329](#)
- disk
  - CP-owned
    - changing [150](#)
    - defining [150](#)
    - displaying cylinder or page allocation [773](#)
    - displaying list [834](#)
  - preventing new operations [386](#)
  - stopping new operations [386](#)
- DISKMAP utility [2178](#)
- display
  - abend dump destinations [887](#)
  - ABEND SOFT status [753](#)
  - access modes to search for system logmsg [988](#)
  - active partition [991](#)
  - active users [532](#)
  - address
    - control information [602](#)
    - CP command table entry block [603](#), [817](#)
    - address of real PCI function block [621](#)
    - address of virtual PCI function block [645](#)
    - address space information [1170](#)
    - addresses of control information [651](#)
  - all
    - partitions [991](#)
    - paths installed to a device [1064](#)
  - APARs [839](#)
  - associated control block [621](#), [645](#)
  - authorized commands [78](#), [802](#)
  - authorized diagnose codes [78](#)
  - authorized DIAGNOSE codes [802](#)
  - AVS information [929](#)
  - buffers, PF key retrieve [1143](#)
  - BYUSER ID of a specified user [781](#)
  - cache fast write status [784](#)
  - cache status [782](#)
  - capability value of processors [786](#)
  - channel-to-channel adapter status [1287](#)
  - channel-to-channel adapters [857](#)
  - chargeable account [755](#)

display (*continued*)

- command limit threshold [799](#)
- commands, pending [1074](#)
- communication lines [976](#)
- concurrent copy session information [804](#)
- configuration mode setting [806](#)
- console color [1151](#)
- console status [1278](#)

 LOCATEVM command  
 command description [651](#)  
 stopping [96](#)

location  
 of CP module, displaying [832](#)  
 of CP nucleus, displaying [832](#)  
 of parm disk, displaying [832](#)  
 storing data at specified (ESA/XC, z/XC) [1881](#)

LOCATION operand  
 QUERY MDISK command [1004](#)

LOCK command [654](#)

LOCK operand  
 SET D8ONECMD command [1482](#)  
 SET PRIVCLASS command [1616](#)

lock pages of guest storage to host storage [654](#)

log on  
 defining new CP command to issue before [143](#)  
 to another virtual machine using AUTOLOG [50](#)

LOG operand  
 QUERY HOLD command [936](#)  
 SET D8ONECMD command [1482](#)

log, messages  
 displaying [988](#)  
 migration note [988](#)

logging to another virtual machine  
 using XAUTOLOG [2100](#)

logical device  
 attaching to host system [32](#)

logical line editing symbols [2267](#)

logical partition (LPAR)  
 active, displaying [991](#)  
 all, displaying [991](#)  
 displaying [991](#)

LOGIN command [662](#)

logo configuration file  
 adding to [1380](#)  
 replacing [1380](#)

LOGOFF command [659](#)

LOGON command [662](#)

LOGOUT command [659](#)

LOGROUTE parameter of the RETRIEVE utility [2219](#)

## M

machine check  
 I/O  
 initializing devices after [1581](#)

magnetic tape drives, displaying status [1207](#)

MANUAL operand  
 START UR command [1869](#)

MAP operand  
 LOCK command [655](#)  
 QUERY ALLOC command [773](#)  
 QUERY NSS command [1042](#)

MASTER operand  
 SET TRACEFRAMES command [1742](#)

maximum  
 number of PF key RETRIEVE buffers, setting [1681](#)

MAXIMUM operand  
 SET RETRIEVE command [1681](#)

maximum user limit [51](#), [999](#), [1559](#)

MDC operand  
 RDEVICE statement [1642](#)

MDR (Miscellaneous Data Record), retrieving [1910](#)

MEMBER operand  
 CPLISTFILE command [100](#)  
 CPTYPE command [105](#)  
 CPXLOAD command [112](#)

merging trace traps into one trace set  
 using TRACE APPEND [1965](#)

message  
 controlling display of warning [1784](#)  
 controlling receipt of special [1703](#)

log on  
 displaying [988](#)  
 recalling guest operating system [1349](#)  
 sending [673](#), [676](#)  
 sending special [1800](#)  
 sending to all active users [674](#)

MESSAGE (user) command [676](#)

MESSAGE ALL command [674](#)

MESSAGE command [673](#)

message examples, notation used in [6](#)

message repository  
 files, purging [745](#)

MIGR51D utility [2211](#)

migration note about system log messages [988](#)

minidisk  
 accessing  
 by CP [89](#)  
 adding [188](#)  
 adding temporary [223](#)  
 defining [188](#)  
 defining temporary [223](#)  
 displaying device characteristics [1004](#)
