{NGROUPS\_MAX} is the maximum number of POSIX Supplementary Group IDs (SGIDs) associated with a single POSIX process or POSIX database entry. If the ESM is providing the POSIX database information for the system, it is permitted to support a different number of SGIDs than CP does when an ESM is not providing the POSIX database information. If this is the case, the ESM must inform CP of its {NGROUPS\_MAX} value. The value must be within the valid range supported by CP. The minimum value can be determined from the QPXFCONF function of DIAGNOSE code X'2A0'; the maximum value is 125. The ESM is only permitted to supply the value to CP a single time. It becomes the system's {NGROUPS\_MAX} value for the duration of the CP system IPL. It is recommended that the ESM inform CP of its {NGROUPS\_MAX} value during ESM initialization, so that all users have the same capabilities and the system behaves in a POSIX-compliant manner.

For performance and storage utilization reasons, it is recommended that this value be no larger than necessary. The number of SGIDs in the largest SGID list in the database, plus a small margin for growth, would be a reasonable value.

**Descriptive Name:** Notify CP of POSIX capabilities

**Function:** Registers that there is an ESM installed that provides support for POSIX functions and the POSIX system databases. Accepts the value of {NGROUPS\_MAX} that the ESM supports and makes it the system value.

**Input Registers:**

**R0**

{NGROUPS\_MAX} value supported by the ESM.

**R1**

Must contain zero (X'00000000')

**R11**

Address of the dispatched VMDBK

**Output:** See Exit Values (Normal and Error)

**Note:** R15 will be changed for each exit. See each particular exit case, for the registers which contain meaningful information for that case.

**Exit Values:**

Normal:

**R15 = 0**

Function Completed

Error:

**R15 = 4**

The ESM has already informed CP of its capabilities and its {NGROUPS\_MAX} value

**R15 = 8**

The {NGROUPS\_MAX} value supplied in R0 is invalid

**Attributes:** Resident, MP, Reentrant

**Linkage:** Call with a dynamic save area

**Abend Codes:** None

**Messages** None

**Responses:** None

**Wait States:** None

**General Notes:** Registers R11 and R13 should not be changed by the installation-supplied code.

*Figure 79. Interface Specifications for the HCPRPEPX Entry Point*

## Entry Point HCPRPESG - Refresh a user's POSIX SGID list

If a user's POSIX database information is updated such that the POSIX Supplementary GID (SGID) list is affected, the user normally has to LOGOFF and log back on to have the new SGIDs take effect. However, if an ESM wishes to have the change take effect sooner, it may use the following interface to notify CP of the change. The ESM passes the SGIDs to CP, and CP causes them to be in effect for subsequent POSIX programs. Existing POSIX programs are not affected by this action; they continue to execute with their own SGIDs.

There is no need to inform CP of such a change if the affected user is not logged on. For performance and efficiency reasons, the ESM should only inform CP of changes to logged on or disconnected users' SGID lists.

**Descriptive Name:** Refresh a user's POSIX Supplementary GIDs (SGIDs)

**Function:** Accepts a notification from the ESM that a user's Supplementary GIDs in the POSIX database have changed. CP makes them take effect for certain new POSIX processes created by the user.

**Input Registers:**

**R0**

z/VM user ID of the user whose SGIDs have changed.

**R1**

This user ID must be specified in upper case and be left-justified and padded with blanks.

**R2**

Address of a buffer containing the new SGID list. The buffer consists of contiguous four-byte entries, each containing a GID.

**R3**

Number of SGIDs contained in the buffer pointed to by R2.

**R11**

Address of dispatched VMDBK.

**Output:** See Exit Values (Normal and Error)

**Note:** R15 will be changed for each exit. See each particular exit case, for the registers which contain meaningful information for that case.

**Exit Values:**

Normal:

**R15 = 0**

Function Completed

Error:

**R15 = 4**

The new SGID list contains an invalid number of SGIDs:

- The list contains 0 SGIDs
- The list contains more than {NGROUPS\_MAX} SGIDs.

**R15 = 8**

The input user ID is not logged on.

**R15 = 12**

A CP error condition was detected that prevented the replacement of the user's SGID list. A soft abend or SNAP dump may have occurred.

**Attributes:** Resident, MP, Reentrant

*Figure 80. Interface Specifications for the HCPRPESG Entry Point (Part 1 of 2)*

**Linkage:** Call with a dynamic save area

**Abend Codes:** None

**Messages:** None

**Responses:** None

**Wait States:** None

**General Notes:** Registers R11 and R13 should not be changed by the installation-supplied code.

*Figure 81. Interface Specifications for the HCPRPESG Entry Point (Part 2 of 2)*

## HCPRPF Module

CP's version of HCPRPF is a data area, not an executable module. It is empty, nonexecutable, static, and resident. An ESM may replace CP's stub module with its own copy of HCPRPF, which it may use as a data area. CP makes no reference to this module.

## HCPRPG Module

CP's version of HCPRPG contains an entry point, HCPRPGPH, and serves only as a place holder. An ESM may replace CP's stub module with its own copy of HCPRPG. CP makes no reference to this module. This module is resident, MP, and dynamic.

## HCPRPL Module

CP's version of HCPRPL contains an entry point, HCPRPLPH, and serves only as a place holder. An ESM may replace CP's stub module with its own copy of HCPRPL. CP makes no reference to this module. This module is resident, MP, and dynamic.

## HCPRPP Module

CP's version of HCPRPP contains six entry points for ESM single system image (SSI) support: HCPRPPEN, HCPRPPJN, HCPRPPPC, HCPRPPPS, HCPRPPSC, and HCPRPPWC. It also contains the following local entry points: HCPRPPHR, HCPRPPJD, HCPRPPJR, and HCPRPPHS.

### Entry Point HCPRPPEN

This entry point is used for single system image enablement processing. HCPRPPEN issues:

```
HCPSOCK CREATE_PORT,PORT='*RPI',RETSID=(R),EP=HCPRPPHR
```

This establishes the socket and stacks a call to the local entry point for the code that handles incoming messages, HCPRPPHR. The returned socket id is stored for subsequent use in the table HCPRWAPP mapped by the RWAESM DSECT.

The portname \*RPI should be used by all HCPSOCK macros in HCPRPP.

### Entry Point HCPRPPJN

This entry point is used for single system image join processing. HCPRPPJN stacks a deferred call to HCPRPPJD and returns with RC=4.

### Entry Point HCPRPPPC

CP calls this entry point to handle an upgrade to the single system image level. The CP stub entry point is not used.

## Entry Point H CPRPPPS

CP calls this entry point when a single system image mode change to STABLE is about to occur. The CP stub entry point is not used.

## Entry Point H CPRPPWC

CP calls this entry point to perform local worthiness checks. When omitted, the service is assumed to be single system image-worthy. The CP stub entry point is not used.

## Entry Point H CPRPPSC

CP calls this entry point when a single system image state change occurs. The CP stub entry point is not used.

## SSI join time processing

A deferred call to H CPRPPJD is stacked by H CPRPPJN after it is called by the single system image Configuration Manager at SSI join time. H CPRPPJD compares this system's installed ESM/level (if any) with that of the already joined nodes. If any compare is incompatible the result is PXMREJCT. This code works in conjunction with the table at EP H CPRWAPP, mapped by DSECT RWAESM in ACIPARMS COPY. An ESM should provide updates to H CPRWA to ensure that the SSI join time checks use the correct product and version information. The comparison data from the already joined nodes in the SSI cluster is provided by local entry point H CPRPPJR. Communication between nodes is by the H CPSOCK service, and local entry point H CPRPPHS provides a H CPSOCK SEND\_REPLY service.

## H CPRWA Module

CP's version of H CPRWA contains an entry point, H CPRWACP, which is empty, nonexecutable, static, and resident. An ESM may replace CP's stub module with its own copy of H CPRWA, which it may use as a work area. CP makes no reference to this module.

## CP Callable Services for the ACI

The following CP services are intended to be called by any of the ACI modules. The use of such services is optional.

## Entry Point H CPPWAPF

If the ESM supports optional features, such as the use of password phrases or mixed-case passwords, it should inform CP by calling H CPPWAPF. By default, there is no ESM support for password phrases or mixed-case passwords. When calling H CPPWAPF the ESM must indicate the level of support for optional features in the low order byte of register 1.

[Figure 82 on page 606](#) lists the interface specifications for this entry point.

**Input Registers:****R1**

A four-byte parameter containing:

X'00000001' - The ESM supports the extended form of the LOGON ACI call. For more information, refer to the notes for the [“LOGON Command”](#) on page 650.

**R11**

Address of the dispatched VMDBK

**Output:****R15**

See Exit Values (Normal and Error)

**Exit Values:**

Normal:

**R15 = 0**

Optional features support flag updated

Error:

**R15 = 4**

Optional features support flag not updated

**Attributes:** MP, dynamic, resident

**Linkage:** Call with a dynamic save area

*Figure 82. Interface Specifications for the HCPPWAPF Entry Point*

## Summary of CP Modules and Entry Points

The following table summarizes the module and entry point function information given on pages [“HCPRPPI Module”](#) on page 591 through [“HCPRPG Module”](#) on page 604:

| Module  | Entry Point | Function/Description                                                                                                                                                                                                                 |
|---------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HCPRPPI | HCPRPICN    | IUCV Connect interrupt handler                                                                                                                                                                                                       |
|         | HCPRPIIL    | IUCV message pending interrupt handler                                                                                                                                                                                               |
|         | HCPRPISV    | IUCV Sever interrupt handler                                                                                                                                                                                                         |
|         | HCPRPIQS    | IUCV Quiesce interrupt handler                                                                                                                                                                                                       |
|         | HCPRPIRM    | IUCV Resume interrupt handler                                                                                                                                                                                                        |
|         | HCPRPIRA    | Defined to support authorization requests (calls) from CP to the ESM. For commands, DIAGNOSE codes, and a subset of system functions, it is called to check whether a user is authorized prior to performing the requested function. |
| HCPRPW  | HCPRPWEP    | Defined to support password authorization checking on the LOGON, AUTOLOG, and XAUTOLOG commands (checked prior to processing the command).                                                                                           |
| HCPRPD  | HCPRPDEP    | Functions as a DIAGNOSE code X'A0' processor. This entry point calls HCPRPE at entry point HCPRPEEP, which processes subcodes X'00', X'08', and X'48'.                                                                               |

| Module | Entry Point | Function/Description                                                                                                                                                   |
|--------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HCPRPE | HCPRPEEP    | Handle DIAGNOSE code X'A0' subcodes X'00', X'08', and X'48'                                                                                                            |
|        | HCPRPEPX    | Notify CP of POSIX capabilities                                                                                                                                        |
|        | HCPRPESG    | Refresh a user's POSIX SGID list.                                                                                                                                      |
| HCPRPF | (none)      | Functions as a data area only, not an executable module.                                                                                                               |
| HCPRPG | HCPRPGPH    | Serves only as a place holder.                                                                                                                                         |
| HCPRPL | HCPRPLPH    | Serves only as a place holder.                                                                                                                                         |
| HCPRWA | HCPRWA      | This module is nonexecutable, static, and resident. The entry point of the ESM product information table, used by HCPRPEEP, HCPRPPEN, HCPRPPJD, HCPRPPJR and HCPRPPHS. |
|        | HCPRWAPP    |                                                                                                                                                                        |
| HCPPWA | HCPPWAPF    | Called by the ESM to indicate to CP the level of support provided for optional features.                                                                               |

## ACI Security Bits

The term, *event*, will be used to refer to all CP commands, all CP DIAGNOSE codes, and selected 'system functions' which have associated ACI Security bits. These selected system functions are listed below:

### **APPCON**

APPC connect

### **APPCWVL**

APPC connect with password

### **APPCSEV**

APPC sever

### **DIRECTORY\_CMD**

CP command issued from user directory

### **IUCVCON**

IUCV connect

### **IUCVSEV**

IUCV sever

### **MAINTCCW**

Maintenance CCW

### **MDISK**

MDISK and LINK-to-self

### **RSTDSEG**

Load/find a restricted NSS or DCSS

### **SDF\_CREATE**

SDF file create

### **SDF\_DELETE**

SDF file delete

### **SDF\_OPEN**

SDF file open

### **SNIFFER\_MODE**

Guest LAN Sniffing ON/OFF

### **SPF\_CREATE**

Spool file create

**SPF\_DELETE**

Spool file delete

**SPF\_OPEN**

Spool file open

**UTLPRINT**

CP PRINT function

There are three different types of security bits:

- AUDIT
- PROTECT(DAC)
- MAC (Mandatory Access Control).

These bits control the calls that CP makes to the ESM. PROTECT and MAC checks are types of authorization control. AUDITing consists of logging a record to show that the event was issued.

**Setting the ACI Security Bits**

CP provides the initial settings of the security bits; all AUDIT and MAC bits are initialized to off. The following is the list of those events for which the PROTECT bit is initialized to ON.

AUTOLOG

DIAGNOSE code X'D4'

DIAGNOSE code X'E4'

DIAGNOSE code X'280'

LINK

LOGOFF

LOGON

TAG

TRANSFER (see the note below)

TRSOURCE

XAUTOLOG

**Note:** If the PROTECT Bit is on for TRANSFER, then the ACI is called for CHANGE, CLOSE, SPOOL, TRSAVE, VMDUMP, and DIAGNOSE code X'94', if that event is used to change the ownership of a spool file, such as when the TO option is specified. The format of ACIPARMS on these calls is similar to the format used on the call for the TRANSFER command.

If an ESM is installed, it may set the security bits by invoking HCPDA0 (see [“HCPDA0 Module for Updating ACI Security Bits”](#) on page 610). CP enforces restrictions on setting the ACI Security bits. The AUDIT bit may be set for all events; the PROTECT and MAC bits can be set only for a predefined subset of events. The AUDIT and PROTECT bits can be set independently on an individual event basis. The MAC bits, however can only be set either all on or all off.

The following is the list of those events for which the PROTECT bit can be enabled or disabled.

APPC connect with password validation

## Checking the Security Bits and Calling the ESM

Each time CP processes an event, it checks the associated ACI Security bits. If any are on, CP sets up an ACIPARMS parameter list and calls the ESM, passing the address of ACIPARMS in General Register 1. See “CP Calls to the ACI” on page 637 for the parameter lists on the CP calls to the ACI. The ACIBMAPA, ACIBMAPP, and ACIBMAPM fields indicate which security bits were enabled. These three fields contain respectively the AUDIT, PROTECT, and MAC setting for the event executing. For DIAGNOSEs, system functions, and 'ANY' class commands, the high order (X'80') bit in the ACIBMAPx fields contains the security setting. For privileged commands, the ACIBMAPx fields contain settings for privilege classes A through G of the command (X'80' - X'20').

Upon return from the ESM, the return code in the ACICODE field is checked. The supported ESM return codes for each call are documented in [“CP Calls to the ACI” on page 637](#). In general, the return code handling is as follows:

There are four main ESM return codes defined in the ACIPARMS control block:

### **ACIAUTH 0**

Authorization is granted

### **ACIDEFR 4**

ESM is not there or defers

### **ACINOAC 8**

Authorization is denied

## ACIUNAV 20

ESM is not available (could not complete function)

### Notes:

1. Audit-only calls to the ESM support the ACIAUTH, ACIDEFR and ACIUNAV return codes.
2. ACIAUTH and ACIDEFR return codes are handled the same: processing continues.
3. If ACINOAC is received, the event will fail with an error message, or condition applicable to the event which was issued.
4. If ACIUNAV is returned then the event will not be allowed. Most commands fail with message:

```
6525E    The ESM is unavailable
```

Diagnose codes and system functions end with various failing return conditions.

LOGON, AUTOLOG, XAUTOLOG POSIX SET ID, POSIX GROUP DATABASE QUERY, and POSIX USER DATABASE QUERY ESM calls recognize additional return codes. These are documented in [“CP Calls to the ACI”](#) on page 637.

## HCPDA0 Module for Updating ACI Security Bits

HCPDA0 is a CP module which can be called by an ESM to control the ACI Security bit settings for CP commands, diagnose codes and selected system functions. Three entry points are provided for ACI Security bit manipulation:

### Entry Point Function

#### HCPDA0RL

To return the general ACI Security bit settings

#### HCPDA0UL

To update general ACI AUDIT and PROTECT bits

#### HCPDA0MC

To update the ACI MAC bits

The suggested way for an ESM to call HCPDA0 is through HCPRPD, the DIAGNOSE code X'A0' processor (see [“HCPRPD Module”](#) on page 597). After the appropriate input parameters are set up, the HCPDA0 call can be coded as follow:

```
HPCALL HCPDA0xx
```

where xx are the last two letters of the entry point name.

## Entry Point HCPDA0RL - Return ACI Security Bit Settings

Figure 83 on page 611 lists the interface specifications for the HCPDA0RL entry point. To determine the buffer size needed for the return data, this entry point can be called with a buffer size of zero. Upon return, general register zero will contain the number of entries to be returned by HCPDA0RL. Each returned entry will be mapped by an HCPA0LBK of size: A0LSIZE. (See [“HCPA0LBK Control Block”](#) on page 615 for format of HCPA0LBK. The required buffer size can then be calculated, and HCPDA0RL can be called again with the correct buffer size specified.

**Descriptive Name:** Return General ACI Security bits

**Function:** Returns to caller a list of all CP commands, diagnose codes, and some system functions, with the associated system security data.

**Input Registers:**

**R1**

Guest real address of buffer in which to return data.

The data is returned as a list of entries mapped by HCPA0LBK, one for each command, diagnose codes, and system function.

**R2**

Size of Buffer

**R11**

Address of the dispatched VMDBK

**Output:** See Exit Values (Normal and Error)

**Note:** R0, R1, R2, and R15 will be changed for each exit. See each particular exit case, for the registers which contain meaningful information for that case.

**Exit Values:**

Normal:

**R15 = 0**

Function Completed

**R1 =**

The number of entries that were processed.

Error:

**R15 = 4**

The size of the buffer was not large enough to hold all the entries.

**R0 =**

The number of entries that remain (i.e. could not fit into the buffer).

**R1 =**

The number of entries that were processed.

**R15 = 8**

Processing failed due to a condition which would cause a guest program check, or guest program exception.

**R0 =**

Program exception code representing the error. A negative value indicates instruction nullification is required.

**R15 = 12**

Processing failed due to a host paging or storage error.

**Attributes:** MP, Reentrant

*Figure 83. Interface Specifications for the HCPDA0RL Entry Point (Part 1 of 2)*

**Linkage:** Call with a dynamic save area

**Abend Codes:** None

**Messages:** None

**Responses:** None

**Wait States:** None

**General Notes:** Registers R11 and R13 should not be changed by the installation-supplied code.

*Figure 84. Interface Specifications for the HCPDA0RL Entry Point (Part 2 of 2)*

## **Entry Point HCPDA0UL - Update ACI AUDIT and PROTECT Bits**

Following are the interface specifications for the HCPDA0UL entry point.

**Descriptive Name:** Update AUDIT and PROTECT Security bits

**Function:** Update general audit and protect bits for all CP commands, DIAGNOSE codes, and security-relevant system functions.

**Input Registers:**

**R1**

Guest real address which contains the input entries, mapped by HCPA0UBK.

**R2**

Number of entries in the input buffer

**R11**

Address of the dispatched VMDBK

**Output:** See Exit Values (Normal and Error)

**Note:** R0, R1, R2, and R15 will be changed for all Normal and Error exits. See each particular exit case for the registers which contain meaningful information for that case.

**Exit Values:**

Normal:

**R15 = 0**

Function Completed

Error:

**R15 = 4**

Security data was not updated because of an error with one or more of the input A0UBK entries. 'A0UECODE' has been set for all entries. If A0UECODE equals A0UNOERR then there was no error with that entry. Otherwise, the appropriate error code (as defined in the HCPA0UBK) has been stored in A0UECODE.

**R1 =**

The number of entries that were incorrect.

**R15 = 8**

Processing failed due to a condition which would cause a guest program check, or guest program exception.

**R0 =**

Program exception code representing the error. A negative value indicates instruction nullification is required.

**R15 = 12**

Processing failed due to a host paging or storage error.

**Attributes:** MP, Reentrant

*Figure 85. Interface Specifications for the HCPDA0UL Entry Point (Part 1 of 2)*

**Linkage:** Call with a dynamic save area

**Abend Codes:** None

**Messages:** None

**Responses:** None

**Wait States:** None

**General Notes:** Registers R11 and R13 should not be changed by the installation-supplied code.

For commands whose protection setting (CMDPROT in the HCPCMDBK control block) can not be changed (A0LCPROT=OFF in the HCPA0LBK or CMDVPROT=OFF in the HCPCMDBK control block), the A0UBK entry must have A0UPROT set to off. For commands whose "valid before logon" setting (A0LCLOGN=OFF in the HCPA0LBK or CMDXLOG=OFF in the HCPCMDBK control block), the A0UBK entry must have A0ULOGON set to off.

*Figure 86. Interface Specifications for the HCPDA0UL Entry Point (Part 2 of 2)*

## **Entry Point HCPDA0MC - Update ACI MAC Bits**

Following are the interface specifications for the HCPDA0MC entry point.

**Descriptive Name:** Update ACI Security MAC bits

**Function:** Update MAC security bits for CP commands, diagnose codes, and system functions. MAC bits will be updated only for those events which are defined to have MAC protection, and they will be updated to be either all on or all off.

**Input Registers:**

**R3**

Address of 1 byte parameter list in the following format:

X'80' - Enable MAC

X'40' - Disable MAC

Either Enable\_MAC or Disable\_MAC must be set, and both may not be set.

**R11**

Address of the dispatched VMDBK

**Output:** See Exit Values (Normal and Error)

**Exit Values:**

Normal:

**R15 = 0**

Function Completed

Error:

**R15 = 8**

Request-type parameter was not set correctly (see Input Registers), no processing was done.

**Attributes:** MP, Reentrant

**Linkage:** Call with a dynamic save area

**Abend Codes:** None

**Messages** None

**Responses:** None

**Wait States:** None

**General Notes:** Registers R11 and R13 should not be changed by the installation-supplied code.

## HCPA0LBK Control Block

The following table gives the format of information in the HCPA0LBK control block.

*Table 80. Format of information in the HCPA0LBK control block*

| Offsets |      |           |     |            |                                            |
|---------|------|-----------|-----|------------|--------------------------------------------|
| Dec     | Hex  | Type      | Len | Name (Dim) | Description                                |
| 0       | (00) | STRUCTURE |     | A0LBK      | Describes each entry                       |
| 0       | (00) | CHARACTER | 12  | A0LNAME    | Command, diagnose, or system function name |

Table 80. Format of information in the HCPA0LBK control block (continued)

| Offsets                           |      |            |     |            |                                                                                                                 |
|-----------------------------------|------|------------|-----|------------|-----------------------------------------------------------------------------------------------------------------|
| Dec                               | Hex  | Type       | Len | Name (Dim) | Description                                                                                                     |
| 12                                | (0C) | CHARACTER  | 12  | A0LCMDOP   | Command operand. Valid only if entry type (i.e. A0LENTYP) is A0LCPCMD, A0LSTCMD, or A0LQYCMD and A0LOPRND is on |

## ACIPARMS Control Block

The following table gives the format of information in the ACIPARMS control block.

**Note:** All fields, codes, and flags defined in the ACIPARMS parameter list that are not specifically defined are reserved and are not to be used by an ESM for other purposes.

**Offsets**

| Dec | Hex | Type      | Len | Name (Dim) | Description          |
|-----|-----|-----------|-----|------------|----------------------|
| 0   | (0) | STRUCTURE |     | ACIPARMS   |                      |
| 0   | (0) | BITSTRING | 1   | ACIFCN     | A 1 function request |

**CODES DEFINED IN ACIFCN:**

The code in this field indicates class of event for the purposes of the authorization check associated with the ACIBMAPP setting. On calls where no authorization corresponding to the ACIBMAPP setting is applicable, ACIVMCMD should be used.

|           |          |                                          |

| ..1. .... | ACINSSEG | X'20' Restricted Load/Find of an NSS     |
| ..1. .1.. | ACIDCSEG | X'24' Restricted Load/Find of a DCSS     |
| ..1. 1... | ACIFESM1 | X'28' Reserved for ESM internal use      |
| ..1. 11.. | ACIFESM2 | X'2C' Reserved for ESM internal use      |
| ..11 .... | ACISETID | X'30' POSIX set ID request               |
| ..11 .1.. | ACIQGDB  | X'34' POSIX group database query request |
| ..11 1... | ACIQADB  | X'38' POSIX user database query request  |

## ACIPARMS Control Block

| Offsets |     |           |     |            |                             |
|---------|-----|-----------|-----|------------|-----------------------------|
| Dec     | Hex | Type      | Len | Name (Dim) | Description                 |
|         |     | ..11 11.. |     | ACIRSCHK   | X'3C' Resource access check |
| 1       | (1) | BITSTRING | 1   | ACICODE    | A 2 return code field       |

### CODES DEFINED IN ACICODE:

**Note:** The values X'2C' and X'28' are reserved for ESM (External Security Manager) use in the ACIFCN field. When adding new function codes, do not use these values.

|      |      |         |                                              |
|------|------|---------|----------------------------------------------|
| .... | .... | ACIAUTH | X'00' Access authorized, or successful audit |
| .... | .1.. | ACIDEFR | X'04' Access deferred                        |
| .... | 1... | ACINOAC | X'08' Access denied                          |

The following two return codes are defined only for LOGON (ACIFCN=ACILOG) calls.

|      |      |          |                                                                                                               |
|------|------|----------|---------------------------------------------------------------------------------------------------------------|
| .... | 11.. | ACIFAIL  | X'0C' Fail command and issue no message. For the LOGON command, force user. Only possible when ACIFCN=ACILOG. |
| ...1 | .... | ACITERM  | X'10' Fail command and issue no message. Only possible when ACIFCN=ACILOG.                                    |
| ..1. | .... | ACIUNAV  | X'20' ESM was unable to process request                                                                       |
| ..1. | .1.. | ACINFND  | X'24' Input group or user does not exist                                                                      |
| ..1. | 1... | ACIBFSM  | X'28' Access authorized, but the data buffer is too small to contain the requested data                       |
| ..1. | 11.. | ACINVAL  | X'2C' ACINUID or ACINGID contains an invalid value                                                            |
| ..11 | .... | ACINGMEM | X'30' ACITUSR not a member of the group identified in ACIGGNAM or ACIGGID. Only possible when ACIPXQGM=1.     |

|   |     |           |   |        |                           |
|---|-----|-----------|---|--------|---------------------------|
| 2 | (2) | BITSTRING | 2 | ACILEN | ACIPARMS length, in bytes |
|---|-----|-----------|---|--------|---------------------------|

The ACIBMAPA, ACIBMAPP and ACIBMAPM fields contain the audit, protect and MAC settings respectively. For privileged commands, the bits in the field contain the settings for CLASSA-CLASSG of the command. For ANY class commands, diagnose codes, and system functions, the flags defined after each field are used to indicate the setting. (ACIBMAPM is located after ACIENV)

|   |     |           |   |          |               |

## CP Calls to the ACI

The following sections describe the format of the ACIPARMS parameter list, that CP passes on the call to the ESM, for each of the commands and diagnose codes that support ESM protection. For more information about CP commands, see [z/VM: CP Commands and Utilities Reference](#). For more information about diagnose codes, see [Part 1, "CP DIAGNOSE Instructions," on page 1](#).

### Generic Command and DIAGNOSE Audit Calls

This section specifies ACIPARMS formats for the audit-only calls made for the majority of commands and diagnose codes. These calls are made to HCPRPIRA.

#### Generic Audit Call for CP Commands

This is the ACIPARMS format for commands which are audited from the command router. The command router will also make this call in the case of privilege failure for commands which are normally audited from the command processor. In addition, some command processors use this format for audit-only calls in error cases. [Table 81 on page 637](#) shows the ACIPARMS format for the command router audit call.

*Table 81. Generic command audit format of ACIPARMS*

| Label    | Contents                                                                              |
|----------|---------------------------------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                                              |
| ACILEN   | ACISIZE + ACIDATA (in bytes)                                                          |
| ACIBMAPA | Audit setting for each privilege class or ACIANYAU if this is an 'ANY' class command. |
| ACIENV   | ACIXAC                                                                                |
| ACIRUSR  | Command issuer's user ID.                                                             |
| ACIRGRP  | Command issuer's ACI group name.                                                      |
| ACIVERS  | ACIVERS1                                                                              |
| ACIFLAG  | ACIGOOD   ACIBAD + ACIANY (if this is an 'ANY' class command)                         |
| ACICMDTP | Command version<br><b>Note:</b> This field is not filled in for 'ANY' class commands. |
| ACISLAB  | Command issuer's SECLABEL.                                                            |

Table 81. Generic command audit format of ACIPARMS (continued)

| Label    | Contents                         |
|----------|----------------------------------|
| ACIEVENT | Command name padded with blanks. |
| ACIDATA  | Command line.                    |

Table 82 on page 638 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 82. Supported Return Codes

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'00' | Processing continues.                                                             |
| X'04' | Processing continues.                                                             |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

### Generic Audit Call for **DIAGNOSE** Codes

Table 83 on page 638 shows the ACIPARMS parameter list for the DIAGNOSE router audit call.

Table 83. Generic DIAGNOSE Call Format of the ACIPARMS Parameter List

| Label    | Contents                            |
|----------|-------------------------------------|
| ACIFCN   | ACIVMCMD                            |
| ACILEN   | ACISIZE + ACIDISZ (in bytes)        |
| ACIBMAPA | ACIDGNAU                            |
| ACIENV   | ACIXAD                              |
| ACIRUSR  | DIAGNOSE issuer's user ID.          |
| ACIVERS  | ACIVERS1                            |
| ACIFLAG  | ACIANY + ACIGOOD   ACIBAD           |
| ACISLAB  | Command issuer's SECLABEL.          |
| ACIEVENT | DIAGxxx padded with blanks.         |
| ACIRX    | Contents of Rx register (in hex).   |
| ACIRY    | Contents of Ry register (in hex).   |
| ACIRX1   | Contents of Rx+1 register (in hex). |
| ACIRY1   | Contents of Ry+1 register (in hex). |

If the diagnose processor has detected an error prior to making the audit call, then no return code checking is done after the HCPRPIRA call, and CP will continue with the error processing for the condition detected.

Table 84 on page 638 shows the return code (ACICODE) checking performed on the return from HCPRPIRA in the case where no error was detected prior to the call.

Table 84. Supported Return Codes

| RC    | Status                |
|-------|-----------------------|
| X'00' | Processing continues. |
| X'04' | Processing continues. |

Table 84. Supported Return Codes (continued)

| RC    | Status                                                                                                                                                                                                               |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'20' | DIAGNOSE fails: <ul style="list-style-type: none"> <li>• If DIAGNOSE code X'04', X'34', or X'3C', then reflect a specification exception.</li> <li>• Otherwise, reflect a privileged operation exception.</li> </ul> |

## ACIPARMS Parameter Lists for CP Commands

This section specifies the ACIPARMS formats that individual CP commands pass to the ESM. The calls are made to HCPRPIRA unless otherwise stated.

An ESM can provide security control and audit ability for guest LANs and virtual switches. Valid VLAN IDs range from x'0001'-x'0FFE'. The ESM keeps the VLAN ID list for each User ID and Owner/LANNAME combination, and it must provide the VLAN IDs in ascending sequence.

If there is not enough space to complete the initial ESM request, previously allocated space is released, and a call is made with a buffer with enough space for all the VLAN IDs. If there are more than the allowed 2000 VLAN IDs available, message HCP6528E is issued, access is denied, and the return call to HCPRPI is not made.

**Note:** Table 85 on page 639 shows examples of different access levels and their corresponding buffer size.

| Table 85. ACILVIDL and Buffer Data Examples for VLAN AWARE Virtual Switches |             |                 |
|-----------------------------------------------------------------------------|-------------|-----------------|
| Access Level                                                                | Buffer Size | Buffer Content  |
| Access allowed for VLANs 1, 2, & 3                                          | 6           | X'000100020003' |
| Access allowed for VLAN 2                                                   | 2           | X'0002'         |
| Access allowed - no VLANs                                                   | 2           | X'FFFF'         |

| Table 86. ACILVIDL and Buffer Data Examples for Guest LANs and VLAN UNAWARE virtual switches |             |                |
|----------------------------------------------------------------------------------------------|-------------|----------------|
| Access Level                                                                                 | Buffer Size | Buffer Content |
| Access allowed — no VLANs                                                                    | 0           |                |
| Access allowed — no VLANs                                                                    | 2           | X'FFFF'        |

For MAC processing, CP provides the SECLABEL for the requester, but the ESM must determine and maintain the SECLABEL for the LAN. The scope of this User ID and Owner/LANNAME combination does not extend beyond a router. If MAC processing is turned on, but protect is not turned on, MAC processing returns a return code of 0, with no VLANs. CP checks its own control blocks for both permission and VLANs, and then treats this case as if the ESM returned a DEFER.

Both the ESM and CP can participate in allowing the COUPLE command to complete. If AUDIT is requested, the AUDIT bit is turned off for the initial ESM call. After both the ESM and CP have determined if the COUPLE command is allowed, another ESM call is made requesting that the AUDIT record be created by the ESM. This AUDIT record shows the final result.

## AUTOLOG and XAUTOLOG Commands

Table 87 on page 640 shows the ACIPARMS parameter list for the ESM call for the AUTOLOG and XAUTOLOG commands. The call is made to HCPRPWEF. CP will not expect or accept the POSIX-related information unless the ESM has previously informed CP that it contains POSIX support. See [“Entry Point HCPRPEPX - Notify CP of POSIX capabilities”](#) on page 601 for additional information.

Table 87. (X)AUTOLOG Command Format of the ACIPARMS Parameter List

| Label    | Contents                                                                                                                                                                                                                                                                                                                                                                                                                           |

| ACILEN   | ACILGNSB                                                                                                                                                                                                                                                                                                                                                                                                                           |
| ACIBMAPA | Class AB, G, or ABG or X'00'.                                                                                                                                                                                                                                                                                                                                                                                                      |
| ACIBMAPP | Class AB, G, or ABG or X'00'.                                                                                                                                                                                                                                                                                                                                                                                                      |
| ACIBMAPM | Class AB, G or, ABG or X'00'.                                                                                                                                                                                                                                                                                                                                                                                                      |
| ACIENV   | ACIAUTO                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ACIRUSR  | Command issuer's userid, unless ACIRMSRC is set in ACIFLAG2.                                                                                                                                                                                                                                                                                                                                                                       |
| ACITGRP  | Target's ACI group name ((x)autologee).                                                                                                                                                                                                                                                                                                                                                                                            |
| ACITUSR  | User ID of the target (user being (x)autologged).                                                                                                                                                                                                                                                                                                                                                                                  |
| ACILGOPT | Logon options:<br><b>ACINOPAS</b><br>No password check requested.<br><b>ACINPMT</b><br>No password prompt requested.                                                                                                                                                                                                                                                                                                               |
| ACIVERS  | ACIVERS1                                                                                                                                                                                                                                                                                                                                                                                                                           |
| ACIFLAG  | ACIGOOD + ACIWO or ACIGOOD + ACIWO + ACIRW<br><b>Note:</b> ACIRW will only be set for XAUTOLOG ON when the target is a logical device.                                                                                                                                                                                                                                                                                             |
| ACICMDTP | Class AB (X'C0') or class G (X'02').                                                                                                                                                                                                                                                                                                                                                                                               |
| ACIFLAG2 | <ul style="list-style-type: none"> <li>ACIRMSRC is set if a private server is being xautologged by a remote source. In this case, an effective source is not available and ACIRUSR will not be set.</li> <li>ACINPASS is set if the user ID being autologged is defined with the NOPASS operand in its directory entry.</li> </ul>                                                                                                 |
| ACISLAB  | Command issuer's SECLABEL.                                                                                                                                                                                                                                                                                                                                                                                                         |
| ACIEVENT | "AUTOLOG" or "XAUTOLOG" padded with blanks.                                                                                                                                                                                                                                                                                                                                                                                        |
| ACIVMDBK | VMDBK address of the user logging on.                                                                                                                                                                                                                                                                                                                                                                                              |
| ACIPASS  | Contains password in EBCDIC format padded with blanks. If no password is set, this field will be all blanks.                                                                                                                                                                                                                                                                                                                       |
| ACITRMID | Terminal ID.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ACINWQFR | If ACINQLUN is on, the network qualifier of the SNA logical unit identifier defined in ACITRMID.                                                                                                                                                                                                                                                                                                                                   |
| ACILBUFL | (X)AUTOLOG data buffer list. A list of contiguous entries describing the output buffers for this request. Each entry consists of a buffer address and length (in bytes). A buffer address of zero indicates that the corresponding database information, and its length, should not be returned. ACILEN can be used to calculate the number of entries in the list. The address and length field of each entry is described below. |
| ACILUIDA | Address of the buffer to contain the user's POSIX UID.                                                                                                                                                                                                                                                                                                                                                                             |
| ACILUIDL | Length of the buffer pointed to by ACILUIDA.                                                                                                                                                                                                                                                                                                                                                                                       |
| ACILGIDA | Address of the buffer to contain the user's POSIX GID.                                                                                                                                                                                                                                                                                                                                                                             |

Table 87. (X)AUTOLOG Command Format of the ACIPARMS Parameter List (continued)

| Label    | Contents                                                            |
|----------|---------------------------------------------------------------------|
| ACILGIDL | Length of the buffer pointed to by ACILGIDA.                        |
| ACILSGIA | Address of the buffer to contain the user's Supplementary GID list. |
| ACILSGIL | Length of the buffer pointed to by ACILSGIA.                        |

Table 88 on page 641 shows the output fields set by the ESM in ACIPARMS on the return from HCPRPWEP.

| Label    | Contents                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACILOPTS | Flags, as follows: <ul style="list-style-type: none"> <li>• ACILSIDE indicates that the ESM has provided the user's ACILSIDA value.</li> <li>• ACILSIDA indicates that the user is permitted to set other users' POSIX IDs. This replaces CP's POSIXOPT SETIDS value for the user.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ACILBUFL | (X)AUTOLOG data buffer list. If ACICODE = X'00', the high-order bit of each length field indicates whether the ESM has chosen to provide the corresponding data or to defer it to CP. If this bit is on, the data that the ESM wishes to provide has been placed in the buffers, and the length field of the entry contains the length, in bytes, of the data placed in the buffer pointed to by that entry. If this bit is off, CP will use its own data (usually from the user directory or a default value). <p>If the Supplementary GID list was returned, it must include the user's primary GID.</p> <p>If ACICODE = X'28', the high-order bit of each length field indicates whether the ESM would provide the corresponding data or defer it to CP. If this bit is on, the length field of the entry contains the length, in bytes, of the buffer necessary to contain the corresponding information.</p> |

Table 89 on page 641 shows the return codes that CP supports in ACICODE on the return from HCPRPWEP.

Table 89. Supported HCPRPWEP Return Codes for the AUTOLOG and XAUTOLOG

| RC              | Meaning                                                                                                                                                                                                                                                                                          |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00'           | Authorization is granted and processing continues.                                                                                                                                                                                                                                               |
| X'04'           | Authorization is deferred; CP performs appropriate authorization checks. <ul style="list-style-type: none"> <li>• Password check for AUTOLOG and XAUTOLOG PROMPT PASSWORD</li> <li>• Directory check for XAUTOLOG G</li> </ul> <p>POSIX database information is acquired from the directory.</p> |
| X'08'           | The command fails with an error message: <ul style="list-style-type: none"> <li>• HCP059E for AUTOLOG and XAUTOLOG PASSWORD PROMPT</li> <li>• HCP6050E for XAUTOLOG G</li> </ul>                                                                                                                 |
| X'0C' and X'10' | The command fails, and no message is issued.                                                                                                                                                                                                                                                     |
| X'20'           | The command fails with error message HCP6525E, indicating the ESM is unavailable.                                                                                                                                                                                                                |

Table 89. Supported HCPRPWEP Return Codes for the AUTOLOG and XAUTOLOG (continued)

| RC    | Meaning                                                                                                                                                                                                                                                                                                                                                                     |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'28' | One or more of the buffers provided on input is too small to contain the requested data. The length field of each ACILBUFL entry whose high-order bit of the length field is on contains the required buffer length, in bytes, for that item. CP can be expected to acquire larger buffers and request all of the data from the ESM again, via a POSIX User Database query. |

### **AUTOLOG and XAUTOLOG Error Case Audit-Only Call**

When the AUTOLOG, or XAUTOLOG, processor detects an error during command processing, an audit-only call will be made (if audit is on) to HCPRPPIRA with the ACIPARMS format given in [“Generic Audit Call for CP Commands”](#) on page 637.

### **CHANGE TO Authorization Call**

See [“TRANSFER Command Authorization”](#) on page 662.

### **CHANGE Command Auditing**

Table 90 on page 642 shows ACIPARMS parameter list for a CHANGE command audit call.

Table 90. CHANGE Command Audit Format of the ACIPARMS Parameter List

| Label    | Contents                     |
|----------|------------------------------|
| ACIFCN   | ACIVMCMD                     |
| ACILEN   | ACISIZE + ACIDATA (in bytes) |
| ACIBMAPA | Audit settings.              |
| ACIENV   | ACIXAC                       |
| ACIRUSR  | Command issuer's user ID.    |
| ACIFLAG  | ACIGOOD or ACIBAD            |
| ACIVERS  | ACIVERS1                     |
| ACICMDTP | Command version.             |
| ACIEVENT | "CHANGE" padded with blanks. |
| ACISLAB  | Command issuer's SECLABEL.   |
| ACIDATA  | Command line.                |

Table 91 on page 642 shows the return codes that CP supports in ACICODE on the return from HCPRPPIRA.

Table 91. Supported HCPRPPIRA Return Codes

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'00' | Processing continues.                                                             |
| X'04' | Processing continues.                                                             |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

## CHANGE Command MAC/AUDIT

Table 92 on page 643 shows ACIPARMS for the MAC/AUDIT call for each file changed. Only the Class G version of the CHANGE command will be subject to MAC checking. Only a D Class user can use the SECLABEL option on the CHANGE command.

Table 92. CHANGE Command Format of the ACIPARMS Parameter List

| Label    | Contents                                            |
|----------|-----------------------------------------------------|
| ACIFCN   | ACIVMCMD                                            |
| ACILEN   | ACISIZE + ACISPLSZ (in bytes)                       |
| ACIBMAPA | AUDIT settings.                                     |
| ACIBMAPM | MAC settings.                                       |
| ACIENV   | ACISPF                                              |
| ACIRUSR  | Command issuer's user ID.                           |
| ACIVERS  | ACIVERS1                                            |
| ACIFLAG  | ACIGOOD + ACIWO                                     |
| ACICMDTP | Command version.                                    |
| ACIEVENT | "CHANGE" padded with blanks.                        |
| ACISLAB  | Command issuer's SECLABEL.                          |
| ACITLAB  | Spool file SECLABEL.                                |
| ACIORIG  | Spool file origin ID.                               |
| ACIFSTPG | DASD address of first page.                         |
| ACISPLID | Spool ID.                                           |
| ACINSPLD | New SECLABEL value if the SECLABEL option was used. |

Table 93 on page 643 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 93. Supported HCPRPIRA Return Codes

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                |
| X'04' | Authorization is deferred and processing continues.                               |
| X'08' | The command fails with error message HCP356E, indicating access denied.           |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

## CLOSE TO Command Authorization Call

This call is controlled by the TRANSFER class G protect setting.

**Note:** The CLOSE command is audited generically from the command router.

Table 94 on page 644 shows the ACIPARMS parameter list for a DAC HCPRPIRA call for the CLOSE command, when the TO option is used, and the target is not the issuer.

Table 94. CLOSE TO Command Format of the ACIPARMS Parameter List

| Label    | Contents                                                     |
|----------|--------------------------------------------------------------|
| ACIFCN   | ACISPOOL                                                     |
| ACILEN   | ACISIZE (in bytes)                                           |
| ACIBMAPP | Transfer's protect settings.                                 |
| ACIENV   | ACITRANS                                                     |
| ACIRGRP  | Command issuer's ACI group name from user's directory entry. |
| ACIRUSR  | Command issuer's user ID.                                    |
| ACITGRP  | ACI group name of user ID to whom files are being sent.      |
| ACITUSR  | User ID of user to whom files are being sent.                |
| ACIVERS  | ACIVERS1                                                     |
| ACIFLAG  | ACIGOOD                                                      |
| ACICMDTP | Class G (X'02').                                             |
| ACIEVENT | "CLOSE" padded with blanks.                                  |
| ACISLAB  | Command issuer's SECLABEL.                                   |

Table 95 on page 644 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 95. Supported HCPRPIRA Return Codes for the CLOSE TO Command

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                |
| X'04' | Authorization is deferred and processing continues                                |
| X'08' | The command fails with error message HCP007E, indicating an invalid user ID.      |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

### COUPLE Command MAC/AUDIT

**Note:** If the target of the couple was not successfully found, then a MAC authorization ESM call will not be made. This means that when the 'target SECLABEL' is not available, MAC checking will not be requested. Table 96 on page 644 shows the ACIPARMS parameter list for an HCPRPIRA call for the COUPLE command.

Table 96. COUPLE Command Format of the ACIPARMS Parameter List

| Label    | Contents                     |
|----------|------------------------------|
| ACIFCN   | ACIVMCMD                     |
| ACILEN   | ACISIZE + ACIDATA (in bytes) |
| ACIBMAPA | AUDIT settings.              |
| ACIBMAPM | MAC settings.                |
| ACIENV   | ACIXAC                       |
| ACIRUSR  | Command issuer's user ID.    |
| ACIVERS  | ACIVERS1                     |

Table 96. COUPLE Command Format of the ACIPARMS Parameter List (continued)

| Label    | Contents                                                                         |
|----------|----------------------------------------------------------------------------------|
| ACIFLAG  | ACIGOOD + ACIRW                                                                  |
| ACICMDTP | Command version.                                                                 |
| ACIEVENT | Command name padded with blanks.                                                 |
| ACIDATA  | Command line data.                                                               |
| ACISLAB  | Command issuer's SECLABEL.                                                       |
| ACITLAB  | SECLABEL of target user ID if successfully obtained by CP, otherwise from X'00'. |

Table 97 on page 645 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 97. Supported HCPRPIRA Return Codes for the COUPLE Command

| RC    | Meaning                                                                                     |
|-------|---------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                          |
| X'04' | Authorization is deferred and processing continues.                                         |
| X'08' | The command fails with error message HCP644, indicating an unknown/unauthorized CP command. |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable.           |

### COUPLE (COUPLEN) Network Command

**Note:** An ESM audit call may be made after both the ESM and CP have made their decisions about whether to return the VLAN list. Table 98 on page 645 shows the ACIPARMS parameter list for an HCPRPIRA call for the COUPLE (COUPLEN) Network command.

Table 98. COUPLEN Command Format of the ACIPARMS Parameter List

| Label    | ORG | IPUSER | Contents                                                         |
|----------|-----|--------|------------------------------------------------------------------|
| ACIRUSR  | DS  | CL8    | Requester's user ID.                                             |
| ACITUSR  | DS  | CL8    | Target LAN owner.                                                |
| ACILFLAG | DS  | X      | Audit promiscuous mode.                                          |
| ACINODE  | DS  | CL8    | Target <lanname> (ACILNID).                                      |
| ACIRSECL | DS  | CL8    | Requester's SECLABEL.                                            |
| ACILVIDA | DS  | A      | ADDR of buffer to contain VLAN IDs. VLAN IDs are two bytes each. |
| ACILVIDL | DS  | F      | Buffer size in bytes.                                            |
| ACIVLANC | DS  | 0D     | Variable command data.                                           |
| ACICPLSZ | EQU |        | (*ACIVLANC+7)/8                                                  |

Table 99 on page 646 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 99. Supported HCPRPIRA Return Codes for the COUPLEN Command

| RC    | Meaning                                                                                                                                                                                                                                                                                                                                      |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                                                                                                                                                                                                                                                                           |
| X'04' | Authorization is deferred and processing continues.                                                                                                                                                                                                                                                                                          |
| X'08' | The command fails with error message HCP6011E, indicating the user ID is not authorized to COUPLE to the specified LAN.                                                                                                                                                                                                                      |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable.                                                                                                                                                                                                                                                            |
| X'28' | Buffer is too small. ACILVIDL contains the total bytes needed, and the External Security Manager writes as many as space allows. A maximum of 2000 VLAN IDs is allowed. If the buffer size indicates that the ESM wants to return more than the allowed maximum, error message HCP6528E is issued, and the COUPLE command does not complete. |
| Other | The command fails with error message HCP644E, indicating an unknown CP command, if a return code other than the ones listed above is received.                                                                                                                                                                                               |

**FOR Command MAC/AUDIT**

Table 100 on page 646 shows the ACIPARMS parameter list passed to HCPRPIRA for a MAC/AUDIT call made by the FOR command.

Table 100. FOR Command MAC/AUDIT Format of the ACIPARMS Parameter List

| Label    | Contents                                                                                                                                                                                                                                     |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                                                                                                                                                                                                     |

Table 100. FOR Command MAC/AUDIT Format of the ACIPARMS Parameter List (continued)

| Label    | Contents                                                |
|----------|---------------------------------------------------------|
| ACITLAB  | SECLABEL of the FOR command target user ID.             |
| ACIEVENT | "FOR" padded on the right with blanks.                  |
| ACIDATA  | The FOR command issued without PATH and TOKEN operands. |

Table 101 on page 647 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 101. Supported Return Codes for the FOR Command

| RC    | Meaning                                                                                                      |
|-------|--------------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                                           |
| X'04' | Authorization is deferred and processing continues.                                                          |
| X'08' | The command fails with error message HCP070E, indicating the user issuing the FOR command is not authorized. |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable.                            |

### **GIVE (Auditing the Return of a Given Device)**

Table 102 on page 647 shows the ACIPARMS format for an HCPRPIRA audit call when a given device is returned via DETACH or LOGOFF. This call is based on the audit bit for the GIVE command. The GIVE command is audited generically from the command router.

Table 102. GIVE return

| Label    | Contents                                                                 |
|----------|--------------------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                                 |
| ACILEN   | ACISIZE + ACIGIVSZ (in bytes)                                            |
| ACIBMAPA | CLASSB                                                                   |
| ACIENV   | ACIGVRTN                                                                 |
| ACIRUSR  | Requestor (user returning the given device).                             |
| ACITUSR  | Target user (original giver, now getting device back).                   |
| ACIVERS  | ACIVERS1                                                                 |
| ACIFLAG  | ACIGOOD                                                                  |
| ACICMDTP | Command version.                                                         |
| ACIEVENT | "GIVERETN" padded with blanks.                                           |
| ACISLAB  | Requestor's SECLABEL.                                                    |
| ACITLAB  | Target SECLABEL (SECLABEL of the giver).                                 |
| ACIDETAD | VDEV returner's device (the device was given to this user).              |
| ACIRECAD | VDEV of the Giver's device (this user is now receiving the device back). |

There is no return code checking performed after the ESM call.

***IPL of a RESTRICTED Segment***

See “RSTDSEgt” on page 691.

***LINK Command Authorization/Audit Call***

**Note:** The MDISK function, and not LINK, controls LINKs-to-self.

The LINK authorization call is based off the audit, protect, and MAC bits for the LINK command. If, after making the call and receiving ESM authorization, CP denies or downgrades the requested access, then an audit-only call will be made. The ACIPARMS format for this audit-only call will be the same as below and:

- ACIBMAPP and ACIBMAPM will be zeroes.
- ACIMODE will be 'RR' if the access has been downgraded to read and 'XX' if the access has been denied.

Table 103 on page 648 shows the ACIPARMS format for the LINK command.

*Table 103. LINK Command Format of the ACIPARMS Parameter List*

| <b>Label</b> | <b>Contents</b>                                                                                                                                                                        |

| ACIBMAPA     | Class G (X'02') or X'00'.                                                                                                                                                              |
| ACIBMAPP     | Class G (X'02') or X'00'.                                                                                                                                                              |
| ACIBMAPM     | Class G (X'02') or X'00'.                                                                                                                                                              |
| ACIENV       | ACIDISK                                                                                                                                                                                |
| ACIRGRP      | Command issuer's ACI group name from user's directory entry.                                                                                                                           |
| ACIRUSR      | Command issuer's user ID.                                                                                                                                                              |
| ACITGRP      | ACI group name of the minidisk owner user ID.                                                                                                                                          |
| ACITUSR      | Owning user ID of the minidisk that is being linked to.                                                                                                                                |
| ACIMODE      | Minidisk access mode in EBCDIC format.                                                                                                                                                 |
| ACIADDR      | Link-To address in EBCDIC format.                                                                                                                                                      |
| ACIVERS      | ACIVERS1                                                                                                                                                                               |
| ACITADDR     | Link-As address in EBCDIC format.                                                                                                                                                      |
| ACIFLAG      | ACIRO or ACIRW + ACIGOOD                                                                                                                                                               |
| ACICMDTP     | Class G (X'02').                                                                                                                                                                       |
| ACIEVENT     | "LINK" padded with blanks.                                                                                                                                                             |
| ACISLAB      | Command issuer's SECLABEL.                                                                                                                                                             |
| ACITOD       | Additional field passed only for a shareable virtual disk in storage; contains the virtual disk in storage identifier (the TOD stamp for the creation of the virtual disk in storage). |

Table 104 on page 648 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

*Table 104. Supported HCPRPIRA Return Codes for the LINK Command*

| <b>RC</b> | <b>Meaning</b>                                     |
|-----------|----------------------------------------------------|
| X'00'     | Authorization is granted and processing continues. |

Table 104. Supported HCPRPIRA Return Codes for the LINK Command (continued)

| RC    | Meaning                                                                              |
|-------|--------------------------------------------------------------------------------------|
| X'04' | Authorization is deferred, and CP performs the authorization check.                  |
| X'08' | The command fails with error message HCP298E, indicating the minidisk is not linked. |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable.    |

### LINK Audit-Only Call in Error Processing

When the LINK processor detects an error during command processing before the ESM is called for authorization, then an audit-only call will be made (if audit is on) to HCPRPIRA with the ACIPARMS format given in “Generic Audit Call for CP Commands” on page 637. This call will not be made if the call described in “LINK Command Authorization/Audit Call” on page 648 has been made.

### LOGOFF Command

Table 105 on page 649 shows the ACIPARMS parameter list for an HCPRPIRA call which is made when a virtual machine is being logged off. For example, when a user LOGOFFs or is FORCED off.

Table 105. LOGOFF Command Format of the ACIPARMS Parameter List

| Label                                                                                                    | Contents                                                                             |
|----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| ACIFCN                                                                                                   | ACIDEL                                                                               |
| ACILEN                                                                                                   | ACIPARMS (in bytes)                                                                  |

| ACISLAB                                                                                                  | Command issuer's SECLABEL.                                                           |
| The following fields are valid only for a logoff due to a successful guest relocation:                   |                                                                                      |
| ACIRLODT                                                                                                 | "RELOCATE TO"                                                                        |
| ACIRLODN                                                                                                 | The name of the SSI cluster member that is the target destination of the relocation. |
| ACIRLOBY                                                                                                 | "BY"                                                                                 |
| ACIRLOCI                                                                                                 | The userid of the VMRELOCATE command issuer.                                         |
| ACIRLOAT                                                                                                 | "AT"                                                                                 |
| ACIRLOIN                                                                                                 | The SSI cluster member name where the command issuer was logged on.                  |
| The following fields are valid only for a skeleton VMDBK logoff due to an unsuccessful guest relocation: |                                                                                      |
| ACIRLAFA                                                                                                 | "RELOCATE FROM"                                                                      |
| ACIRLASC                                                                                                 | The name of the SSI cluster member that was the source for the relocation.           |
| ACIRLAAC                                                                                                 | "ABORTED"                                                                            |

CP does not check for a return code on the return from HCPRPIRA.

### ***LOGOFF of an AT Command Guest***

Table 106 on page 650 shows the ACIPARMS parameter list for an HCPUSP call for the logoff of a guest that has issued the AT command.

*Table 106. AT Command Guest LOGOFF Format of the ACIPARMS Parameter List*

| <b>Label</b> | <b>Contents</b>                                       |
|--------------|-------------------------------------------------------|
| ACIFCN       | ACIDEL                                                |
| ACILEN       | ACIATCSD * 8                                          |
| ACIBMAPA     | ACIANYAU if LOGOFF is audited.                        |
| ACIBMAPP     | ACIANYPR                                              |
| ACIENV       | ACIXAC                                                |
| ACIRGRP      | ACI group name.                                       |
| ACIRUSR      | User ID of the AT command guest.                      |
| ACIVERS      | ACIVERS1                                              |
| ACIFLAG      | ACIANY                                                |
| ACIEVENT     | "LOGOFF" padded with blanks.                          |
| ACIVMDBK     | Address of the AT command guest VMDBK.                |
| ACISLAB      | Security label.                                       |
| ACIATCDT     | "AT_LOGOFF"                                           |
| ACIATCDN     | The target node on which the AT command was executed. |
| ACIATCBY     | "BY"                                                  |
| ACIATCCI     | User ID of the AT command issuer.                     |
| ACIATCAT     | "AT"                                                  |
| ACIATCIN     | Node of the AT command issuer.                        |

### ***LOGON Command***

| ACIFLAG  | ACIANY + ACIGOOD + ACIRW                                                                                                                                                                                                                                                                                                                                              |
| ACIFLAG2 | ACINPASS is set if the user ID being logged on is defined with the NOPASS operand in its directory entry.                                                                                                                                                                                                                                                             |
| ACIEVENT | "LOGON" padded with blanks.                                                                                                                                                                                                                                                                                                                                           |
| ACIPASS  | Contains password in EBCDIC format padded with blanks. If no password is set, this field will be blank.                                                                                                                                                                                                                                                               |
| ACIVMDBK | Address of the VMDBK for the user logging on. This field is guaranteed to be valid only until the first loss of control after entry to HCPRPWEF.                                                                                                                                                                                                                      |
| ACIBYVAL | The user ID following the BY operand of the LOGON command, if the BY operand was specified, or zeros.                                                                                                                                                                                                                                                                 |
| ACISLAB  | Specified SECLABEL padded with blanks, or zeros if no SECLABEL was specified.                                                                                                                                                                                                                                                                                         |
| ACITLAB  | Creator of the logical device's SECLABEL or zeros if not a LOGON through a logical device.                                                                                                                                                                                                                                                                            |
| ACITRMID | One of the following: <ul style="list-style-type: none"> <li>• Terminal ID.</li> <li>• If ACILOGCL and ACILOGIP are set in ACILGOPT, an IPv4 address (see Note <a href="#">“1”</a> on page 652).</li> <li>• If ACILOGCL is not set, but ACILOGIP is set, the 8 high-order bytes of an IPv6 address. The 8 low-order bytes are in ACITRMI2..</li> </ul>                |
| ACITRMI2 | If ACILOGCL is not set, but ACILOGIP is set, the 8 low-order bytes of an IPv6 address.                                                                                                                                                                                                                                                                                |
| ACIDSPID | Dispatched user ID.                                                                                                                                                                                                                                                                                                                                                   |

Table 107. LOGON Command Format of the ACIPARMS Parameter List (continued)

| Label    | Contents                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACILBUFL | LOGON data buffer list. A list of contiguous entries describing the output buffers for this request. Each entry consists of a buffer address and length (in bytes). A buffer address of zero indicates that the corresponding database information, and its length, should not be returned. ACILEN can be used to calculate the number of entries in the list. The address and length field of each entry is described below. |
| ACILUIDA | Address of the buffer to contain the user's POSIX UID.                                                                                                                                                                                                                                                                                                                                                                        |
| ACILUIDL | Length of the buffer pointed to by ACILUIDA.                                                                                                                                                                                                                                                                                                                                                                                  |
| ACILGIDA | Address of the buffer to contain the user's POSIX GID.                                                                                                                                                                                                                                                                                                                                                                        |
| ACILGIDL | Length of the buffer pointed to by ACILGIDA.                                                                                                                                                                                                                                                                                                                                                                                  |
| ACILSGIA | Address of the buffer to contain the user's Supplementary GID list.                                                                                                                                                                                                                                                                                                                                                           |
| ACILSGIL | Length of the buffer pointed to by ACILSGIA.                                                                                                                                                                                                                                                                                                                                                                                  |

**Notes:**

1. IP addresses are normally written in dotted decimal format (for example, 9.130.58.78). In the LOGON command parameter list, each segment of the IP address is converted to a two-digit hexadecimal value. For example, 9 is converted to 09, and 130 is converted to 82. The result is an eight-byte string of four two-digit hexadecimal numbers in character form. So, 9.130.58.78 becomes the character string 09823A4E.
2. If the ESM supports password phrases, then ACIPASS is blank and the following fields are filled in:

**ACIOPPLN**

Contains the length of the password phrase. If no password phrase is set, this field will contain zero.

**ACIOPP**

Contains the password phrase in EBCDIC.

Table 108 on page 652 shows the output fields set by the ESM in ACIPARMS on the return from HCPRPWEP.

Table 108. LOGON ESM output fields in ACIPARMS

| Label    | Contents                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACILOPTS | Flags, as follows: <ul style="list-style-type: none"> <li>• ACILSIDE indicates that the ESM has provided the user's ACILSIDA value.</li> <li>• ACILSIDA indicates that the user is permitted to set other users' POSIX IDs. This replaces CP's POSIXOPT SETIDS value for the user.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ACILBUFL | LOGON data buffer list. If ACICODE = X'00', the high-order bit of each length field indicates whether the ESM has chosen to provide the corresponding data or to defer it to CP. If this bit is on, the data that the ESM wishes to provide has been placed in the buffers, and the length field of the entry contains the length, in bytes, of the data placed in the buffer pointed to by that entry. If this bit is off, CP will use its own data (usually from the user directory or a default value). <p>If the Supplementary GID list was returned, it must include the user's primary GID.</p> <p>If ACICODE = X'28', the high-order bit of each length field indicates whether the ESM would provide the corresponding data or defer it to CP. If this bit is on, the length field of the entry contains the length, in bytes, of the buffer necessary to contain the corresponding information.</p> |

Table 109 on page 653 shows the return codes that CP supports in ACIPARMS on the return from HCPRPWEF.

*Table 109. Supported HCPRPWEF Return Codes for the LOGON Command*

| RC    | Meaning                                                                                                                                                                                                                                                                                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                                                                                                                                                                                                                                                                                                            |
| X'04' | Authorization is deferred for CP to perform password verification. POSIX database information is acquired from the directory.                                                                                                                                                                                                                                                 |
| X'08' | The command fails with error message HCP050E, indicating logon was unsuccessful due to an incorrect password.                                                                                                                                                                                                                                                                 |
| X'0C' | The command fails, no message is issued, and the logon skeleton is forced off the system.                                                                                                                                                                                                                                                                                     |
| X'10' | The command fails and no message is issued (logon prompt is displayed).                                                                                                                                                                                                                                                                                                       |
| X'20' | The command fails. Error message HCP6525E, indicating the ESM is unavailable, is sent to the issuing user and to the system operator.                                                                                                                                                                                                                                         |
| X'28' | One or more of the buffers provided on input is too small to contain the requested data. The length field of each ACILBUFL entry whose high-order bit of the length field is on contains the required buffer length, in bytes, for that item. CP can be expected to acquire larger buffers and request all of the data from the ESM again, using a POSIX User Database query. |

### ***LOGON of an AT Command Guest***

Table 110 on page 653 shows the ACIPARMS parameter list for an HCPXAT call for the LOGON of a guest that will issue the AT command.

*Table 110. AT Command Guest LOGON Format of the ACIPARMS Parameter List*

| Label    | Contents                                                      |
|----------|---------------------------------------------------------------|
| ACIFCN   | ACILOG                                                        |
| ACILEN   | ACIATCSB                                                      |
| ACIBMAPA | ACIANYAU if LOGON command is audited.                         |
| ACIBMAPP | ACIANYPR                                                      |
| ACIBMAPM | ACIANYMC                                                      |
| ACIENV   | ACIXAC                                                        |
| ACIRGRP  | ACI group name.                                               |
| ACIRUSR  | User ID of the AT command guest.                              |
| ACIVERS  | ACIVERS1                                                      |
| ACIDSPID | User ID the AT command was initiated from on the target node. |
| ACIFLAG  | ACIANY + ACIGOOD.                                             |
| ACIEVENT | AT "LOGON" padded with blanks.                                |
| ACIVMDBK | Address of the AT command guest VMDBK.                        |
| ACISLAB  | Security label.                                               |
| ACIATCDT | "AT_LOGON"                                                    |
| ACIATCDN | The target node on which the AT command will be executed.     |

Table 110. AT Command Guest LOGON Format of the ACIPARMS Parameter List (continued)

| Label    | Contents                          |
|----------|-----------------------------------|
| ACIATCBY | "BY"                              |
| ACIATCCI | User ID of the AT command issuer. |
| ACIATCAT | "AT"                              |
| ACIATCIN | Node of the AT command issuer.    |

**MESSAGE Command MAC/AUDIT**

Table 111 on page 654 shows the ACIPARMS parameter list for an HCPRPIRA call for the MESSAGE command.

**Note:** MAC will not be performed when:

- The ALL option is specified.
- The sender or the receiver is the system operator.

Table 111. MESSAGE Command MAC/AUDIT Format of the ACIPARMS Parameter List

| Label    | Contents                                                                                                                         |
|----------|----------------------------------------------------------------------------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                                                                                         |
| ACILEN   | ACISIZE + ACIDATA (in bytes)                                                                                                     |
| ACIBMAPA | AUDIT settings.                                                                                                                  |
| ACIBMAPM | MAC settings.                                                                                                                    |
| ACIENV   | ACIXAC                                                                                                                           |
| ACIRGRP  | Command issuer's ACI group name from user's directory entry.                                                                     |
| ACIRUSR  | Command issuer's user ID.                                                                                                        |
| ACIVERS  | ACIVERS1                                                                                                                         |
| ACIFLAG  | ACIGOOD ACIBAD + ACIWO + ACIANY (for the 'ANY' class message command)                                                            |
| ACICMDTP | CLASSA+CLASSB (for message and warning all), CLASSB (for MSGNOH), CLASSG (for msg) or CLASSA+CLASSB+CLASSC (Warning not to ALL). |
| ACIEVENT | "MESSAGE" or "MSGNOH" or "MSG" or "WARNING" padded with blanks.                                                                  |
| ACISLAB  | Command issuer's SECLABEL.                                                                                                       |
| ACITLAB  | SECLABEL of target user ID if valid user ID found.                                                                               |
| ACIDATA  | Command line data.                                                                                                               |

Table 112 on page 654 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 112. Supported Return Codes for the MESSAGE Command

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                |
| X'04' | Authorization is deferred and processing continues.                               |
| X'08' | The command fails with error message HCP003E, indicating an invalid option.       |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

## MSGNOH Function MAC/AUDIT

See “MESSAGE Command MAC/AUDIT” on page 654.

### PURGE Command Audit

The PURGE command calls for audit with the ACIPARMS format shown in “Generic Audit Call for CP Commands” on page 637.

Table 113 on page 655 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 113. Supported HCPRPIRA Return Codes for the PURGE Command

| RC    | Meaning                                                                                                                                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                                                                                                                                                            |
| X'04' | Authorization is deferred and processing continues.                                                                                                                                                                           |
| X'20' | If Purge command processing detected an error prior to the ESM call then the purge processor will issue the appropriate message. Otherwise, the command fails with error message HCP6525E, indicating the ESM is unavailable. |

### QUERY TAG and TAG QUERY Command MAC/AUDIT

Table 114 on page 655 shows the ACIPARMS parameter list for an HCPRPIRA call for the QUERY TAG and TAG QUERY commands. For QUERY TAG file and TAG QUERY file this is a MAC/AUDIT call. Otherwise, it is audit-only.

Table 114. QUERY TAG FILE Command Format of the ACIPARMS Parameter List

| Label    | Contents                                                                    |
|----------|-----------------------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                                    |
| ACILEN   | ACISIZE + ACIDATA (in bytes).                                               |
| ACIBMAPA | AUDIT Settings.                                                             |
| ACIBMAPM | MAC Settings (only for QUERY TAG and TAG QUERY file).                       |
| ACIENV   | ACIXAC                                                                      |
| ACIRGRP  | Command issuer's ACI group name from user's directory entry.                |
| ACIRUSR  | Command issuer's user ID.                                                   |
| ACIVERS  | ACIVERS1                                                                    |
| ACIFLAG  | ACIGOOD + ACIRO                                                             |
| ACICMDTP | Class G (X'02')                                                             |
| ACIEVENT | "TAG" padded with blanks.                                                   |
| ACISLAB  | Command issuer's user SECLABEL.                                             |
| ACITLAB  | SECLABEL of target spool file (only for TAG QUERY file and QUERY TAG file). |
| ACIDATA  | Command line data.                                                          |

Table 115 on page 656 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 115. Supported Return Codes

| RC    | Meaning                                                                                |
|-------|----------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                     |
| X'04' | Authorization is deferred and processing continues.                                    |
| X'08' | The command fails with error message HCP026E, indicating a missing or invalid operand. |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable.      |

**QUERY RDR/PRT/PUN Command**

Table 116 on page 656 shows the ACIPARMS parameter list for a MAC-only HCPRPIRA call to determine whether key fields can be displayed in the command response.

**Note:** The QUERY RDR/PRT/PUN command is audited generically with a separate call.

Table 116. QUERY RDR/PRT/PUN Command Format of the ACIPARMS Parameter List

| Label    | Contents                                                       |
|----------|----------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                       |
| ACILEN   | ACISIZE + ACISPLSZ (in bytes)                                  |
| ACIBMAPM | MAC Settings.                                                  |
| ACIENV   | ACISPF                                                         |
| ACIRUSR  | Command issuer's user ID.                                      |
| ACIVERS  | ACIVERS1                                                       |
| ACIFLAG  | ACIRO + ACIGOOD                                                |
| ACICMDTP | Command version.                                               |
| ACIEVENT | Command operand (READER, PRINTER or PUNCH) padded with blanks. |
| ACISLAB  | Command issuer's SECLABEL.                                     |
| ACITLAB  | SECLABEL of target spool file.                                 |
| ACIORIG  | Spool file origin ID.                                          |
| ACIFSTPG | DASD address of first page.                                    |
| ACISPLID | Spool file ID.                                                 |

Table 117 on page 656 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 117. Supported HCPRPIRA Return Codes

| RC    | Meaning                                                                                       |
|-------|-----------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                            |
| X'04' | Authorization is deferred and processing continues                                            |
| X'08' | All fields except ORIGINID, FILEID, CLASS, HOLD, DATE and TIME will be filled with asterisks. |
| X'20' | All fields except ORIGINID, FILEID, CLASS, HOLD, DATE and TIME will be filled with asterisks. |

### ***SEND Command Audit***

Table 118 on page 657 shows the ACIPARMS parameter list for an HCPRPIRA call for the audit call made by the SEND command.

*Table 118. SEND Command Audit Call Format of the ACIPARMS Parameter List*

| <b>Label</b> | <b>Contents</b>           |
|--------------|---------------------------|
| ACIFCN       | ACIVMCMD                  |
| ACILEN       | ACISIZE (in bytes)        |
| ACIBMAPA     | CLASSC+CLASSG             |
| ACIENV       | ACIXAC                    |
| ACIRUSR      | Issuer's user ID          |
| ACITUSR      | Target user ID            |
| ACIVERS      | ACIVERS1                  |
| ACIFLAG      | ACIGOOD or ACIBAD         |
| ACISLAB      | Issuer's SECLABEL         |
| ACITLAB      | Target user's SECLABEL    |
| ACICMDTP     | User's privilege classes  |
| ACIEVENT     | 'SEND' padded with blanks |

There is no return code checking performed after the ESM call.

### ***SEND Command Security Label MAC Check***

Table 119 on page 657 shows the ACIPARMS parameter list for an HCPRPIRA call for the SEND command security label MAC check.

*Table 119. SEND Command Security Label MAC Check Format of the ACIPARMS Parameter List*

| <b>Label</b> | <b>Contents</b>                                      |
|--------------|------------------------------------------------------|
| ACIFCN       | ACIVMCMD                                             |
| ACILEN       | ACISIZE (in bytes)                                   |
| ACIBMAPA     | ACISYSMC                                             |
| ACIENV       | ACIXAC                                               |
| ACIRUSR      | Issuer's user ID                                     |
| ACITUSR      | Target user ID                                       |
| ACIVERS      | ACIVERS1                                             |
| ACIFLAG      | ACIANY + ACIGOOD + ACIRW or ACIANY + ACIGOOD + ACIWO |
| ACISLAB      | Issuer's SECLABEL                                    |
| ACITLAB      | Target user's SECLABEL                               |
| ACIEVENT     | 'SEND_SECLBL' padded with blanks                     |

Table 120 on page 658 shows the ACICODE return codes checked on return from HCPRPIRA.

Table 120. Supported Return Codes

| RC       | Meaning                                                                                             |
|----------|-----------------------------------------------------------------------------------------------------|
| <= X'04' | Authorization is granted and processing continues.                                                  |
| > X'04'  | The command fails with error message HCP068E, indicating the user's SECLABELs failed the MAC check. |

**SMSG Function MAC/AUDIT**

See “MESSAGE Command MAC/AUDIT” on page 654.

**SPOOL TO Command**

This call is controlled by the TRANSFER class G protect setting.

**Note:** The SPOOL command is audited generically from the command router.

Table 121 on page 658 shows the ACIPARMS parameter list for a DAC HCPRPIRA call for the SPOOL command, when the TO or FOR option is used, and the target is not the issuer.

Table 121. SPOOL Command Format of the ACIPARMS Parameter List

| Label    | Contents                                                     |
|----------|--------------------------------------------------------------|
| ACIFCN   | ACISPOOL                                                     |
| ACILEN   | ACISIZE (in bytes)                                           |
| ACIBMAPP | Transfer's protect settings.                                 |
| ACIENV   | ACITRANS                                                     |
| ACIRGRP  | Command issuer's ACI group name from user's directory entry. |
| ACIRUSR  | Command issuer's user ID.                                    |
| ACITGRP  | ACI group name of user ID to whom files are being sent.      |
| ACITUSR  | User ID of user to whom files are being sent.                |
| ACIVERS  | ACIVERS1                                                     |
| ACIFLAG  | ACIGOOD                                                      |
| ACICMDTP | Class G (X'02').                                             |
| ACIEVENT | "SPOOL" padded with blanks.                                  |
| ACISLAB  | Command issuer's SECLABEL.                                   |

Table 122 on page 658 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 122. Supported HCPRPIRA Return Codes for the SPOOL TO Command

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                |
| X'04' | Authorization is deferred and processing continues.                               |
| X'08' | The command fails with error message HCP007E, indicating an invalid user ID.      |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

## SPXTAPE Dumping and Loading of Files

Table 123 on page 659 shows the ACIPARMS format for an audit-only call for each file dumped or loaded by the SPXTAPE DUMP or LOAD command. The SPXTAPE command is audited generically.

Table 123. ACIPARMS format

| Label    | Contents                                         |
|----------|--------------------------------------------------|
| ACIFCN   | ACIVMCMD                                         |
| ACILEN   | ACISIZE + ACISPLSZ (in bytes)                    |
| ACIBMAPA | AUDIT Settings.                                  |
| ACIENV   | ACISPTAP                                         |
| ACIRUSR  | Spool file owner's user ID.                      |
| ACIVERS  | ACIVERS1                                         |
| ACIFLAG  | ACIGOOD                                          |
| ACICMDTP | CLASSE+CLASSD   CLASSD   CLASSG                  |
| ACIEVENT | "SPLDUMP" or "SPLLOAD" padded with blanks.       |
| ACITLAB  | Spool file SECLABEL.                             |
| ACIORIG  | Spool file origin ID.                            |
| ACIFSTPG | DASD address of first page.                      |
| ACISPLID | Spool file ID.                                   |
| ACITOD   | TOD clock value at time of SPXTAPE DUMP or LOAD. |
| ACICMDIS | Command issuer's user ID.                        |

Table 124 on page 659 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 124. Supported Return Codes

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'00' | Processing continues.                                                             |
| X'04' | Processing continues.                                                             |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

## START Real Printer SECLABEL Authorization Call

Table 125 on page 659 shows the ACIPARMS format for the HCPRPIRA call for the STARTing a real device.

This call is based on MAC bit for the START command. This is an authorization-only call. The START command is audited from the command router.

Table 125. START real printer with SECLABEL option authorization call

| Label    | Contents           |
|----------|--------------------|
| ACIFCN   | ACIVMCMD           |
| ACILEN   | ACISIZE (in bytes) |
| ACIBMAPM | CLASSD (X'10')     |

Table 125. START real printer with SECLABEL option authorization call (continued)

| Label    | Contents                                                     |
|----------|--------------------------------------------------------------|
| ACIENV   | ACIXAC                                                       |
| ACIRGRP  | Command issuer's ACI group name from user's directory entry. |
| ACIRUSR  | Command issuers user ID.                                     |
| ACIVERS  | ACIVERS1                                                     |
| ACITADDR | Address of printer right justified in EBCDIC.                |
| ACIFLAG  | ACIGOOD + ACIWO                                              |
| ACICMDTP | CLASSD                                                       |
| ACIEVENT | "START" padded with blanks.                                  |
| ACISLAB  | Command issuers SECLABEL.                                    |
| ACITLAB  | Existing SECLABEL of the printer.                            |
| ACINSPLD | SECLABEL printer is being started at.                        |

Table 126 on page 660 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 126. Supported Return Codes for the START Real Printer with SECLABEL

| RC    | Meaning                                                                                                 |
|-------|---------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                                      |
| X'04' | Authorization is deferred and processing continues.                                                     |
| X'08' | The command fails with error message HCP1013E, indicating an invalid operand was supplied for SECLABEL. |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable.                       |

### STORE HOST Command

Table 127 on page 660 shows the ACIPARMS parameter list for the DAC/audit call for the STORE command when used with the HOST operand.

Table 127. STORE HOST Command Format of the ACIPARMS Parameter List

| Label    | Contents                         |
|----------|----------------------------------|
| ACIFCN   | ACIVMCMD                         |
| ACILEN   | ACISIZE + ACIDATA (in bytes)     |
| ACIBMAPA | Audit setting.                   |
| ACIBMAPP | Protect setting.                 |
| ACIENV   | ACIXAC                           |
| ACIRUSR  | Command issuer's user ID.        |
| ACIRGRP  | Command issuer's ACI group name. |
| ACIVERS  | ACIVERS1                         |
| ACIFLAG  | ACIGOOD   ACIBAD                 |
| ACICMDTP | Class C (X'20').                 |

Table 127. STORE HOST Command Format of the ACIPARMS Parameter List (continued)

| Label    | Contents                         |
|----------|----------------------------------|
| ACISLAB  | Command issuer's SECLABEL.       |
| ACIEVENT | Command name padded with blanks. |
| ACIDATA  | Command line.                    |

Table 128 on page 661 displays the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 128. Supported Return Codes

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                |
| X'04' | Authorization is deferred and processing continues.                               |
| X'08' | The command fails with error message HCP003E, indicating an invalid option.       |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

### **TAG QUERY Command MAC/AUDIT**

See “[QUERY TAG and TAG QUERY Command MAC/AUDIT](#)” on page 655.

### **TAG Command MAC/DAC/Audit**

Table 129 on page 661 shows the ACIPARMS parameter list for an HCPRPIRA call for the TAG device command and TAG file command.

**Note:** MAC is only applicable to the TAG file command.

Table 129. TAG Command Format of the ACIPARMS Parameter List

| Label    | Contents                                                                |
|----------|-------------------------------------------------------------------------|
| ACIFCN   | ACITAG                                                                  |
| ACILEN   | ACISIZE + ACIDATA size (in bytes)                                       |
| ACIBMAPA | Class G (X'02') or X'00'.                                               |
| ACIBMAPP | Class G (X'02') or X'00'.                                               |
| ACIBMAPM | Class G (X'02') or X'00'.                                               |
|          | <b>Note:</b> The MAC setting can only be on for TAG FILE.               |
| ACIENV   | ACITAGN                                                                 |
| ACIRGRP  | Command issuer's ACI group name from user's directory entry.            |
| ACIRUSR  | Command issuers user ID.                                                |
| ACIVERS  | ACIVERS1                                                                |
| ACIFLAG  | ACIGOOD + ACIWO                                                         |
| ACINODE  | The first token of the tag text (padded with blanks if < 8 characters). |
| ACICMDTP | Class G (X'02').                                                        |
| ACIEVENT | "TAG" padded with blanks.                                               |
| ACISLAB  | Command issuers SECLABEL.                                               |

Table 129. TAG Command Format of the ACIPARMS Parameter List (continued)

| Label   | Contents                                                  |
|---------|-----------------------------------------------------------|
| ACITLAB | SECLABEL of target spool file (For the TAG file command). |
| ACIDATA | Command line data.                                        |

Table 130 on page 662 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 130. Supported Return Codes for the TAG Command

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                |
| X'04' | Authorization is deferred and processing continues.                               |
| X'08' | The command fails with error message HCP003E, indicating an invalid option.       |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

### TRANSFER Command Authorization

Table 131 on page 662 shows the ACIPARMS parameter list for an HCPRPIRA DAC call for the TRANSFER and CHANGE TO commands when the file is being sent to someone other than the issuer.

**Note:** This is a DAC-only call. The CHANGE and TRANSFER commands are audited generically.

Table 131. TRANSFER Command Format of the ACIPARMS Parameter List

| Label    | Contents                                                     |
|----------|--------------------------------------------------------------|
| ACIFCN   | ACISPOOL                                                     |
| ACILEN   | ACISIZE (in bytes)                                           |
| ACIBMAPP | PROTECT settings.                                            |
| ACIENV   | ACITRANS                                                     |
| ACIRGRP  | Command issuer's ACI group name from user's directory entry. |
| ACIRUSR  | Command issuer's user ID.                                    |
| ACITGRP  | ACI group name of user ID to whom files are being sent.      |
| ACITUSR  | User ID of user to whom files are being sent.                |
| ACIVERS  | ACIVERS1                                                     |
| ACIFLAG  | ACIGOOD   ACIBAD                                             |
| ACICMDTP | Class DG (X'12') or CLASS G (X'02').                         |
| ACIEVENT | "TRANSFER" or "CHANGE" padded with blanks.                   |
| ACISLAB  | Command issuer's SECLABEL.                                   |

Table 132 on page 662 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 132. Supported Return Codes for the TRANSFER Command

| RC    | Meaning                                            |
|-------|----------------------------------------------------|
| X'00' | Authorization is granted and processing continues. |

Table 132. Supported Return Codes for the TRANSFER Command (continued)

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'04' | Authorization is deferred, and CP performs the authorization check.               |
| X'08' | The command fails with error message HCP007E, indicating an invalid user ID.      |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

**TRANSFER Command**

Table 133 on page 663 shows the ACIPARMS parameter list for an HCPRPIRA audit-only call for each file transferred as a result of the TRANSFER or CHANGE TO command.

Table 133. TRANSFER Command Format of the ACIPARMS Parameter List

| Label    | Contents                             |
|----------|--------------------------------------|
| ACIFCN   | ACIVMCMD                             |
| ACILEN   | ACISIZE + ACISPLSZ (in bytes)        |
| ACIBMAPA | AUDIT Settings.                      |
| ACIENV   | ACIXAT                               |
| ACIRUSR  | Spool file owner ID.                 |
| ACITUSR  | User ID to whom files are being sent |
| ACIEVENT | "TRANSFER" padded with blanks.       |
| ACIVERS  | ACIVERS1                             |
| ACIFLAG  | ACIGOOD                              |
| ACICMDTP | Command version.                     |
| ACISLAB  | Command issuer's SECLABEL.           |
| ACITLAB  | SPOOL file's SECLABEL.               |
| ACIORIG  | Spool file origin ID.                |
| ACIFSTPG | DASD address of first page.          |
| ACISPLID | Old spool ID.                        |
| ACISPIDN | New spool ID.                        |
| ACICMDIS | Command issuer's user ID.            |

Table 134 on page 663 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 134. Supported HCPRPIRA Return Codes

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                |
| X'04' | Authorization is granted and processing continues.                                |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

**TRSAVE TO Command**

This call is controlled by the TRANSFER class D protect setting.

**Note:** The TRSAVE command is audited generically from the command router.

Table 135 on page 664 shows the ACIPARMS parameter list for an HCPRPIRA DAC call for the TRSAVE TO command when the target is not the issuer.

*Table 135. TRSAVE TO Command Format of the ACIPARMS Parameter List*

| Label    | Contents                                                    |
|----------|-------------------------------------------------------------|
| ACIFCN   | ACISPOOL                                                    |
| ACILEN   | ACISIZE (in bytes)                                          |
| ACIBMAPP | Transfer's protect settings.                                |
| ACIENV   | ACITRANS                                                    |
| ACIRGRP  | Command issuer's ACI group name.                            |
| ACIRUSR  | Command issuer's user ID.                                   |
| ACITGRP  | ACI group name of the user ID to whom files are being sent. |
| ACITUSR  | User ID to whom files are being sent.                       |
| ACIVERS  | ACIVERS1                                                    |
| ACIFLAG  | ACIGOOD                                                     |
| ACICMDTP | Class D (X'10').                                            |
| ACIEVENT | "TRSAVE" padded with blanks.                                |
| ACISLAB  | Command issuer's SECLABEL.                                  |

Table 136 on page 664 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

*Table 136. Supported HCPRPIRA Return Codes for the TRSAVE TO Command*

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                |
| X'04' | Authorization is deferred and processing continues.                               |
| X'08' | The command fails with error message HCP003E, indicating an invalid option.       |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

### **TRSOURCE Command**

Table 137 on page 664 shows the ACIPARMS parameter list for a DAC/audit call for the TRSOURCE command.

*Table 137. TRSOURCE Command Format of the ACIPARMS Parameter List*

| Label    | Contents                                                     |
|----------|--------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                     |
| ACILEN   | ACISIZE + ACIDATA size (in bytes)                            |
| ACIBMAPA | Class C (X'20') or X'00'.                                    |
| ACIBMAPP | Class C (X'20') or X'00'.                                    |
| ACIENV   | ACIXAC                                                       |
| ACIRGRP  | Command issuer's ACI group name from user's directory entry. |

Table 137. TRSOURCE Command Format of the ACIPARMS Parameter List (continued)

| Label    | Contents                       |
|----------|--------------------------------|
| ACIRUSR  | Command issuer's user ID.      |
| ACIVERS  | ACIVERS1                       |
| ACIFLAG  | ACIGOOD                        |
| ACICMDTP | Class C (X'20').               |
| ACISLAB  | Command issuer's SECLABEL.     |
| ACIEVENT | "TRSOURCE" padded with blanks. |
| ACIDATA  | Command line.                  |

Table 138 on page 665 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 138. Supported HCPRPIRA Return Codes for the TRSOURCE Command

| RC    | Meaning                                                                                      |
|-------|----------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                           |
| X'04' | Authorization is granted and processing continues.                                           |
| X'08' | The command fails with error message HCP644E, indicating an unknown/unauthorized CP command. |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable.            |

### **TRSOURCE ENABLE Command (VMGROUP)**

Table 139 on page 665 shows the ACIPARMS parameter list for a MAC call for the TRSOURCE ENABLE command in the case of a VMGROUP.

Table 139. TRSOURCE ENABLE Command Format of the ACIPARMS Parameter List

| Label    | Contents                       |
|----------|--------------------------------|
| ACIFCN   | ACINSSEG                       |
| ACILEN   | ACISIZE + ACIDISZ (in bytes)   |
| ACIBMAPM | CLASSC (X'20')                 |
| ACIENV   | ACISEG                         |
| ACIRUSR  | Command issuer's user ID.      |
| ACIEVENT | "TRSOURCE" padded with blanks. |
| ACISLAB  | Command issuer's SECLABEL.     |
| ACIVERS  | ACIVERS1                       |
| ACIFLAG  | ACIRW                          |
| ACICMDTP | CLASS C (X'20')                |
| ACISEGNM | VMGROUP name.                  |

Table 140 on page 666 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 140. Supported Return Codes

| RC    | Meaning                                                                                               |
|-------|-------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted, SDFSCLAB is set to the command issuer's SECLABEL, and processing continues. |
| X'04' | Processing continues.                                                                                 |
| X'08' | The command fails with error message HCP644E, indicating an unknown/unauthorized CP command.          |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable.                     |

**VMRELOCATE Command**

Table 141 on page 666 shows the ACIPARMS parameter list for an HCPRPIRA call on the destination system for the VMRELOCATE command.

Table 141. VMRELOCATE Command Format of the ACIPARMS Parameter List

| Label    | Contents                                                                                                                                              |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACIFCN   | ACILOG                                                                                                                                                |
| ACILEN   | ACIRLOSB                                                                                                                                              |
| ACIBMAPA | ACIANYAU                                                                                                                                              |
| ACIBMAPP | ACIANYPR                                                                                                                                              |
| ACIBMAPM | ACIANYMC                                                                                                                                              |
| ACIENV   | ACIXAC                                                                                                                                                |
| ACIRGRP  | ACI group name from the user directory entry of the virtual machine being relocated.                                                                  |
| ACIRUSR  | User ID of the virtual machine being relocated.                                                                                                       |
| ACIVERS  | ACIVERS1                                                                                                                                              |
| ACIFLAG  | ACIANY + ACIGOOD                                                                                                                                      |
| ACIEVENT | "RELOCATE" padded with blanks.                                                                                                                        |
| ACIVMDBK | Address of the VMDBK for the user being relocated. This field is guaranteed to be valid only until the first loss of control after entry to HCPRPIRA. |
| ACISLAB  | SECLABEL padded with blanks of the guest being relocated, or zeros if no SECLABEL                                                                     |
| ACIDSPID | Dispatched user ID                                                                                                                                    |
| ACIRLODT | "RELOCATE TO"                                                                                                                                         |
| ACIRLODN | The name of the SSI cluster member that is the target destination of the relocation.                                                                  |
| ACIRLOBY | "BY"                                                                                                                                                  |
| ACIRLOCI | The userid of the VMRELOCATE command issuer.                                                                                                          |
| ACIRLOAT | "AT"                                                                                                                                                  |
| ACIRLOIN | The SSI cluster member name where the command issuer was logged on.                                                                                   |

**VMDUMP TO Command and DIAGNOSE X'94'**

This call is controlled by the TRANSFER class G protect setting.

**Note:** VMDUMP and DIAGNOSE code X'94' are audited generically from the command and DIAGNOSE router respectively.

Table 142 on page 667 shows the ACIPARMS parameter list for an HCPRPIRA DAC call for the VMDUMP and for DIAGNOSE code X'94', when the TO option is used, and the target is not the issuer.

*Table 142. VMDUMP TO Command and DIAGNOSE X'94' Format of the ACIPARMS Parameter List*

| Label    | Contents                                                  |
|----------|-----------------------------------------------------------|
| ACIFCN   | ACISPOOL                                                  |
| ACILEN   | ACISIZE (in bytes)                                        |
| ACIBMAPP | Transfer's protect settings.                              |
| ACIENV   | ACITRANS                                                  |
| ACIRGRP  | Command issuer's ACI group name.                          |
| ACIRUSR  | Issuer's user ID.                                         |
| ACITGRP  | ACI group name of the user ID to whom dump is being sent. |
| ACITUSR  | User ID to whom dump is being sent.                       |
| ACIVERS  | ACIVERS1                                                  |
| ACIFLAG  | ACIGOOD                                                   |
| ACICMDTP | Class G (X'02').                                          |
| ACIEVENT | "VMDUMP" or "DIAG094" padded with blanks.                 |
| ACISLAB  | Issuer's SECLABEL.                                        |

Table 143 on page 667 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

*Table 143. Supported Return Codes*

| RC    | Meaning                                                                                                                                                                                                                                                               |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                                                                                                                                                                                                    |
| X'04' | Authorization is deferred and processing continues                                                                                                                                                                                                                    |
| X'08' | <ul style="list-style-type: none"> <li>• VMDUMP command</li> <li>The command fails with message HCP003E, indicating an invalid option.</li> <li>• DIAGNOSE code X'94'</li> <li>The DIAGNOSE fails with return code X'6C' and condition code 2.</li> </ul>             |
| X'20' | <ul style="list-style-type: none"> <li>• VMDUMP command</li> <li>The command fails with error message HCP6525E, indicating the ESM is unavailable.</li> <li>• DIAGNOSE code X'94'</li> <li>The DIAGNOSE fails with return code X'6C' and condition code 2.</li> </ul> |

## ACIPARMS Parameter Lists for DIAGNOSE Codes

This section specifies the different ACIPARMS formats that CP diagnose codes pass to the ESM. The calls are made to HCPRPIRA unless otherwise stated.

### DIAGNOSE Code X'14'

Table 144 on page 668 shows the ACIPARMS parameter list for a MAC call for subcodes X'04', X'08', X'FFE', and X'FFF', when they return SFBLOK data.

Table 144. DIAGNOSE Code X'14' Format of the ACIPARMS Parameter List

| Label    | Contents                       |
|----------|--------------------------------|
| ACIFCN   | ACIVMCMD                       |
| ACILEN   | ACISIZE + ACIDSIZ (in bytes)   |
| ACIBMAPM | ACIDGNMC                       |
| ACIENV   | ACIXAD                         |
| ACIRUSR  | DIAGNOSE issuer's user ID.     |
| ACIVERS  | ACIVERS1                       |
| ACIFLAG  | ACIANY + ACIGOOD + ACIRO       |
| ACIEVENT | "DIAG014" padded with blanks.  |
| ACISLAB  | DIAGNOSE issuer's SECLABEL.    |
| ACITLAB  | SECLABEL of target spool file. |

Table 145 on page 668 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 145. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'14'

| RC    | Meaning                                                     |
|-------|-------------------------------------------------------------|
| X'00' | Processing continues.                                       |
| X'04' | Processing continues.                                       |
| X'08' | The selected spool file is treated as if it does not exist. |
| X'20' | The selected spool file is treated as if it does not exist. |

### DIAGNOSE Code X'64'

Table 146 on page 668 shows the ACIPARMS parameter list for the audit call for DIAGNOSE code X'64'. This call does not include DIAGNOSE code X'64' invocations that load or find a restricted segment. "RSTDSEgt" on page 691 shows the ACIPARMS format for LOAD/FIND of a restricted segment.

Table 146. DIAGNOSE Code X'64' Format of the ACIPARMS Parameter List

| Label    | Contents                     |
|----------|------------------------------|
| ACIFCN   | ACIVMCMD                     |
| ACILEN   | ACISIZE + ACIDSIZ (in bytes) |
| ACIBMAPA | ACIDGNAU                     |
| ACIENV   | ACISEG                       |
| ACIRUSR  | DIAGNOSE issuer's user ID.   |

Table 146. DIAGNOSE Code X'64' Format of the ACIPARMS Parameter List (continued)

| Label    | Contents                        |
|----------|---------------------------------|
| ACIVERS  | ACIVERS1                        |
| ACIFLAG  | ACIANY + ACIGOOD ACIBAD         |
| ACIEVENT | "DIAG064" padded with blanks.   |
| ACISLAB  | DIAGNOSE issuer's SECLABEL.     |
| ACISEGNM | DCSS name.                      |
| ACIRY    | Contents of user's Ry register. |

Table 147 on page 669 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 147. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'64'

| RC    | Meaning                                                                                           |
|-------|---------------------------------------------------------------------------------------------------|
| X'00' | Processing continues.                                                                             |
| X'04' | Processing continues.                                                                             |
| X'20' | Condition code 2 and return code 449 (X'1C1') is returned, indicating the user is not authorized. |

### DIAGNOSE Code X'68'

Table 148 on page 669 shows the ACIPARMS parameter list for an HCPRPIRA MAC/audit call for DIAGNOSE code X'68'. This call is not made if running on the SYSTEM VMDBK.

**Note:** This call is only made for the SEND, SEND/RECEIVE, SENDX, RECEIVE, REPLY, and IDENTIFY subfunctions of DIAGNOSE code X'68'. The other subfunctions are not auditable.

Table 148. DIAGNOSE Code X'68' Format of the ACIPARMS Parameter List

| Label    | Contents                                                                                                                                           |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                                                                                                           |
| ACILEN   | ACISIZE + ACIVMCSZ (in bytes)                                                                                                                      |
| ACIBMAPA | AUDIT setting.                                                                                                                                     |
| ACIBMAPM | MAC setting.                                                                                                                                       |
| ACIENV   | ACIXAV                                                                                                                                             |
| ACIVERS  | ACIVERS1                                                                                                                                           |
| ACIFLAG  | ACIANY + ACIGOOD ACIBAD + ACIRO (receive) ACIWO (send, sendx and reply)   ACIRW ( send/receive and Iidentify)                                      |
| ACIRUSR  | DIAGNOSE issuer's user ID.                                                                                                                         |
| ACITUSR  | Target user ID.                                                                                                                                    |
| ACIEVENT | "DIAG068" padded with blanks.                                                                                                                      |
| ACISLAB  | DIAGNOSE issuer's SECLABEL.                                                                                                                        |
| ACITLAB  | DIAGNOSE target userid's SECLABEL, if available.                                                                                                   |
| ACIVMCF  | "DIAGNOSE 68 SEND" or "DIAGNOSE 68 SEND/RECEIVE" or "DIAGNOSE 68 SENDX" or "DIAGNOSE 68 RECEIVE" or "DIAGNOSE 68 REPLY" or "DIAGNOSE 68 IDENTIFY". |

Table 149 on page 670 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 149. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'68'

| RC    | Meaning                                                                             |
|-------|-------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                  |
| X'04' | Authorization is deferred and processing continues.                                 |
| X'08' | The DIAGNOSE fails with a return code, indicating the target user is not available. |
| X'20' | The DIAGNOSE fails with a return code, indicating the target user is not available. |

### DIAGNOSE Code X'88'

Table 150 on page 670 shows the ACIPARMS parameter list for an HCPRPIRA protect/audit call for DIAGNOSE code X'88'.

Table 150. DIAGNOSE Code X'88' Format of the ACIPARMS Parameter List

| Label    | Contents                                                                                                                                                                |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                                                                                                                                |
| ACILEN   | ACISIZE + ACIVMCSZ (in bytes)                                                                                                                                           |
| ACIBMAPP | PROTECT setting.                                                                                                                                                        |
| ACIBMAPA | AUDIT setting.                                                                                                                                                          |
| ACIENV   | ACIXAD                                                                                                                                                                  |
| ACIVERS  | ACIVERS1                                                                                                                                                                |
| ACIFLAG  | <ul style="list-style-type: none"> <li>• If the user has OPTION DIAG88: ACIANY + ACIGOOD</li> <li>• If the user does not have OPTION DIAG88: ACIANY + ACIBAD</li> </ul> |
| ACIEVENT | "DIAG088" padded with blanks.                                                                                                                                           |
| ACIRUSR  | DIAGNOSE issuer's user ID.                                                                                                                                              |
| ACIRX    | Contents of user's Rx register.                                                                                                                                         |
| ACIRY    | Contents of user's Ry register.                                                                                                                                         |
| ACISLAB  | DIAGNOSE issuer's SECLABEL.                                                                                                                                             |

Table 151 on page 670 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 151. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'88'

| RC    | Meaning                                             |
|-------|-----------------------------------------------------|
| X'00' | Authorization is granted and processing continues.  |
| X'04' | Authorization is deferred and processing continues. |

### DIAGNOSE Code X'94' with the TO Option

See “VMDUMP TO Command and DIAGNOSE X'94'” on page 666.

**DIAGNOSE Code X'B8'**

Table 152 on page 671 shows the ACIPARMS parameter list for an HCPRPIRA MAC/audit call for DIAGNOSE code X'B8' when a spool file is opened. This call is based on the security settings for SPF\_OPEN. In addition to this call, DIAGNOSE code X'B8' is audited from the DIAGNOSE router.

*Table 152. DIAGNOSE Code X'B8' Format of the ACIPARMS Parameter List*

| Label    | Contents                                                         |
|----------|------------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                         |
| ACILEN   | ACISIZE + ACISPLSZ (in bytes)                                    |
| ACIBMAPA | AUDIT Settings.                                                  |
| ACIBMAPM | MAC Settings.                                                    |
| ACIENV   | ACISPF                                                           |
| ACIVERS  | ACIVERS1                                                         |
| ACIFLAG  | ACIGOOD + ACIANY + ACIRO (subcode X'00')   ACIWO (subcode X'04') |
| ACIRUSR  | DIAGNOSE issuer's user ID.                                       |
| ACIEVENT | "SPF_OPEN" padded with blanks.                                   |
| ACISLAB  | DIAGNOSE issuer's SECLABEL.                                      |
| ACITLAB  | Spool file's SECLABEL.                                           |
| ACISPLID | Spool ID of the owning X'AB' to be opened.                       |
| ACICMDIS | Command issuer's user ID.                                        |
| ACIORIG  | Spool file origin user ID.                                       |
| ACIFSTPG | DASD address of first page.                                      |

Table 153 on page 671 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

*Table 153. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'B8'*

| RC    | Meaning                                                             |
|-------|---------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                  |
| X'04' | Authorization is deferred and CP performs the authorization check.  |
| X'08' | The DIAGNOSE fails with a return code, indicating access is denied. |
| X'20' | The DIAGNOSE fails with a return code, indicating access is denied. |

**DIAGNOSE Code X'BC'**

Table 154 on page 671 shows the ACIPARMS parameter list for an HCPRPIRA call for the DIAGNOSE code X'BC'.

*Table 154. DIAGNOSE Code X'BC' Format of the ACIPARMS Parameter List*

| Label    | Contents                     |
|----------|------------------------------|
| ACIFCN   | ACIVMCMD                     |
| ACILEN   | ACISIZE + ACIDISZ (in bytes) |
| ACIBMAPM | ACIDGNMC                     |

Table 154. DIAGNOSE Code X'BC' Format of the ACIPARMS Parameter List (continued)

| Label    | Contents                       |
|----------|--------------------------------|
| ACIENV   | ACIXAD                         |
| ACIRUSR  | DIAGNOSE issuer's user ID.     |
| ACIVERS  | ACIVERS1                       |
| ACIFLAG  | ACIRO+ACIANY+ACIGOOD           |
| ACIEVENT | "DIAG0BC" padded with blanks.  |
| ACISLAB  | Command issuer's SECLABEL.     |
| ACITLAB  | SECLABEL of target spool file. |
| ACIRX    | Rx register.                   |
| ACIRX1   | Rx+1 register.                 |
| ACIRY    | Ry register.                   |
| ACIRY1   | Ry+1 register.                 |

Table 155 on page 672 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 155. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'BC'.

| RC    | Meaning                                               |
|-------|-------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.    |
| X'04' | Authorization is granted and processing continues.    |
| X'08' | The command fails with key fields having '*' in them. |
| X'20' | The command fails with key fields having '*' in them. |

### DIAGNOSE Code X'D4'

Table 156 on page 672 shows the ACIPARMS parameter list for an HCPRPIRA call for DIAGNOSE code X'D4'. See also "APPC Setting of VMDALTID" on page 677.

Table 156. DIAGNOSE Code X'D4' Format of the ACIPARMS Parameter List

| Label    | Contents                        |
|----------|---------------------------------|
| ACIFCN   | ACIALTU                         |
| ACILEN   | ACISIZE + ACIDISZ (in bytes)    |
| ACIBMAPA | ACIDGNAU (X'80') if audit on.   |
| ACIBMAPP | ACIDGNPR (X'80') if protect on. |
| ACIBMAPM | ACIDGNMC (X'80') if MAC on.     |
| ACIENV   | ACIXAD                          |
| ACIRUSR  | DIAGNOSE issuer's user ID.      |
| ACIWUSR  | Worker user ID.                 |
| ACIAUSR  | Alternate (end user) user ID.   |
| ACIVERS  | ACIVERS1                        |

Table 156. *DIAGNOSE Code X'D4' Format of the ACIPARMS Parameter List (continued)*

| Label    | Contents                                                                                                                                                    |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACIFLAG  | ACIGOOD+ACIRW+ACIANY                                                                                                                                        |
| ACIEVENT | "DIAG0D4" padded with blanks.                                                                                                                               |
| ACIRX    | Contents of user's Rx register.                                                                                                                             |
| ACIRY    | Contents of user's Ry register.                                                                                                                             |
| ACISLAB  | DIAGNOSE issuer's SECLABEL.                                                                                                                                 |
| ACIALAB  | Alternate user ID's SECLABEL ( specified in the DD4ALTSC field of the DIAGNOSE code X'D4' parameter list).                                                  |
| ACITLAB  | Worker's user ID's SECLABEL (SECLABEL of the user specified in DD4PALT of the DIAGNOSE code X'D4' parameter list, or zeroes if that user is not logged on). |

Table 157 on page 673 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 157. *Supported HCPRPIRA Return Codes for DIAGNOSE Code X'D4'*

| RC    | Meaning                                                                                  |
|-------|------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                       |
| X'04' | Authorization is deferred, and CP performs the authorization check.                      |
| X'08' | The DIAGNOSE fails with return code 12 (in Rx), indicating the issuer is not authorized. |
| X'20' | The DIAGNOSE fails with return code 12 (in Rx), indicating the issuer is not authorized. |

### **DIAGNOSE Code X'E4'**

Table 158 on page 673 shows the ACIPARMS parameter list for an HCPRPIRA call for DIAGNOSE code X'E4'.

Table 158. *DIAGNOSE Code X'E4' Command Format of the ACIPARMS Parameter List*

| Label    | Contents                                                       |
|----------|----------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                       |
| ACILEN   | ACISIZE + ACIDE4SZ (in bytes)                                  |
| ACIBMAPA | ACIDGNAU or X'00'                                              |
| ACIBMAPP | ACIDGNPR or X'00'                                              |
| ACIENV   | ACIDIAE4                                                       |
| ACIRUSR  | DIAGNOSE issuer's user ID.                                     |
| ACITUSR  | User ID that owns the minidisk (used for subcodes 0,1, and 2). |
| ACIMODE  | Access mode in EBCDIC (used for subcodes 2 and 3).             |
| ACIADDR  | Link-to address in EBCDIC.                                     |
| ACIVERS  | ACIVERS1                                                       |
| ACITADDR | Link-As address in EBCDIC (used for subcodes 2 and 3).         |
| ACIFLAG  | ACIANY+ACIGOOD                                                 |
| ACIEVENT | "DIAG0E4" padded with blanks.                                  |

Table 158. DIAGNOSE Code X'E4' Command Format of the ACIPARMS Parameter List (continued)

| Label    | Contents                                                                                                                                                                               |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACISLAB  | DIAGNOSE issuer's SECLABEL.                                                                                                                                                            |
| ACISUBC  | DIAGNOSE subcode in EBCDIC.                                                                                                                                                            |
| ACITCYL  | Cylinder number in EBCDIC (used for subcode 3).                                                                                                                                        |
| ACIETCYL | Extended Address Volume (EAV) cylinder number in EBCDIC (used for subcode 3).                                                                                                          |
| ACITOD   | Additional field passed only for a shareable virtual disk in storage; contains the virtual disk in storage identifier (the TOD stamp for the creation of the virtual disk in storage). |

Table 159 on page 674 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA. In cases where CP has detected an error before the ESM call, and the ESM returns an error return code, the CP detected error will be reflected to the user.

Table 159. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'E4'

| RC    | Meaning                                                                                                                                |
|-------|----------------------------------------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues. For subcodes 2 and 3, CP performs a directory check for DEVMAINT.                   |
| X'04' | Authorization is deferred, and CP performs directory checks (DEVINFO or DEVMAINT for subcodes 0 and 1, DEVMAINT for subcodes 2 and 3). |
| X'08' | The DIAGNOSE fails with condition code 1 and return code (in Ry) 5 indicating the issuer is not authorized.                            |
| X'20' | The DIAGNOSE fails with condition code 1 and return code (in Ry) 5 indicating the issuer is not authorized.                            |

### DIAGNOSE Code X'290'

Table 160 on page 674 shows the ACIPARMS parameter list for an HCPRPIRA call for DIAGNOSE code X'290'.

Table 160. DIAGNOSE Code X'290' Command Format of the ACIPARMS Parameter List

| Label    | Contents                              |
|----------|---------------------------------------|
| ACIFCN   | ACIVMCMD                              |
| ACILEN   | ACISIZE + ACID290SZ (in bytes)        |
| ACIBMAPA | ACIDGNAU or X'80' if audit on         |
| ACIENV   | ACIXAD                                |
| ACIRUSR  | DIAGNOSE issuer's user ID.            |
| ACIVERS  | ACIVERS1                              |
| ACIFLAG  | ACIANY+ACIGOOD                        |
| ACIEVENT | "DIAG290" padded with blanks          |
| ACISLAB  | DIAGNOSE issuer's SECLABEL.           |
| ACI290SC | DIAGNOSE X'290' subcode issued        |
| ACI290UI | Target userid                         |
| ACI290DN | Target device number (subcode 4 only) |

Table 160. DIAGNOSE Code X'290' Command Format of the ACIPARMS Parameter List (continued)

| Label    | Contents                              |
|----------|---------------------------------------|
| ACI290Q  | Target spool queue (subcode 0 only)   |
| ACI290ID | Target spool file ID (subcode 0 only) |

Table 161 on page 675 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 161. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'290'

| RC    | Meaning                                             |
|-------|-----------------------------------------------------|
| X'00' | Authorization is granted and processing continues.  |
| X'04' | Authorization is deferred and processing continues. |

### **PERMIT to Address Space MAC (DIAGNOSE Code X'23C' Subcode X'03')**

Table 162 on page 675 shows the ACIPARMS parameter list for an HCPRPIRA MAC only call for the PERMIT subfunction of DIAGNOSE code X'23C'. DIAGNOSE code X'23C' is audited generically from the DIAGNOSE router.

Table 162. DIAGNOSE Code X'23C' Format of the ACIPARMS Parameter List

| Label    | Contents                                               |
|----------|--------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                               |
| ACILEN   | ACISIZE + ACIDISZ (in bytes)                           |
| ACIBMAPM | ACIDGNMC                                               |
| ACIENV   | ACIXAD                                                 |
| ACIRUSR  | User ID of grantee (the user who is being permitted).  |
| ACITUSR  | Userid of grantor (the DIAGNOSE issuer).               |
| ACIVERS  | ACIVERS1                                               |
| ACIFLAG  | ACIRW or ACIRO + ACIANY                                |
| ACIEVENT | "DIAG23C" padded with blanks.                          |
| ACISLAB  | SECLABEL of grantee (the user who is being permitted). |
| ACITLAB  | SECLABEL of grantor (the DIAGNOSE issuer).             |
| ACIRX    | Contents of Rx.                                        |

Table 163 on page 675 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 163. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'23C'

| RC    | Meaning                                                                          |
|-------|----------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                               |
| X'04' | Authorization is deferred and processing continues                               |
| X'08' | The DIAGNOSE fails with return code 32, indicating the issuer is not authorized. |
| X'20' | The DIAGNOSE fails with return code 32, indicating the issuer is not authorized. |

## ACIPARMS Parameter Lists for System Functions

This section specifies the different ACIPARMS formats that CP system functions pass to the ESM. The calls are made to HCPRPIRA unless otherwise stated.

### APPC CONNECT

Table 164 on page 676 shows the ACIPARMS format for an HCPRPIRA call for MAC and audit of APPC connect.

Table 164. APPC CONNECT Format of the ACIPARMS Parameter List

| Label     | Contents                                                                                                                                                                                                                                                                                                         |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACIFCN    | ACIVMCMD                                                                                                                                                                                                                                                                                                         |
| ACILEN    | ACISIZE + ACICONSZ (in bytes)                                                                                                                                                                                                                                                                                    |
| ACIBMAPA  | AUDIT Setting                                                                                                                                                                                                                                                                                                    |
| ACIBMAPM  | MAC Setting                                                                                                                                                                                                                                                                                                      |
| ACIENV    | ACICNCT                                                                                                                                                                                                                                                                                                          |
| ACIRUSR   | Effective Source - on whose behalf the connect is being done: <ul style="list-style-type: none"> <li>• VMDUSER if non-communication server without alternate user ID</li> <li>• CONALTID if non-communication server with alternate user ID</li> <li>• IPV MID if communication server issued connect</li> </ul> |
| ACITUSR   | Target user ID (Specified resource ID)                                                                                                                                                                                                                                                                           |

Table 167 on page 677 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 167. Supported Return Codes

| RC    | Meaning                                             |
|-------|-----------------------------------------------------|
| X'00' | Authorization is granted and processing continues.  |
| X'04' | Authorization is deferred and processing continues. |
| X'08' | The connect fails. IPRCODE=IPRCNAUT.                |
| X'20' | The connect fails. IPRCODE=IPRCNAUT.                |

**APPC SEVER**

Table 168 on page 678 shows the ACIPARMS format for an APPC SEVER.

*Table 168. APPC SEVER Format of the ACIPARMS Parameter List*

| <b>Label</b> | <b>Contents</b>               |
|--------------|-------------------------------|
| ACIFCN       | ACIVMCMD                      |
| ACILEN       | ACISIZE + ACISEVSZ (in bytes) |
| ACIBMAPA     | ACISYSAU                      |
| ACIENV       | ACISEVER                      |
| ACIRUSR      | Issuer's user ID              |
| ACIVERS      | ACIVERS1                      |
| ACIFLAG      | ACIANY + ACIGOOD              |
| ACIEVENT     | "APPCSEV" padded with blanks  |
| ACISLAB      | Requestor's SECLABEL          |
| ACIPATH      | APPC path ID                  |

There is no ESM return code checking.

**APPCPWVL**

Table 169 on page 678 shows the ACIPARMS format for an HCPRPIRA call for audit and authorization for APPC CONNECT with password validation. This call is controlled by the APPCPWVL security settings.

*Table 169. APPC connect with password validation*

| <b>Label</b> | <b>Contents</b>                                                  |
|--------------|------------------------------------------------------------------|
| ACIFCN       | ACILOG if calling for authorization; otherwise, ACIVMCMD         |
| ACILEN       | ACISIZE + ACIPWSZ (in bytes)                                     |
| ACIBMAPA     | ACISYSAU (X'80') if audit on                                     |
| ACIBMAPP     | ACISYSPR (X'80') if protect on                                   |
| ACIENV       | ACIAPPW                                                          |
| ACIRGRP      | Blanks                                                           |
| ACIRUSR      | Userid whose password is being checked                           |
| ACITUSR      | Local source (userid who issued the connect)                     |
| ACILGOPT     | ACIVAL if calling for authorization; otherwise, zeroes           |
| ACIVERS      | ACIVERS1                                                         |
| ACIFLAG      | ACIANY + ACIGOOD ACIBAD                                          |
| ACIEVENT     | "APPCPWVL" padded with blanks                                    |
| ACIPWLEN     | Length of password (not included in some audit-only error cases) |
| ACIPSWRD     | Password (masked) (not included in some audit-only error cases)  |

Table 170 on page 679 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 170. Supported Return Codes

| RC    | Meaning                                                             |
|-------|---------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                  |
| X'04' | Authorization is deferred and the CP directory password is checked. |
| X'08' | The connect fails. IPRCODE=IPRCNAUT.                                |
| X'20' | The connect fails. IPRCODE=IPRCNAUT.                                |

### Directory Command Audit-Only Call

Table 171 on page 679 shows the ACIPARMS format for an audit-only call for a command executed automatically upon logon through the use of the COMMAND directory control statement. (See the COMMAND directory control statement in [z/VM: CP Planning and Administration](#) for more information.)

Table 171. Directory Command Format of the ACIPARMS Parameter List

| Label    | Contents                                                                               |
|----------|----------------------------------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                                               |
| ACILEN   | ACISIZE + ACIDATA (in bytes)                                                           |
| ACIBMAPA | Audit setting for each privilege class or ACIANYU if this is an 'ANY' class command.   |
| ACIENV   | ACICPAUD                                                                               |
| ACIRUSR  | Command issuer's user ID.                                                              |
| ACIRGRP  | Command issuer's ACI group name.                                                       |
| ACIVERS  | ACIVERS1                                                                               |
| ACIFLAG  | ACIGOOD   ACIBAD + ACIANY (if this is an 'ANY' class command)                          |
| ACICMDTP | Command version.<br><b>Note:</b> This field is not filled in for 'ANY' class commands. |
| ACISLAB  | Command issuer's SECLABEL.                                                             |
| ACIEVENT | 'DIRECTRY_CMD'                                                                         |
| ACIDATA  | 'TO userid: ' followed by command line.                                                |

Table 172 on page 679 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 172. Supported Return Codes for a Directory Command

| RC    | Meaning                                                                           |
|-------|-----------------------------------------------------------------------------------|
| X'00' | Processing continues.                                                             |
| X'04' | Processing continues.                                                             |
| X'20' | The command fails with error message HCP6525E, indicating the ESM is unavailable. |

### IUCV CONNECT

Table 173 on page 680 shows the ACIPARMS parameter list for the HCPRPIRA call for MAC and audit of an IUCV CONNECT.

Table 173. IUCV CONNECT Format of the ACIPARMS Parameter List

| Label    | Contents                                                                                                                         |
|----------|----------------------------------------------------------------------------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                                                                                         |
| ACILEN   | ACISIZE + ACIUCVSZ (in bytes)                                                                                                    |
| ACIBMAPA | AUDIT Setting                                                                                                                    |
| ACIBMAPM | MAC Setting                                                                                                                      |
| ACIENV   | ACICNCT                                                                                                                          |
| ACIRUSR  | Issuer's user ID                                                                                                                 |
| ACITUSR  | Target user ID of the connect (from IPVMID)                                                                                      |
| ACIVERS  | ACIVERS1                                                                                                                         |
| ACIFLAG  | ACIANY + ACIGOOD ACIBAD + ACIRW                                                                                                  |
| ACIEVENT | "IUCVCON" padded with blanks                                                                                                     |
| ACISLAB  | Command issuer's SECLABEL                                                                                                        |
| ACITLAB  | Target user ID's SECLABEL, if the target is logged on. If the target is a system service, then ACITLAB will be set to "SYSNONE." |
| ACIPATH  | IUCV path ID                                                                                                                     |

If CP processing detected an error before the ESM call, the call will be made for auditing purposes only and the ESM return code is not checked. The IPRCODE for the connect will be set to the CP-detected error code. Otherwise, the ESM return codes are as displayed in [Table 174 on page 680](#).

Table 174. Supported HCPRPIRA Return Codes for IUCV CONNECT

| RC    | Meaning                                                                  |
|-------|--------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                       |
| X'04' | The ESM defers any judgement on the user's status. Processing continues. |
| X'08' | The connect fails. IPRCODE=IPRCBADR.                                     |
| X'20' | The connect fails. IPRCODE=IPRCBADR.                                     |

## IUCV SEVER

[Table 175 on page 680](#) shows the ACIPARMS format for an IUCV SEVER.

Table 175. IUCV SEVER Format of the ACIPARMS Parameter List

| Label    | Contents                      |
|----------|-------------------------------|
| ACIFCN   | ACIVMCMD                      |
| ACILEN   | ACISIZE + ACISEVSZ (in bytes) |
| ACIBMAPA | ACISYSAU                      |
| ACIENV   | ACISEVER                      |
| ACIRUSR  | Issuer's user ID              |
| ACIVERS  | ACIVERS1                      |
| ACIFLAG  | ACIANY + ACIGOOD              |
| ACIEVENT | "IUCVSEV" padded with blanks  |

Table 175. IUCV SEVER Format of the ACIPARMS Parameter List (continued)

| Label   | Contents             |
|---------|----------------------|
| ACISLAB | Requestor's SECLABEL |
| ACIPATH | IUCV path ID         |

There is no ESM return code checking.

### **MAINTCCW Audit**

Table 178 on page 682 shows the ACIPARMS parameter list for an HCPRPIRA audit call for the MAINTCCW function. This will audit the issuances of diagnostic CCW's. The audit call will be made only once per channel program.

Table 176. MAINTCCW Format of ACIPARMS

| Label    | Contents                         |
|----------|----------------------------------|
| ACIFCN   | ACIVMCMD                         |
| ACILEN   | ACISIZE + ACICWSZ (in bytes)     |
| ACIBMAPA | ACISYSAU                         |
| ACIENV   | ACIXACCW                         |
| ACIRUSR  | Diagnostic CCW issuer's user ID  |
| ACIADDR  | Virtual device number            |
| ACIVERS  | ACIVERS1                         |
| ACIFLAG  | ACIANY + ACIGOOD                 |
| ACIEVENT | "MAINTCCW" padded with blanks    |
| ACISLAB  | Diagnostic CCW issuer's SECLABEL |
| ACISCYL  | Starting cyl/blk on the DASD     |
| ACIECYL  | Ending cyl/blk on the DASD       |
| ACIRDEV  | Real device number               |
| ACIVOLSR | Volume serial                    |

Table 177 on page 681 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 177. Supported HCPRPIRA Return Codes

| RC    | Meaning                                             |
|-------|-----------------------------------------------------|
| X'00' | Authorization is granted and processing continues.  |
| X'04' | Authorization is deferred and processing continues. |
| X'20' | The argument of keyword INDICATOR is set to "NO."   |

### **MDISK Command**

Table 178 on page 682 shows the ACIPARMS parameter list for an HCPRPIRA audit/DAC/MAC call for the MDISK function.

**Note:** The MDISK function, and not LINK, controls LINKs-to-self.

If after making the call and receiving ESM authorization, CP denies or downgrades the requested access, then an audit-only call will be made. The ACIPARMS format for this audit-only call will be the same as below and:

- ACIBMAPP and ACIBMAPM will be zeroes
- ACIMODE will be 'RR' if the access has been downgraded to read and 'XX' if the access has been denied

*Table 178. MDISK Command Format of the ACIPARMS Parameter List*

| Label    | Contents                                                                              |
|----------|---------------------------------------------------------------------------------------|
| ACIFCN   | ACILINK                                                                               |
| ACILEN   | ACISIZE (in bytes)                                                                    |
| ACIBMAPA | Class G (X'02'). or X'00'                                                             |
| ACIBMAPM | Class G (X'02'). or X'00'                                                             |
| ACIBMAPP | Class G (X'02'). or X'00'                                                             |
| ACIENV   | ACIDISK                                                                               |
| ACIRGRP  | Command issuer's ACI group name from user's directory entry                           |
| ACIRUSR  | Command issuer's user ID                                                              |
| ACITGRP  | ACI group name of the minidisk owner user ID (same as ACIRGRP in this case)           |
| ACITUSR  | Owning user ID of the minidisk that is being linked to (same as ACIRUSR in this case) |
| ACIMODE  | Minidisk access mode in EBCDIC format                                                 |
| ACIADDR  | Link-To address in EBCDIC format                                                      |
| ACIVERS  | ACIVERS1                                                                              |
| ACITADDR | Link-As address in EBCDIC format                                                      |
| ACIFLAG  | ACIRO or ACIRW                                                                        |
| ACICMDTP | Class G (X'02')                                                                       |
| ACIEVENT | "MDISK" padded with blanks                                                            |
| ACISLAB  | Command issuer's SECLABEL                                                             |

Table 179 on page 682 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

*Table 179. Supported HCPRPIRA Return Codes for MDISK*

| RC    | Meaning                                                                                                                                                                                                                                                                                                                                                          |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                                                                                                                                                                                                                                                                                               |
| X'04' | Authorization is deferred, and CP performs the authorization check if needed.                                                                                                                                                                                                                                                                                    |

| X'20' | The command fails with an error message.                                                                                                                                                                                                                                                                                                                         |

## POSIX Set ID Functions

Table 180 on page 683 shows the ACIPARMS parameter list for the call to HCPRPIRA. CP will not invoke the ESM for POSIX set ID requests unless the ESM has previously informed CP that it contains POSIX support. See [“Entry Point HCPRPEPX - Notify CP of POSIX capabilities” on page 601](#) for additional information.

Table 180. POSIX Set ID Format of the ACIPARMS Parameter List

| Label    | Contents                                                                                                                                                |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACIFCN   | ACISETID                                                                                                                                                |
| ACILEN   | ACISIDSB                                                                                                                                                |
| ACIBMAPP | ACIDGNPR                                                                                                                                                |
| ACIENV   | One of the following: ACISETUI, ACISETEU, ACISETGI, ACISETEG, ACIEXEC, ACINWGRP, or ACISETSG.                                                           |
| ACIRGRP  | Access control group name from the user directory entry of the user identified in ACIRUSR.                                                              |
| ACISLAB  | SECLABEL of the user identified in ACIRUSR.                                                                                                             |
| ACIRUSR  | Issuer's user ID (user whose IDs are to change).                                                                                                        |
| ACIVERS  | ACIVERS1                                                                                                                                                |
| ACIFLAG  | ACIGOOD + ACIANY                                                                                                                                        |
| ACIFLAG2 | Flags, as follows: <ul style="list-style-type: none"> <li>• ACIPXUSN if supplying a group name in ACINGNAM (as opposed to a GID in ACINGID).</li> </ul> |
| ACIEVENT | “POSIXSETID”, left-justified and padded with blanks.                                                                                                    |
| ACIORUID | Old (current) real UID.                                                                                                                                 |
| ACIOEUID | Old (current) effective UID.                                                                                                                            |
| ACIOSUID | Old (current) saved set-UID.                                                                                                                            |
| ACIORGID | Old (current) real GID.                                                                                                                                 |
| ACIOEGID | Old (current) effective GID.                                                                                                                            |
| ACIOSGID | Old (current) saved set-GID.                                                                                                                            |
| ACINUID  | New UID (equal to ACIORUID if UID not being changed).                                                                                                   |
| ACINGID  | If ACIPXUSN is off, the new GID (equal to ACIORGID if GID not being changed); otherwise, not used as input to the ESM.                                  |
| ACINGNAM | If ACIPXUSN is on, the group name that identifies the new GID; otherwise, not used. May be in mixed case.                                               |
| ACIOSGCT | If ACIENV=ACISETSG, count of old (current) SGIDs; otherwise, not used.                                                                                  |
| ACIOSGLS | If ACIENV=ACISETSG, address of old SGID list; otherwise, not used.                                                                                      |
| ACINSGCT | If ACIENV=ACISETSG, count of new SGIDs; otherwise, not used.                                                                                            |
| ACINSGLS | If ACIENV=ACISETSG, address of new SGID list; otherwise, not used.                                                                                      |

Table 181 on page 684 shows the output fields set by the ESM in ACIPARMS on the return from HCPRPIRA.

Table 181. POSIX Set IDs ESM output fields in ACIPARMS

| Label    | Contents                                                                                                                                                                                                                                                         |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACIFLAG2 | Flags, as follows: <ul style="list-style-type: none"> <li>ACIPXALL indicates that all three (real, effective and saved set) POSIX UIDs and/or GIDs are to be set to the new value. ACIPXALL is only valid when ACIENV is either ACISETUI or ACISETGI.</li> </ul> |
| ACINGID  | If ACIPXUSN is on, the GID associated with the input group name passed in ACINGNAM.                                                                                                                                                                              |

Table 182 on page 684 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 182. Supported HCPRPIRA Return Codes for POSIX Set ID Functions

| RC    | Meaning                                                                                                                     |
|-------|-----------------------------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                                                          |
| X'04' | Authorization is deferred and processing continues. CP performs authorization checking.                                     |
| X'08' | Authorization is denied. If invoked during DIAGNOSE code X'29C', it fails with return code SPXEAUTH (5).                    |
| X'20' | The ESM is unavailable. If invoked during DIAGNOSE code X'29C', it fails with return code SPXEDBAS (9).                     |
| X'24' | The input group does not exist. If invoked during DIAGNOSE code X'29C', it fails with return code SPXENFND (6).             |
| X'2C' | ACINUID or ACINGID contains an invalid value. If invoked during DIAGNOSE code X'29C', it fails with return code SPXEID (8). |

### POSIX Group Database Query Function

This function returns data from the POSIX group database. Table 183 on page 684 shows the ACIPARMS parameter list for the call to HCPRPIRA. CP will not invoke the ESM for POSIX database queries unless the ESM has previously informed CP that it contains POSIX support. See “Entry Point HCPRPEPX - Notify CP of POSIX capabilities” on page 601 for additional information.

Table 183. Query POSIX Group Database Format of the ACIPARMS Parameter List

| Label    | Contents                                                                                                                                                                |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACIFCN   | ACIQGDB                                                                                                                                                                 |
| ACILEN   | ACIGB1SB + length of ACIGBUFL buffer list (in bytes)                                                                                                                    |
| ACIBMAPP | ACIDGNPR                                                                                                                                                                |
| ACIENV   | ACIPQGDB                                                                                                                                                                |
| ACIRGRP  | Access control group name from the user directory entry of the user identified in ACIRUSR, if any; otherwise, zeros. If ACIRUSR is “*SYSTEM*”, ACIRGRP is set to zeros. |
| ACISLAB  | SECLABEL of the user identified in ACIRUSR, if any; otherwise, zeros. If ACIRUSR is “*SYSTEM*”, ACISLAB is set to “SYSHIGH”.                                            |
| ACIRUSR  | If ACIPXSYS is off, issuer's user ID; otherwise, “*SYSTEM*”. The data must be left-justified and padded with blanks.                                                    |
| ACITUSR  | If ACIPXQGM is on, user whose group membership is being queried; otherwise, zeros.                                                                                      |

Table 183. Query POSIX Group Database Format of the ACIPARMS Parameter List (continued)

| ACIGBUFL | <p>Group database buffer list. If ACICODE = X'00', the user names of the members of the input group have been placed in the buffers and the length field of each entry contains the length, in bytes, of the data placed in the buffer pointed to by that entry. The data consists of contiguous user names that are left-justified and padded on the right with blanks to a length of 8 characters each. If there are no user names to be returned, then the length fields in the group buffer list must be set to zero. Before returning this list to the requestor, CP will translate all user names to lower case.</p> <p>If ACICODE = X'28', the length field of the first entry contains the length, in bytes, of the buffer necessary to contain the entire member list.</p> <p>If ACICODE is not X'00' or X'28', the buffer list is unchanged.</p> |

Table 185 on page 686 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 185. Supported HCPRPIRA Return Codes for POSIX group database query

| RC    | Meaning                                                                                                                                                                                                                                                                                                                                                                      |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted. If requested, the buffers contain the member list, and the buffer length fields have been updated accordingly. If ACIPXQGM was specified on input, ACITUSR is a member of the group identified in ACIGGNAM/ACIGGID. CP will acquire any deferred data items from the directory or use default values, without performing any authorization checks. |
| X'04' | Authorization is deferred and processing continues. CP performs authorization checking and provides the database information to authorized requestors.                                                                                                                                                                                                                       |
| X'08' | Authorization is denied. If invoked during DIAGNOSE code X'2A0', it fails with return code QPXEAUTH (5).                                                                                                                                                                                                                                                                     |
| X'20' | The ESM is unavailable. If invoked during DIAGNOSE code X'2A0', it fails with return code QPXEDBAS (9).                                                                                                                                                                                                                                                                      |
| X'24' | The input group does not exist. If invoked during DIAGNOSE code X'2A0', it fails with return code QPXENFND (6).                                                                                                                                                                                                                                                              |
| X'28' | Authorization is granted, but the buffers provided on input are too small to contain the entire group member list. The length field of the first ACIGBUFL entry contains the total required buffer length, in bytes. CP can be expected to acquire larger buffers and request all of the data from the ESM again.                                                            |
| X'30' | ACITUSR is not a member of the group identified in ACIGGNAM/ACIGGID. This ACICODE is only possible when ACIPXQGM was specified on input.                                                                                                                                                                                                                                     |

### POSIX User Database Query Function

This function returns data from the POSIX user database. Table 186 on page 686 shows the ACIPARMS parameter list for the call to HCPRPIRA. CP will not invoke the ESM for POSIX database queries unless the ESM has previously informed CP that it contains POSIX support. See “Entry Point HCPRPEPX - Notify CP of POSIX capabilities” on page 601 for additional information.

Table 186. User Database Query Format of the ACIPARMS Parameter List

| Label  | Contents                                             |
|--------|------------------------------------------------------|
| ACIFCN | ACIUQDB                                              |
| ACILEN | ACIUDBSB + length of ACIUBUFL buffer list (in bytes) |

| Label    | Contents                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACIBMAPP | ACIDGNPR                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ACIENV   | ACIPQUDB                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ACIRGRP  | Access control group name from the user directory entry of the user identified in ACIRUSR, if any; otherwise, zeros. If ACIRUSR is “*SYSTEM*”, ACIRGRP is set to zeros.                                                                                                                                                                                                                                                                     |
| ACISLAB  | SECLABEL of the user identified in ACIRUSR, if any; otherwise, zeros. If ACIRUSR is “*SYSTEM*”, ACISLAB is set to “SYSHIGH”.                                                                                                                                                                                                                                                                                                                |
| ACIRUSR  | If ACIPXSYS is off, issuer's user ID; otherwise, “*SYSTEM*”. The data must be left-justified and padded with blanks.                                                                                                                                                                                                                                                                                                                        |
| ACIVERS  | ACIVERS1                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ACIFLAG  | ACIGOOD + ACIANY                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ACIFLAG2 | Flags, as follows: <ul style="list-style-type: none"> <li>• ACIPXUSN if supplying a user name in ACIUUNAM (as opposed to a UID in ACIUUID).</li> <li>• ACIPXSYS if this is a CP-initiated query (as opposed to a user-initiated query). No authority checking should be performed.</li> <li>• ACIPXIDS if the query was initiated by a POSIX process. ACIURID, ACIUEID, ACIUSUID, ACIURGID, ACIUEGID and ACIUSGID are filled in.</li> </ul> |
| ACIEVENT | “POSIXUSERDB”, left-justified and padded with blanks                                                                                                                                                                                                                                                                                                                                                                                        |
| ACIURUID | If ACIPXIDS is on, real UID of the process requesting the data. Otherwise, unpredictable and should not be used.                                                                                                                                                                                                                                                                                                                            |
| ACIUEUID | If ACIPXIDS is on, effective UID of the process requesting the data. Otherwise, unpredictable and should not be used.                                                                                                                                                                                                                                                                                                                       |
| ACIUSUID | If ACIPXIDS is on, saved set-UID of the process requesting the data. Otherwise, unpredictable and should not be used.                                                                                                                                                                                                                                                                                                                       |
| ACIURGID | If ACIPXIDS is on, real GID of the process requesting the data. Otherwise, unpredictable and should not be used.                                                                                                                                                                                                                                                                                                                            |
| ACIUEGID | If ACIPXIDS is on, effective GID of the process requesting the data. Otherwise, unpredictable and should not be used.                                                                                                                                                                                                                                                                                                                       |
| ACIUSGID | If ACIPXIDS is on, saved set-GID of the process requesting the data. Otherwise, unpredictable and should not be used.                                                                                                                                                                                                                                                                                                                       |
| ACIUUNAM | If ACIPXUSN is on, user name (user ID) for which information is to be returned. Must be in upper case.                                                                                                                                                                                                                                                                                                                                      |
| ACIUUID  | If ACIPXUSN is off, UID for which information is to be returned                                                                                                                                                                                                                                                                                                                                                                             |
| ACIUBUFL | User database buffer list. A list of contiguous entries describing the output buffers for this request. Each entry consists of a buffer address and length (in bytes). A buffer address of zero indicates that the corresponding database information, and its length, should not be returned. ACILEN can be used to calculate the number of entries in the list. The address and length field of each entry is described below.            |
| ACIUIWDA | Address of the buffer to contain the user's initial working directory                                                                                                                                                                                                                                                                                                                                                                       |
| ACIUIWDL | Length of the buffer pointed to by ACIUIWDA                                                                                                                                                                                                                                                                                                                                                                                                 |
| ACIUIUPA | Address of the buffer to contain the user's initial user program                                                                                                                                                                                                                                                                                                                                                                            |

Table 186. User Database Query Format of the ACIPARMS Parameter List (continued)

| Label    | Contents                                                           |
|----------|--------------------------------------------------------------------|
| ACIUIUPL | Length of the buffer pointed to by ACIUIUPA                        |
| ACIUFSRA | Address of the buffer to contain the user's file system root       |
| ACIUFSRL | Length of the buffer pointed to by ACIUFSRA                        |
| ACIUSGIA | Address of the buffer to contain the user's supplementary GID list |
| ACIUSGIL | Length of the buffer pointed to by ACIUSGIA                        |

Table 187 on page 688 shows the output fields set by the ESM in ACIPARMS on the return from HCPRPIRA.

Table 187. Query POSIX user database output fields in ACIPARMS

| Label    | Contents                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| ACIUUNAM | If ACIPXUSN is off, the user name (user ID) corresponding to the input UID. CP will translate this to lower case before returning it to the requestor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| ACIUUID  | If ACIPXUSN is on, the UID corresponding to the input user name (user ID).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ACIUGNAM | Group name of the user's primary POSIX group. May be in mixed case.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| ACIUGID  | GID of the user's primary POSIX group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| ACIUBUFL | <p>User database buffer list. If ACICODE = X'00', the high-order bit of each length field indicates whether the ESM has chosen to provide the corresponding data or to defer it to CP. If this bit is on, the data that the ESM wishes to provide has been placed in the buffers, and the length field of the entry contains the length, in bytes, of the data placed in the buffer pointed to by that entry. If this bit is off, CP will use its own data (usually from the user directory or a default value).</p> <p>CP preserves the case of the data pointed to by ACIUIWDA, ACIUIUPA and ACIUFSRA. These strings must be no longer than 1023 characters.</p> <p>If the Supplementary GID list was returned, it must include the user's primary GID. It is recommended, but not required, that the primary GID be the first one in the list. This list must contain no more than {NGROUPS_MAX} GIDs.</p> <p>If ACICODE = X'28', the length field of each entry whose high-order bit of the length field is on contains the length, in bytes, of the buffer necessary to contain the corresponding database information. If ACICODE is not X'00' or X'28', the buffer list is unchanged.</p> |

Table 188 on page 688 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 188. Supported HCPRPIRA Return Codes for user database query

| RC    | Meaning                                                                                                                                                                                                                                                                                                             |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted. The ACIUBUFL entries indicate whether the buffers contain the requested user database information. The buffer length fields have been updated accordingly. CP will acquire any deferred data items from the directory or use default values, without performing any authorization checks. |
| X'04' | Authorization is deferred and processing continues. CP performs authorization checking and provides the database information to authorized requestors.                                                                                                                                                              |

Table 188. Supported HCPRPIRA Return Codes for user database query (continued)

| RC    | Meaning                                                                                                                                                                                                                                                                                                                                                                                         |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'08' | Authorization is denied. If invoked during DIAGNOSE code X'2A0', it fails with return code QPXEAUTH (5).                                                                                                                                                                                                                                                                                        |
| X'20' | The ESM is unavailable. If invoked during DIAGNOSE code X'2A0', it fails with return code QPXEDBAS (9).                                                                                                                                                                                                                                                                                         |
| X'24' | The input user does not exist. If invoked during DIAGNOSE code X'2A0', it fails with return code QPXENFND (6).                                                                                                                                                                                                                                                                                  |
| X'28' | Authorization is granted for all requested data, but one or more of the buffers provided on input is too small to contain the requested data. The length field of each ACIUBUFL entry whose high-order bit of the length field is on contains the required buffer length, in bytes, for that item. CP can be expected to acquire larger buffers and request all of the data from the ESM again. |

### Resource Access Authorization Check

This function returns data from a resource access authorization check. It can be called by any part of CP and operates similarly to a RACROUTE REQUEST=AUTH call.

If access is denied or deferred (ACICODE = ACINOAC or ACIDEFR), the ACIREASON label will contain an additional explanation. For more information on class and resource names and return and reason codes, see [z/VM: Security Server RACROUTE Macro Reference](#).

Table 189 on page 689 shows the ACIPARMS parameter list for a call to HCPRPIRA.

Table 189. Resource Access Authorization Check Format of the ACIPARMS Parameter List

| Label    | Contents                                                                                                                                                                                         |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| ACICLASS      | Resource class name, padded on the right with blanks.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ACILOGGING    | <p>Either:</p> <ul style="list-style-type: none"> <li>• ACILOGPERESM where ESM audit settings are honored (default).</li> <li>• ACILOGNOFAIL to disable authorization failure audits.</li> <li>• ACILOGNONE to disable the creation of an audit record.</li> <li>• ACILOGNOSTAT is the same as ACILOGNONE, but without updating access statistics.</li> </ul>                                                                                                                        |
| ACIRESNAME    | Resource name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ACIRESNAMELEN | Length of the resource name (in bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| ACILOGDATA    | Caller-defined string to be included in the audit record.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ACILOGDATALEN | Length of the string in ACILOGDATA (in bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 190 on page 690 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 190. Supported HCPRPIRA Return Codes for Resource Access Authorization Check

| RC    | Meaning                                                        |
|-------|----------------------------------------------------------------|
| X'00' | Authorization is granted or deferred and processing continues. |
| X'08' | Authorization is denied.                                       |
| X'0C' | Authorization failed.                                          |
| X'10' | Password is expired.                                           |
| X'20' | The ESM is unavailable.                                        |

Table 191 on page 690 shows the list of class and resource names used by CP.

Table 191. Class and Resource Names Used by CP for Resource Access Authorization Check

| Class Name | Resource Name                                                   | Used By                                                                                                                |
|------------|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| SURROGAT   | LOGONBY.userid                                                  | <ul style="list-style-type: none"> <li>• DIAGNOSE X'88' subcode 8</li> <li>• FOR command</li> </ul>                    |
| VMDEV      | RDEV.nnnn, where nnnn is the 4-digit hexadecimal device number. | <ul style="list-style-type: none"> <li>• DEDICATE command</li> <li>• ATTACH command</li> <li>• GIVE command</li> </ul> |

**RSTDSEgt**

Table 192 on page 691 shows the ACIPARMS parameter list for an HCPRPIRA call for LOAD and FIND of a RESTRICTED NSS/DCSS. This function can be invoked using DIAGNOSE code X'64' or the IPL command.

Table 192. RSTDSEG format of the ACIPARMS Parameter List

| Label    | Contents                                                                                                      |
|----------|---------------------------------------------------------------------------------------------------------------|
| ACIFCN   | Either: <ul style="list-style-type: none"> <li>• ACIDCSEG for DCSS's</li> <li>• ACINSSEG for NSS's</li> </ul> |
| ACILEN   | ACISIZE + ACIDSIZ (in bytes)                                                                                  |
| ACIBMAPA | X'00' or X'80' (ACISYSAU)                                                                                     |
| ACIBMAPP | X'00' or X'80' (ACISYSPR)                                                                                     |
| ACIBMAPM | X'00' or X'80' (ACISYSMC)                                                                                     |
| ACIENV   | ACISEG                                                                                                        |
| ACIRUSR  | Command issuers user ID.                                                                                      |
| ACIVERS  | ACIVERS1                                                                                                      |
| ACIFLAG  | ACIANY + ACIRW ACIRO + ACIGOOD ACIBAD                                                                         |
| ACIEVENT | "RSTDSEG" padded with blanks                                                                                  |
| ACISLAB  | Command issuer's SECLABEL                                                                                     |
| ACISEGNM | DCSS name                                                                                                     |
| ACIRY    | Contents of user's Ry register (for calls invoked via DIAGNOSE code X'64' only)                               |

Table 193 on page 691 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 193. Supported HCPRPIRA Return Codes for RSDTSEG.

| RC    | Meaning                                                                                                                                                                                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                                                                                                                                                                                                                    |
| X'04' | Authorization is deferred, and CP performs the authorization check.                                                                                                                                                                                                                   |
| X'08' | <p>If invoked by DIAGNOSE code X'64', condition code 2 and return code 449 (X'1C1') is returned, indicating user is not authorized.</p> <p>If invoked by the IPL command, the command fails. Message HCP449E 'Your userid is not authorized to IPL system <i>name</i>' is issued.</p> |
| X'20' | <p>If invoked by DIAGNOSE code X'64', condition code 2 and return code 449 (X'1C1') is returned, indicating user is not authorized.</p> <p>If invoked by the IPL command, the command fails. Message HCP449E 'Your userid is not authorized to IPL system <i>name</i>' is issued.</p> |

**SCIF Event Audit**

Table 194 on page 692 shows the ACIPARMS parameter list for an HCPRPIRA call for the audit of a SCIF event.

Table 194. SCIF Event Audit Format of the ACIPARMS Parameter List

| Label    | Contents                                         |
|----------|--------------------------------------------------|
| ACIFCN   | ACIVMCMMD                                        |
| ACILEN   | ACISIZE+ACIVMCSZ (in bytes)                      |
| ACIBMAPA | ACISYSAU                                         |
| ACIENV   | ACISCIF                                          |
| ACIRUSR  | Primary user ID                                  |
| ACITUSR  | Secondary user ID                                |
| ACIVERS  | ACIVERS1                                         |
| ACIFLAG  | ACIANY+ACIGOOD or ACIANY+ACIBAD                  |
| ACISLAB  | Primary user's SECLABEL                          |
| ACITLAB  | Secondary user's SECLABEL                        |
| ACIEVENT | 'SCIF' padded with blanks                        |
| ACIVMCF  | 'SCIF EVENT- CHECKED' or 'SCIF EVENT- UNCHECKED' |

There is no return code checking performed after the ESM call.

### SCIF Event MAC Check

Table 195 on page 692 shows the ACIPARMS parameter list for an HCPRPIRA call for the MAC check of a SCIF event.

Table 195. SCIF Event MAC Check Format of the ACIPARMS Parameter List

| Label    | Contents                        |
|----------|---------------------------------|
| ACIFCN   | ACIVMCMMD Default function code |
| ACILEN   | ACISIZE (in bytes)              |
| ACIBMAPM | ACISYSMC                        |
| ACIENV   | ACISCIF                         |
| ACIRUSR  | Secondary user ID               |
| ACITUSR  | Primary user ID                 |
| ACIVERS  | ACIVERS1                        |
| ACIFLAG  | ACIANY+ACIRO+ACIGOOD            |
| ACISLAB  | Secondary user's SECLABEL       |
| ACITLAB  | Primary user's SECLABEL         |
| ACIEVENT | 'SCIF' padded with blanks       |

Table 196 on page 692 shows the ACICODE return codes checked on return from HCPRPIRA.

Table 196. Supported Return Codes

| RC       | Meaning                                            |
|----------|----------------------------------------------------|
| <= X'04' | Authorization is granted and processing continues. |

Table 196. Supported Return Codes (continued)

| RC      | Meaning                                                                                             |
|---------|-----------------------------------------------------------------------------------------------------|
| > X'04' | The command fails with error message HCP6768I, indicating SECUSER or observation is not functional. |

**SPF\_OPEN, SPF\_CREATE, SDF\_OPEN, SDF\_CREATE**

Table 197 on page 693 ACIPARMS format for an audit call for SPF\_CREATE and SDF\_CREATE and for a MAC/AUDIT call for SPF\_OPEN and SDF\_OPEN. These system functions can be invoked in various ways, for example DIAGNOSE codes X'14', X'34', and X'E0'.

**Note:** MAC checking will not be performed when running on the system VMDBK.

Table 197. SPFOPEN Format of the ACIPARMS Parameter List

| Label    | Contents                                                                             |
|----------|--------------------------------------------------------------------------------------|
| ACIFCN   | ACIVMCMD                                                                             |
| ACILEN   | ACISIZE + ACISPLSZ (in bytes)                                                        |
| ACIBMAPA | AUDIT Setting                                                                        |
| ACIBMAPM | MAC Setting (only for SPF_OPEN and SDF_OPEN)                                         |
| ACIENV   | ACISPF                                                                               |
| ACIRUSR  | Spool file owner's user ID                                                           |
| ACIVERS  | ACIVERS1                                                                             |
| ACIFLAG  | ACIANY + ACIGOOD + ACIRO                                                             |
| ACIEVENT | "SPF_OPEN", "SDF_OPEN", "SPF_CREATE", "SDF_CREATE"                                   |
| ACISLAB  | Command issuer's SECLABEL<br>If running on the system VMDBK, system VMDBK's SECLABEL |
| ACITLAB  | Spool file's SECLABEL                                                                |
| ACIORIG  | Spool file origin user ID                                                            |
| ACIFSTPG | DASD address of first page                                                           |
| ACISPLID | Spool ID of file to be opened                                                        |
| ACICMDIS | Command issuer's user ID                                                             |

Table 198 on page 693 shows the return codes that CP supports in ACICODE on the return from HCPRPIRA.

Table 198. Supported HCPRPIRA Return Codes

| RC    | Meaning                                                                                             |
|-------|-----------------------------------------------------------------------------------------------------|
| X'00' | Authorization is granted and processing continues.                                                  |
| X'04' | Authorization is deferred and processing continues.                                                 |
| X'08' | The function fails and HCPSFSOR returns R15=12 and CC=3 to the caller, indicating access is denied. |
| X'20' | The function fails and HCPSFSOR returns R15=12 and CC=3 to the caller, indicating access is denied. |

**SPF\_DELETE and SDF\_DELETE audit**

Table 199 on page 694 ACIPARMS format for SPF\_DELETE and SDF\_DELETE.

*Table 199. ACIPARMS Parameter List*

| <b>Label</b> | <b>Contents</b>                                 |
|--------------|-------------------------------------------------|
| ACIFCN       | ACIVMCMD                                        |
| ACILEN       | ACISIZE + ACISPLSZ (in bytes)                   |
| ACIBMAPA     | AUDIT Setting (X'80' or X'00')                  |
| ACIENV       | ACISPF                                          |
| ACIRUSR      | Spool file owner's user ID                      |
| ACIVERS      | ACIVERS1                                        |
| ACIFLAG      | ACIGOOD + ACIANY                                |
| ACIEVENT     | "SPF_DELETE" or "SDF_DELETE" padded with blanks |
| ACISLAB      | Issuer's SECLABEL                               |
| ACITLAB      | Spool file's SECLABEL                           |
| ACIFSTPG     | DASD address of first page                      |
| ACISPLID     | Spool ID of file to be deleted                  |
| ACIORIG      | Spool file origin user ID                       |
| ACICMDIS     | Command issuer's user ID                        |

There is no return code checking done on this audit call.

**SNIFFER\_MODE Function**

Table 200 on page 694 shows the ACIPARMS parameter list for the HCPRPIRA call to audit promiscuous mode.

*Table 200. ACIPARMS Parameter List*

| <b>Label</b> | <b>Contents</b>                            |
|--------------|--------------------------------------------|
| ACIFCN       | ACIVMCMD                                   |
| ACILEN       | Length of parameter list in bytes          |
| ACIBMAPA     | AUDIT Setting                              |
| ACIENV       | ACISNIF                                    |

| X'20' | <p>The printer is drained, the file is requeued, and the following messages are issued:</p> <ul style="list-style-type: none"> <li>• HCP2514E 'Printer <i>rdev</i> was drained because the external security manager is unavailable.'</li> <li>• HCP1561E 'User <i>userid</i>'s file <i>spoolid</i> is requeued.'</li> </ul> |

## Chapter 12. Account System Service (\*ACCOUNT)

An installation may write an application to run in a guest virtual machine that has the authorization to use the IUCV interface to receive accounting records from the z/VM control program supporting it. This IUCV authorization is defined within the IUCV directory control statement of the guest virtual machine. The IUCV control statement must name \*ACCOUNT as the CP system service to which a communication path will be established. The user ID of the guest virtual machine may also be identified to the control program during system generation so that records can be accumulated for the virtual machine before it has connected to the system service.

For more information on the IUCV functions mentioned in this chapter, refer to Chapter 5, “IUCV Function Descriptions,” on page 317 and Chapter 8, “IUCV Macro Functions for Use in APPC/VM,” on page 521.

The Account system service (\*ACCOUNT) in CP supports both 1-way and 2-way IUCV protocols when sending records to authorized virtual machines. When a **1-way** IUCV SEND function is issued by CP, the virtual machine to which the accounting record is sent cannot issue an IUCV REPLY function but must issue a RECEIVE function. When a **2-way** IUCV SEND function is issued by CP, the virtual machine to which the accounting record is sent must issue an IUCV REPLY function. Response data may not be sent on an IUCV REPLY function. The reply buffer length field in the IUCV parameter list, IPBFLN2F, must contain zeros. To do this, set a register to zero and code ANSLN=(register) on the IUCV REPLY function.

### Establishing Communication

Before issuing the IUCV CONNECT function to the Account system service, a virtual machine must issue a DECLARE BUFFER request to IUCV to provide an external interrupt buffer. The virtual machine must be enabled for IUCV interrupts in Control Register 0, and the PSW must be set to enable external interrupts.

The connection with the Account system service is created by issuing the IUCV CONNECT function, specifying the user ID as \*ACCOUNT. The use of the 2-way protocol for gathering accounting records from the CP Account system service is specified by the virtual machine in the IPUSER data area when it issues the IUCV CONNECT function to the Account system service. This area must contain X'02' at offset 8 if the application is written to issue the IUCV REPLY function after data is received from the Account system service. If the area does not contain a X'02', the default is 1-way communication. The CONNECT parameter list must also indicate that you do not want to receive messages with data in the parameter list. This is indicated by specifying or defaulting to the PRMDATA=NO option on the IUCV CONNECT function.

A virtual machine is not allowed to issue the IUCV SEND function to the Account system service (the path is quiesced by CP recording services). A virtual machine may only have one communication path to the Account system service. CP Recording system services will only send records with the PRTY=NO option.

When an application running in a virtual machine issues the CONNECT function to the accounting system service, the connection is either completed successfully (by ACCEPT) or rejected (by SEVER). If the connection is accepted, IUCV returns a path ID to the application that must be specified on all subsequent IUCV requests to the system service. Only one CONNECT can be issued by a virtual machine to the Account system service.

If the connection is severed, the Account system service places a 1-byte code at offset 9 of the IPUSER field of the IPARML to indicate why. A code of:

- X'04' indicates that the virtual machine already has a connection to the Account system service.
- X'08' indicates that the virtual machine made a protocol error on the CONNECT request. The PRMDATA=YES option was specified, but it should not have been.
- X'0C' indicates that the limit of 100 recording table entries has been reached and there is no room for another.

The data format of an accounting record is identical to the records recorded through use of the RETRIEVE ACCOUNT command. More than one user ID may be authorized to use this service.

## Receiving Accounting Records

---

To obtain an accounting record, when the application is notified by an external interrupt that one is available, the IUCV RECEIVE function must be issued. The Account system service does not send another record until either a response (when the application indicates that data is to be sent to it using the 1-way protocol) or a REPLY (when an application indicates that data is sent to it using the 2-way protocol) is received by CP recording services to the previous record sent.

The Account system service maintains a threshold limit which indicates when to notify the system operator and the receiving virtual machine that uncollected records are accumulating in host storage. The default value is 20 for accounting records. This value may be changed using the CP RECORDING command. For more information on using CP commands, see [z/VM: CP Commands and Utilities Reference](#).

To stop the receipt of records temporarily, you may issue the IUCV SEVER function. CP continues to queue records for your virtual machine until a CP RECORDING ACCOUNT OFF command is issued specifying your user ID. To resume receiving records, you may issue the IUCV CONNECT function specifying USERID=\*ACCOUNT.

If the CP abends while a virtual machine is collecting accounting data, accounting records not received by the virtual machine are checkpointed and requeued to the virtual machine on a subsequent warm or force start of the CP. The virtual machine is also logged onto the system automatically by CP if it is identified on the SYSTEM\_USERIDS statement in the system configuration file.

## Disconnecting from the Accounting System Service

---

You can terminate collection of accounting records by issuing the IUCV SEVER function or the IUCV RETRIEVE BUFFER function for your accounting system service path. SEVER may be initiated by the system due to virtual machine reset or an IUCV RETRIEVE BUFFER request. CP continues to queue records for your virtual machine until a CP RECORDING ACCOUNT OFF command is issued specifying your user ID.

## Accounting Record Formats

---

CP produces the following types of accounting records:

- Virtual machine user records (record type 1).
- Records for devices dedicated to a virtual machine user (record type 2).
- Records for temporary disk space dedicated to a virtual machine user (record type 3).
- Records that are written when CP detects that a user has entered enough LOGON, AUTOLOG, XAUTOLOG, or APPCVM CONNECT invocations with an invalid password to reach or exceed an installation-defined threshold value (record type 04).
- Records that are written when CP detects that a user has successfully entered a LINK command to a protected minidisk not owned by the user (record type 05).
- Records that are written when CP detects that a user has entered enough LINK commands with an invalid password to reach or exceed an installation-defined threshold value (record type 06).
- Records generated whenever a user logs off or disconnects from a device controlled by the VCNA or VSCS (record type 07).
- Records that are written when CP detects that a user has successfully entered a LINK command to a protected minidisk not owned by that user's virtual machine (record type 08). Record type 08 is also generated when the user logs off or disconnects or when a SHUTDOWN or FORCE command causes a logged-on virtual machine to be forced off the system. Disconnected virtual machines do not have another 08 record generated for them if they are forced off.
- Records generated about ISFC (record type 09).
- Records logging changes to a user's privilege class (record type 0A)
- Records for virtual disk in storage space (record type B)

- Records for Network Data Transmissions (record type C)
- Records generated as a result of a user-initiated DIAGNOSE X'4C' instruction (record type C0)
- Records for CPU capability (record type D).

**Note:** Record types 04, 05, 06, and 08 are generated only when LOGON, AUTOLOG, XAUTOLOG, LINK, and CONNECT journaling is on.

These records are all 80-character card images.

The size of the fields in the accounting records restricts the data limit that each field can contain. To find the available field size, refer to each record type. Since the fields are limited in their capacity, it is recommended that you cut accounting records at least once a day.

## Accounting Records for Virtual Machine Resource Usage (Record Type 1)

Type 1 accounting records are produced whenever a user logs off or the ACNT command is entered. These records can also be produced when a DEFINE CPU command issued from the command line specifies a change in CPU type. If a DEFINE CPU command is issued through a COMMAND directory statement, no accounting records are produced. The state of CPU affinity during the accounting interval will determine primary and secondary CPU usage. When there is usage on both primary and secondary types, two type 1 accounting records are produced. In this case, only the first record contains data in columns 41 through 64 and 73 through 76. Columns 1 through 28 and 79 and 80 of this record contain character data; all other data is in hexadecimal form (the hexadecimal data is unprintable). All reserved columns contain EBCDIC blanks. If the records are produced as a result of the DEFINE CPU command, the records contain usage information for only the CPU being redefined.

### **Column Contents**

#### **1-8**

User ID

#### **9-16**

Account number

#### **17-28**

Date and time of accounting (*mmddyyhhmmss*)

#### **29-32**

Number of seconds connected to CP

#### **33-36**

Milliseconds of processor time used, including time for supervisor functions (see Note “3” on page [700](#))

#### **37-40**

Milliseconds of virtual CPU time used (see Note “3” on page [700](#))

#### **41-44**

Number of page reads

#### **45-48**

Number of page writes

#### **49-52**

Number of requested virtual I/O starts for non-spooled I/O

#### **53-56**

Number of virtual punch cards sent to a virtual punch

#### **57-60**

Number of virtual print lines sent to a virtual printer (this includes one line for each carriage control command)

#### **61-64**

Number of virtual punch cards received from a virtual reader

## \*ACCOUNT

**65**

Virtual CPU type code (see Note “2” on page 700 )

**66**

Real CPU type code (see Note “2” on page 700 )

**67**

Number of threads on the Real CPU on which the virtual CPU was dispatched (see Note “4” on page 700 )

**68–72**

Reserved

**73–76**

Number of completed virtual I/O starts for non-spoiled I/O (except DIAGNOSE X'58' and DIAGNOSE X'98')

**77–78**

CPU address (for the SYSTEM VMDBK, this is the real processor address)

**79**

Card generator field (C if Diag 4C has been issued, A if adjunct configuration record, or 0 otherwise)

**80**

Accounting record identification code (1)

### Notes:

1. User virtual machine time may be recorded in more than one record entry. For example:
  - Processor time is accumulated under connect time (bytes 29 - 32) and processor time (bytes 33 - 40)
2. Virtual and Real CPU Type Codes:
  - X'00' – general purpose Central Processor (CP)
  - X'03' – IBM Integrated Facility for Linux (IFL)
  - X'04' - Internal Coupling Facility (ICF)
  - X'05' – IBM z Integrated Information Processor (zIIP)
3. If simultaneous multithreading is not installed on the hardware or not enabled on the system, these fields contain the raw time reported by the hardware CPU timer (and identical to the MT-1 equivalent time). If multithreading is enabled, these time fields contain the MT-1 equivalent time and a type F accounting record is generated. For the raw time and prorated core time values, see “Accounting Records for Virtual Machine Resource Usage 2 (Record Type F)” on page 715.
4. This is the number of threads on the Real CPU on which the virtual CPU was dispatched for the time accrued in this accounting record, or an EBCDIC blank (equivalent to binary integer 64). The number of threads is between 1 and 32. When the number is 1, the CPU time used on that CPU will be identical regardless of whether it is reported as raw time or MT-1 equivalent time. This allows the type of CPU time reported in this record to apply to all CPUs on the system. If multithreading is not supported on the hardware or is not installed, the value will be 1. If this column contains an EBCDIC blank (equivalent to binary integer 64), the Real CPU is running single threaded and the value should be treated as 1.

## Accounting Records for Dedicated Devices (Record Type 2)

A type 2 accounting record is produced whenever a virtual machine user releases a previously dedicated device. Columns 1 through 28 and 79 and 80 of this record contain character data; all other data is in hexadecimal form (the hexadecimal data is unprintable). For translation codes in columns 33 through 36, see Device Class and Type Codes in *z/VM: CP Planning and Administration*. See the documentation for each specific device for more complete information on model numbers.

### Column

#### Contents

**1–8**

User ID

**9–16**

Account number

**17–28**Date and time of accounting (*mmddyymmss*)**29–32**

Number of seconds since the virtual disk was created or the number of seconds since the last accounting record was cut for this virtual disk

**33**

Device class

**34**

Device type

**35**

Device model (if any)

**36**

Device features (if any)

**37–78**

Reserved

**79**

Card generator field (C if Diag 4C has been issued, A if adjunct configuration record, or 0 otherwise)

**80**

Accounting record identification code (2)

## Accounting Records for Temporary Disk Space (Record Type 3)

A type 3 accounting record is produced whenever a virtual machine user releases temporary disk space. Columns 1 through 28 and 79 and 80 of this record contain character data; all other data is in hexadecimal form (the hexadecimal data is unprintable). See Device Class and Type Codes in *z/VM: CP Planning and Administration* for information about translation codes for columns 33 through 36. See the documentation for each device for more information on model numbers.

### Column

#### Contents

**1–8**

User ID

**9–16**

Account number

**17–28**Date and time of accounting (*mmddyymmss*)**29–32**

Number of seconds since the TDISK was created or the number of seconds since the last accounting record was cut for this TDISK

**33**

Device class

**34**

Device type

**35**

Device model (if any)

**36**

Device features (if any)

## \*ACCOUNT

### 37–38

CKD and ECKD Only Number of cylinders of temporary disk space used (only present for CKD or ECKD architected device types)

### 39–40

CKD and ECKD Only Reserved

### 37–40

FBA Only Number of FBA blocks used (only present for FBA architected device types)

### 41–44

Number of 4-KB pages used (present for all device types)

### 45–78

Reserved

### 79

Card generator field (C if Diag 4C has been issued, A if adjunct configuration record, or 0 otherwise)

### 80

Accounting record identification code (3)

## Accounting Records for Journaling (Record Types 04, 05, 06, 08, and 0I)

When LOGON, AUTOLOG, XAUTOLOG, LINK, or APPCVM CONNECT journaling is on, CP may create type 04, type 05, type 06, type 08, and type 0I accounting records.

A type 04 accounting record is written whenever CP detects that a user has issued enough LOGON, AUTOLOG, XAUTOLOG, or APPCVM CONNECT invocations with an invalid password to reach or exceed an installation-defined threshold value. This record has the following format:

### Column

#### Contents

### 1–8

User ID specified on the command

### 9–16

Reserved for IBM use

### 17–28

Date and time of accounting (*mmdyyhhmmss*)

### 29–32

Terminal address (see Note “1” on page 705)

### 33–40

Invalid password (see Note “2” on page 705)

### 41–48

User ID that entered AUTOLOG, XAUTOLOG, APPCVM CONNECT, or the BYUSER ID that entered LOGON (see Note “4” on page 705).

### 49–51

Reserved for IBM use

### 52–53

Current invalid password count in hexadecimal

### 54–55

Accounting record limit in hexadecimal

### 56

Blank

### 57–62

Reserved

### 63–70

Network qualifier for SNA terminal. Host virtual machine name for TCP/IP terminal.

**71-78**

LUNAME for SNA terminal. IP address for TCP/IP terminal (see Note [“5” on page 705](#)).

**79-80**

Accounting card identification code (04)

A type 05 accounting record is produced whenever CP detects that a user has successfully entered a LINK command to a minidisk protected by a password and not owned by that user. This record is always produced when an external security manager authorizes the link. This record has the following format:

**Column****Contents****1-8**

User ID that entered the command

**9-16**

Account number

**17-28**

Date and time of accounting (*mmddyymmss*)

**29-32**

Terminal address (see Note [“1” on page 705](#))

**33-40**

Reserved for IBM use

**41-48**

User ID of the user that owns the minidisk

**49-52**

The minidisk address for which the LINK command was entered

**53**

Type of minidisk linked (see Note [“3” on page 705](#))

**54-55**

Reserved for IBM use

**56-57**

Blank

**58-62**

Reserved

**63-70**

Network qualifier for SNA terminal. Host virtual machine name for TCP/IP terminal.

**71-78**

LUNAME for SNA terminal. IP address for TCP/IP terminal (see Note [“5” on page 705](#)).

**79-80**

Accounting card identification code (05)

A type 06 accounting record is produced whenever CP detects that a user has entered enough LINK commands with an invalid password to reach or exceed an installation-defined threshold value. This record has the following format:

**Column****Contents****1-8**

User ID that entered the command

**9-16**

Account number

**17-28**

Date and time of accounting (*mmddyymmss*)

## \*ACCOUNT

### 29–32

Terminal address (see Note [“1” on page 705](#))

### 33–40

Invalid password (see Note [“2” on page 705](#))

### 41–48

User ID of the user that owns the minidisk

### 49–51

Reserved for IBM use

### 52–53

Invalid password count in hexadecimal

### 54–55

Invalid password limit in hexadecimal

### 56

Blank

### 57–60

Minidisk address for which the LINK command was entered

### 61–62

Reserved

### 63–70

Network qualifier for SNA terminal. Host virtual machine name for TCP/IP terminal.

### 71–78

LUNAME for SNA terminal. IP address for TCP/IP terminal (see Note [“5” on page 705](#)).

### 79–80

Accounting card identification code (06)

A type 08 record is generated when a user logs off or disconnects or when a SHUTDOWN or FORCE command causes that logged-on user to be forced off the system. Disconnected users do not have another 08 record generated for them if they are forced off. This record has the following format:

#### **Column**

#### **Contents**

### 1–8

User ID

### 9–16

Account number

### 17–28

Date and time of accounting (*mmddyyhhmmss*)

### 29–48

Reserved

### 49–56

LUNAME for SNA terminal. IP address for TCP/IP terminal (see Note [“5” on page 705](#)).

### 57–64

Network qualifier for SNA terminal. Host virtual machine name for TCP/IP terminal.

### 65–72

Terminal identification (logical device number, real device number, LUNAME for SNA terminal or NONE)

### 73–78

Reserved

### 79–80

Accounting record identification code (08)

#### **Notes:**

1. For the terminal address, columns 29 through 32 may contain one of the following:
  - NONE—if no terminal is found
  - SNA—if terminal is SNA (LUNAME is in columns 71–78)
  - A real or logical device number in the form *Lnnn*, where *nnn* is the logical device number, for all other cases.
2. For the invalid password, columns 33 through 40 may contain one of the following:
  - Incorrect password
  - TOO LONG—if entered password is more than 8 characters.
3. For the type of minidisk linked, column 53 may contain one of the following:
  - X'00'—if the link is to a user's minidisk
  - X'10'—if the link is to a full-pack overlay minidisk.
4. A by-user is a user who logs on to a virtual machine using the BY operand of the LOGON command. The by-user's own password is used for LOGON authorization checking for the virtual machine, so the invalid password attempts are counted against the by-user ID, not the user ID of the virtual machine.
5. IP addresses are normally written in dotted-decimal format (for example, 9.130.58.78). In journal records, each segment of the IP address is converted to a two-digit hexadecimal value. For example, 9 is converted to 09, and 130 is converted to 82. The result is an eight-byte string of four two-digit hexadecimal numbers in character form. So, 9.130.58.78 becomes the character string 09823A4E.

A type 0I record is generated when the user is logged on through a logical device with an associated IPv6 address. This record has the following format:

**Column**  
**Contents**

|              |                                                   |
|--------------|---------------------------------------------------|
| <b>1–8</b>   | VM user ID                                        |
| <b>9–16</b>  | Account number                                    |
| <b>17–28</b> | Date and time of accounting ( <i>mmddyymmss</i> ) |
| <b>29–36</b> | Host virtual machine name                         |
| <b>37–68</b> | IPv6 address (see note “1” on page 705)           |
| <b>69–78</b> | Reserved                                          |
| <b>79–80</b> | Accounting record identification code (0I)        |

**Note:**

1. IPv6 addresses are normally written in hexadecimal text representation.

**Example:** 0123:4567:89AB:CDEF:FEDC:BA98:7654:3210

In type 0I records, each segment of the IP address is converted from binary to character form. The result is a 32-byte string of 16 two-digit hexadecimal numbers in character form. So, the address shown above becomes 0123456789ABCDEFEDCBA9876543210.

## Accounting Records for SNA/CCS (Record Type 07)

A type 07 accounting record is produced whenever a user logs off or disconnects from a device controlled by VCNA or VSCS. The record indicates the user's share of the VCNA/VSCS resource used. Columns 1 through 16 and 79 and 80 of this record contain character data. See the *VCNA Installation and Terminal*

## \*ACCOUNT

Use *Guide* for details of VM/VCNA accounting records and the *ACF/VTAM Planning and Installation* book for details of VSCS accounting records.

| <b>Column</b> | <b>Contents</b> |
|---------------|-----------------|
|---------------|-----------------|

|              |                                            |
|--------------|--------------------------------------------|
| <b>1-8</b>   | User ID                                    |
| <b>9-16</b>  | Account number                             |
| <b>17-78</b> | VSCS/VCNA accounting data                  |
| <b>79-80</b> | Accounting record identification code (07) |

## Accounting Records for Inter-System Facility for Communications (Record Type 09)

A type 09 accounting record is produced when the ALL option of the ACNT command is entered. Accounting records are generated for all active conversations and all active links.

There are four different categories of ISFC accounting records:

- Initialization accounting records
- Conversation accounting records
- Link statistics accounting records
- Termination accounting records.

ISFC produces the initialization accounting record during its initialization on the z/VM system. This record, along with the termination accounting record indicates the time frame in which ISFC was active on the z/VM system.

The format of the initialization accounting record is:

| <b>Column</b> | <b>Contents</b> |
|---------------|-----------------|
|---------------|-----------------|

|              |                                                                                |
|--------------|--------------------------------------------------------------------------------|
| <b>1-8</b>   | SYSISFC, indicating that this record was created by the z/VM domain controller |
| <b>9-12</b>  | Initialization record identifier, ISFI                                         |
| <b>13-16</b> | Reserved for IBM use                                                           |
| <b>17-28</b> | Date and time the accounting record is generated                               |
| <b>29-78</b> | Reserved for IBM use                                                           |
| <b>79-80</b> | ISFC accounting record identifier                                              |

The format of the conversation start accounting record is:

| <b>Column</b> | <b>Contents</b> |
|---------------|-----------------|
|---------------|-----------------|

|             |                                                                                |
|-------------|--------------------------------------------------------------------------------|
| <b>1-8</b>  | SYSISFC, indicating that this record was created by the z/VM domain controller |
| <b>9-12</b> | Conversation start accounting record identifier, ISFS                          |

**13–16**

Conversation ID

**17–28**

Date and time the accounting record is generated

**29–36**

User ID of the user that initiated the conversation

**37–59**

Reserved for IBM use

**60**

Type of name in bytes 61–68. R indicates a global resource. G indicates a gateway name. U indicates a private resource server virtual machine or workstation user ID. I indicates IUCV.

**61–68**

Resource name, a gateway name, the user ID of the private resource server virtual machine or workstation, or target userid for an IUCV CONNECT.

**69–78**

Reserved for IBM use

**79–80**

ISFC accounting record identifier

The format of the conversation active and conversation end accounting records is:

**Column****Contents****1–8**

SYSISFC, indicating that this record was created by the z/VM domain controller

**9–12**

Conversation record identifier. ISFA indicates a conversation active accounting record; ISFE, a conversation end accounting record.

**13–16**

Conversation ID

**17–28**

Date and time the accounting record is generated

**29–32**

Number of bytes received from the remote domain controller since the conversation started or since the last conversation active accounting record was issued.

**33–36**

Number of bytes sent to the remote domain controller since the conversation started or since the last conversation active accounting record was issued.

**37–78**

Reserved for IBM use.

**79–80**

ISFC accounting record identifier

The format of the link statistics accounting records is:

**Column****Contents****1–8**

SYSISFC, indicating that this record was created by the z/VM domain controller

**9–12**

Link statistics record identifier, ISFL

**13–16**

Reserved for IBM use

## \*ACCOUNT

### 17-28

Date and time the accounting record is generated

### 29-32

Number of bytes of data received (unsigned binary fullword)

### 33-36

Number of bytes of data sent since the link came up or since the last accounting record was generated for this link (unsigned binary fullword)

### 37-40

Unit address of the link

### 41-44

Number of attention interrupts

### 45-48

Number of write operations that result in collisions

### 49-52

Number of successful write operations

### 53-56

Number of successful read operations

### 57-78

Reserved for IBM use.

### 79-80

ISFC accounting record identifier

The format of the termination accounting record is:

#### Column

#### Contents

### 1-8

SYSISFC, indicating that this record was created by the z/VM domain controller

### 9-12

Termination record identifier, ISFT.

### 13-16

Reserved for IBM use

### 17-28

Date and time the accounting record was generated

### 29-78

Reserved for IBM use

### 79-80

ISFC accounting record identifier

## Accounting Records for logging changes to a user's privilege (Record Type 0A)

A type 0A accounting record is produced whenever a SET PRIVCLASS command is successfully issued. The record tracks changes to a user's privilege class and their ability to change their privilege class settings.

There are 4 subtypes of this record.

#### Subtype

#### Description

#### **L**

SET PRIVCLASS LOCK has been issued

#### **U**

SET PRIVCLASS UNLOCK has been issued

**C**

The user's privilege class(es) have been changed via the SET PRIVCLASS command.

**R**

SET PRIVCLASS RESET has been issued

The format for subtypes 'L' (SET PRIVCLASS LOCK) and 'U' (SET PRIVCLASS UNLOCK) appears below. Columns 1 through 36 and 78 through 80 of this record contain character data; all other data is in hexadecimal form (the hexadecimal data is unprintable).

**Column****Contents****1-8**

User ID of the issuer of the SET PRIVCLASS command.

**9-16**

Account number

**17-28**

Date and time of accounting (*mmddyyhhmmss*)

**29-36**

Target user ID. User ID that is the target of the SET PRIVCLASS lock or unlock

**37-77**

Reserved

**78**

Subtype

**Character****Subtype Meaning****L**

SET PRIVCLASS LOCK has been issued

**U**

SET PRIVCLASS UNLOCK has been issued

**79-80**

Accounting record identification code (0A)

The format for subtypes 'C' (SET PRIVCLASS change) and 'R' (SET PRIVCLASS RESET) appears below. Columns 1 through 36 and 78 through 80 of this record contain character data; all other data is in hexadecimal form (the hexadecimal data is unprintable). The privilege class information consists of bits representing privilege classes A-Z, and 1-6 respectively. The bit definitions are defined in HCPCLASS COPY.

**Column****Contents****1-8**

User ID of the issuer of the SET PRIVCLASS command

**9-16**

Account number

**17-28**

Date and time of accounting (*mmddyyhhmmss*)

**29-36**

Target user ID. User ID whose settings are being changed

**37-40**

User privilege classes before the change or reset

**41-44**

User privilege classes after the change or reset

**45-48**

User privilege classes as indicated in the directory

## \*ACCOUNT

### 49-77

Reserved

### 78

Subtype

#### Character

#### Subtype Meaning

#### **C**

The User's privilege class has been changed

#### **R**

The User's privilege class has been reset

### 79-80

Accounting record identification code (0A)

## Accounting Records for virtual disk in storage space (Record Type B)

A type B accounting record is produced for a virtual disk in storage. Columns 1 through 28 and 79 and 80 of this record contain character data; all other data is in hexadecimal form (the hexadecimal data is unprintable). For translation codes in columns 33 through 36, see Device Class and Type Codes in [z/VM: CP Planning and Administration](#). See the documentation for each specific device for more complete information on model numbers.

#### Column

#### Contents

### 1-8

User ID. This user ID is defined as follows:

- If the virtual disk in storage is defined in the directory, this is the user ID which contains the MDISK definition for this virtual disk in storage.
- If the virtual disk in storage was defined using the CP DEFINE command, this is the user ID that issued the DEFINE command.

### 9-16

Account number

### 17-28

Date and time of accounting (*mmddyymmss*)

### 29-32

Number of seconds connected to CP

### 33

Device class

### 34

Device type

### 35

Device model (if any)

### 36

Device features (if any)

### 37-40

Number of FBA blocks used

### 41-44

Number of 4 KB pages used (present for all device types)

### 45

Sub-type of virtual disk accounting record. The only volume defined is zero. If non-zero, the contents of bytes 1-44 and 46-78 are undefined.

**46-78**

Reserved

**79**

Card generator field (C if Diag 4C has been issued, A if adjunct configuration record, or 0 otherwise)

**80**

Accounting record identification code (B)

**Accounting Records Network Data Transmissions (Record Type C)**

Type C accounting records may be produced for any virtual machine user with NETAccounting or NETRouter specified as an option in its user directory. The account records are produced when accounting is performed (CP ACNT command), or when a field in the accounting record is about to overflow, and the user has sent or received data from a Network device. These records are only produced when fields containing byte counters for a device are non-zero.

Network devices to be included in these counts are:

- Virtual network interface cards (NIC)
- Virtual Channel to Channel Adapters
- IUCV and APPC/VM connection paths

The contents of Network Data Transmission accounting records depends on the type of Network device being used. There are 3 different formats, designated by a subtype in byte 78. For subtype 00 (Virtual NIC records), an additional 4 subformats, designated in byte 77, indicate what type of network data is counted in the record.

Type C account record describing data transfer involving routers through a Virtual NIC (Network device type 00). Columns 1 through 28, 35 through 50, and 79 through 80 of this record contain character data; all other data is in hexadecimal form (the hexadecimal data is unprintable.)

**Column****Contents****1-8**

VM Userid (Owner of the Virtual NIC)

**9-16**

Account number

**17-28**

Date and time of accounting (mmddyyhhmmss)

**29-30**

Base VDEV address of the Virtual NIC

**31-34**

Default IP Address for this network adapter

**35-42**

LAN or virtual switch owner

**43-50**

LAN name or virtual switch name

**51-58**

Bytes Sent (See Data Descriptor)

**59-66**

Bytes Received (See Data Descriptor)

**67-76**

Reserved

**77**

Data Descriptor:

## \*ACCOUNT

- 00 - Bytes sent to or received from Routers
- 01 - Bytes sent to or received from non-Routers
- 02 - Bytes sent to or received via Broadcast
- 03 - Bytes sent to or received via Multicast

**78**

Network device type (00) Virtual NIC

**79**

Card generator field (C if Diag 4C has been issued, A if adjunct configuration record, or 0 otherwise)

**80**

Accounting record identification code (C)

### Notes:

1. Hardware headers which appear before the IP Header are not included in the byte counts reported for simulated network adapters.
2. IP addresses are normally written in dotted-decimal format (for example, 9.130.58.78). In journal records, each segment of the IP address is converted to a two-digit hexadecimal value. For example, 9 is converted to 09, and 130 is converted to 82. The result is an 8-byte string of four 2-digit hexadecimal numbers in character form. So, 9.130.58.78 becomes the character string 09823A4E.

TYPE C accounting record for data transfer with a Virtual Channel to Channel Adapter. Columns 1 through 28, 35 through 42, and 79 through 80 of this record contain character data; all other data is in hexadecimal form (the hexadecimal data is unprintable.)

### Column

#### Contents

**1-8**

VM Userid (owner of the local CTCA)

**9-16**

Account number

**17-28**

Date and time of accounting (mmddyyhhmmss)

**29-30**

VDEV address of the local CTCA

**31-34**

Reserved

**35-42**

Userid of the owner of the remote CTCA

**43-44**

VDEV address of the remote CTCA

**45-50**

Reserved

**51-58**

Number of bytes sent to the remote CTCA.

**59-66**

Number of bytes received from the remote CTCA.

**67-77**

Reserved

**78**

Network device type (01) virtual CTCA

**79**

Card generator field (C if Diag 4C has been issued, A if adjunct configuration record, or 0 otherwise)

**80**

Accounting record identification code (C)

TYPE C account record for data transfer with an IUCV or APPC/VM connection. Columns 1 through 28, 35 through 42, and 79 through 80 of this record contain character data; all other data is in hexadecimal form (the hexadecimal data is unprintable.)

**Column****Contents****1-8**

VM Userid (Owner of the local connection.)

**9-16**

Account number

**17-28**

Date and time of accounting (mmddyyhhmmss)

**29-34**

Reserved

**35-42**

Connected VM Userid (remote)

**43-50**

Reserved

**51-58**

Number of bytes sent to the remote user.

**59-66**

Number of bytes received from the remote user.

**67-77**

Reserved

**78**

Network device type (02) IUCV or APPC path

**79**

Card generator field (C if Diag 4C has been issued, A if adjunct configuration record, or 0 otherwise)

**80**

Accounting record identification code (C)

**Notes:**

1. Byte count values are reset to zero after an accounting record is created.
2. Byte count values represent data read or written to the device. They will not typically contain bytes transferred as a result of initialization, termination, or error recovery.
3. Accounting for a particular LAN may be controlled by the DEFINE LAN, and SET LAN commands, and default settings may be set by the VMLAN command or VMLAN statement in the system config file.

## Accounting Records for CPU Capability (Record Types D and E)

A type D accounting record is produced to record the CPU capability of the processors in the system. A record is generated during z/VM system initialization and whenever the CPU capability changes. All fields of the record contain character data.

**Column****Contents****1-16**

Reserved

**17-28**

Date and time of accounting (mmddyyhhmmss)

## **\*ACCOUNT**

### **29-36**

Primary CPU capability

### **37-44**

Secondary CPU capability

### **45-52**

Nominal CPU capability

### **53-55**

Capacity-Change Reason

### **56-58**

Capacity-Adjustment Indication

### **59-78**

Reserved

### **79**

Card generator field (0)

### **80**

Accounting record identification code (D)

#### **Notes:**

1. When the secondary CPU capability value is zero, it means all CPUs of any CPU type in the configuration have the same capability, as specified by the primary CPU capability.
2. When the nominal CPU capability value is zero, it means the system is not operating at reduced speed, so the primary CPU capability value applies.

A type E (CPU Capability continuation data) accounting record is produced at the same time as the CPU Capability (type D) accounting record. All fields of the record contain character data. The capability fields contain 8-digit approximations of the binary-floating point values and the reserved fields contain blanks.

#### **Column**

##### **Contents**

### **1-8**

User ID

### **9-16**

Account number

### **17-28**

Date and time of accounting (mmddyhhmmss)

### **29-36**

Primary CPU capability decimal value (see note 1)

### **37-44**

Secondary CPU capability decimal value (see note 1)

### **45-52**

Nominal CPU capability decimal value (see note 1)

### **53-78**

Reserved

### **79**

Card generator field (0)

### **80**

Accounting record identification code (E)

#### **Notes:**

1. These fields will be reported as "OVERFLOW" if the capability value is greater than or equal to 100000000 (decimal). These fields will be reported as "UNDERFLO" if the capability value is less than or equal to  $10^{-7}$ .

2. When the secondary CPU capability value is zero, it means all CPUs of any CPU type in the configuration have the same capability, as specified by the primary CPU capability.
3. When the nominal CPU capability value is zero, it means the system is not operating at reduced speed, so the primary CPU capability value applies.

## Accounting Records for Virtual Machine Resource Usage 2 (Record Type F)

Type F accounting records are a continuation of the type 1 record. When multithreading is enabled on the system, a single type F record is produced for each virtual CPU for which one or two type 1 accounting records (for primary and secondary CPU types) are produced. Columns 1 through 28, 61 through 68, and 79 and 80 of this record contain character data; all other data is in hexadecimal form (the hexadecimal data is unprintable). All reserved columns contain binary zeros.

### Column

#### Contents

#### 1-8

User ID

#### 9-16

Account number

#### 17-28

Date and time of accounting (*mmddyyhhmmss*)

#### 29-32

Milliseconds of processor time used on the primary CPU type, including time for supervisor functions, in raw time.

#### 33-36

Milliseconds of virtual CPU time used on the primary CPU type, in raw time.

#### 37-40

Milliseconds of processor time used on the secondary CPU type, including time for supervisor functions, in raw time.

#### 41-44

Milliseconds of virtual CPU time used on the secondary CPU type, in raw time.

#### 45-48

Milliseconds of processor time used on the primary CPU type, including time for supervisor functions, in prorated core time (see Note “1” on [page 716](#) )

#### 49-52

Milliseconds of virtual CPU time used on the primary CPU type, in prorated core time (see Note “1” on [page 716](#) )

#### 53-56

Milliseconds of processor time used on the secondary CPU type, including time for supervisor functions, in prorated core time (see Note “1” on [page 716](#) )

#### 57-60

Milliseconds of virtual CPU time used on the secondary CPU type, in prorated core time (see Note “1” on [page 716](#) )

#### 61-68

Name of the CPU pool (see Note “2” on [page 716](#) )

#### 69-76

Reserved

#### 77

Codes regarding this accounting record:

#### X'80'

The prorated core time fields in this record are valid.

## \*ACCOUNT

**78**

Reserved

**79**

Card generator field (C if Diag 4C has been issued, A if adjunct configuration record, or 0 otherwise)

**80**

Accounting record identification code (F)

### Notes:

1. When APAR VM65680 is applied and multithreading is enabled, prorated core times are calculated and reported for every virtual machine. The prorated core code provided in column 77 of this record indicates whether these values are included in the accounting record.
2. When the virtual machine is not assigned to a CPU pool, this field contains EBCDIC blanks.

## Adding Your Own Accounting Records and Source Code

---

CP allows you to customize the way it collects accounting records in two ways:

- A virtual machine can use the DIAGNOSE instruction to initiate the generation of a virtual machine accounting record. For more information, see [“User-Initiated Accounting Records \(Record Type C0\)”](#) on page 716
- You can add your own source code to the CP accounting exit module. For more information, see CP Accounting Exit in [z/VM: CP Exit Customization](#).

### User-Initiated Accounting Records (Record Type C0)

A virtual machine user can initiate the creation of an accounting record that contains up to 70 bytes of information of the user's choosing. To do this, the user enters a DIAGNOSE code X'4C' instruction with the following operands (the [z/VM: CP Programming Services](#) describes how to enter a DIAGNOSE code):

- The address of a data area in virtual storage that contains the information that the user wants in columns 9 through 78 of the card image record. (This information is placed in the accounting record exactly as it appears in the data area. If more than 70 bytes of data are included, only the first 70 bytes appear in the accounting record.)
- A function code of X'10'.
- The length of the data area in bytes.

The information on this type of accounting record is as follows:

#### **Column**

#### **Contents**

**1–8**

User ID

**9–78**

User-formatted data

**79–80**

Accounting record identification code (C0)

File pool service virtual machines can generate accounting records in this category. For details, see [z/VM: CMS File Pool Planning, Administration, and Operation](#).

---

## Chapter 13. Asynchronous CP Command Response System Service (\*ASYNCMD)

The Asynchronous CP Command Response (\*ASYNCMD) system service lets a virtual machine receive CP command responses that come from CP as result of issuing the CP FOR command, rather than displaying them on the terminal. (The texts of the CP command responses and the messages themselves is not part of the programming interface.)

\*ASYNCMD is the assigned Asynchronous CP Command Response system service user ID. You establish communication with this user ID by specifying USERID=\*ASYNCMD when issuing the IUCV CONNECT function.

For more information on the IUCV functions mentioned in this chapter, refer to [Chapter 5, "IUCV Function Descriptions,"](#) on page 317.

---

### Establishing Communication

Your virtual machine does not need any special authorization to use the Asynchronous CP Command Response system service. To establish IUCV communication, issue IUCV DECLARE BUFFER followed by IUCV CONNECT with USERID=\*ASYNCMD.

After a successful IUCV CONNECT to \*ASYNCMD, the IUCV path ID returned by the connect may be used on FOR commands to receive command responses, on that path, from the Asynchronous CP Command Response system service. For more information, see the ["DECLARE BUFFER Function"](#) on page 331 and the ["CONNECT Function"](#) on page 324.

Your virtual machine may have up to 8 communication paths with the Asynchronous CP Command Response system service. If your virtual machine attempts to establish a new IUCV connection while there are 8 communication paths already in use, the attempt will be terminated by the system service with the IUCV SEVER function. You may terminate your connection by using the IUCV SEVER function. For more information, see the ["SEVER Function"](#) on page 376.

---

### Message Limits

The Asynchronous CP Command Response system service uses a default value of 16000 for the number of outstanding messages allowed on the path unless the user specifies a lower value for the MSGLIM parameter. If a lower value is specified, that value is used for the number of messages allowed on the path.

If the message limit is exceeded, any additional incoming messages are discarded and the "end of command record" shows the number of records that have been discarded. This situation is most likely to occur when there is a high volume of incoming message and the virtual machine is running with external interrupts disabled.

---

### Sending and Receiving Data

After your virtual machine issues IUCV CONNECT to the Asynchronous CP Command Response system service, FOR commands can be issued specifying the path ID returned from IUCV CONNECT along with a *token* value. The Asynchronous CP Command Response system service will issue the IUCV SEND function to send the data to your virtual machine on your specified path where you can issue IUCV RECEIVE to receive the data. For more information, see the ["SEND Function"](#) on page 366 and the ["RECEIVE Function"](#) on page 348.

**Note:** Your virtual machine is not allowed to issue the IUCV SEND function to the Asynchronous CP Command Response system service. Do not quiesce a path to the Asynchronous CP Command Response

system service or you could lose messages. The Asynchronous CP Command Response system service will only send records with the PRTY=NO option.

## Record Types

There are two types of records which can be received over an IUCV connection to the Asynchronous CP Command Response system service:

1. Command response records.
2. End of command record.

The command response records are the output records generated by the CP command issued for the target virtual machine. The end of command record is the last record associated with a CP command which includes the return code and count of discarded messages.

### Command response record format

### End of command record format

#### userid

is the user ID specified on the FOR command which is the target of the CP command.

#### token

is the user-specified correlation token specified on the FOR command, or blanks if nothing was specified.

#### msg type

is a 1-byte EBCDIC value with the following values defined:

##### X'F0'

is a command response record.

##### X'F1'

is an end of command record.

#### component ID

is a 3-character prefix indicating which component generated the message. For example, HCP.

#### msg number

is the CP message number displayed in character format. If no message number was received, the field is blank.

#### severity

is a 1-character message severity associated with the CP message. For more information on severities, see [z/VM: CP Messages and Codes](#).

#### text

is the actual response that would have displayed on the target user's display terminal using the MSG ON setting. This field does not contain the message number or severity.

#### return code

is a 4-character return code from the CP command that was executed.

#### number of messages discarded

is a 4-character value indicating how many messages were discarded. The value is zero if there were no messages discarded and padded to 4 characters.

## Chapter 14. DASD Block I/O System Service (\*BLOCKIO)

The DASD Block I/O system service (\*BLOCKIO) provides a virtual machine with device-independent, asynchronous access to its CMS-formatted virtual disk devices.

For more information on the IUCV functions mentioned in this chapter, refer to [Chapter 5, “IUCV Function Descriptions,”](#) on page 317. To see a sample program, see [Appendix B, “Sample Programs Using DASD Block I/O System Service,”](#) on page 997.

### Establishing Communication with the DASD Block I/O System Service

The DASD Block I/O system service uses IUCV to set up communication between itself and a virtual machine. The virtual machine issues the IUCV DECLARE BUFFER function to initialize for IUCV communication; the IUCV processor initializes the DASD Block I/O system service for IUCV communication by issuing the DECLARE BUFFER function for the system service.

After communication is established with IUCV, the virtual machine must issue a CONNECT command to establish a path between itself and the DASD block I/O system service. Only one CONNECT may be issued to the DASD Block I/O system service for each virtual device that is intended to receive I/O requests.

No special authorization is required for a virtual machine to use the DASD block I/O system service. The maximum connection limit (MAXCONN) in the directory can be enlarged to satisfy the user's requirements. The DASD block I/O system service allows connection from any user.

The IUCV macro checks the validity of all the IUCV parameters. Any IUCV errors are handled according to IUCV specifications. The DASD Block I/O system service checks the validity of all the parameters it requires. Any errors resulting from this check are handled as described in the following sections.

### IUCV CONNECT to the DASD Block I/O System Service

An IUCV CONNECT is issued by the virtual machine with USERID=\*BLOCKIO, and PRMDATA=YES specified in the IUCV CONNECT parameter list. The IPARML DSECT and IPARML COPY files are located in the HCPGPI macro library. The user data field (IPUSER) in the IUCV parameter list must have the following format:

#### Block size

contains the block size of the specified disk; the block size can be 512, 1K, 2K, or 4K bytes.

#### Offset

contains the number of sequential blocks used at the beginning of the disk by the CMS file system to implement its structure. \*BLOCKIO uses the offset so that the first block after these used blocks is addressed as block 1. \*BLOCKIO does not check the validity of the offset; therefore the application can change the number if desired.

#### Vdevaddr

contains the virtual device address of the disk on which the block I/O is to be performed.

### Usage Notes

1. All reserved fields must be set to zero.

## \*BLOCKIO

2. The disk must be in CMS format. Although not required by \*BLOCKIO, the CMS RESERVE command is normally then used to allocate all available blocks of this formatted minidisk to a unique CMS file.
3. If the minidisk has been reserved, an application can use the DISKID CMS function to obtain the block size, offset, and virtual device address information. DISKID is described in [z/VM: CMS Macros and Functions Reference](#).
4. The \*BLOCKIO system service does not support HyperPAV alias devices.
5. The \*BLOCKIO system service is limited to a minidisk size of 65520 cylinders, regardless of formatted block size. If the \*BLOCKIO request was issued for a minidisk larger than 65520 cylinders, error code X'02' will be returned in the first byte of the IPUSER field.

## IUCV ACCEPT

If all parameters required by \*BLOCKIO are valid, \*BLOCKIO issues an IUCV ACCEPT on the path specifying PRMDATA=YES.

The following information is returned in the IPUSER field of the IUCV connection-complete external interrupt buffer:

### Start block

contains 1 minus the offset specified in the IUCV CONNECT. Start block and end block specify the range of block numbers allowable on the \*BLOCKIO request.

### End block

contains the number of blocks on the specified device minus the offset specified on the IUCV CONNECT. End block and start block specify the range of block numbers allowable on the \*BLOCKIO request.

### Flags

contains a set of bits defining the status of the virtual device. One bit is defined; the others are reserved.

#### **RONLY X'0001'**

the virtual device is read-only

**Note:** All reserved fields must be set to zero.

## IUCV SEVER

If any of the parameters passed to \*BLOCKIO are invalid, \*BLOCKIO issues an IUCV SEVER on the path and flags the error.

The first byte of the IPUSER field contains one of the following error codes:

### Code

#### Meaning

#### **X'01'**

the virtual device is not defined.

#### **X'02'**

the virtual device is not supported.

#### **X'03'**

the block size is not supported.

#### **X'04'**

the IUCV path already exists for this device.

#### **X'05'**

the connection is not using PRMDATA=YES.

**X'06'**

the reserved field is not set to zero.

## IUCV SEND to \*BLOCKIO

---

When the connection is accepted by \*BLOCKIO, you can start sending I/O requests to \*BLOCKIO. You can specify the TRGCLS=, DATA=PRMSG, and PRMSG= options on the IUCV SEND, or you can move the necessary data into the IUCV parameter list yourself. The TRGCLS= option sets the type of I/O requested. The DATA=PRMSG option sets a flag in IPRFLAGS1, and the PRMSG option sets up IPRMSG1 and IPRMSG2 in the IUCV parameter list.

There are two different interfaces to \*BLOCKIO. The single block interface is restricted to, and optimized for, single block transfer. The multiple block interface can be used to read/write from 1 to 256 blocks at a time.

### Single Block I/O

The following list defines the input needed by \*BLOCKIO for single block requests on an IUCV SEND:

**IPRMSG1**

specifies the block number.

**IPRMSG2**

specifies the guest absolute data buffer address.

**IPTRGCLS**

specifies the block I/O service requested.

**Code****Meaning****F'01'**

Write request, use the minidisk cache (if present).

**F'02'**

Read request, use the minidisk cache (if present).

**F'81'**

Write request, bypass the minidisk cache.

**F'82'**

Read request, bypass the minidisk cache.

### Usage Notes

1. The SYNC=YES option on the IUCV SEND macro can be specified with the F'02' service request. If SYNC=YES is specified with any of the other three service requests, it will get a return code of F'06', indicating an invalid request.

The synchronous processing option is intended for use when reading blocks. Applications that specify the SYNC=YES option have to be prepared for this request to complete synchronously or asynchronously. If the requested block is in the minidisk cache, the SEND request completes synchronously. If the requested block is not in the minidisk cache, the SEND request completes asynchronously.

2. Use the minidisk cache bypass option when reading or writing blocks that are not referenced frequently. This prevents infrequently-used data from filling the cache and flushing out frequently referenced data.
3. The \*BLOCKIO IUCV system service and Diagnose X'250' do not honor DASD reserves managed by VM's virtual reserve/release function. Therefore, do not use these I/O interfaces if a minidisk is shared by multiple guests on the same VM image where another guest is expecting to use reserve/release I/O to serialize its data access. Also, \*BLOCKIO and Diagnose X'250' do not use reserve/release. Therefore, do not use these interfaces for any DASD (CP-attached or full-pack minidisk) that is shared with other LPARs where another LPAR expects to use reserve/release to serialize its data.

## Condition and Return Codes

The condition codes on the IUCV SEND instruction indicate how processing was completed:

### Code

#### Meaning

#### CC=0

The request has been started. An IUCV Message Complete external interrupt is generated when the request completes.

#### CC=1

A nonzero value is stored in the IPRCODE field of the IPARML DSECT.

#### CC=2

The requested block was found in the minidisk cache and has been written into the guest buffer.

The IUCV protocol may have been correct from an IUCV perspective but does not meet the \*BLOCKIO requirements. In that case, the DASD Block I/O system service issues an IUCV SEVER on the path and flags the error. The first byte of the IPUSER field contains one of the following error codes:

### Code

#### Meaning

#### X'07'

IUCV communication was not sent using DATA=PRMSG.

#### X'08'

No 1-way messages are allowed on the path.

If you coded the IUCV SEND correctly, \*BLOCKIO tries to initiate the request. It uses an IUCV REPLY to return the results of the I/O request. The application's virtual machine is made aware of this response by an IUCV external interrupt. A return code is returned in the IPRMSG1 field of the IUCV parameter list:

### Code

#### Meaning

#### F'00'

I/O completed successfully

#### F'01'

Invalid block number

#### F'02'

Invalid data buffer address

#### F'03'

Write on read-only DASD

#### F'04'

Incorrect block size — format error

#### F'05'

Unrecoverable I/O error

#### F'06'

Invalid service requested

#### F'07'

Protection exception on virtual buffer

If the device is reset, the path is quiesced, and no more requests are allowed. When no I/O requests are outstanding, \*BLOCKIO issues an IUCV SEVER on the path and flags the error. The first byte of the IPUSER field contains the following error code:

### Code

#### Meaning

#### X'09'

Virtual device has been reset

## Multiple Chained Block I/O

Using \*BLOCKIO, you can read and write up to 256 contiguous or discontinuous CMS-formatted blocks with a single \*BLOCKIO request. Individual blocks may be read and written within the same request. Multiple chained block I/O is invoked similarly to single block I/O requests, but the IUCV SEND parameter list is set up as follows:

### IPRMSG1

specifies the number of blocks to process (1 to 256).

### IPRMSG2

specifies the guest absolute address of the multiple block I/O parameter list. This list defines the blocks to be read and written and the buffers to use.

Also returned in the high-order halfword of IPRMSG2 is the sum of Start Subchannel instructions issued and successful minidisk cache read requests needed to satisfy the multi-block request.

### IPTRGCLS

specifies the block I/O service requested.

#### Code

#### Meaning

#### F'03'

Multiple request, use the minidisk cache (if present).

#### F'83'

Multiple request, bypass the minidisk cache.

## Usage Notes

1. The SYNC=YES option on the IUCV SEND macro can be specified with the F'03' service request. If SYNC=YES is specified with the F'83' service request, it will get a return code of F'06', indicating an invalid request.

The synchronous processing option is intended for use when reading blocks. Applications that specify the SYNC=YES option have to be prepared for this request to complete synchronously or asynchronously. If all the requested blocks are in the minidisk cache, the SEND request completes synchronously. If all or some of the requested blocks are not in the minidisk cache, the SEND request completes asynchronously.

2. Use the minidisk cache bypass option when reading or writing data that is not referenced frequently. This prevents infrequently-used data from filling the cache and flushing out frequently referenced data.
3. The multiple block I/O interface can be used to read or write a single block. However, the single block interface provides somewhat better performance.
4. The I/O for the DASD blocks specified in the block I/O entries of the BPLBK may not occur in the same order that they are listed. If the application requires that the DASD blocks or I/O data buffers be updated in a particular order, then that I/O request should be implemented with separate \*BLOCKIO SEND requests.
5. The \*BLOCKIO IUCV system service and Diagnose X'250' do not honor DASD reserves managed by VM's virtual reserve/release function. Therefore, do not use these I/O interfaces if a minidisk is shared by multiple guests on the same VM image where another guest is expecting to use reserve/release I/O to serialize its data access. Also, \*BLOCKIO and Diagnose X'250' do not use reserve/release. Therefore, do not use these interfaces for any DASD (CP-attached or full-pack minidisk) that is shared with other LPARs where another LPAR expects to use reserve/release to serialize its data.

## Multiple Block I/O Parameter List

The IPRMSG2 field of the IUCV SEND parameter list points to a parameter list describing the blocks to be read and written and the buffers to use. Each 16-byte entry contains the information for one block to be read or written. For performance reasons, try not to let the parameter list cross a page boundary.

## \*BLOCKIO

The contents of this multiple block I/O parameter list are as follows (up to 256 entries):

| BPLBK DSECT |     |      |   | BPLBUFAD | BPLBKNUM |            |
|-------------|-----|------|---|----------|----------|------------|
| M*1         | M*2 |      |   |          |          |            |
| 0           |     | //// |   |          |          | ////////// |
| 10          |     | //// |   |          |          | ////////// |
| 20          |     | //// |   |          |          | ////////// |
|             |     | //// |   |          |          | ////////// |
| .           | .   | .    | . | .        | .        | .          |
| .           | .   | .    | . | .        | .        | .          |

### BPLQCOD (M\*1)

is the 1-byte request code indicating a read or write. X'01' indicates Write, and X'02' indicates Read.

### BPLSTAT (M\*2)

is the 1-byte area in which a return code is placed, to indicate the status of the request.

### BPLBUFAD

is a 4-byte field containing the guest absolute address of the buffer area into which this block should be read or written. Although there are no alignment requirements for the buffer itself, try not to let the buffer cross a page boundary.

### BPLBKNUM

is a 4-byte field containing the number of the block to be read or written.

The BPLBK DSECT with the HCPBPLBK COPY files is located in the HCPGPI macro library.

## Condition and Return Codes

The condition codes on the IUCV SEND instruction indicate how processing was completed:

### Code

#### Meaning

#### CC=0

The request has been started. An IUCV Message Complete external interrupt is generated when the request completes.

#### CC=1

A nonzero value is stored in the IPRCODE field of the IPARML DSECT.

#### CC=2

All requested blocks were found in the minidisk cache and have been written into the guest buffers.

The IUCV protocol may have been correct from an IUCV perspective but does not meet the \*BLOCKIO requirements. In that case, the \*BLOCKIO system service issues an IUCV SEVER on the path and flags the error. The first byte of the IPUSER field contains one of the following error codes:

### Code

#### Meaning

#### X'07'

IUCV communication was not sent using DATA=PRMSG.

#### X'08'

No 1-way messages are allowed on the path.

The following conditions are detected by \*BLOCKIO before any I/O is initiated. If any errors are detected, no I/O is performed. The return code is stored in the IPRMSG1 field of the IUCV parameter list as follows:

### Code

#### Description

#### F'00'

The multiple block parameter list is set up correctly.

Note: Check the return code for each entry in the multiple block I/O parameter list to verify that I/O has completed successfully for each block.

**F'02'**

The multiple block parameter list is outside the size of the virtual machine.

**F'06'**

An invalid service was requested.

**F'07'**

A storage protection error has occurred on the multiple block parameter list.

**F'08'**

The block count specified is not between 1 and 256, inclusive.

The following conditions are detected on a per-entry basis and do not prevent other blocks within the same request from being read or written. For those entries in error, no I/O is performed for that block (except where RC = X'05', unrecoverable I/O error). The return code is stored in the status field (BPLSTAT) of the individual entry of the multiple block I/O parameter list that contains the error.

**Code****Description****X'00'**

The block has been successfully processed.

**X'01'**

The block number specified is invalid.

**X'02'**

The buffer is outside the size of the virtual machine.

**X'03'**

A write has been requested to a read-only device.

**X'04'**

The block size specified is incorrect—format error.

**X'05'**

An unrecoverable I/O error has occurred.

**X'06'**

The request code is not X'01' for Write or X'02' for Read.

**X'07'**

A storage protection error has occurred on the buffer.

## Ending Communication with the DASD Block I/O System Service

---

To end communication when all communication with \*BLOCKIO is complete, issue either an IUCV SEVER or an IUCV RETRIEVE BUFFER.

**\*BLOCKIO**

## Chapter 15. Error Logging System Service (\*LOGREC)

An installation may write an application to run in a guest virtual machine which has been authorized to use the IUCV interface to receive LOGREC records from the z/VM control program supporting it. This IUCV authorization is defined using the IUCV directory control statement of the guest virtual machine. The IUCV control statement must name \*LOGREC as the CP system service to which a communication path is established. The user ID of the guest virtual machine may also be identified to the control program during system generation so that records can be accumulated for the virtual machine before it has connected to the system service.

For more information on the IUCV functions mentioned in this chapter, refer to Chapter 5, “IUCV Function Descriptions,” on page 317 and Chapter 8, “IUCV Macro Functions for Use in APPC/VM,” on page 521.

The Error Logging system service (\*LOGREC) in CP supports both 1-way and 2-way IUCV protocols when sending records to authorized virtual machines. When a **1-way** IUCV SEND is issued by the CP, the virtual machine to which the LOGREC record is sent cannot issue an IUCV REPLY but must issue a RECEIVE. When a **2-way** IUCV SEND is issued by the CP, the virtual machine to which the LOGREC record is sent must issue an IUCV REPLY. Response data may not be sent on an IUCV REPLY. The reply buffer length field in the IUCV parameter list, IPBFLN2F, must contain zeros. This can be accomplished by setting a register to zero and coding ANSLN=(reg) on the IUCV REPLY macro.

### Establishing Communications with the Error Logging System Service

Prior to issuing the IUCV CONNECT to the \*LOGREC system service, a virtual machine must issue a DECLARE BUFFER request to IUCV to provide an external interrupt buffer. The virtual machine must be enabled for IUCV interrupts in Control Register 0 and the PSW must be set to enable external interrupts.

The connection with the \*LOGREC system service is created by issuing IUCV CONNECT, specifying the USERID as \*LOGREC. The use of the 2-way protocol for gathering LOGREC records from the CP Error Logging system service is specified by the virtual machine in the IPUSER data area when it issues an IUCV CONNECT to the \*LOGREC service. This area must contain a X'02' at offset 8 if the application is written to issue an IUCV REPLY after data is received from the CP \*LOGREC system service. If the area does not contain a X'02', the default is 1-way communication. The CONNECT parameter list must also indicate that you do not want to receive messages with data in the parameter list. This is indicated by specifying or defaulting to the PRMDATA=NO option on the IUCV CONNECT.

When you issue CONNECT to the Error Logging system service, the connection is either completed successfully (by ACCEPT) or rejected (by SEVER). If the connection is accepted, IUCV returns a PATHID to you, which must be specified on all subsequent IUCV requests to the system service. Only one CONNECT can be issued by a virtual machine to the Error Logging system service.

If the connection is severed, the Error Logging system service places a 1-byte code at offset 9 of the IPUSER field of the IPARML to indicate why.

A code of:

- X'04' indicates that the virtual machine already has a connection to the Error Logging system service.
- X'08' indicates that the virtual machine made a protocol error on the CONNECT request. The PRMDATA=YES option was specified but it should not have been.
- X'0C' indicates that the limit of 100 recording table entries has been reached and there is no room for another.

A virtual machine is not allowed to issue an IUCV SEND to the \*LOGREC service (the path is QUIESCED by CP Recording Services). A virtual machine may only have one communication path to the Error Logging system service. CP Recording services send only records with the PRTY=NO option.

The data format of a LOGREC record is identical to the records recorded through use of the CP RETRIEVE EREP command. More than one user ID may be authorized to use this service. For more information on how to use the CP commands, see [z/VM: CP Commands and Utilities Reference](#).

## Receiving LOGREC Records

---

To obtain a LOGREC record, when the application is notified by an external interrupt that one is available, issue an IUCV RECEIVE. The Error Logging system service does not send another record until either a response (when the application indicates that data is to be sent to it using the 1-way protocol) or a REPLY (when an application indicates that data is to be sent to it using the 2-way protocol) is received by CP Recording services to the previous record sent.

The Error Logging system service maintains a threshold limit which indicates when to notify the system operator and the receiving virtual machine that uncollected records are accumulating in host storage. The default value is 2 for LOGREC records. This value may be changed using the RECORDING command.

To stop receiving records temporarily, you may issue an IUCV SEVER. CP continues to queue records for your virtual machine until a CP RECORDING EREP OFF command is issued, specifying your user ID. To resume receiving records, you may issue an IUCV CONNECT specifying the user ID as \*LOGREC.

If the CP abends while a virtual machine is collecting LOGREC data, LOGREC records not received by the virtual machine are checkpointed and requeued to the virtual machine on a subsequent warm or force-start of the control program. The virtual machine is also logged on the system automatically by CP if it is identified on the SYSTEM\_USERIDS statement in the system configuration file. For more information on the SYSTEM\_USERIDS statement, see [z/VM: CP Planning and Administration](#).

## Disconnecting from the Error Logging System Service

---

You can terminate collection of LOGREC records by issuing IUCV SEVER or IUCV RETRIEVE BUFFER for your \*LOGREC system service path. A SEVER may be initiated by the system due to virtual machine reset or an IUCV RETRIEVE BUFFER request. CP continues to queue records for your virtual machine until a CP RECORDING EREP OFF command is issued specifying your user ID.

## Chapter 16. Identify System Service (\*IDENT)

The Identify system service (\*IDENT) is a CP system service that lets authorized virtual machines connect to it and:

- Identify themselves as resource or gateway managers
- Revoke ownership of a resource or gateway
- Communicate with CP to request that a user's effective and saved-set POSIX user ID (UID) and group ID (GID) be set.

The Identify system service maintains a local system resource/gateway table of all resources and gateways managed on that system. A virtual machine manages a resource or gateway only while it is connected to \*IDENT.

For more information on the IUCV functions mentioned in this chapter, refer to [Chapter 5, "IUCV Function Descriptions,"](#) on page 317 and [Chapter 8, "IUCV Macro Functions for Use in APPC/VM,"](#) on page 521.

### Establishing Communication with the Identify System Service

For a virtual machine to manage or revoke a local, global, or system resource or gateway, it must first be authorized to connect to the identify system service, \*IDENT. Your system administrator is the person who can authorize your virtual machine to manage or revoke a particular resource or gateway. To do this, the administrator must specify a special IUCV \*IDENT statement in your virtual machine's directory entry. Your system administrator also can authorize the AVS virtual machine to revoke a particular gateway by specifying an IUCV \*IDENT statement in the AVS virtual machine's directory entry.

For more information on how a system administrator authorizes virtual machines to manage or revoke resources and gateways, see [z/VM: CP Planning and Administration](#).

Once authorized, your virtual machine must issue an IUCV CONNECT to use \*IDENT. You must specify the user ID as \*IDENT, and the user data field must have the following format:

#### Name

contains the name of the resource or gateway that you are managing or revoking. The first byte of this name must be alphanumeric; IBM reserves names beginning with characters for its own use. This resource/gateway name cannot be blanks (X'40's), nulls (X'00's), ANY, ALLOW, or SYSTEM.

#### Fcode

is the function code. FCODE=1 indicates a request to identify or manage a resource or gateway. FCODE=2 indicates a request to revoke a resource or gateway.

#### Flag

is a flag byte.

For **manage** requests (FCODE=1):

#### Bit 0 on

Defines the resource as being accessible from outside the local system.

- If bit 0 is on and bit 2 is off, this is a global resource, unique in the TSAF or CS collection and accessible throughout the TSAF or CS collection and by AVS.
- If bit 0 is on and bit 2 is on, this is a system resource, accessible throughout the TSAF or CS collection through the system gateway and by AVS.

This bit must be on for a gateway.

## **\*IDENT**

### **Bit 0 off**

Defines the resource as being accessible only from the local system (a local resource).

### **Bit 1 on**

Indicates that the resource manager program accepts connections with SECURITY(NONE).

### **Bit 1 off**

Indicates that the resource manager program does not accept connections with SECURITY(NONE).

### **Bit 2 on**

Defines the resource as a system resource. If this bit is on, bit 0 must also be on.

### **Bit 2 off**

Indicates that this resource is not a system resource.

### **Bits 3-6**

Reserved for IBM use.

### **Bit 7 on**

Defines the resource as one that will communicate with CP and reply to requests from CP's support for the family of POSIX exec functions for information about POSIX security values.

If this bit is on, the resource must also be authorized to set another user's POSIX security values and must be prepared to accept traffic along the connection set up by this \*IDENT request. See [“Communicating with CP” on page 731](#) for details on this interface.

CP checks the system directory to ensure that the virtual machine is authorized to set other users' POSIX security values. If CP determines that the virtual machine is not authorized, or an error occurs while CP is attempting to check the authorization, CP turns off this bit, and the resource will not be able to participate in operations requested by CP's support for the family of POSIX exec functions.

### **Bit 7 off**

Indicates that the resource does not wish to participate in set\_UID and set\_GID operations.

For **revoke** requests (FCODE=2):

### **Bit 0 on**

Tells CP to revoke the global resource or gateway, known to the TSAF or CS collection. It must also be on for revoking a system resource (see bit 2).

### **Bit 0 off**

Tells CP to revoke the local resource, known only to the local system.

### **Bit 2 on**

Indicates that this resource is a system resource. If this bit is on, bit 0 must also be on.

### **Bit 2 off**

Indicates that this resource is not a system resource.

## **Ntype**

Indicates the type for NAME. An Ntype of 0 indicates a resource ID; An Ntype of 1 indicates a gateway name.

When you try connecting to \*IDENT to manage or revoke a resource or gateway, CP checks the validity of the connection pending parameter list and checks the CP directory to verify that you are authorized to make the connection. CP severs your connection to \*IDENT if it detects an error.

For a request to manage a resource or gateway, \*IDENT also checks that the resource or gateway is not currently managed by another virtual machine. \*IDENT accepts the connection if you are accepted as the resource or gateway manager, and your virtual machine gets a connection complete interrupt. So that you do not send any messages over the path, CP accepts connections to \*IDENT by specifying QUIESCE=YES on its IUCV ACCEPT. Because \*IDENT quiesces the path to your resource or gateway manager, \*IDENT can never receive an incoming message on the path. If you issue an IUCV QUIESCE or an IUCV RESUME on the path, IUCV returns with no action taken. \*IDENT severs the connection if your request to manage the resource or gateway is rejected. If your connection is accepted, \*IDENT may sever the connection later if another virtual machine revokes your management of the resource or gateway.

For a request to revoke a resource or gateway, \*IDENT severs the connection to your virtual machine and severs the connection to the resource or gateway manager.

See “\*IDENT Sever Reason Codes” on page 734 for all the sever reason codes used by the Identify system service.

## Handling Connection Requests for the Resource or Gateway

If your virtual machine becomes a local, global, or system resource manager, APPC/VM lets other virtual machines connect to your virtual machine if they specify the resource ID on APPCVM CONNECT.

Assuming your virtual machine is enabled for interrupts, connection pending interrupts are routed to your virtual machine since you are registered as the manager of the resource. You, as the resource manager, can either accept the connection (using IUCV ACCEPT) or sever the connection (using APPCVM SEVER).

When a virtual machine becomes a gateway manager, APPC/VM lets other virtual machines connect to the gateway manager by specifying the gateway name in the connection parameter list extension on the APPCVM CONNECT.

Connections to the gateway name are routed to the registered gateway manager virtual machine. The gateway manager virtual machine can either accept the connection (using IUCV ACCEPT) or sever the connection (using APPCVM SEVER).

## Communicating with CP

If the resource being identified is one that communicates with CP's support for the family of POSIX exec functions, then the parameter list passed to \*IDENT must have bit 7 turned on in the flag byte on the **manage** request. Turning on this bit notifies CP that the application is capable of handling conversations across the \*IDENT path.

In addition to the bit in the parameter list, the virtual machine must have authorization to set other users' UIDs and GIDs. To get this authorization, add the SETIDS option of the POSIXOPT directory statement to the virtual machine's directory entry. If this authorization is not present, and bit 7 is on, \*IDENT will turn bit 7 off, and CP will not use the extended \*IDENT interface and function.

## \*IDENT Interface for Communication with CP's Support for the Family of POSIX exec Functions

When CP receives a request to process one of the POSIX exec functions for a set\_UID and set\_GID file, CP notifies the resource. The resource should provide any necessary authorization checking and notify CP of the results, sending the new UID and GID values if the authorization checking is successful.

The interface between CP and the resource is mapped by control block HCPIRCBK, which consists of two major sections: the header, and the function-specific section. The function-specific section is mapped differently for \*IDENT communication type, and may include both fixed-length and variable length portions. For upward compatibility, the field IRCFFXLN, the length of the fixed-length portion of the function-specific section, must be filled in during the execution-time creation of the block. Any subsequent references to the variable-length portion must always be based on the address of the beginning of the block plus the lengths of the header and the fixed-length portion of the function-specific section.

The format of the header is:

|   |          |  |  |          |
|---|----------|--|--|----------|
| 0 | :TYPE    |  |  | IRCTOTLN |
| 8 | IRCFFXLN |  |  |          |

The format of the IRCBK for the POSIX exec communication type is:

where:

### IRCTYPE

is a 1-byte flag containing the type of communication with the resource. Valid values are:

**1**

Indicates that the information in the block is being communicated on behalf of CP's support for the family of POSIX exec functions.

### IRCTOTLN

is an unsigned fullword containing the total length of the parameter list (the IRCBK) in bytes.

### IRCFXLN

is an unsigned fullword containing the length, in bytes, of the fixed-length portion of the function-specific section of the parameter list.

### IRCIDFLG

is a 1-byte flag set by the resource containing information about the UID and GIDs. Valid values are:

**1... ..**

The UID should be changed.

**.1... ..**

The GID should be changed.

**..1. ....**

Reserved

**...1 ....**

Reserved

**.... 1...**

Reserved

**.... .1..**

Reserved

**.... ..1.**

Reserved

**.... ...1**

Reserved

### If bit zero is on,

the object's access information specifies that the effective and saved-set UID of the process issuing one of the POSIX exec functions should be changed to match the value specified in the IRCNUID field.

### If bit one is on,

the object's access information specifies that the effective and saved-set GID of the process issuing one of the POSIX exec functions should be changed to match the value specified in the IRCNGID field.

### All other bits

are reserved and should be binary zero.

**IRCEUID**

is a fullword field containing the current effective UID of the process issuing one of the POSIX exec functions.

**IRCEGID**

is a fullword field containing the current effective GID of the process issuing one of the POSIX exec functions.

**IRCSRET**

is a fullword field set by the resource with the return code indicating success or failure of its checks. If this value indicates anything other than success (success being indicated by the server return code equal to zero), both bit zero and bit one of IDFLG are ignored.

CP will check this return code to determine whether it should complete its support for the family of POSIX exec functions or return an error. If this field contains zero, CP will continue. Otherwise CP will assume that an error has occurred which precludes CP's support for POSIX exec functions from completing successfully and will so notify the application issuing one of the POSIX exec functions.

**IRCSREAS**

is a fullword field set by the resource with the reason code associated with the server return code. CP does not examine this field, but passes it back to the application issuing one of the POSIX exec functions.

**IRCNUID**

is a fullword field set by the resource containing the UID to which the user's effective and saved-set UID should be set. If the server return code does not indicate success, or bit zero in byte IRCIDFLG is off, the contents of this field are ignored.

**IRCNGID**

is a fullword field set by the resource containing the GID to which the user's effective and saved-set GID should be set. If the server return code does not indicate success, or bit one in byte IRCIDFLG is off, the contents of this field are ignored.

**IRCSGLN**

is an unsigned fullword field containing the length of the supplementary GID data, in bytes. The value in this field must include the length of this field and the length of the supplementary GID information specified in the IRCSGIDS field.

**IRCSGIDS**

is a variable-length field containing the supplementary GIDs of the user whose process is issuing one of the POSIX exec functions.

**IRCOBJLN**

is an unsigned fullword field containing the length of the object token data, in bytes. The value of this field must include the length of this field and the length of the object token specified in the object token field.

**IRCOBJTK**

is a variable-length character field containing the token representing the file to be executed. The object token is left-justified.

## When Your Resource is Revoked

---

The following can revoke a resource:

- A virtual machine authorized to revoke the resource
- A resource manager virtual machine (by severing its path to \*IDENT)
- The TSAF virtual machine
- ISFC.

A virtual machine must be authorized to connect to \*IDENT to revoke a resource or gateway.

To revoke a resource or gateway on your virtual machine, your virtual machine must issue an IUCV SEVER on the path to \*IDENT.

The SEVER does not affect existing APPC/VM paths to your virtual machine. However, CP does not establish any new paths to you. If another virtual machine connects to \*IDENT to manage the resource or gateway that you revoked, requests to connect to the resource go to that virtual machine.

**Note:** If a virtual machine initiates a connection request to a resource that you manage before your revoke completes, the path may be established.

## \*IDENT Sever Reason Codes

When \*IDENT severs one of its paths, it stores a reason code in byte 10 of the IPUSER field in the IUCV SEVER external interrupt buffer. This code indicates the reason for the SEVER.

**Note:** If the virtual machine issues the SEVER, it does not receive an external interrupt; in this case the \*IDENT reason code is X'00'.

The IPUSER field has the following format:

### RCODE

contains the \*IDENT sever reason code. It can be one of the following values:

| Hex Code | Decimal Code | Meaning                                                                                                                                                                                                                  |
|----------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00'    | 0            | *IDENT revoked the resource or gateway as requested.                                                                                                                                                                     |
| X'01'    | 1            | An I/O error occurred while CP was reading the system directory. *IDENT was checking for authorization to manage or revoke the resource or gateway.                                                                      |
| X'02'    | 2            | The IPUSER field in the IUCV CONNECT parameter list was set up incorrectly for a connection to *IDENT.                                                                                                                   |
| X'03'    | 3            | The CONNECT parameter list has an invalid parameter PRMDATA.                                                                                                                                                             |
| X'04'    | 4            | The virtual machine is not authorized to connect to *IDENT for the specified resource or gateway.                                                                                                                        |
| X'05'    | 5            | The virtual machine is not authorized to identify the resource as a global or system resource.                                                                                                                           |
| X'06'    | 6            | The virtual machine is not authorized to revoke the specified resource or gateway.                                                                                                                                       |
| X'07'    | 7            | The virtual machine is not authorized to revoke the specified resource globally.                                                                                                                                         |
| X'08'    | 8            | CP cannot identify the global resource or gateway because the CP resource/gateway table currently contains the maximum of 500 entries owned on the local system.                                                         |
| X'09'    | 9            | A virtual machine already manages the resource or gateway being identified. The virtual machine trying to identify a resource or gateway could be the same virtual machine that already manages the resource or gateway. |
| X'0A'    | 10           | A virtual machine revoked the resource or gateway. The resource or gateway may have been revoked by the virtual machine that managed the resource or gateway.                                                            |
| X'0B'    | 11           | The resource or gateway to be revoked does not exist.                                                                                                                                                                    |

| <b>Hex Code</b> | <b>Decimal Code</b> | <b>Meaning</b>                                                                                                                                                                                                                                                |
|-----------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'0C'           | 12                  | The resource or gateway is pending identification by a virtual machine and is not available to be identified or revoked.                                                                                                                                      |
| X'0D'           | 13                  | The resource or gateway is pending a revoke by a virtual machine and is not available to be identified or revoked. An authorized virtual machine is revoking the resource or gateway, or the resource manager virtual machine is severing its path to *IDENT. |
| X'0E'           | 14                  | The CONNECT parameter list has an invalid resource name or gateway name specified.                                                                                                                                                                            |

**\*IDENT**

## Chapter 17. Message System Service (\*MSG)

The Message system service (\*MSG) lets a virtual machine read messages and responses that come from CP, rather than display these on the terminal. (The texts of CP command responses and messages themselves is not part of the programming interface.)

\*MSG is the assigned Message system service user ID. You establish communication with this user ID by specifying USERID=\*MSG when issuing the IUCV CONNECT function.

Your virtual machine does not need any special authorization to use the Message system service. All you have to do is issue IUCV CONNECT with USERID=\*MSG. A virtual machine may only have one communication path to the \*MSG system service.

For more information on the IUCV functions mentioned in this chapter, refer to [Chapter 5, “IUCV Function Descriptions,”](#) on page 317 and [Chapter 8, “IUCV Macro Functions for Use in APPC/VM,”](#) on page 521.

Once you have issued this, you must specify what kind of messages you want the virtual machine to receive. The Message system service handles virtual console output if the user has specified the IUCV option on the CP SET command, as shown in [Table 204 on page 737](#). There is no SET command for Single Console Image Facility (SCIF) messages; the virtual machine always receives these when it has a connection to the Message system service.

**Note:** When full-screen CMS is on, most CMS console output is not passed to CP. In addition, applications that use the Message system service and SET VMCONIO IUCV do not trap all CMS output. Before running such applications, it is recommended that you suspend full-screen CMS.

Following is a list of CP SET commands that have an IUCV option. All of these commands assume that you have a connection to IUCV and \*MSG.

*Table 204. CP SET Commands with an IUCV Option*

| CP command  | Options  | Function                                                                                                                                                                                |
|-------------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SET MSG     | IUCV     | Passes all messages to the virtual machine using IUCV. The messages do not go into the virtual console spool file.                                                                      |
| SET WNG     | IUCV     | Passes warnings to the virtual machine                                                                                                                                                  |
| SET SMSG    | IUCV     | Passes special messages along to the virtual machine using IUCV                                                                                                                         |
| SET EMSG    | IUCV     | Passes on both text and error code to the virtual machine using IUCV                                                                                                                    |
| SET IMSG    | IUCV     | Passes on information messages to the virtual machine using IUCV                                                                                                                        |
| SET VMCONIO | IUCV/OFF | Passes along responses to the virtual machine using IUCV. If you do not have an IUCV connection, data is handled as if VMCONIO is set to OFF. (Refer to the note preceding this table.) |
| SET CPCONIO | IUCV/OFF | Passes along all CP responses to the virtual machine using IUCV. If there is not an IUCV connection, data is handled as if CPCONIO is set OFF.                                          |

The Message system service uses the IUCV default maximum value of 255 for the number of outstanding messages allowed on the path. The number of outstanding messages can be set below the default by specifying a value for MSGLIM on the IUCV CONNECT to \*MSG. The default maximum value can be changed to 16000 by including an IUCV \*MSG statement in the directory entry for the user issuing the connect (the MSGLIMIT parameter is ignored). If the message limit is exceeded, any additional incoming

messages are routed directly to the virtual machine console, or alternate console, and the virtual machine is not notified about these messages. This situation is most likely to occur when there is a high volume of incoming messages and the virtual machine is running with external interrupts disabled.

The Message system service identifies the source of the message it intercepts by a code in the IUCV message class field. The message source is interpreted as follows:

### **Class**

#### **Message Source**

**1**

Message sent using CP MESSAGE (MSG) or CP MSGNOH

**2**

Message sent using CP WARNING (WNG)

**3**

Asynchronous CP messages, CP messages to a CP command executed by a virtual machine using \*MSG, and any other console I/O initiated by CP

**4**

Message sent using CP SMSG command

**5**

Any data directed to the virtual console by the virtual machine (for example, WRTERM or LINEDIT).

**6**

Error message from CP (EMSG)

**7**

Information messages for CP (IMSG)

**8**

Single console image facility (SCIF) message from CP.

Error and information messages (classes 6 and 7) are types of CP messages and are included in class 3 when EMSG and IMSG are not specifically set to IUCV through the CP SET commands.

The format of the data received from IUCV is as follows:

*User ID* identifies the sender. *Text* is the actual data the user would have received on their terminal. For class 1 and class 2 type messages, the standard header is suppressed. If the data is not received by a MSG, WNG, SMSG, or using SCIF, the user ID is the recipient.

If a virtual machine has both a valid path to \*MSG and a functioning secondary user, incoming messages (except for SMSGs, which are not console messages) are directed to the secondary user instead of the IUCV \*MSG path to the primary user.

If a secondary user has a valid path to the Message system service (\*MSG) and is disconnected, then output on behalf of the primary user normally directed to the secondary user's console is instead directed through the IUCV \*MSG path.

Any output generated by the SET LOGMSG and ECHO commands is always sent to the terminal. The output is not sent over \*MSG.

## Chapter 18. Message All System Service (\*MSGALL)

Like the Message system service, the Message All system service (\*MSGALL) lets a virtual machine read messages and responses that come from CP, rather than displaying these on the terminal.

The Message All system service operates as an alternative to the Message system service. If you use \*MSGALL, all terminal output is received over IUCV. If the user has issued the CP SET command with the IUCV option, that setting overrides \*MSGALL. For example, if the user has issued SET EMSG IUCV, all EMSGs use the \*MSG path, rather than the \*MSGALL path. All the other terminal output still follows the \*MSGALL path.

**Note:** SMSGs are never sent on the \*MSGALL path. They only use the \*MSG path.

Your virtual machine does not need any special authorization to use the Message All system service. All you have to do is issue IUCV CONNECT with USERID=\*MSGALL. A virtual machine may only have one communication path to the \*MSGALL system service.

For more information on the IUCV functions mentioned in this chapter, refer to [Chapter 5, “IUCV Function Descriptions,”](#) on page 317 and [Chapter 8, “IUCV Macro Functions for Use in APPC/VM,”](#) on page 521.

Console output is handled as follows:

### **Console output sent over the \*MSGALL path if unsuccessful with \*MSG:**

- CPCONIO and EMSGs generated as part of a DIAGNOSE code X'08' operation
- MSGs, WNGs, IMSGs, and SCIFed messages.

### **Console output sent directly to the terminal:**

- Asynchronous CPCONIO (including TRACE events) and EMSGs **not** generated as part of a DIAGNOSE code X'08' operation.
- Output generated by the SET LOGMSG and ECHO commands.

### **Console output never sent over \*MSGALL path:**

- SMSGs

The Message All system service uses the IUCV default maximum value of 255 for the number of outstanding messages allowed on the path. The number of outstanding messages can be set below the default by specifying a value for MSGLIM on the IUCV CONNECT to \*MSGALL. The default maximum value can be changed to 16000 by including an IUCV \*MSGALL statement in the directory entry for the user issuing the connect (the MSGLIMIT parameter is ignored). If the message limit is exceeded, any additional incoming messages are routed directly to the virtual machine console, or alternate console, and the virtual machine is not notified about these messages. This situation is most likely to occur when there is a high volume of incoming messages and the virtual machine is running with external interrupts disabled.

**\*MSGALL**

# Chapter 19. SCLP System Service (\*SCLP)

The SCLP system service (\*SCLP) is a CP system service that allows you to receive and transmit Hardware Management Console events. When you connect to the SCLP system service, you register to handle the events for one or more event classes. For a virtual machine to transmit and receive Hardware Management Console events, it must first be authorized to connect to the SCLP system service, \*SCLP. Your system administrator is the person who can authorize a virtual machine to establish a connection. To do this, the administrator must specify a special IUCV \*SCLP statement in the virtual machine's directory entry. For more information on how a system administrator authorizes virtual machines to connect to IUCV system services, see *z/VM: CP Planning and Administration*.

For more information on the IUCV functions mentioned in this section, refer to Chapter 5, "IUCV Function Descriptions," on page 317 and Chapter 8, "IUCV Macro Functions for Use in APPC/VM," on page 521.

## Establishing Communication with the SCLP System Service

The SCLP system service uses IUCV to communicate with a virtual machine. The IUCV macro checks the validity of the IUCV parameters and any errors are handled according to IUCV specifications. The SCLP system service checks the validity of all the parameters it requires. Any errors resulting from this check are handled as described in the remainder of this section.

The first step in establishing IUCV communications with the SCLP system service is to issue an IUCV DECLARE BUFFER. This function initializes the virtual machine for IUCV communication. This function also specifies a buffer where IUCV can store external interruption information.

## Connecting to the SCLP System Service

After initializing for IUCV communication, you must issue an IUCV CONNECT and specify USERID=\*SCLP in the IUCV CONNECT parameter list (IPARML). The user data field must have the following format:

### Event owner

Is a string of eight bytes identifying the owner of the event class and must be "SYSTEM " (two blanks are required at the end).

### Class mask

Is a field of 32 bits defining the event classes your virtual machine registers to handle. Bit zero corresponds to event class 1, bit one to event class 2, and so on. Only one virtual machine can be registered for a particular event class.

If the connection request is rejected, the first byte of the user data field has the return code indicating the reason the connection was severed. The following return codes result from connection errors:

### Code

#### Meaning

- 1  
The Event owner field value is not "SYSTEM ".
- 2  
The Class mask field value is zero.
- 3  
The Reserved field value is not zero.

- 4** The Class mask field includes an unsupported class.
- 5** The Class mask field includes a class that is already registered.
- 6** The IUCV ACCEPT failed.

## Sending SCLP Events

---

Upon notification of a successful connection, your virtual machine is ready to send SCLP events. You may now issue synchronous (SYNC=YES) 1-way (TYPE=1WAY) IUCV SEND requests to the SCLP system service specifying the target event class mask and the event data. Specify the target event class mask as the target class (TRGCLS) in the format of a Class mask (in the mask, only one bit should be on). Specify the BUFFER and BUFLLEN parameters on the IUCV SEND.

If a serious error is encountered, the \*SCLP connection is severed. The first byte of the user data field has the return code indicating the reason the SEND was rejected. The following return codes result from send errors:

- | <b>Code</b> | <b>Meaning</b>                                                                |
|-------------|-------------------------------------------------------------------------------|
| <b>7</b>    | A target event class was not specified.                                       |
| <b>8</b>    | The event was not sent as a synchronous 1-way message.                        |
| <b>9</b>    | No event buffer was supplied or DATA=PRMMSG was specified.                    |
| <b>10</b>   | No connection exists to the *SCLP system service.                             |
| <b>11</b>   | The original CONNECT request did not enable the specified target event class. |

If any other error is encountered, the SEND completes with condition code 1 and an error return code in the IPRCODE field. The following error codes might be presented:

- | <b>Code</b> | <b>Meaning</b>                                                |
|-------------|---------------------------------------------------------------|
| <b>3</b>    | The message could not be sent to the HMC.                     |
| <b>5</b>    | The message is too long.                                      |
| <b>6</b>    | A fetch protection exception was detected on the send buffer. |
| <b>7</b>    | An addressing exception was detected on the send buffer.      |
| <b>22</b>   | The send buffer list is invalid.                              |
| <b>23</b>   | The buffer list contains a negative length.                   |
| <b>24</b>   | The total of the buffer list lengths is incorrect.            |
| <b>26</b>   | The buffer list is not on a doubleword boundary.              |

**30**

The IPAPPC flag in IPFLAGS1 is not 0.

**31**

An IUCV function was specified on an APPC/VM path.

**91**

A paging or storage error was detected in the SEND data area.

If return code 3 is received, a Message Complete external interruption will be presented for the message.

## Receiving SCLP Events

---

The SCLP system service passes events to your virtual machine one at a time by issuing a 1-way IUCV SEND. The target class (TRGCLS) of the message is the event class in the same format as a Class mask. If you want to stop receiving events from the SCLP system service temporarily, you can use IUCV QUIESCE. The SCLP system service queues events while a path is quiescent. The queued events will be available when you issue an IUCV RESUME.

## Disconnecting from the SCLP System Service

---

When all communications with the SCLP system service are completed, you can terminate communication by issuing either an IUCV SEVER or an IUCV RETRIEVE BUFFER.

## Chapter 20. Signal System Service (\*SIGNAL)

The Signal system service (\*SIGNAL) is a CP system service that allows virtual machines in a virtual machine group to signal each other. The Signal system service can only be used by virtual machines in a virtual machine group. Each virtual machine in a group is identified by a unique 16-bit signal ID. When a virtual machine connects to the Signal system service, it may request that a particular signal ID be assigned to it. If you have not set up the virtual machine to request a specific signal ID, the Signal system service automatically assigns one to your virtual machine.

All members of a virtual machine group can send eight bytes of signal data (user information) to any member in the group, specifying the signal ID of the virtual machine they want to receive the signal data on, by using IUCV SEND. A virtual machine can also signal all members in a group using a broadcast signal. Group members can request notification of members entering and leaving the group by specifying Signal-In and Signal-Out flags when they connect to the Signal system service.

Using the Signal system service requires no directory authorization. The Signal system service allows only one connection per virtual machine.

For more information on the IUCV functions mentioned in this chapter, refer to [Chapter 5, "IUCV Function Descriptions,"](#) on page 317 and [Chapter 8, "IUCV Macro Functions for Use in APPC/VM,"](#) on page 521.

### Establishing Communications with the Signal System Service

The Signal system service uses IUCV to communicate between itself and a virtual machine. The IUCV macro checks the validity of all the IUCV parameters and any errors are handled according to IUCV specifications. The Signal system service checks the validity of all the parameters it requires. Any errors resulting from this check are handled as described in the following sections.

Your first step in establishing IUCV communications with the Signal system service is to issue an IUCV DECLARE BUFFER. This initializes the virtual machine for IUCV communication. This function also specifies a buffer where IUCV can store external interrupt information.

### IUCV CONNECT to the Signal System Service

After you establish communications with IUCV, you must issue an IUCV CONNECT with USERID=\*SIGNAL and PRMDATA=YES in the IUCV CONNECT parameter list (IPARML). The user data field must have the following format:

#### Signal data

is the eight bytes of user information or signal you want passed to other members of the group. Only group members that have specified the signal-in flag when they connected receive the data.

#### Flags

is a set of bits defining the signal options chosen by you for your virtual machine. The first three bits are defined, and the others are reserved. The defined bits are:

#### Code

#### Meaning

#### X'80'

Signal-in

#### X'40'

Signal-out

## \*SIGNAL

### X'20'

Signal ID has been specified

### X'1F'

Reserved.

### Signal ID

is the signal ID you want assigned to your virtual machine. This signal ID is used by other group members to communicate with your virtual machine. This field is only used if you set the signal ID flag bit (X'20') in the flags field.

You must set all reserved fields and flags to zero.

If you specify the signal-on flag, your virtual machine is signaled when future group members enter your group by connecting to the Signal system service.

If you specify the signal-out flag, your virtual machine is signaled when group members in your group break their connection (using IUCV SEVER) with the Signal system service.

The IUCV CONNECT function returns a PATHID to your virtual machine. You must specify this PATHID in the IUCV SEND parameter list (IPARML) for all subsequent communication to the Signal system service.

When you issue IUCV CONNECT to the Signal system service, the connection is either accepted (the Signal system service issues an IUCV ACCEPT) or severed (the Signal system service issues an IUCV SEVER).

If the connection is accepted, the user data field on the IUCV connection complete external interrupt has the following format:

### Signal data

is unchanged from the IUCV CONNECT.

### Flags

are unchanged from the IUCV CONNECT.

### Signal ID

is the signal ID you assigned to your virtual machine. If you did not assign a signal ID, the Signal system service assigns a unique signal ID for you and stores it in this field.

All unused fields remain unchanged from the IUCV CONNECT.

If the connection is rejected, the user data field on the IUCV SEVER external interrupt has the following format:

### IPRCODE

is the return code indicating the reason the connection was severed.

Return codes resulting from connection errors:

#### Code

#### Meaning

#### X'01'

You are not a member of a virtual machine group.

#### X'02'

You are already connected to the Signal system service.

#### X'03'

You did not specify PRMDATA=YES in the IUCV CONNECT parameter list (IPARML).

- X'04'**  
The reserved fields were not set to zero.
- X'05'**  
The signal ID you specified was not unique.

## Sending Signals

Upon notification of a successful connection, your virtual machine is ready to send signals. You may now issue IUCV SEND requests to the Signal system service specifying the 8-byte signal (parameter list data), the target's signal ID, and the flag settings. Specify the target's signal ID and the flag settings in the target class (TRGCLS) with the following format:

**Flags**  
is a set of bits defining the handling of the signal. Only two bits are defined and the others are reserved. The defined bits are:

- | Code         | Meaning           |
|--------------|-------------------|
| <b>X'10'</b> | Broadcast signal  |
| <b>X'08'</b> | Invalid signal ID |
| <b>X'E7'</b> | Reserved.         |

**Signal ID**  
is the target's signal ID.

If you specify the broadcast signal (X'10') flag, a signal is sent to all of the other users in your group that are connected to the Signal system service.

If you send a signal using an invalid signal ID, the Signal system service returns the signal to you with an error indicator (X'08') in the FLAGS field. The target class and the signal data remain unchanged.

If the parameter list data option is not used, or if the signal is not 1-way, the connection is severed.

Return codes resulting from send errors:

- | Code         | Meaning                                                       |
|--------------|---------------------------------------------------------------|
| <b>X'06'</b> | The signal was sent without the DATA=PRMMSG option specified. |
| <b>X'07'</b> | The signal sent was not a 1-way signal.                       |

## Receiving Signals

As a member of a virtual machine group, your virtual machine can receive three types of signals. These are signal-in, signal-out, and a normal signal sent by another group member using an IUCV SEND. The Signal system service passes these signals to your virtual machine through an IUCV SEND using a 1-way message with the signal specified in the parameter list data.

Specify the source's signal ID and the flag settings in the target class (TRGCLS) with the following format:

## \*SIGNAL

### Flags

is a set of bits defining the type of signal sent. Only three bits are defined and the others are unused. The defined bits are:

#### Code

##### Meaning

**X'80'**

Signal-In

**X'40'**

Signal-Out

**X'10'**

Broadcast signal

**X'2F'**

Unused

### Signal ID

is the source's signal ID.

The Signal system service sets all unused fields to zero.

If the signal-in flag is on, this signal was specified in the user data of the user's IUCV CONNECT to the Signal system service.

If the signal-out flag is on, this signal was specified in the user data of the user's IUCV SEVER to the Signal system service.

If the broadcast flag or no flags are on, this signal was specified in the parameter list data of the user's IUCV SEND to the Signal system service.

If you want to stop receiving signals from the Signal system service, you can use IUCV QUIESCE. However, the Signal system service does not queue signals, and the signals from other members of the group will be lost until you issue an IUCV RESUME.

## Leaving the Signal System Service

---

When all communications with the Signal system service are completed, you can terminate communication by issuing either an IUCV SEVER or an IUCV RETRIEVE BUFFER. The user data field on a SEVER must have the following format:

### Signal data

is the 8-byte signal you want passed to other members of the group. Only group members that have specified the signal-out flag when they connected to the Signal system service will receive the data.

If a SEVER is generated by the CP system, as on a RETRIEVE BUFFER or a virtual machine reset, the signal data is set to all zeros.

## Chapter 21. Spool System Service (\*SPL)

The Spool System Service is a CP system service that provides an interface using IUCV for communication between CP and virtual machines that provide print services for advanced function printers, and reader services for reader notification.

\*SPL also functions as a generic spool file interface facility that you can use instead of DIAGNOSE code X'14' to select and read files from the CP spool system.

When the virtual machine connects to the spool system service, for printer service it passes an identifier, *prtId*, which is used as the external name of that virtual machine. When the virtual machine connects to the spool system service, for reader service the IPUSER area (first 8 bytes) must be blank (X'40'), and the 9th byte defines a flag byte (IPUFLAG1). A bit is defined in this byte (IPRDR = X'80') to indicate that the connect request is for the reader notification function. For \*SPL to act as a generic spool file interface, the virtual machine must pass the keyword VIRTUAL in place of the *prtId*.

The term *prtId* is synonymous with print server virtual machine in this document. The virtual machine has access to the system printer spool files but these printers, of course, are not supported directly by CP.

Once communication between the *prtId* and the spool system service has been established, a *prtId* can:

- Select a spool file from the print chain for processing
- Close a selected file
- Send messages or command responses to the operator or other users
- Read the spool file descriptor (SFBLOK) (see note “1” on page 749)
- Read the spool file records (SPLINKs) (see note “2” on page 749)
- Read an external attribute buffer (XAB) (see note “3” on page 749).

### Notes:

1. For more information about SFBLOK, refer to [Appendix A, “Data Areas Used by DIAGNOSE Codes,”](#) on page 985.
2. For more information about SPLINK, refer to [Appendix A, “Data Areas Used by DIAGNOSE Codes,”](#) on page 985.
3. The external attribute buffer (XAB) is a control block that contains data the user creates to specify additional information about a print file. Each print file has its own XAB, and CP has the facilities to maintain the XABs. For more information about XABs, refer to [“External Attribute Buffer Used by DIAGNOSE Codes X'B4', X'B8', and X'290'”](#) on page 995.
4. For more information on the IUCV functions mentioned in this chapter, refer to [Chapter 5, “IUCV Function Descriptions,”](#) on page 317 and [Chapter 8, “IUCV Macro Functions for Use in APPC/VM,”](#) on page 521.

Similarly, the spool system service communicates with the *prtId* and can:

- Send commands to the *prtId*
- Notify the *prtId* that a print file is available for processing
- Cancel processing on a print file (PURGE function).

For the second option, you can enter the word VIRTUAL in the field normally used for the *prtId* that the PSF machine represents. VIRTUAL indicates that you want the spool system service to process files in the virtual reader, printer, or punch of a given user. This option enables an application to:

- Read files out of its virtual reader, virtual printer, or virtual punch
- Given the right privilege classes, read files out of another user's virtual reader, virtual printer, or virtual punch

- Allow for selection of files based on the setting of *seen* bits and allow for the *seen* bits to be reset on files.

This function of \*SPL does not require any change in existing applications, such as PSF, that use \*SPL.

Depending on whether you specify VIRTUAL or a *ptid* in the field, all subsequent IUCV SEND, RECEIVE and SEVER functions issued by the application take on different meanings. For instance, the IUCV transmission class used by an application for selecting a spool file will differ depending on the type of IUCV connection established. IUCV connections established using the VIRTUAL keyword will be referred to as the generic \*SPL interface, while connections established using a *ptid* will be referred to as the Advance Function Printers (APF) printing \*SPL interface. The pages that follow describe each of these communication functions in more detail.

## The AFP Printing \*SPL Interface

---

The AFP Printing \*SPL Interface provides print services.

### Establishing Communication with the Spool System Service

The spool system service uses IUCV to communicate with the print server virtual machine, and reader server virtual machine. For you to use the spool system service, the directory entry for the virtual machines must specify the IUCV \*SPL option. \*SPL is the SPOOL system service user ID. The IUCV macro checks the validity of all IUCV parameters. All IUCV errors are handled according to IUCV specifications. The spool system service checks the validity of all required parameters and handles the errors. IUCV requires the virtual machine to do a DECLARE BUFFER to initialize the virtual machine for IUCV communication. The virtual machine does an IUCV CONNECT to the spool system service. The connection lets the *ptid* use the spool system service to obtain spool print files for processing. Operator and user commands can be sent to the server virtual machines through the IUCV connection by specifying the *ptid* defined by the virtual machine at CONNECT time.

### IUCV CONNECT to the Spool System Service

#### *For Printer Service*

An IUCV CONNECT is issued by the virtual machine with USERID=\*SPL, PRTY=NO, PRMDATA=YES, and USERDTA is an address containing the *ptid* name.

A *ptid* name is a 1- to 8-character alphanumeric name your installation assigns. If you specify a *ptid* name of four or fewer characters, then the name *cannot* contain all hexadecimal characters. For example, FFFF is **not** a valid *ptid* name, whereas FFFFFF is. BLD is another example of a valid name. A *ptid* name cannot be ALL. A *ptid* name must **not** contain imbedded blanks; however, trailing blanks are permitted. It is the installation's responsibility to control the names assigned to *ptids*. The name should not conflict with any other names, options, or notation the installation uses.

#### *Example*

It is recommended that a *ptid* name should not:

- Be the same as a user ID on the system
- Be PROC or PROCESSOR
- Include a dash (-)
- Be a name that could be confused with a logical device number, for example, L1234.

The spool system service allows multiple virtual machines to be connected with the same *ptid* name. This way, when you use the spool system service SEND function, each virtual machine of the specified *ptid* name is sent a message.

If you want to create your own IUCV parameter list, then the IPUSER user data field must have the following data:

|         |     |        |       |
|---------|-----|--------|-------|
|         | ORG | IPUSER |       |
| SPLNAME | DC  | CL8    | PRTID |

### For Reader Service

An IUCV CONNECT is issued by the virtual machine with USERID=\*SPL, PRTY=NO, PRMDATA=YES, and USERDTA=IPUSER(1:9). The IPUSER field from bytes 1 to 9 contains the following information:

|                          |     |       |                                           |
|--------------------------|-----|-------|-------------------------------------------|
| RDRID                    | DS  | CL8   | Set to blanks                             |
| Bits Defined in IPRFLAG1 |     |       |                                           |
| IPRDR                    | EQU | X'80' | Connection for the reader notify function |

If all the parameters required by Spool system service are valid, the Spool system service issues an IUCV ACCEPT to complete the connection with the virtual machine. All other Spool system service functions depend on the IUCV CONNECT and ACCEPT being complete.

### Reasons the **CONNECT** Function May Sever

If any of the parameters passed to Spool system service are invalid, Spool system service issues an IUCV SEVER. When the *prt*id is ready to end its connection with \*SPL system service, the *prt*id then issues an IUCV SEVER. Any spool files being processed at the time of the SEVER remain unchanged.

The following situations are considered user errors and cause the Spool system service to sever the IUCV path to the *prt*id:

- A CONNECT issued was with QUIESCE, return code X'80'
- A CONNECT issued was with PRTY, return code X'80'
- A CONNECT issued was with PRMDATA=NO, return code X'80'
- A CONNECT issued was with a *prt*id name, that is:
  - ALL
  - Contains imbedded blanks
  - Is four or less hexadecimal digits.

When the Spool system service CONNECT issues a SEVER, the format of the IPUSER field is:

- IPUSER+0: 1-byte error code of X'80'
- IPUSER+1: 1-byte reserved field of X'00'
- IPUSER+2: 2-bytes, containing IPMSGID from the IUCV parameter list that caused the error.

When the reader service issues a CONNECT, and the Spool system service has 8 (maximum) connections with reader service machines, then \*SPL issues a SEVER, the format of the IPUSER field is:

- IPUSER+0: 1-byte error code of X'80'.

The following situations are considered user errors and cause the Spool system service to sever the IUCV path to the reader service machine:

- A CONNECT issued was with QUIESCE, return code X'80'
- A CONNECT issued was with PRTY, return code X'80'
- A CONNECT issued was with PRMDATA=NO, return code X'80'.

When the Spool system service CONNECT issues a SEVER, the format of the IPUSER field is:

- IPUSER+0: 1-byte error code of X'80'.

## Virtual Machine Communication to the Spool System Service

After the Spool system service accepts the connection (using an IUCV ACCEPT), the virtual machine can send the following types of requests to the Spool system service with an IUCV SEND:

- SELECT
- CLOSE
- MESSAGE
- READ
  - READ SFBLOK (see [Appendix A, “Data Areas Used by DIAGNOSE Codes,”](#) on page 985)
  - READ XAB (see [“External Attribute Buffer Used by DIAGNOSE Codes X'B4', X'B8', and X'290'”](#) on page 995)
  - READ SPLINK (see [Appendix A, “Data Areas Used by DIAGNOSE Codes,”](#) on page 985)
- ENABLE
- DISABLE.

All calls from the virtual machine to \*SPL are 2-way sends. The material that follows describes these functions:

### The SELECT Function

Through a file-select, a *prt*id can obtain a spool print file for processing. To select a file to process, the *prt*id sends a SELECT (through an IUCV SEND specifying TYPE=2WAY, DATA=PRMSG or DATA=BUFFER, the value of 4 in the address specified by TRGCLS) to the Spool system service.

The SELECT function does not require that a previously selected file be closed before another file is selected.

The spool print file can be selected either by specific file (user ID or spool ID), by the generic selection criteria, or by default. In other words, select by:

- Specific criteria (user ID and spool ID), DATA=BUFFER
- Generic criteria, DATA=BUFFER
- Previously specified (default) criteria, DATA=PRMSG.

### **SELECT with Specific or Generic Criteria (DATA=BUFFER)**

When DATA=BUFFER (the user data is in the buffer and IUCV RECEIVE transfers the data), a length of 60 in the address specified by BUFLen, and the buffer contains the following information:

**Note:** Field names used in the following descriptions are used for reference only. You may copy these names, or use any other names, in your own code.

|                          |     |       |                                                                                                                                                                             |
|--------------------------|-----|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SPLSEFLG                 | DS  | 1X    | Selection flag                                                                                                                                                              |
| SPLSETYP                 | DS  | 1X    | Type of file eligible for selection                                                                                                                                         |

| SPLSUSID                 | DS  | CL8   | User ID (if flag SPLSESID is ON)                                                                                                                                            |
| SPLSPID                  | DS  | H     | Spool ID (if flag SPLSESID is ON)                                                                                                                                           |
| Bits Defined in SPLSEFLG |     |       |                                                                                                                                                                             |
| SPLSECHG                 | EQU | X'80' | Change default selection criteria to the new selection criteria sent in the BUFFER.<br>Note: All selection criteria is changed so all data must be specified in the buffer. |
| SPLSECON                 | EQU | X'40' | Select spool file for "convert" process.                                                                                                                                    |

## Bits Defined in SPLSETYP

|          |     |       |                                                                                       |
|----------|-----|-------|---------------------------------------------------------------------------------------|
| SPLSE5AC | EQU | X'80' | Select files using X'5A' CCWs                                                         |
| SPLSEN5A | EQU | X'40' | Select files not using X'5A' CCWs                                                     |
| SPLSECNV | EQU | X'20' | Select files that are converted                                                       |
| SPLSENCV | EQU | X'10' | Select files that are not converted                                                   |
| SPLSN38L | EQU | X'08' | Select files not using 3800 load CCWs                                                 |
| SPLSBE38 | EQU | X'04' | Select files containing 3800 load CCWs at the beginning of the file                   |
| SPLSAN38 | EQU | X'02' | Select files containing 3800 load CCWs anywhere within the file                       |
| SPLSESID | EQU | X'01' | Select a specific spool file by ID (used in conjunction with the SPLSPID and SPLUSID) |

If the three flags—SPLSN38L, SPLSBE38, and SPLSAN38—are all OFF, then the 3800 load CCW characteristics of the spool file do not affect whether the file is selected (the tests are bypassed).

**Notes:**

1. If the SPLSESID bit is off, then select the next available file matching the default selection criteria.
2. If the user ID is less than 8 characters, it must be left-justified and padded with blanks.
3. If the select is by spool ID, the selection criteria are not changed.
4. If the SPLSECON bit is off, then select a spool file to start the print process.

A file that is selected for print processing is similar to files being handled by CP-driven system printers. The file is marked as being open for system use.

A file that is selected for conversion processing is special because the *prt*id for which the file was selected is notified when CP CHANGE, CP PURGE, and CP TRANSFER commands are issued for the file. See the Spool system service PURGE function ([“The PURGE Function” on page 763.](#))

5. When the select is not by spool ID, you must specify at least one each of CLASS, FLASH, FORM, DESTination, either SPLSE5AC or SPLSEN5A, and either SPLSECNV or SPLSENCV in SPLSETYP.

If you specify a value of blank for CLASSES, FLASH, FORM, or DESTinations, then no file is selected.

6. Any unused length of the CLASSES, FLASH, FORM, or DESTinations fields must be padded with blanks.
  - An asterisk (\*) specified for a CLASS, means that any CLASS file can be selected.
  - An asterisk (\*) specified for FORM (or DESTination) means that any FORM (or DESTination) file can be selected.
  - An asterisk (\*) specified for FLASH means that any FLASH file can be selected.
  - OFF specified for FORM means that a file is eligible for selection if it has either been assigned a FORM of OFF or if it has been assigned the default printer FORM. For more information about setting default forms, see the PRINTER operand on the FORM\_DEFAULT statement in the system configuration file. The FORM\_DEFAULT statement is described in [z/VM: CP Planning and Administration](#).
  - OFF specified for DESTination means that files which do not have a destination assigned to them, or have been assigned OFF, can be selected.
  - OFF specified for FLASH means that files which do not have a FLASH assigned to them, or have been assigned OFF, can be selected.
7. If SPLSESID is specified, then no other bits in SPLSETYP may be specified.

**REPLY Information**

If a file is selected, the Spool system service always responds using an IUCV REPLY with DATA=BUFFER and a length of 14 in the address specified by ANSLEN.

ANSBUF=address, where address points to a buffer that contains the following information:

|             |    |     |                                 |
|-------------|----|-----|---------------------------------|
| IPUSER + 0: | DS | H   | Spool ID                        |
| IPUSER + 2: | DS | H   | COPY count for the file or zero |
| IPUSER + 4: | DS | XL1 | Primary flag = X'00'            |
| IPUSER + 5: | DS | XL1 | Secondary flag                  |

```

IPUSER + 6:   DS   CL8   User ID

Meaning of Bits in Secondary Flag
EQU X'80'    SFBL0K marked to be purged
EQU X'40'    File has been converted
EQU X'20'    File contains X'5A' CCWs
EQU X'10'    Reserved
EQU X'08'    Reserved
EQU X'04'    Reserved
EQU X'02'    Reserved
EQU X'01'    Reserved

```

If no file is selected, the Spool system service always responds using an IUCV REPLY with DATA=PRMMSG. PRMMSG contains the following information:

```

IPRMMSG1      Bytes 0 to 3      Reserved
IPRMMSG2      Byte 0           Primary flag = X'04'
              Byte 1           Secondary flag
              Bytes 2 to 3     Reserved

Meaning of Bits in Secondary Flag
EQU X'80'    Reserved
EQU X'40'    Reserved
EQU X'20'    Reserved
EQU X'10'    Specified file not found on PRINT queue
EQU X'08'    Specified file in USER HOLD status
EQU X'04'    Specified file in SYSTEM HOLD status
EQU X'02'    File is in the process of being printed
EQU X'01'    Reserved

```

The select was by spool ID; the file was not selected and has one of the characteristics shown in the secondary flag.

### ***SELECT by Previously-Specified Criteria (DATA=PRMMSG)***

When DATA=PRMMSG (select using default selection criteria), then PRMMSG contains the following information:

```

IPRMMSG1      Bytes 0 to 3      Reserved
IPRMMSG2      Byte 0           Flag
              Bytes 1 to 3     Reserved

Bits Defined in Byte 0 of IPRMMSG2
EQU X'80'    Reserved
SPLSECON      EQU X'40' If set ON, select spool file for "convert" process
              If set OFF, select file for "print" processing

```

All other bits are reserved and must be set to zero.

#### **Notes:**

1. A file that is selected for print processing is similar to files that are being handled by CP-driven system printers. The file is marked as being open for system use.

When a file is selected for convert processing, the *prt*id for which the file was selected is notified if the CP CHANGE, CP PURGE, and CP TRANSFER commands are issued for the file. This is so the print server can discard the current conversion and redo it in light of the new characteristics. See the Spool system service PURGE function ([“The PURGE Function” on page 763.](#))

2. Default selection criteria is defined by the last issued SELECT.

### ***Reasons the SELECT Function May Sever***

The following situations are considered user errors and cause the Spool system service to sever the IUCV path to a *prt*id:

Return code=X'80':

- Use of TYPE=1WAY communication
- Incorrect buffer length. The specified buffer length on the SEND must be 60 bytes.
- Conflicting selection criteria options:

- DATA=PRMSG, and default selection criteria are not defined.
- DATA=BUFFER, and both the SPLSE5AC and SPLSEN5A flags are OFF.
- DATA=BUFFER and both the SPLSECNV and SPLSENCV flags are OFF.
- Incorrect flag specification. No other bit in SPLSETYP can be ON if SPLSESID is ON.

When the Spool system service SELECT does a SEVER, the format of the IPUSER field length is:

```
IPUSER + 0:   Return code
IPUSER + 1:   X'04' - Identifies the type of IUCV
                SEND that caused the sever
IPUSER + 2:   IPMSGID from the IUCV parameter list
                that caused the error
```

## The CLOSE Function

A *prt*id uses the Spool system service CLOSE function to take one of these actions:

1. End the processing of a selected file:

The CLOSE functions are performed if a new copy count is not requested.

In this case, when the CLOSE is complete, the *prt*id can specify to delete the print file or leave it on the VM spool.

2. Change the spool file copy count:

If SPLCCOPY is greater than 0 and less than X'00FF', the change function is performed. (If SPLCCOPY is greater than X'00FF', then the Spool system service severs the IUCV path.)

To use the CLOSE function, the *prt*id sends a CLOSE request (using an IUCV specifying SEND TYPE=2WAY, DATA=BUFFER, a length of 30 in the address specified by BUFLN, and a value of 5 in the address specified by TRGCLS) to the Spool system service.

The buffer contains the following information:

|          |    |     |                                                                                |
|----------|----|-----|--------------------------------------------------------------------------------|
| SPLCSPID | DS | 1H  | File spool ID                                                                  |
| SPLCFLCL | DS | 1X  | Flag (If the function is to change the copy count, then this flag is ignored.) |
| SPLCCLAS | DS | 1X  | CLASS                                                                          |
| SPLCFORM | DS | CL8 | FORM                                                                           |
| SPLCDEST | DS | CL8 | DESTination                                                                    |
| SPLCCOPY | DS | 1H  | Copy count                                                                     |
| SPLCUSID | DS | CL8 | User ID of the owner of the spool file                                         |

Bits Defined in SPLSFLCL

|          |     |       |                                        |
|----------|-----|-------|----------------------------------------|
| SPLCLPUR | EQU | X'80' | Close and purge file                   |
| SPLCLUHO | EQU | X'40' | Close and requeue in user hold         |
| SPLCLSHO | EQU | X'20' | Close and requeue in system hold       |
| SPLCLCON | EQU | X'10' | Close and requeue converted            |
| SPLCLCLA | EQU | X'08' | Close and requeue with new CLASS       |
| SPLCLFRM | EQU | X'04' | Close and requeue with new FORM        |
| SPLCLDES | EQU | X'02' | Close and requeue with new DESTination |
| SPLCLUNC | EQU | X'01' | Close and requeue nonconverted         |

### Notes:

1. If the user ID is less than 8 characters, it must be left-justified and padded with blanks.
2. When you specify SPLCLPUR, it is invalid to specify any other option in SPLCFLCL.
3. It is invalid to specify both SPLCLCON and SPLCLUNC.
4. If SPLCLPUR is not specified, either SPLCLCON or SPLCLUNC must be specified.
5. When SPLCCOPY is not zero, CLOSE updates the copy count, but the file remains in SELECT status; no other changes occur.
6. SPLCCOPY cannot be greater than 255.
7. When you specify SPLCLPUR and the file has the KEEP attribute, the file is closed in USER hold. When you specify SPLCLPUR and the file has the NOKEEP attribute, the file is purged.

8. When you specify either SPLCLCON or SPLCLUNC, the file is closed according to the settings of SPLCLUHO and SPLCLSHO. If neither SPLCLUHO or SPLCLSHO is specified, the file is closed NOHOLD regardless of the KEEP attribute of the file.

### **REPLY Information**

The Spool system service responds to the CLOSE request using an IUCV REPLY with DATA=PRMMSG, and PRMMSG containing the following information:

```
IPRMSG1  Bytes 0 to 3      Reserved
IPRMSG2  Byte  0          Flag
          Bytes 1 to 3      Reserved

Bit Defined in Byte 0 of IPRMSG2
EQU  X'04'      File not selected; message already sent to the
                  prtid that selected the file.
```

### **Reasons the CLOSE Function May Sever**

The following situations are considered user errors and cause the Spool system service to sever the IUCV path to a *prtid*:

Return code=X'80':

- Use of TYPE=1WAY communication
- Incorrect buffer length. The specified buffer length must be 30-bytes.
- Conflicting file-disposition options. For example, specifying close and purge file at the same time you specify close and requeue in user hold.
- Use of DATA=PRMMSG in the IUCV SEND
- SPLCCOPY is greater than 255.

Return code=X'10': I/O pending

When the Spool system service CLOSE does a SEVER, the format of the IPUSER field is:

```
IPUSER + 0:  Return code
IPUSER + 1:  X'05' - Identifies the type of IUCV
                  SEND that caused the sever
IPUSER + 2:  IPMSGID from the IUCV parameter list
                  that caused the error
```

### **The MESSAGE Function**

A *prtid* uses the Spool system service MESSAGE function to send messages or command responses to the operator or other users. To do this, the *prtid* uses an IUCV SEND specifying TYPE=2WAY, DATA=BUFFER, BUFFER=address, and BUFLN=address, a value of 6 in the address specified by TRGCLS to the Spool system service.

When a *prtid* sends a message, it sends the following information to the Spool system service in a buffer:

| SPLMSUID | DS | CL8    | User ID to receive the message                                                                                         |
|----------|----|--------|------------------------------------------------------------------------------------------------------------------------|
| SPLMSTYP | DS | CL1    | TYPE of message:<br>S - Sent via CP SMSG<br>M - Sent via CP MSG<br>W - Sent via CP MSGNOH and console alarm is sounded |
| SPLMSARE | DS | 0XL224 | Message area (maximum size is 224 bytes)<br>- First 2 bytes: Message area length<br>- Next 'n' bytes: Message text     |
| SPLMSLEN | DS | XL2    | Message area length<br>(actual size of SPLMSARE)                                                                       |
| SPLMSTXT | DS | CL222  | Message text (maximum size is 222.)                                                                                    |

**Note:** When a message is sent to a remote node, the issuer is responsible for placing the necessary networking control sequence and the actual message.

To send a message, the issuer uses the following format:

|         |        |        |         |
|---------|--------|--------|---------|
| RSCScmd | VMnode | userid | message |
|---------|--------|--------|---------|

For example, if a user wants to send a message (HI from OVERHERE) to a remote VM node (RCVNODE) user ID OVERTHER, then the issuer specifies the message text be sent to the RSCS machine as follows.

|     |         |          |                  |
|-----|---------|----------|------------------|
| MSG | RCVNODE | OVERTHER | HI from OVERHERE |
|-----|---------|----------|------------------|

## REPLY Information

When the Spool system service MESSAGE finishes processing the issuer's request, the Spool system service MESSAGE replies to the issuer with return codes indicating the success or failure of the function. The reply is sent using an IUCV REPLY, DATA=PRMSG, and PRMSG=return code.

Return codes which do *not* sever the path are:

### Code

#### Meaning

#### X'00'

Successful message

#### X'03'

USERID=ALL is invalid, when message type is S

#### X'2D'

User ID not logged on

#### X'39'

User ID not receiving.

## Reasons the MESSAGE Function May Sever

The following situations are considered user errors and cause the Spool system service to sever the IUCV path to a *ptid*:

Return code=X'80':

- Use of TYPE=1WAY communication
- Use of DATA=PRMSG. The Spool system service MESSAGE allows only DATA=BUFFER.
- Target user ID is all blanks. The Spool system service MESSAGE does not allow character blanks for the target user ID.
- Invalid message type.
- Invalid data buffer length. The Spool system service allows only message types S, M, and W. The Spool system service requires that the data buffer length be greater than or equal to 12 and less than or equal to 240.
- Invalid message area format. The length of the message area must be greater than 2 but less than or equal to 224.

When the Spool system service MESSAGE does a SEVER, the format of the IPUSER field is:

|             |                                                                 |
|-------------|-----------------------------------------------------------------|
| IPUSER + 0: | Return code                                                     |
| IPUSER + 1: | X'06'—Identifies the type of IUCV<br>SEND that caused the sever |
| IPUSER + 2: | IPMSGID from the IUCV parameter list<br>that caused the error   |

## The READ-SFBLOK Function

With this function, a *ptid* can read the information contained in a selected spool file's SFBLOK.

When a *ptid* does a READ-SFBLOK, it sends the following information to the Spool system service:

- The spool ID of the file
- The size of the buffer
- The address of the receiving buffer
- The user ID of the owner of the file.

The READ-SFBLOK function uses the IUCV SEND specifying TYPE=2WAY, DATA=BUFFER (all the user data is in a buffer), and a value of 2 in the address specified by TRGCLS. BUFFER=address and a value of 16 in the address specified by BUFLen are also specified.

The buffer contains the following information:

|          |    |     |                |
|----------|----|-----|----------------|
| SPLRFSID | DS | 1H  | Spool ID       |
| SPLRFSIZ | DS | 1H  | Buffer size    |
| SPLRFADR | DS | 1F  | Buffer address |
| SPLRFUID | DS | CL8 | User ID        |

**Note:** If the user ID is less than 8 characters, it must be left-justified and padded with blanks.

When READ-SFBLOK is complete, the Spool system service replies using an IUCV REPLY with DATA=PRMMSG, and PRMMSG containing the following information:

|                                   |                                                                                                                                                                              |                |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| IPRMSG1                           | Bytes 0 and 1                                                                                                                                                                | Reserved       |
|                                   | Bytes 2 and 3                                                                                                                                                                | Length of data |
| IPRMSG2                           | Byte 0                                                                                                                                                                       | Flag           |
|                                   | Bytes 1 to 3                                                                                                                                                                 | Reserved       |
| Bits Defined in Byte 0 of IPRMSG2 |                                                                                                                                                                              |                |
| EQU X'20'                         | CP paging error                                                                                                                                                              |                |
| EQU X'08'                         | User buffer not large enough to hold requested data                                                                                                                          |                |
| EQU X'04'                         | File not selected, or Spool system service processing for the file stopped, and a Spool system service PURGE message already sent to the <i>ptid</i> that selected the file. |                |

#### Notes:

1. If the READ-SFBLOK was successful, then bytes 2 and 3 of IPRMSG1 contain the actual length of the SFBLOK.
2. If the READ-SFBLOK was unsuccessful, then bytes 2 and 3 of IPRMSG1 contain zeros.

#### ***Reasons the READ-SFBLOK Function May Sever***

The following situations are considered user errors and cause the Spool system service to sever the IUCV path to a *ptid*:

Return code=X'80':

- The use of TYPE=1WAY communication.
- The use of DATA=PRMMSG. The Spool system service READ-SFBLOK only allows DATA=BUFFER on the IUCV SEND.
- Incorrect buffer length. The message buffer length must be 16-bytes.

Return code=X'08':

- Protection or addressing violation for the user buffer. Either there is a storage protection violation involving the user buffer, or the address range specified for the buffer is not addressable.

When the Spool system service READ-SFBLOK does a SEVER, the format of the IPUSER field is:

|             |                                                              |
|-------------|--------------------------------------------------------------|
| IPUSER + 0: | Return code                                                  |
| IPUSER + 1: | X'02'—Identifies the type of IUCV SEND that caused the sever |
| IPUSER + 2: | IPMSGID from the IUCV parameter list that caused the error   |

## The READ-XAB Function

Use the READ-XAB function to allow a *ptid* to read the information contained in a selected spool file's external attribute buffer (XAB).

When a *ptid* does a READ-XAB, it sends the following information to the Spool system service:

- The spool ID of the file
- The size of the buffer
- The address of the receiving buffer
- The user ID of the owner of the file.

The READ-XAB function uses the IUCV SEND, specifying TYPE=2WAY, DATA=BUFFER (all the user data is in a buffer), and a value of 3 in the address specified by TRGCLS. BUFFER=*address* and a value of 16 in the address specified by BUFLen are also specified. The buffer contains the following information:

|          |    |     |                |
|----------|----|-----|----------------|
| SPLRXSID | DS | 1H  | Spool ID       |
| SPLRXSIZ | DS | 1H  | Buffer size    |
| SPLRXADR | DS | 1F  | Buffer address |
| SPLRXUID | DS | CL8 | User ID        |

**Note:** If the user ID is less than 8 characters, it must be left-justified and padded with blanks.

## REPLY Information

When the Spool system service READ-XAB is complete, the Spool system service replies using an IUCV REPLY, with DATA=PRMMSG, and PRMMSG containing the following information:

|         |               |                |
|---------|---------------|----------------|
| IPRMSG1 | Bytes 0 and 1 | Reserved       |
|         | Bytes 2 and 3 | Length of data |
| IPRMSG2 | Byte 0        | Flag           |
|         | Bytes 1 to 3  | Reserved       |

Bits Defined in Byte 0 of IPRMSG2

|           |                                                                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EQU X'20' | CP I/O error                                                                                                                                                               |
| EQU X'08' | User buffer not large enough to hold requested data                                                                                                                        |
| EQU X'04' | File not selected or Spool system service processing for the file stopped and a Spool system service PURGE message already sent to the <i>ptid</i> that selected the file. |

**Note:** If there is no XAB, then the size returned is zero. If the size returned is greater than the size of the buffer provided, then no data was put in the buffer. In this case, the requester must get a buffer large enough to hold the XAB and repeat the READ-XAB function.

## Reasons the READ-XAB Function May Sever

The following situations are considered user errors and cause the Spool system service to sever the IUCV path to a *ptid*:

Return code=X'80':

- The use of TYPE=1WAY communication.
- The use of DATA=PRMMSG on the IUCV SEND. The Spool system service READ XAB only allows DATA=BUFFER.
- Incorrect buffer length. The specified buffer length must be 16 bytes.

Return code=X'08':

- An invalid user buffer length. The buffer length cannot be greater than 32,767 bytes.
- A protection or addressing violation for the user buffer. There is either a storage protection violation involving the user buffer, or the address range specified for the buffer is not addressable.

When the Spool system service READ-XAB does a SEVER, the format of the IPUSER field is:

```

IPUSER + 0:  Return code
IPUSER + 1:  X'03'—Identifies the type of IUCV
              SEND that caused the sever
IPUSER + 2:  IPMSGID from the IUCV parameter list
              that caused the error

```

## The READ-SPLINK Function

You use this function to read print data from a file. With this function, a *ptid* can read the CP DASD records (SPLINKs) for a selected spool file.

When a *ptid* requests a READ-SPLINK, it sends the following information to the Spool system service:

- The spool ID of the file
- The user ID of the owner of the file
- The number of SPLINKs to be read
- The address of the receiving buffer, which must be on a 4KB boundary.

The READ-SPLINK function uses an IUCV SEND specifying TYPE=2WAY, DATA=BUFFER, BUFFER=*address*, a length of 16 in the address specified by BUFLen, and a value of 1 in the address specified by TRGCLS. The buffer contains the following information:

|          |    |     |                                |
|----------|----|-----|--------------------------------|
| SPLRPSID | DS | 1H  | Spool ID                       |
| SPLRPSIZ | DS | 1H  | <i>n</i> data pages to be read |
| SPLRPADR | DS | 1F  | Buffer address                 |
| SPLRPUID | DS | CL8 | User ID                        |

### Notes:

1. *n* is the number of data pages to be read (each page is 4KB). SPLINKs are read in sequential order. The first READ for a SPLINK after the file has been selected, reads the first *n* SPLINKs for that file. Following READS read the next *n* SPLINKs for the file. Reads can be continued until the end-of-file is reached.
2. If the user ID is less than 8 characters, it must be left-justified and padded with blanks.

## REPLY Information

When the READ-SPLINK is complete, the Spool system service replies using an IUCV REPLY with DATA=PRMMSG, and PRMMSG containing the following:

|          |               |                        |
|----------|---------------|------------------------|
| IPRMMSG1 | Bytes 0 and 1 | Reserved               |
|          | Bytes 2 and 3 | Number of SPLINKs read |
| IPRMMSG2 | Byte 0        | Flag                   |
|          | Bytes 1 to 3  | Reserved               |

Bits Defined in Byte 0 of IPRMMSG2

|           |                                                                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EQU X'20' | CP I/O error                                                                                                                                                               |
| EQU X'04' | File not selected or Spool system service processing for the file stopped and a Spool system service PURGE message already sent to the <i>ptid</i> that selected the file. |
| EQU X'02' | End-of-file for READ-SPLINK                                                                                                                                                |

## Reasons the READ-SPLINK Function May Sever

The following situations are considered user errors and cause the Spool system service to sever the IUCV path to a *ptid*:

Return code=X'80':

- The use of TYPE=1WAY communication.
- The use of DATA=PRMMSG on the IUCV SEND. The Spool system service READ SPLINK only allows DATA=BUFFER on the IUCV SEND.
- Incorrect buffer length. The message buffer length must be 16 bytes.

Return code=X'08':

- A protection or addressing violation for the user buffer

Any of the following has happened:

- The address of the user buffer is not on a 4KB boundary.
- There is a storage protection violation involving the user buffer.
- The address range specified for the buffer is not addressable.

- The number of SPLINKs specified was zero.

Return code=X'10': I/O pending

The READ-SPLINK or READ-XAB function was done while a previous READ-SPLINK/READ-XAB request was outstanding for the file. The IUCV REPLY for the previous request must be received before the next READ can be done.

When the Spool system service READ-SPLINK does a sever (using the SEVER function), the format of the IPUSER field is:

```
IPUSER + 0:  Return code
IPUSER + 1:  X'01' - Identifies the type of IUCV
                SEND that caused the sever
IPUSER + 2:  IPMSGID from the IUCV parameter list
                that caused the error
```

## The ENABLE Function

This function enables reader notification for a specified user ID. It sends an ENABLE (though an IUCV SEND specifying TYPE=2WAY, DATA=PRMSG PRMSG=user ID (to be enabled) and a value of 10 in the address specified by TRGCLS) to the Spool system service.

### **REPLY Information**

When the Spool system service ENABLE is completed, the Spool system service replies using an IUCV REPLY, with DATA=PRMSG, and PRMSG containing the following information:

```
IPRMSG2  Byte  0          X'00' function request has been
                           completed successfully
```

When the user ID does not exist, the Spool system service always responds using an IUCV REPLY with DATA=PRMSG, and PRMSG containing the following information:

```
IPRMSG2  Byte  0          X'04' Userid not found
```

When the Spool system service ENABLE does a SEVER, the format of the IPUSER field is:

```
IPUSER + 0:  Return code
IPUSER + 1:  X'0A' - Identifies the type of IUCV
                SEND that caused the sever
IPUSER + 2:  IPMSGID from the IUCV parameter list
                that caused the error
```

## The DISABLE Function

This function disables reader notification for a specified user ID. It sends a DISABLE (though an IUCV SEND specifying TYPE=2WAY communication, DATA=PRMSG, PRMSG=user ID (to be enabled), and a value of 11 in the address specified by TRGCLS) to the Spool system service.

## **REPLY Information**

When the Spool system service DISABLE is completed, the Spool system service replies using an IUCV REPLY, with DATA=PRMSG, and PRMSG containing the following information:

```
IPRMSG2  Byte  0          X'00' function request has been
                           completed successfully
```

When the Spool system service DISABLE does a SEVER, the format of the IPUSER field is:

```
IPUSER + 0:  Return code
IPUSER + 1:  X'0B' -  Identifies the type of IUCV
                   SEND that caused the sever
IPUSER + 2:  IPMSGID from the IUCV parameter list
                   that caused the error
```

## **Spool System Service Communication to a Virtual Machine**

When the Spool system service accepts the connection to a *ptid*, the Spool system service can send the following types of requests to a *ptid*:

- SEND
- NOTIFY
- PURGE.

The pages that follow describe these functions.

### **The SEND Function**

The Spool system service uses the Spool system service SEND function to pass printer type commands directly to a *ptid*.

The Spool system service SEND function is used in two ways:

1. To pass data from a non-privileged user to a *ptid* by specifically issuing the CP SEND command.
2. To route operator commands dealing with printer internals to *ptids*. The commands in this group are those existing class D, spool operator, and CP commands that control physical system printers. These commands are:
  - DRAIN
  - FLUSH
  - QUERY
  - START.

The Spool system service routes any of the commands issued from the virtual console which specifies a *ptid* in place of an *rdev*.

The Spool system service SEND function is an IUCV SEND specifying TYPE=1WAY, DATA=BUFFER, BUFFER=*address*, a length of 253 in the address specified by BUFLN, and a value of 9 in the address specified by TRGCLS.

**Note:** When the ALL parameter is specified on the DRAIN, QUERY, or START command, the Spool system service SEND function sends the text to every CONNECTed *ptid*. Also, when *ptids* have the same name, the Spool system service SEND function is done to each of them independently.

It is the responsibility of the print server to do the necessary privilege class and authorization checks for all commands sent to it using the Spool system service SEND function. The *ptid* uses the Spool system service MESSAGE function to respond to the issuer of the command.

With Spool system service SEND, the Spool system service passes the following information to a *ptid*:

|          |    |       |                                      |
|----------|----|-------|--------------------------------------|
| SPLSNUID | DS | CL8   | User ID of the issuer of the command |
| SPLSNPCS | DS | XL4   | Privilege classes of the issuer      |
| SPLSNTXT | DS | CL240 | Text of the command                  |
|          | DC | X'15' | End-of-text indicator                |

The end-of-text indicator can occur anywhere within the SPLSNTXT field or in the byte following this field.

## The NOTIFY Function

The Spool system service NOTIFY function informs an idle *ptid* that a print file is available for processing. It also informs the reader service machine that a reader file has been added or deleted to the specified user's queue.

The Spool system service notifies the *ptid* through an IUCV SEND specifying TYPE=1WAY, DATA=PRMMSG, and a value of 8 in the address specified by TRGCLS. No information is sent to the *ptid* concerning the spool files associated with the NOTIFY.

### Notes:

1. A *ptid* is considered to be *idle* when it has done a SELECT and received a response of *file not available* from the Spool system service.
2. When a *ptid* obtains a file for processing by issuing a SELECT request, the Spool system service stops sending notifications to the *ptid* because the *ptid* is no longer idle.

The Spool system service notifies the reader service machine through an IUCV SEND specifying TYPE=1WAY, DATA=BUFFER, a length of 9 in the address specified by BUFLN, and a value of 8 in the address specified by TRGCLS. The 9-bytes of data in the buffer consist of the user ID whose reader queue changed, the user's spool ID of the reader file, and the number of reader files currently on the user's queue.

## The PURGE Function

The Spool system service PURGE function signals a *ptid* to immediately stop processing a print file that the *ptid* has selected and is in the process of converting. The Spool system service PURGE is done when a CP PURGE, CP CHANGE, or CP TRANSFER command is issued for a file being converted.

For the PURGE function, the Spool system service does an IUCV SEND specifying (TYPE=1WAY, DATA=BUFFER, a length of 10 in the address specified by BUFLN, and a value of 7 in the address specified by TRGCLS) to the *ptid*. The 10-bytes of data in the buffer consist of the spool ID of the file to be *purged* and the user ID that owns the file. The buffer is formatted as follows:

|      |    |     |          |
|------|----|-----|----------|
| + 0: | DS | XL2 | Spool ID |
| + 2: | DS | CL8 | User ID  |

**Note:** If the user ID is less than 8 characters, it is left-justified and padded with blanks.

## The Generic \*SPL Interface

The \*SPL also functions as a generic spool file interface facility.

## Establishing Communication with the Spool System Service

The spool system service uses IUCV to communicate with an application. To create a path to be used in conjunction with the generic \*SPL interface, the application must issue an IUCV CONNECT with *userid* set to \*SPL, PRTY=NO, PRMDATA=YES, and USERDTA is an address containing the word *VIRTUAL* followed by a blank in the first 8 bytes.

## Processing a File

Each generic \*SPL interface path created between the application and the spool system service can be used to read data from only one file at a time. The process of reading the contents of a file can be summarized as follows:

1. IUCV CONNECT to \*SPL with the first 8 bytes of IPUSER set to VIRTUAL (followed by a blank).
2. IUCV SEND a SELECT request to \*SPL specifying a file to be selected for reading.

**Note:** You can have the SFBLOK, 3800 information, any number of SPLINKs and the XAB data of the selected file to be transmitted back to you using the SELECT request.

The data becomes available in the specified buffers when the message complete interrupt occurs.

3. IUCV SEND a GET request for SFBLOK, 3800 information, SPLINKs, XAB, or any combination thereof.

The data becomes available in the specified buffers when the message complete interrupt occurs.

4. IUCV SEND a CLOSE request for the file.

At this point the IUCV path may be reused or SEVERed. To reuse, simply send another SELECT request to \*SPL informing it of the next file to be selected.

## Selecting a File To Be Read

To select a file to be made active on an established generic \*SPL connection, use IUCV SEND to send a SELECT request to the \*SPL System Service.

A SELECT request involves issuing an IUCV SEND request TYPE=2WAY, DATA=BUFFER, BUFFER = address of 48 byte parameter list (mapped by SPGBK), BUFLen = address of field containing length of the parameter list (SPGSIZEB), a value of 1 in the address specified by TRGCLS, ANSBUF = address of 16-byte reply buffer (mapped by SPRBK), ANSLen = address of field containing length of the reply buffer (SPRSIZEB). The parameter list sent to \*SPL for a SELECT request is mapped by SPGBK. The reply buffer is mapped by SPRBK. SPGBK DSECT and SPRBK DSECT are both in the HCPGPI MACLIB.

A SELECT request is required to activate a file on an IUCV path. SELECTs fall into two possible categories:

- Select Specific - selecting by user ID, spool ID, and spool queue
- Select Next - select next unseen file by user ID and spool queue

Thus, the SPGSPEC and SPGNEXT bit settings in the SPGOPTN byte are mutually exclusive. After a file is selected on a given \*SPL connection no reference needs to be made to the spool ID of the file; all transactions that follow refer specifically to the attached file. To request files from spool queues belonging to a user other than that of the virtual machine the application is running on, the virtual machine running the application must have class D privileges.

| SPGBK                                                   | DSECT |               |  |                                                 |
|---------------------------------------------------------|-------|---------------|--|-------------------------------------------------|

Figure 89. SPRBK DSECT

In the case of a SELECT that does not request any additional information to be transferred, the only field set in the SPRBK is SPRGENRC:

**Code****Meaning****0**

Request completed successfully

**4**

No file meeting requested criteria found

**8**

Previously selected file still active

**12**

Not authorized to select another user's files

**16**

Value specified for queue (SPGQUEUE) is not valid.

**20**

Specified user ID (SPGUSER) not found.

**24**

ESM check failed.

**255**

Invalid parameter list encountered:

Select Specific (SPGSPEC) and Select Next (SPGNEXT) were specified

Neither Select Specific (SPGSPEC) nor Select Next (SPGNEXT) was specified and there was not an active file on the path already.

The SELECT request can be combined with a GET request to select a file and get information such as SFBLOK, 3800 information (in SPLINK), SPLINK(s), and XAB information as part of the initial reply. This is accomplished by setting transfer options bits in the SPGOPTN option byte. See the following section for details of the GET request.

**Note:** The SPGRESET option bit is used to indicate to \*SPL that all files in the user's selected queue are to have their seen bits reset. This action will supersede any other selection request. Thus, if SPGRESET and SPGNEXT are set, all seen bits will be reset and the application will end up attaching the first file in the selected queue (based on SPGQUEUE) to the \*SPL IUCV connection.

## Transferring Information About a Selected File

As mentioned before, the GET request may be combined with the SELECT request described in the previous section. As with SELECT requests, GET requests are made by sending the \*SPL System service a SPGBK parameter list using TYPE=2WAY and a value of 1 in the address specified by TRGCLS. Combined SELECT and GET requests are recognized through the bit settings in the SPGOPTN byte. A pure GET request will fail if no file is currently active on the chosen \*SPL path.

With a GET request or a combined SELECT and GET (assuming the SELECT request does not fail), the application can expect additional data to accompany the REPLY from the \*SPL System Service. The GET request is formulated as follows:

- If the SPGGSFB bit is set, the first SPGSFBL double words of the SFBLOK of the attached file is placed at the address specified in SPGSFBA. The minimum length that can be specified by SPGSFBL is 24 d-words.
- If the SPGG3800 bit is set, the first SPG3800L bytes of the 3800 section of the attached file is placed at the address specified in SPG3800A.
- If the SPGGSPLK bit is set, the number of SPLINKs specified in SPGSPLKN is placed at the address specified in SPGSPLKA.

The SPGSPLKS and SPGSPLKN settings determine what SPLINKs of the file are placed at the specified address. The value of SPGSPLKS determines which SPLINK the transfer will start from. The value of SPGSPLKN determines how many SPLINKs will be transferred with this request.

For example, a value of 2 in SPGPKLS and a value of 3 in SPGSPLKN would indicate that the transfer of SPLINK data should start with the second SPLINK in the file and that a total of three SPLINKs would be placed into storage starting at the address specified in SPGSPLKA.

If the value of SPGPKLS is 0, the read will start from wherever the file is currently positioned. Multiple SPLINKs are copied into contiguous storage starting at the address specified in SPGSPLKA.

All write CCWs in the SPLINKs transferred by \*SPL remain as the original opcode. This is different from Diagnose X'14', which converts all write CCWs in punch files to X'41' opcodes.

- If the SPGGXAB bit is set, the first SPGXABL bytes of the XAB of the attached file are placed at the address specified in SPGXABA.

If the settings of the SPGSFBL, SPG3800L, SPGSPLKN or SPGXABL fields exceed the length of the corresponding areas for the file, only the data available is transferred to the buffer. The remainder of the buffer is unchanged. If the settings of the SPG3800L, SPGSPLKN or SPGXABL fields are less than amount of data available, then the amount of data specified in the length field is transferred. If SFBLOK data is being requested, SPGSFBL must be set to a minimum of 24 double words. The SPRSPLKN, SPRSFBL, SPR3800L or SPRXABL fields will contain actual number of transferred splinks, double words or bytes. If the amount of data transferred is not equal to the amount requested, the SPRSFBL, SPRSPKRC, SPRXABRC or SPR38RC fields will contain a return code to indicate this. If SPGSFBL, SPG3800L, SPGSPLKN or SPGXABL are equal to 0, then the corresponding return code in the SPRBK (SPRSFBL, SPRSPKRC, SPRXABRC or SPR38RC) will be 0 and the corresponding length field in the SPRBK (SPRSPLKN, SPRSFBL, SPR3800L or SPRXABL) will be 0.

The GET request may cause the following return codes to be reflected in the SPRBK. For a combined SELECT and GET request, these return codes can be set in addition to those already outlined in the SELECT section above.

The settings for SPRGENRC can be the following:

#### **Code**

##### **Meaning**

**0**

Request completed successfully.

**255**

Invalid parameter list encountered:

SPGNOSEL was specified with Transfer SPLINK (SPGGSPLK) and/or Transfer XAB (SPGGXAB)

The settings for SPRSFBL can be the following:

#### **Code**

##### **Meaning**

**0**

Requested SFBLOK information transferred successfully.

**4**

Paging error encountered when attempting to transfer SFBLOK information to your virtual machine.

**8**

Addressing or protection exception encountered due to invalid SFBLOK data area address specified on request.

**12**

Data area address length that was specified was smaller than size of the SFBLOK (192 bytes).

**16**

The amount of data requested was greater than the amount of data available. SPRSFBL contains the number of double words of data returned.

The settings for SPRSPKRC can be the following:

**Code****Meaning****0**

Requested SPLINK information transferred successfully.

**4**

Paging error encountered attempting to access SPLINKs or transfer SPLINK information to your virtual machine.

**8**

Addressing or protection exception encountered due to invalid SPLINK address specified on request.

**12**

Starting SPLINK number specified in SPGSPLKS exceeded the number of SPLINKs contained in the file.

**16**

The amount of data requested is not equal to the amount available. SPRSPLKN contains the actual number of SPLINKs returned. If SPRSPLKN is less than the number of SPLINKs requested, end of file was reached.

**20**

There was already an outstanding read for this file

The settings for SPRXABRC can be the following:

**Code****Meaning****0**

Requested XAB information transferred successfully.

**4**

Paging error encountered when attempting to access XAB or transfer XAB information to your virtual machine.

**8**

Addressing or protection exception encountered due to invalid XAB data area address specified on request or length of data requested (SPGXABL) was greater than 32,767 bytes.

**12**

File does not have an XAB defined.

**16**

The amount of data requested is not equal to the amount available. SPRXABL contains the actual number of bytes of XAB data returned. If SPRXABL is less than the amount of XAB data requested (SPGXABL), then all of the available XAB data was returned. If SPRXABL is equal to the amount of XAB data requested, there is more data available.

**20**

There was already an outstanding read for this file

The settings for SPR38RC can be the following:

**Code****Meaning****0**

Requested 3800 information transferred successfully.

**4**

Paging error encountered when attempting to access 3800 data or transfer 3800 information to your virtual machine.

**8**

Addressing or protection exception encountered due to invalid 3800 data area address specified on request.

**16**

The amount of data requested is not equal to the amount available. SPR3800L contains the actual number of bytes of 3800 data returned. If SPR3800L is less than the amount of 3800 data requested (SPG3800L), then all of the available 3800 data was returned. If SPR3800L is equal to the amount of 3800 data requested, there is more data available.

If more than one of the transfer bits is set in the GET request, the operations are handled by \*SPL independently. For example, if an invalid SPLINK start counter is specified in the SPGSPLKS field, no SPLINK information will be transferred to the user's virtual machine, but any other information requested will be placed at the requested locations in storage.

## Closing a File

Once all needed information for a given file has been obtained, the file can be closed by issuing a CLOSE request to the \*SPL System Service.

A CLOSE request involves issuing an IUCV SEND request TYPE=2WAY, DATA=BUFFER, BUFFER = address of 48 byte parameter list (mapped by SPGBK), BUFLN = address of field containing length of the parameter list (SPGSIZEB), a value of 2 in the address specified by TRGCLS, ANSBUF = address of 16 byte reply buffer (mapped by SPRBK), ANSLN = address of field containing length of the reply buffer (SPRSIZEB). The parameter list sent to \*SPL for a CLOSE request is mapped by SPGBK. Required fields are SPGUSER and SPGSPID. SPGOPTN can be used to specify whether the file should be closed or the copy count decremented. SPGOPTN is defined as follows for the CLOSE function:

**X'80'**

Purge the file

**X'40'**

Place file in user hold

**X'20'**

Place file in system hold

**X'10'**

Decrement the copy count of file. This option does not close the file. If the copy count is already set to 1, purge the file.

The purge option cannot be used in conjunction with the other three options. If the purge option is specified with any of the other three options, the path is severed. No other restrictions exist. If none of the bits are set, the file is closed and its characteristics are not changed.

The \*SPL System Service replies to the CLOSE request by sending an SPRBK back in the address specified by the ANSBUF parameter on the IUCV SEND.

The possible settings for SPRGENRC are as follows:

**Code****Meaning****0**

File closed and options set as requested

**4**

No file active on this \*SPL connection

**8**

File purged (either because of a purge request or a decremented copy count)

Once the file has been closed, the path to \*SPL need not be severed; instead the path may be reused by a new SELECT request attaching a new file to the path.

## Clearing an Existing Connection

Should the application lose track of what file is active on a path or should it wish to clear out any file attached to the path, it can issue a CLEAR request for the \*SPL path.

## **\*SPL**

A CLEAR request involves issuing an IUCV SEND request TYPE=2WAY, DATA=BUFFER, BUFLen = address of field containing a value of 0, a value of 3 in the address specified by TRGCLS, ANSBUF = address of 16 byte reply buffer (mapped by SPRBK), ANSLen = address of field containing length of the reply buffer (16).

The \*SPL System Service replies to a CLEAR request by returning an SPRBK in the address specified on the ANSBUF parameter of the IUCV SEND. The only significant field in the SPRBK is the SPRGENRC field, which may be set as follows:

### **Code**

#### **Meaning**

**0**

Active file on path has been closed

**4**

No file was active on the path

## Chapter 22. Symptom System Service (\*SYMPTOM)

An application may be written by an installation to run in a guest virtual machine that has been authorized to use the IUCV interface to collect symptom records from the z/VM control program supporting it. This IUCV authorization is defined within the IUCV Directory Control Statement of the guest virtual machine. The IUCV control statement must name \*SYMPTOM as the CP system service to which a communication path will be established. The user ID of the guest virtual machine may also be identified to the control program during system generation or in the system configuration file so that records can be accumulated for the virtual machine before it has connected to the system service. For more information on the required IUCV authorization and identifying the virtual machine that contains a data retrieval application to the control program (the SYSTEM\_USERIDS statement in the system configuration file), see [z/VM: CP Planning and Administration](#).

For more information on the IUCV functions mentioned in this chapter, see Chapter 5, “IUCV Function Descriptions,” on page 317 and Chapter 8, “IUCV Macro Functions for Use in APPC/VM,” on page 521.

The Symptom system service (\*SYMPTOM) in CP supports both 1-way and 2-way IUCV protocols when sending records to authorized virtual machines. When a **1-way** IUCV SEND is issued by z/VM, the virtual machine to which the symptom record is sent cannot issue an IUCV REPLY but must issue a RECEIVE. When a **2-way** IUCV SEND is issued by z/VM, the virtual machine to which the symptom record is sent must issue an IUCV REPLY. Response data may not be sent on an IUCV REPLY. The reply buffer length field in the IUCV parameter list, IPBFLN2F, must contain zeros. This can be accomplished by setting a register to zero and coding ANSLN=(reg) on the IUCV REPLY macro.

### Connecting to the Symptom System Service

Before issuing the IUCV CONNECT to the CP \*SYMPTOM system service, a virtual machine must issue a DECLARE BUFFER request to IUCV to provide an external interrupt buffer. The virtual machine must be enabled for IUCV interrupts in Control Register 0, and the PSW must be set to enable external interrupts.

The connection with the Symptom system service is established by issuing an IUCV CONNECT, specifying USERID=\*SYMPTOM. The use of the IUCV 1-way or 2-way protocol for gathering symptom records from the CP Symptom system service is specified by the virtual machine in the IPUSER data area when it issues an IUCV CONNECT to the Symptom System Service. This area must contain a X'02' at offset 8 to indicate 2-way protocol. Otherwise, the 1-way protocol is used by default. The CONNECT parameter list must also indicate that you do not want to receive messages with data in the parameter list. This is indicated by specifying or defaulting to the PRMDATA=NO option on the IUCV CONNECT.

A virtual machine is not allowed to issue an IUCV SEND to the Symptom system service (the path is QUIESCED by the CP Symptom system service). A virtual machine may only have one communication path to the Symptom system service. The Symptom system service only sends records with the PRTY=NO option.

When an application running in an authorized virtual machine issues a CONNECT to the CP Symptom system service, the connection is either completed successfully (by ACCEPT) or rejected (by SEVER). If the connection is accepted, IUCV returns a PATHID to the virtual machine, which must be specified on all subsequent IUCV requests to the system service. Only one CONNECT can be issued by a virtual machine to the Symptom system service.

If the connection is severed, the Symptom system service places a 1-byte code at offset 9 of the IPUSER field of the IPARML to indicate why. A code of X'04' indicates that the virtual machine already has a connection to the Symptom system service. A code of X'08' indicates that the virtual machine made a protocol error on the CONNECT request. The PRMDATA=YES option was specified but should not have been. A code of X'0C' indicates that the maximum number of connections to the Symptom system service has been exceeded.

The data format of a symptom record is identical to records recorded using the RETRIEVE SYMPTOM command. More than one user ID may be authorized to connect to this service.

## Receiving Symptom Records

---

To obtain a symptom record, when the application is notified by an external interrupt that one is available, an IUCV RECEIVE must be issued. The Symptom system service does not send another record until either a response (when the application indicates that data is to be sent to it using the 1-way protocol) or a REPLY (when an application indicates that data is to be sent to it using the 2-way protocol) is received by the CP Symptom system service to the previous record sent.

The CP Symptom system service maintains a threshold limit which indicates when to notify the system operator and the receiving virtual machine that uncollected records are accumulating in host storage. The default value is 2 for symptom records. The system operator may change this value by issuing the RECORDING SYMPTOM command.

To stop receiving records temporarily, the application must issue an IUCV SEVER. CP continues to queue records for your virtual machine until a CP RECORDING SYMPTOM OFF command is issued for your user ID. To resume receiving records, the system operator may issue an IUCV CONNECT specifying USERID as \*SYMPTOM.

If z/VM abends while a virtual machine is collecting symptom record data, symptom records not received by the virtual machine are checkpointed and requeued to the virtual machine on a subsequent warm or force start of the control program.

The virtual machine is logged on the system automatically by CP if it is identified on the SYSTEM\_USERIDS statement in the system configuration file as part of your system generation.

## Disconnecting from the Symptom System Service

---

You can terminate collection of symptom records by issuing IUCV SEVER or IUCV RETRIEVE BUFFER for your \*SYMPTOM path. A SEVER may be initiated by the system due to virtual machine reset or an IUCV RETRIEVE BUFFER request.

---

# Chapter 23. VM Event System Service (\*VMEVENT)

The VM Event system service (\*VMEVENT) is a CP system service that notifies you about certain events that occur in the VM system. When you connect to the VM Event system service, you receive notification of all events that occur from that point forward. For a virtual machine to receive notifications about VM system events, it must first be authorized to connect to the VM Event system service, \*VMEVENT. Your system administrator is the person who can authorize a virtual machine to establish a connection. To do this, the administrator must specify a special IUCV \*VMEVENT statement in the virtual machine's directory entry. For more information on how a system administrator authorizes virtual machines to connect to IUCV system services, see [z/VM: CP Planning and Administration](#).

For more information on the IUCV functions mentioned in this section, refer to Chapter 5, “IUCV Function Descriptions,” on page 317 and Chapter 8, “IUCV Macro Functions for Use in APPC/VM,” on page 521.

---

## Establishing Communication with the VM Event System Service

The VM Event system service uses IUCV to communicate with a virtual machine. The IUCV macro checks the validity of the IUCV parameters and any errors are handled according to IUCV specifications. Your first step in establishing IUCV communications with the VM Event system service is to issue an IUCV DECLARE BUFFER. This function initializes the virtual machine for IUCV communication. This function also specifies a buffer where IUCV can store external interruption information.

---

## Connecting to the VM Event System Service

After you initialize for IUCV communication, you must issue an IUCV CONNECT and specify USERID=\*VMEVENT in the IUCV CONNECT parameter list (IPARML).

---

## Receiving \*VMEVENT Events

Upon notification of a successful connection, your virtual machine is ready to receive \*VMEVENT events. The VM Event system service passes events to your virtual machine one at a time by issuing a 1-way IUCV SEND. Each event contains class and type identifiers and event data.

The target class (TRGCLS) is a four byte field that identifies the class and type of the event. The target class field has the following format:

The class and type fields are 16-bit binary integers.

The data that is associated with each class-type combination is listed in the sections that follow.

**Important:** Earlier levels of z/VM might provide shorter versions of certain records. The programmer is advised to check the message length to determine whether the fields are present in the record. Changes to \*VMEVENT records are documented in [CP System Services](#) in *z/VM: Migration Guide*.

### Class 0 Events

The class 0 event types and associated data are indicated in [Table 205](#) on page 774.

Table 205. Class 0 Events: Type, Data, and Event

| Class  | Type     | Event                      | Data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |        |        |         |   |   |         |   |   |                  |    |          |                      |

| Offset | Length   | Element                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |        |        |         |   |   |         |   |   |                  |    |          |                      |
| 0      | 8        | User ID                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |        |        |         |   |   |         |   |   |                  |    |          |                      |
| 8      | 8        | Logon-By User ID                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |        |        |         |   |   |         |   |   |                  |    |          |                      |
| 16     | variable | Terminal information                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |        |        |         |   |   |         |   |   |                  |    |          |                      |
| 0      | 29       | Virtual Machine (Guest) is disconnecting | <p><b>User ID</b><br/>Character string, 8 bytes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |        |        |         |   |   |         |   |   |                  |    |          |                      |

**Notes:**

1. If either of the following events occur, a logoff timeout is started and that VM event is reported:

- A forced disconnection occurred
- A console read was attempted on a disconnected guest that had no functional secondary user

However, if the Disconnect\_Timeout value in the system configuration file is zero, a forced sleep occurs and that VM event is reported instead. For more information, see [FEATURES Statement in z/VM: CP Planning and Administration](#).

2. A "Runnable state entered" (Type 5) event is sent when a virtual machine enters the runnable state from a non-runnable state that was reported by an event type 0, 2, 3, 4, 6, or 27.

**Terminal Information Data Elements**

The length and type of terminal information depend on the device type. Terminal information begins with a 1-byte unsigned binary value that indicates the length of the terminal information structure, including the initial byte. Following the length field are a hexadecimal device identifier code and 1-4 other data elements. The locations of the data elements relative to the start of the terminal information structure and the lengths of the elements are described for each device type. The attributes of the data elements are described in [Table 206 on page 781](#).

**For a disconnected device:**

| Offset (bytes) | Length (bytes) | Data Element                |
|----------------|----------------|-----------------------------|
| 0              | 1              | Terminal information length |
| 1              | 1              | Device ID: X'00'            |

| Offset (bytes) | Length (bytes) | Data Element   |
|----------------|----------------|----------------|
| 2              | 1              | <i>conmode</i> |

**For a local 3270 device:**

| Offset (bytes) | Length (bytes) | Data Element                |
|----------------|----------------|-----------------------------|
| 0              | 1              | Terminal information length |
| 1              | 1              | Device ID: X'01'            |
| 2              | 1              | <i>conmode</i>              |
| 3              | 4              | <i>rdev</i>                 |

**For a logical device:**

| Offset (bytes) | Length (bytes) | Data Element                |
|----------------|----------------|-----------------------------|
| 0              | 1              | Terminal information length |
| 1              | 1              | Device ID: X'02'            |
| 2              | 1              | <i>conmode</i>              |
| 3              | 4              | <i>ldev</i>                 |
| 7              | 8              | <i>owner</i>                |
| 15             | 1              | <i>origin_type</i>          |
| 16             | 0-16 bytes     | <i>origin</i>               |

**For a VTAM device:**

| Offset (bytes) | Length (bytes) | Data Element                |
|----------------|----------------|-----------------------------|
| 0              | 1              | Terminal information length |
| 1              | 1              | Device ID: X'03'            |
| 2              | 1              | <i>conmode</i>              |
| 3              | 17             | <i>extended_luname</i>      |
| 20             | 8              | <i>owner</i>                |

**For a line-mode integrated console (SYSC):**

| Offset (bytes) | Length (bytes) | Data Element                |
|----------------|----------------|-----------------------------|
| 0              | 1              | Terminal information length |
| 1              | 1              | Device ID: X'04'            |
| 2              | 1              | <i>conmode</i>              |

**For a 3270 integrated console (SYSG):**

| Offset (bytes) | Length (bytes) | Data Element                |
|----------------|----------------|-----------------------------|
| 0              | 1              | Terminal information length |
| 1              | 1              | Device ID: X'05'            |

| Offset (bytes) | Length (bytes) | Data Element   |
|----------------|----------------|----------------|
| 2              | 1              | <i>conmode</i> |

**For other connections without identifying information:**

| Offset (bytes) | Length (bytes) | Data Element                |
|----------------|----------------|-----------------------------|
| 0              | 1              | Terminal information length |
| 1              | 1              | Device ID: X'FF'            |
| 2              | 1              | <i>conmode</i>              |

Table 206. Attributes of Terminal Information Data Elements

| Terminal information data element | Length                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |         |       |                        |       |                                      |       |                                       |
|-----------------------------------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------|-------|------------------------|-------|--------------------------------------|-------|---------------------------------------|

Table 206. Attributes of Terminal Information Data Elements (continued)

| Terminal<br>information data<br>element | Length   | Value                                                                                                                                                                                                                 |
|-----------------------------------------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>extended_luname</i>                  | 17 bytes | The <i>extended_luname</i> element is a string that contains the VTAM network qualifier and logical unit name in the format <i>netname.luname</i> . The string is left justified and padded with blanks on the right. |

## Class 1 Events: Exception Status

When you first connect to the VM Event system service, it generates events to report to you the current status of all logged-on virtual machines that have some sort of exception. The class 1 event types, associated data, and status are indicated in [Table 207 on page 782](#).

Table 207. Class 1 Events: Type, Data, and Status

| Class  | Type   | Status                   | Data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |        |        |         |   |   |         |   |   |             |

## Class 2 Events: SSI Status Change

Class 2 events are reported when the SSI mode or an SSI member state changes. The class 2 event types, associated data, and status are indicated in [Table 208 on page 785](#)

Table 208. Class 2 Events: Type, Data, and Status

| Class  | Type    | Status        | Data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |        |        |         |   |   |          |   |   |               |   |   |          |       |         |       |        |       |        |       |      |

Table 208. Class 2 Events: Type, Data, and Status (continued)

| Class | Type | Status | Data |
|-------|------|--------|------|
|-------|------|--------|------|

2      8      SSI member state

The following table indicates the offset and length of the data elements. The values are a decimal number of bytes.

| Offset | Length | Element            |
|--------|--------|--------------------|
| 0      | 8      | SSI name           |
| 8      | 8      | Member system name |
| 16     | 1      | Previous state     |
| 17     | 1      | New state          |

The data elements are described:

**SSI name**

Character string, 8 bytes.

**Member system name**

Character string, 8 bytes.

**Previous state**

1 byte, one of the following values:

| Value | Meaning   |
|-------|-----------|
| X'00' | Down      |
| X'01' | Joining   |
| X'02' | Joined    |
| X'03' | Leaving   |
| X'04' | Isolated  |
| X'05' | Suspended |
| X'80' | Unknown   |

For more information, see [QUERY SSI](#) in *z/VM: CP Commands and Utilities Reference*.

**New state**

1 byte, one of the values that is possible for Previous state

## Class 3 Events: \*VMEVENT Connection Status

Class 3 events are reported when a guest on an SSI member connects to \*VMEVENT. The class 3 event types, associated data, and status are indicated in [Table 209 on page 787](#).

Table 209. Class 3 Events: Type, Data, and Status

| Class  | Type    | Status        | Data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |        |        |         |   |   |          |   |   |               |   |   |              |       |         |       |        |       |        |       |      |
|--------|---------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|--------|---------|---|---|----------|---|---|---------------|---|---|--------------|-------|---------|-------|--------|-------|--------|-------|------|
| 3      | 7       | SSI mode      | <p>The following table indicates the offset and length of the data elements. | X'03'  | Safe    |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |        |        |         |   |   |          |   |   |               |   |   |              |       |         |       |        |       |        |       |      |

Table 209. Class 3 Events: Type, Data, and Status (continued)

| Class | Type | Status | Data |
|-------|------|--------|------|
|-------|------|--------|------|

3      8      SSI member state

The following table indicates the offset and length of the data elements. The values are a decimal number of bytes.

| Offset | Length | Element            |
|--------|--------|--------------------|
| 0      | 8      | SSI name           |
| 8      | 8      | Member system name |
| 16     | 1      | Previous state     |
| 17     | 1      | Current state      |

The data elements are described:

**SSI name**

Character string, 8 bytes.

**Member system name**

Character string, 8 bytes.

**Previous state**

1 byte, one of the following values:

| Value | Meaning   |
|-------|-----------|
| X'00' | Down      |
| X'01' | Joining   |
| X'02' | Joined    |
| X'03' | Leaving   |
| X'04' | Isolated  |
| X'05' | Suspended |
| X'80' | Unknown   |

For more information, see [QUERY SSI](#) in *z/VM: CP Commands and Utilities Reference*.

**Current state**

1 byte, one of the values that is possible for Previous state.

**Note:** Class 3 events indicate the conditions at the time the program connected to \*VMEVENT. Class 3 events do not indicate a change in condition. Hence, the current state is always the same value as the previous state.

## Class 4 Events: Networking Status

Class 4 events are networking events. The class 4 event types, associated data, and status are indicated in [Table 210 on page 789](#).

Table 210. Class 4 Events: Type, Data, and Status

| Class  | Type   | Status                                                                                     | Data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |        |        |         |   |   |                     |   |   |                 |    |   |             |    |   |             |    |   |             |    |   |                    |    |   |                |    |   |                   |

| 9      | 1      | IVL flag                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |        |        |         |   |   |                 |   |   |            |   |   |          |    |   |             |
| 10     | 1      | Port number                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |        |        |         |   |   |                 |   |   |            |   |   |          |    |   |             |
| 4      | 25     | The System has left the IVL Domain.                | The data includes the same elements as <u><a href="#">*VMEVENT</a></u> class 4 type 24.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |        |        |         |   |   |                 |   |   |            |   |   |          |    |   |             |

You can issue IUCV QUIESCE to temporarily stop receiving events from the VM Event system service. The VM Event system service queues events while a path is quiescent. The queued events will be available when you issue an IUCV RESUME.

## Disconnecting from the VM Event System Service

When all communications with the VM Event system service are completed, you can terminate communication by issuing either an IUCV SEVER or an IUCV RETRIEVE BUFFER.

---

## Part 5. CP Macros for VM Data Spaces and Other Services

This part contains the following chapters:

- [Chapter 24, “VM Data Spaces Overview,” on page 797](#)
- [Chapter 25, “CP Macros,” on page 807](#)

## Chapter 24. VM Data Spaces Overview

Using extensions to the interpretive-execution facility, z/VM enables applications to take advantage of hardware support for multiple address spaces. This support is available to applications that run in MACHINE XC virtual machines. MACHINE XC virtual machines includes Enterprise Systems Architecture/Extended Configuration (ESA/XC) and z/Architecture Extended Configuration (z/XC) architecture.

When used without a qualifier, the term *XC* encompasses both ESA/XC and z/XC architectures. The qualified terms *ESA/XC* and *z/XC* are used only when it is important to distinguish one architecture from the other.

This chapter introduces VM Data Spaces support and briefly outlines the function provided by seven CP macros available to programmers working with virtual machines. These macros, described in detail in the next chapter, are:

### **ADRS**SPACE

Provides services for creating, sharing, destroying, and managing address spaces

### **ALSERV**

Provides services for obtaining and relinquishing access to an address space

### **DEFWORKA**

Defines the work areas required for one or more CP macros contained within your program

### **MAPMDISK**

Provides services for mapping data on a direct access storage device (DASD) to pages of an address space

### **PFAULT**

Provides for asynchronous handling of page faults

### **REFPAGE**

Provides notification to CP of expected page reference patterns.

### **VMUDQ**

Provides an application interface for making specified queries against the CP User Directory

For information about the addition of commands and command operands, and a directory control statement and operands related to these CP macros and VM Data Spaces, see [z/VM: CP Commands and Utilities Reference](#) and [z/VM: CP Planning and Administration](#).

## What Are Data Spaces?

The guest main storage of an XC virtual machine consists of one or more extents of storage known as absolute storage address spaces, or simply address spaces. Each virtual machine has an initial extent of main storage, called its primary address space, at logon. An application running in an XC virtual machine can create multiple address spaces of up to 2 gigabytes (2GB) each for data storage in addition to its primary address space, as shown in [Figure 90 on page 798](#). These address spaces are also called data spaces because they can be used only for data storage and manipulation. An authorized application can share its data spaces with other virtual machines on the same z/VM system. In the figure, the User1 virtual machine can share one or both of its data spaces as well as its primary address space with the User2 virtual machine.

Figure 90. Guest data spaces

In addition, data space support allows an application executing on a non-XC virtual machine to share its primary address space as well as copy data from other virtual machines' address spaces into its primary address space.

## Uses for Data Spaces

Certain applications require vast amounts of storage to work efficiently. One such class of applications includes database managers, which can map an entire database into storage at one time rather than explicitly managing I/O. Another class of applications requires large storage buffers, which now can reside outside the virtual machine's primary address space. The graphic representation of three-dimensional objects, image processing, and numerically-intensive computation all require such large storage areas.

Applications in an XC virtual machine can use data spaces to:

- Dynamically obtain more storage than is available in its virtual machine's primary address space
- Isolate data from other programs that may execute in the same virtual machine
- Share data located in a data space among programs executing in the same or other virtual machines
- Isolate data by its particular usage and then share that data only among related users (this is an alternative to using a common area that may contain data for various uses)
- Share data located in its virtual machine primary address space with programs executing in other virtual machines.

In addition, applications (particularly those that provide database management services) can use data spaces with the minidisk mapping services. This can improve overall system performance by replacing virtual machine I/O, such as DIAGNOSE I/O, with paging I/O, which is more efficient.

## ESA/XC Architecture

VM Data Space support is tailored to the XC architecture virtual machine environment. ESA/XC is a derivative of the ESA/390 architecture and z/XC is a derivative of the z/Architecture. However, the XC architecture differs from the native architectures in several important ways:

- XC architecture is a virtual machine architecture designed to satisfy CMS application program requirements. Other virtual machine architectures are simulations of architectures implemented on real hardware. For example, an ESA/390 virtual machine is the functional equivalent of a real ESA/390 processor.
- XC services are available specifically for guests, such as CMS, that run with dynamic address translation (DAT) off.
- The interpretive-execution facility is not provided in XC architecture. This facility is intended for use by a host for the emulation of virtual machines. XC architecture is intended for application programs, not hosts like z/VM, so the interpretive execution facility is not needed.
- CP manages the address spaces created by XC virtual machines. As a result, address spaces created from one virtual machine can be shared with other virtual machines on the same z/VM system. In contrast, ESA/390 architecture requires that the virtual machine operating system run with DAT on and

manage its own data spaces, thus precluding the virtual machine from sharing its data spaces with other users.

Other features of ESA/390 architecture, such as channel subsystem I/O and bimodal addressing, exist in ESA/XC architecture. Trimodal addressing exists in z/XC architecture. For details of ESA/XC architecture, see *z/VM: ESA/XC Principles of Operation*. For details of z/XC architecture, see *z/VM: z/Architecture Extended Configuration (z/XC) Principles of Operation*.

## Address Space Support

As the previous section indicates, XC architecture support for multiple address spaces differs from that of ESA/390 architecture and z/Architecture. The capabilities available to applications running in an XC virtual machine, however, are similar to those provided by ESA/390 architecture and z/Architecture. The combination of XC architecture and the services provided by CP macros enable applications running in an XC virtual machine to own multiple address spaces. In addition, XC architecture allows sharing of address spaces among multiple virtual machines.

Every XC virtual machine owns at least one address space, the primary address space, given to the user by CP when the user logs on to the z/VM system. The size of this primary address space is determined from the entry describing that user ID in the user directory, or from a subsequent `DEFINE STORAGE` command.

In addition to the primary address space, a user whose CP directory contains authorization can create multiple data spaces and share them with other users. Both creating and sharing require separate authorization in the user's directory. A data space exists until it is either explicitly destroyed by the owner or until the owning virtual machine goes through a virtual machine reset operation. Virtual machine reset occurs as part of the processing of the CP `LOGOFF`, `SYSTEM RESET`, and `IPL` commands.

Address spaces created by programs running in an XC virtual machine are maintained by CP. The structures used to control access to address spaces thus reside in CP-controlled storage. CP also maintains a host access list for each virtual machine logged on to the z/VM system. This list contains information that designates the address spaces the associated virtual machine is allowed to access. By default, each access list can hold 62 entries, and thus can identify 62 address spaces accessible to the virtual machine in addition to the primary address space. The `XCONFIG ACCESSLIST` directory control statement can be used to increase the number of entries allowed on the access list.

In addition to the access lists, CP maintains a list of permitted users that is associated with each address space. To access or manipulate data in an address or data space, an application must own (or have been permitted access to) the address space.

The ability to own multiple address spaces brings to mind the question of how a program specifies which address space should be referenced by an instruction. The answer lies in ESA/390 hardware support in the form of a set of access registers. Each access register is paired with a general register. The access registers indicate which address space contains the data being referenced by an address in the associated general register.

The address translation mode determines whether the access registers are used when resolving an address. When in access-register mode (AR mode), assembler instructions (such as load, store, and move character) can move data in and out of a data space and manipulate data within it. Assembler instructions can also perform arithmetic operations on the data.

The access registers are used for addressing only when a program running on an XC virtual machine is executing in AR mode. The usual address translation mode is called primary-space mode. The non-privileged instruction called `SET ADDRESS SPACE CONTROL (SAC)` is used by an application program to set a bit in the program status word (PSW) that indicates which address translation mode is in effect.

## Summary of Data Space Operations

To exploit data space support, use the CP macros described in detail in [Chapter 25, “CP Macros,” on page 807](#). These macros provide system services for creating, controlling, and deleting data spaces.

An application running in a virtual machine that is allowed to **own** a data space can use the following CP macros to perform various address space functions:

### **ADRSPACE CREATE**

Create a data space

### **ADRSPACE DESTROY**

Destroy a data space

### **ADRSPACE PERMIT**

Permit other users (virtual machines) or applications to access an address space

### **ADRSPACE ISOLATE**

Isolate an address space from other users

### **ADRSPACE QUERY**

Ask for the identification token and size of any address space it owns or is permitted to access

### **ALSERV ADD**

Add an entry to the host access list

### **ALSERV REMOVE**

Remove an entry from the host access list

A data space can be created and deleted only from an XC virtual machine that has been authorized using an XCONFIG ADDRSPACE directory statement. With the SHARE option on that directory statement, your application can share address spaces it created with applications running on other virtual machines.

An application running in a non-XC virtual machine that is allowed to access an address space belonging to another virtual machine can use the following operations to perform certain address space functions:

|                      |                                                                                          |
|----------------------|------------------------------------------------------------------------------------------|
| ADRSPACE QUERY       | Ask for the identification token of the address space it needs to access                 |
| ALSERV ADD           | Add an entry to the host access list                                                     |
| ALSERV REMOVE        | Remove an entry from the host access list                                                |
| DIAGNOSE code X'248' | Copy from another address space into primary address space (for non-XC virtual machines) |

**Note:** Although data space management also can be performed using callable services library (CSL) routines in CMS, do not mix that programming interface with this one. CMS relies on the CP interface and any mixing of the interfaces may inhibit CMS from performing its error checking. Thus, performing data space management directly using data space CP macros or DIAGNOSE codes along with the CMS interface may cause unexpected results.

## Using Data Spaces in Your Applications

This section describes how to use the CP macros in your applications to set up and manage data spaces. Before you assemble a program that uses these macros, however, you must issue the GLOBAL command for HCPGPI MACLIB.

### Creating and Using Data Spaces

A program's ability to create, delete, and access data spaces depends on whether the virtual machine that it executes in has been authorized to do so through CP directory control statements. Because the use of data spaces consumes system resources, such as real and auxiliary storage, their use is controlled by the installation. System programmers responsible for tuning and maintaining z/VM use the following directory control statements to control these resources:

- XCONFIG ADDRSPACE directory control statement — This statement authorizes an XC virtual machine to create and delete data spaces, specifies the maximum size of the data spaces, and indicates whether they can be shared. For non-XC virtual machines, it allows sharing of the primary address space.

- XCONFIG ACCESSLIST directory control statement — This statement allows any type of virtual machine to access more than 62 address spaces (the number allowed without an XCONFIG ACCESSLIST statement), specifying the number of data spaces that can be accessed at any given time. The access list is maintained for the virtual machine by CP and is used to keep track of address space addressability. Note that a non-XC virtual machine can reference data in another virtual machine's address space only by using the DIAGNOSE code X'248' (copy-to-primary service).

As an application developer, you should be aware of these installation-established limits and how they relate to return codes associated with the ADRSPACE and ALSERV macros.

## Creating a Data Space

When a program executing in an XC virtual machine uses the ADRSPACE CREATE macro to create a data space, it needs to provide the name and size (number of pages) of the data space.

Upon return from ADRSPACE CREATE, the address provided on the ASIT operand contains the **address space identification token** (ASIT) of the newly-created data space. This ASIT is a system-wide unique identifier for this data space. It is not used again during the current system IPL. The application must retain the ASIT for subsequent address space related service calls. An application can obtain the ASIT of an existing data (or address) space by calling the QUERY function with the name and owner of the address space.

An ASIT identifies an **instance** of a data space. An instance of a data space is a temporal concept that means a particular *version* of the data in a data space. For example, when a data space is deleted and a new data space with the same name is created, the new data space can be considered a new instance of the original data space. Even though the name is the same, re-creating a data space results in a new ASIT being assigned. Thus, the ASIT can be used to ensure that only users authorized for a particular instance of a data space can access it.

## Permitting Another User to Access an Address Space

Recall that in addition to access lists, CP maintains a list of permitted users for each address space on the z/VM system. To access an address space that it does not own, a user must have been granted access by the owner and thus be listed on the permitted-users list for that address space by CP. The owner of an address space can grant either read-only or read/write access to one or more other users.

To grant another user access to an address space, call the ADRSPACE PERMIT macro, supplying the ASIT of the address space, the identity of the virtual machine that is to be given access, and the type of permission (read-only or read/write). Although the PERMIT function grants the access, it does not establish it. The user authorized to access the address space must then call the ALSERV ADD macro to establish the access. Figure 91 on page 801 shows that User1 has created a data space, DataSpaceA, and permitted User2 read-only access to it.

Figure 91. Granting Another User Access to an Address Space

The permitted user needs the ASIT of the address space to establish addressability. Typically, the owner informs the permitted user through standard z/VM communications facilities, such as APPC/VM.

The owner of the address space always has read/write permission. It is an error for an owner to call ADRSPACE PERMIT to permit itself.

Permission to access an address space remains in effect until the owner either isolates or destroys the address space, or until a virtual machine reset occurs on either the owning or the permitted virtual machine.

### Accessing Data Space Storage

To gain access to the data space, the program calls the ALSERV ADD macro, specifying the ASIT of the data space, which was returned on the ADRSPACE CREATE or QUERY call.

In the example of [Figure 91 on page 801](#), both User1 and User2 must call ALSERV ADD to establish addressability to DataSpaceA. User1 can establish its access as read/write, because as the owner, it automatically has read/write access, while User2 can establish read-only access. ALSERV ADD fills in an unused entry in the access list as requested by the program and returns an **access-list-entry token (ALET)**. The ALET is then used by the program to select the access list entry (ALE) that identifies the newly-created address space.

An ALE, as depicted graphically in [Figure 92 on page 803](#), can be thought of as comprising several components:

#### ***A state***

An ALE is always in one of three states: **unused**, **valid**, or **revoked**. An unused ALE is one that either has never been used or has become available as a result of the REMOVE function. A valid ALE is one that has been filled in by the ADD function. A valid ALE enters the revoked state as a result of the address space owner's destroying the address space or explicitly isolating it from other users. The revoked state is different from the unused state in that an ALE can enter the revoked state without any action by the owner of the access list.

#### ***An ALET***

The access list entry token that selects the ALE when it is in a valid or revoked state.

#### ***An ASIT***

The address space identification token designates the address space represented by the ALE.

#### ***A read/write authorization***

When a program calls the ALSERV ADD macro, it stipulates whether accesses using the resulting ALET are to be read-only, or whether they can be read/write. The program can call ALSERV ADD more than once with the same ASIT to obtain different ALETs for a particular address space, for instance, one for read-only and one for read/write access.

#### ***A fault resolution flag***

To use storage efficiently, CP might temporarily page out data from an address space to auxiliary storage. When an application program references a paged-out portion of an address space, CP receives notification of this as a page fault. CP then reads the data back into storage and reruns the virtual machine. Aside from a slight time delay, the virtual machine is unaware of this synchronous activity. If this slight delay in execution is a problem for an application, the program can specify that CP resolve page faults asynchronously. A program that specifies asynchronous page-fault resolution is not delayed by page faults, but must contain additional logic to complete the *handshaking* required to use this function. See the section entitled "[PFAULT Macro -- Page-Fault Handshaking Services](#)" on page 866 for more information.

Here is a graphic representation of an access-list entry:

Figure 92. Graphic Representation of an ALET and an ALE

Once the application has the ALET, it can access an address space by placing the ALET in the access register associated with the general register being used for the storage operand of the instruction. Before executing instructions that use access register references, the application must enter AR mode (available only to XC virtual machines). When in AR mode, the access register corresponding to the general register specified in the base register field of the instruction is examined to determine which address space is being referenced.

The ALET in the access register indicates the address space containing the operand and the address in the general register (possibly modified by a displacement or index specified in the instruction) indicates the location of the operand within the address space, as shown in Figure 93 on page 803. For instructions such as MOVE (MVC) that have multiple storage operands, each operand can be designated by a different access-and-general register pair, so the operands can reside in different address spaces.

Figure 93. Accessing an Address Space

An access register should contain either zeros or an ALET that was obtained by the application when adding an ALE to its access list. If the access register contains zeros, the reference is to the primary address space. If the access register contains an ALET selecting a valid access-list entry, the reference is to the address space designated by that entry. If the selected ALE is in the unused or revoked state, a program interruption results.

## Dropping Addressability to an Address Space

When access to an address space is no longer required, a virtual machine can call the ALSERV REMOVE macro to drop addressability to it. This function changes a valid (or revoked) access-list entry's state to unused so the entry can be used again later. Removing addressability does not change the virtual machine's permission to access the address space. As long as the owning virtual machine does not revoke permission, the permitted user can establish addressability again.

Maintaining addressability to an address space longer than necessary is not generally harmful, so most applications would need to remove addressability only during termination. Long-running applications, such as resource managers in server machines or very complex applications requiring access to more

address spaces than the number of entries available, may need to actively manage the contents of the access list. Such applications could temporarily remove addressability to one address space to free up an access-list entry for another address space.

## Isolating a Shared Address Space

If widespread changes need to be made to the data stored in a shared address space, these changes may need to be made with the assurance that no user references are in process. In this case, the owner can return the address space to a private state by calling the `ADRSPACE ISOLATE` macro. This function rescinds all permissions to the address space previously granted using the `ADRSPACE PERMIT` macro and cancels any current addressability that other virtual machines may have to the address space. When the `ISOLATE` function completes, only the owning virtual machine is able to access the isolated address space.

The current addressability of other virtual machines is cancelled by changing applicable entries in their access lists from the valid to the revoked state. The sharing virtual machines find out that their access has been revoked when their next attempt to reference the address space results in an addressing-capability exception.

After updating the data in the address space, the owner must repeatedly call the `ADRSPACE PERMIT` macro to restore permission for each virtual machine that it wants to allow access to the address space again. The permitted virtual machines then must call `ALSERV ADD` to re-establish their addressability to the address space.

To reduce the cost in overall system performance, an application requiring a shared address space that periodically needs to be isolated for refresh activity may want to implement its own locking protocol instead of using the isolate service.

## Destroying a Data Space

When a data space is no longer needed, the owner should call the `ADRSPACE DESTROY` macro to destroy it. Only the owner of a data space can destroy it. Because a data space always requires some host real storage, it is a good practice to destroy data spaces when finished with them.

The `DESTROY` function discards the current contents of the data space and frees all control structures associated with it. In addition, this function changes the state of the access-list entry designating the data space to revoked. If the data space was shared with other virtual machines, an implicit `ISOLATE` function is performed to terminate the other users' access to the data space. The owner, as well as any other virtual machines permitted to access the data space, should issue `ALSERV REMOVE` to change the state of the access-list entry designating the destroyed data space from revoked to unused.

## Mapping Minidisks to Address Spaces

---

Applications that require access to very large amounts of data may be able to derive a performance benefit by establishing a mapping between the minidisks in its virtual machine's I/O configuration and a data space owned by the virtual machine, in effect using the data space as a huge buffer for DASD blocks. By temporarily placing the minidisk data in a data space, the application can use ordinary CPU instructions to access the data rather than I/O instructions.

The `MAPMDISK` macro lets a program establish an association between a collection of minidisk blocks on one or more minidisks and a collection of address space pages in one or more address spaces. The address spaces used for mapping can be the virtual machine's primary address space as well as data spaces that it owns. When a mapping exists, an image of the data that resides on the mapped minidisk blocks appears in the associated address space pages without requiring the application to issue I/O instructions to load the data. The I/O operations are performed implicitly by CP as references are made to the mapped address spaces.

An application executing in an XC virtual machine can invoke the following mapping service functions using the `MAPMDISK` macro:

**IDENTIFY**

Identify the minidisk pool and the pool-relative block numbers of the minidisk blocks within the pool.

**DEFINE**

Establish a mapping between a range of pages in an address space and a set of blocks residing in the minidisk pool.

**SAVE**

Initiate a request to write ranges of mapped pages to their corresponding minidisks.

**REMOVE**

Remove a mapping between a range of pages in an address space and a set of minidisk blocks residing in the minidisk pool.

An application using these mapping services must be in primary-space mode.

The application's first step in preparation for mapping minidisk storage to an address space is to call the MAPMDISK IDENTIFY macro to identify the collection of minidisks in its virtual machine's I/O configuration that will be mapped. This collection is known as a minidisk pool. The IDENTIFY function assigns a pool-relative block number to each block within the minidisk pool. The result of this operation is an image of a single large minidisk comprising a consecutive range of 4KB blocks of storage. The pool-relative block numbers are used by the mapping services to establish the association between address-space pages and blocks within the minidisk pool.

Once the minidisk pool has been identified, the application uses the DEFINE function of the MAPMDISK macro to establish the mapping. When a mapping exists between an address space page and a minidisk block, a correlation is maintained between the contents of the page and the contents of the block such that data contained in the minidisk block is available in the page where it can be manipulated with CPU instructions. Upon completion of the DEFINE operation, the data that is contained on the minidisk blocks is available in the newly-mapped pages. Actual movement of the data from a minidisk block to the address space page, however, does not occur until the first reference is made to the page.

A page for which a current mapping is defined is known as a **mapped** page. A page that has never had a mapping defined or one whose mapping was subsequently removed, is known as an **unmapped** page.

When an application wants to store changes back on DASD, it uses the SAVE function of the MAPMDISK macro. The SAVE function initiates an asynchronous operation that writes mapped pages to the associated minidisk blocks. These mapped pages are those changed since they were written out to DASD.

When an application is finished referencing the mapped data, it can use the REMOVE function to discontinue the mapping association. This operation changes the status of the address space pages to unmapped, so they can be used as ordinary storage.

## Notifying CP of Future Reference Patterns

---

If an application accesses certain data in a regular or predictable way, the tuning function provided by the REFPAGE macro may be helpful in reducing page faults and thus improving overall performance of the application. The REFPAGE macro lets you specify a range of pages that will be referenced in sequential order within a specified address space. These pages comprise a logical block. With this information, CP can pre-fetch pages into its dynamic paging area (DPA) allowing the program immediate access to its pages.

Reference patterns specified on REFPAGE can be regular or irregular. A regular pattern might occur during the processing of large arrays. Such patterns could be specified in block form. An irregular pattern might be encountered during a database server's indexed scan of data. Although the individual references may appear unrelated, they are predictable based on the contents of the index. Such apparently irregular patterns can be specified in list form, because the order of page reference is known ahead of time for a list of unordered pages.

As with any tuning function, incorrect application of the REFPAGE macro can degrade rather than improve performance. If the page ranges specified on the macro do not closely match the actual reference pattern, increased paging may result.

---

## Chapter 25. CP Macros

This chapter contains information on the following:

- Coding CP macros
- ADRSPACE – address space services
- ALSERV – access list services
- DEFWORKA – define macro work area
- MAPMDISK – mapping services
- PFAULT – page-fault handshaking services
- REFPAGE – page reference services.
- VMUDQ – VM user directory query

If you are unfamiliar with reading syntax diagrams, see [“Syntax, Message, and Response Conventions”](#) on page xxxv.

---

### Using the Online HELP Facility for CP Macros

You can receive online information about the CP and VM data space macros by using the z/VM HELP Facility. For example, to display a menu of the CP and data space macros, enter:

```
help vmads menu
```

To display information about a specific macro (PFAULT in this example), enter:

```
help vmads pfault
```

For more information about using the HELP Facility, see [z/VM: CMS User's Guide](#). To display the main HELP task panel, enter:

```
help
```

For more information about the HELP command, see [z/VM: CMS Commands and Utilities Reference](#) or enter:

```
help cms help
```

---

### Coding CP Macros

This section describes both the preferred way to code CP and VM data spaces macros and alternative methods.

#### Preferred Use

To simplify CP macros in both nonreentrant and reentrant environments, the macros can *automatically* control and define the work area required to execute the macro function. You must code the DEFWORKA macro once, with no operands, after the invocation of the CP macros prior to the assembler END statement (see examples). The DEFWORKA macro does not generate any executable code. It collects and defines, with proper alignment, any CP macro work areas required in your program.

#### Usage Notes:

1. For a reentrant program, code the DEFWORKA macro within a DSECT for which storage is acquired and released within the program. This makes a separate instance of the storage available to each

dispatchable unit executing the same reentrant program. Addressability to the storage is required prior to the invocation of the CP macros using the work area.

2. If you are coding in a nonreentrant environment, the invocation of DEFWORKA may appear within the program's control section (CSECT). This defines the macro work area as part of the program's storage.
3. If you code any CP or VM Data Spaces macro within your program and fail to code the DEFWORKA macro, you receive error messages from the assembly of your program indicating undefined references.

The use of DEFWORKA can be seen in the following examples.

### Example 1: A Reentrant Program

You can reduce the complexity of coding within a reentrant environment by deferring the definition of the macro work areas to the DEFWORKA macro coded at the end of your program.

The following segments of a reentrant program outline a method for managing the CP macro work area storage. The DEFWORKA macro is coded within a DSECT, called MYDATA, containing other variables modified within this program. The program obtains CMS free storage for the area reserved by the MYDATA DSECT and then releases this storage before exiting. Two CP macros, ADRSPACE and ALSERV, are used within the program; however, the same implementation can be applied to any CP macro that relies on the DEFWORKA macro for work area definition.

```

MYCSECT  CSECT
        .
        CMSSTOR  OBTAIN,BYTES=MYDATALN,...          ACQUIRE FREE STORAGE
        LR      R10,R1                             SAVE THE ADDR OF THE STORAGE
        USING   MYDATA,R10                          ESTABLISH ADDRESSABILITY
        .
        .
        ADRSPACE CREATE,NAME='MYSPACE',SIZE=SPACESIZ,          X
                ASIT=MYASIT                                INVOKE A CP MACRO
        .
        .
        ALSERV  ADD,ASIT=MYASIT,                      X
                ALET=MYALET                                INVOKE ANOTHER CP MACRO
        .
        .
        CMSSTOR  RELEASE,BYTES=MYDATALN,              X
                ADDR=(R10),...                            RELEASE THE STORAGE
        .
        .
        BR      R14                                    EXIT THE PROGRAM
R1       EQU    1
R10      EQU    10
R14      EQU    14

MYDATA   DSECT
MYASIT   DS     D                                    PARAMETER FOR ADRSPACE
MYALET   DS     F                                    PARAMETER FOR ALSERV
DEFWORKA
+HCPWORKA DS     (0)D,64X
MYDATALN EQU    *-MYDATA
END                                END OF MYCSECT

```

Figure 94. Using DEFWORKA within a Reentrant Program

### Example 2: A Non-Reentrant Program

In this example, a nonreentrant program invokes the DEFWORKA macro within the program's CSECT. This causes the work area for the macro to reside within the storage for the program.

```

MYCSECT  CSECT
        .
        .
        .
        ADRSPACE CREATE,NAME='MYSPACE',SIZE=SPACESIZ,          X
            ASIT=MYASIT                                INVOKE A CP MACRO
        .
        .
        .
        ALSERV ADD,ASIT=MYASIT,                                X
            ALET=MYALET                                INVOKE ANOTHER CP MACRO
        .
        .
        .
        BR      R14
R14      EQU    14
SPACESIZ DC    F'10'      PARAMETER FOR ADRSPACE
MYASIT   DS     D          PARAMETER FOR ADRSPACE
MYALET   DS     F          PARAMETER FOR ALSERV
        DEFWORKA          DEFINE CP MACRO WORK AREA
+HCPWORKA DS     (0)D,64X
        END              END OF MYCSECT

```

Figure 95. Using DEFWORKA within a Non-reentrant Program

## Alternative Methods

In most cases you will find that DEFWORKA's management of the CP macro work areas satisfies the needs of your program. However, there may be instances when you do not want to give DEFWORKA complete control over the definition of the CP macro work areas. For instance, you may want to embed the work area within a control block that persists beyond the execution of a particular program. This can be done through the CP macro's DECLARE function. DEFWORKA expands any CP macro work areas that have not yet been defined within the program by this or a preceding DEFWORKA invocation, or by the DECLARE function of the CP macros contained within the program.

The examples that follow show alternate ways to manage the macro work area should you have a requirement to do so. These examples use the CP ADRSPACE macro; any CP macro which relies on the DEFWORKA macro can be used in the same manner.

### Example 1: Forcing Unique Work Areas

The following program assigns a unique workarea to each invocation of the ADRSPACE macro by using the WORKAREA operand on the ADRSPACE macro invocations. You may choose to force unique macro work areas in order to preserve the data within the work area for problem determination. The WORKAREA operand is an optional operand that can be used to identify the label associated with the work area storage.

```

MYCSECT  CSECT
        .
        .
        ADRSPACE CREATE, ..., WORKAREA=WORK1
        .
        .
        ADRSPACE CREATE, ..., WORKAREA=WORK2
        .
        .
        ADRSPACE CREATE, ...
        .
        BR      R14          EXIT THE PROGRAM
R14      EQU    14
        DEFWORKA          DEFINE CP MACRO WORK AREA
+WORK1   DS      (0)D,64X
+WORK2   DS      (0)D,64X
+HCPWORKA DS      (0)D,64X
        END              END OF MYCSECT

```

Figure 96. Using DEFWORKA to Force Unique Macro Work Areas

In this program the ADRSPACE macro is invoked three times: the first invocation uses area WORK1 as its work area; the second invocation uses area WORK2; and, since the third invocation of ADRSPACE does not include the WORKAREA operand, the default area assigned by the DEFWORKA macro is used. DEFWORKA expands the required storage definitions for all three work areas.

**Example 2:** The DECLARE Function - Creating a Remote Work Area

You may have the requirement to embed the CP macro workarea in another data area (or control block) to be used by several programs. Suppose you have coded a macro, called CBLOCK, that generates a DSECT in which you want to embed the CP macro workarea. The CBLOCK macro may look like this:

```

                MACRO
CBLOCK          CBLOCK
                DSECT
CBLONE          DS      F          A FIELD WITHIN THIS CONTROL BLOCK
CBLTWO          DS      F          ANOTHER FIELD
CBLTHREE        DS      F          ANOTHER FIELD
CBLMACWA        ADRSPACE DECLARE  DEFINE THE WORKAREA FOR ADRSPACE
CBLLENTH        EQU      *-CBLOCK  LENGTH OF THE CONTROL BLOCK
                MEND

```

The CBLOCK macro expands a DSECT defining a data area called CBLOCK. The labels CBLONE, CBLTWO, and CBLTHREE are other fields within the CBLOCK that you define; they are shown to indicate that the control block contains data other than the CP macro workarea. You can use the DECLARE function of the ADRSPACE macro to define the storage required for the executable functions of the ADRSPACE macro. To see how the storage is defined, look at the expansion of the CBLOCK macro in the following program. Assume that storage for the CBLOCK was obtained within the calling program, and its address is provided as input to this program in register 10.

```

MYCSECT  CSECT
        .
        USING CBLOCK,R10
        .
        ADRSPACE CREATE,...,WORKAREA=CBLMACWA
        .
        .
        BR      R14
R14      EQU    14
        CBLOCK
+CBLOCK  DSECT
+CBLONE  DS      F      A FIELD WITHIN THIS CONTROL BLOCK
+CBLTWO  DS      F      ANOTHER FIELD
+CBLTHREE DS      F      ANOTHER FIELD
+CBLMACWA DS      (0)D,64X
CBLLENTH EQU    *-CBLOCK  LENGTH OF THE CONTROL BLOCK
        END          END OF MYCSECT

```

Figure 97. Using a Remote Macro Work Area

The ADRSPACE DECLARE function within the CBLOCK macro defines the storage required for the CP macro workarea. The DEFWORKA macro is not required within this program. If you were to code DEFWORKA, the expansion of the ADRSPACE DECLARE function would indicate to DEFWORKA that workarea CBLMACWA was already defined, and DEFWORKA would not define any additional work areas.

In this example, a label is coded on the invocation of the ADRSPACE DECLARE function. This label is assigned to the work area storage and is used as the value of the WORKAREA operand.

When using a scheme such as this, you must ensure compatibility between the definition and usage of the macro work area. Any time you reassemble one of the programs using the macro work area with a new level of CP, you must also reassemble the program which uses the DECLARE function to allocate that work area.

## ADRSPACE — Address Space Services

### Purpose

Use the ADRSPACE macro to create or destroy address spaces and to control other virtual machine accesses to the address spaces owned by your virtual machine. You can also use the ADRSPACE macro to return information about an address space that your virtual machine owns or is authorized to access.

The following address-space service functions can be invoked using this macro:

#### CREATE

Create a new address space

#### DECLARE

Define the macro work area

#### DESTROY

Destroy an address space

#### ISOLATE

Restore an address space to the private state

#### PERMIT

Authorize another virtual machine for access to an address space

#### QUERY

Return information for an address space

## Usage Notes

**XC Address Spaces:** The guest main storage of an XC virtual machine consists of one or more extents of storage known as absolute-storage address spaces, or simply address spaces. Each virtual machine is provided with an initial extent of main storage, called its host-primary address space, at logon. Using this macro, a virtual machine can request that CP provide additional address spaces, each from 64 kilobytes to 2 gigabytes in size. These additional address spaces are sometimes called data spaces because only data can be within the address space; a program cannot execute in a data space.

The host-primary address space of a virtual machine is always directly addressable by that virtual machine. An XC virtual machine can directly access other address spaces when the virtual machine is in the access-register mode, provided that it has a valid host access-list entry designating the address space. An XA, ESA, or Z virtual machine can indirectly access other address spaces by using DIAGNOSE code X'248' (Copy-to-primary service), provided that it has a valid host access-list entry designating the address space.

A virtual machine can use the ALSERV macro to add a host access-list entry to the virtual machine's host access list.

**Address Space States:** An address space is considered to be in one of two states: private or shareable.

When an address space is created by CP, it is initially in the private state. While in this state, it can only be accessed by the virtual machine that owns the address space.

An address space is changed from the private to the shareable state when the owning virtual machine uses the ADRSPACE PERMIT function to authorize another virtual machine to access the address space. When an address space is in the shareable state, it is possible for the address space to be accessed by other virtual machines (using CP commands, a program's use of access-register mode, or DIAGNOSE code X'248').

Certain DIAGNOSE code X'64' operations are prohibited when the host-primary address space is in the shareable state.

Once an address space is placed in the shareable state, it remains in this state until the owning virtual machine subsequently uses the ADRSPACE ISOLATE function to return it to the private state, or until a subsystem-reset operation is performed on the owning virtual machine.

**Address Space Identification:** Two identifying values are associated with each address space: an address-space name, and an address space identification token (ASIT).

An address-space name is a string of 1 to 24 characters that is assigned to an address space. The name can contain only uppercase letters (A through Z), numbers (0 through 9), and certain special characters (# \$ @ \_ -). Each address space owned by your virtual machine must have a different address-space name. CP assigns the name *BASE* to the host-primary address space of your virtual machine; your virtual machine assigns a name to each address space that it creates using the ADRSPACE CREATE function. Although all of the address spaces owned by your virtual machine must have different address-space names, there is no requirement that the names of your virtual machine's address spaces be different from the names of another virtual machine's address space.

The address-space name is a component of a larger identifier called a *spaceid*. A space ID is a fully-qualified name for an address space consisting of an address-space name prefixed by the user ID of the virtual machine that owns the address space. A space ID is used as a parameter for some operations, for example the DISPLAY STORAGE command, to identify a particular address space in the system.

Also associated with each address space is an address space identification token (ASIT). An ASIT is an 8-byte value assigned to the address space by CP when the address space is created. When an address space is created by the ADRSPACE CREATE function, the ASIT is returned by that function. The ADRSPACE QUERY function can be used to return the ASIT associated with the host-primary address space of your virtual machine. The ASIT is an input to functions of the ADRSPACE and other macros to designate the address space for those other operations.

An ASIT is a system-wide token that is unique for the scope of a z/VM (CP) IPL. That is, once a particular ASIT value has been assigned by CP to an address space, it will not be reassigned to another address space created by CP during the life of the current CP IPL. In addition, when CP returns the

ASIT associated with an address space (for example, as a result of the ADRSPACE QUERY function), it always returns the same value regardless of the virtual machine to which the ASIT is being returned. These characteristics let a program determine if two address spaces are the same by testing the ASITs associated with the address spaces for equality.

The ASIT associated with the host-primary address space of a virtual machine is sometimes used as an alternative to a userid as a means of identifying a virtual machine. When the primary-space ASIT is used in this way, it is known as a virtual configuration identification token (VCIT). Because a VCIT is in fact an ASIT, VCITs share the same characteristics as ASITs; they are system-wide tokens unique for the life of the CP IPL.

## Program Exceptions

The ADRSPACE macro may result in one of the following program exceptions:

| Problem Encountered                                                         | Cause                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access exception (See page <a href="#">“Access Exceptions” on page 8.</a> ) | <p>An error occurred trying to</p> <ul style="list-style-type: none"> <li>• Fetch or store the macro parameter list (in macro work area)</li> <li>• Fetch a macro operand</li> <li>• Store the ASIT operand (CREATE or QUERY functions)</li> <li>• Store the SIZE operand (QUERY function)</li> </ul> |
| Specification exception                                                     | <ul style="list-style-type: none"> <li>• The CREATE or DESTROY function was requested and your virtual machine is an XA, ESA, or Z virtual machine.</li> <li>• The macro work area is not doubleword aligned.</li> <li>• The parameter list generated by the macro is in error.</li> </ul>            |

## ADRSAPCE CREATE

### Purpose

This function creates a new address space and returns the ASIT associated with the new address space. All pages of the newly created address space will contain binary zeros and have the same storage key.

The maximum number of address spaces, and the maximum total size of all address spaces that your virtual machine can create is specified by the XCONFIG ADRSPACE statement in your virtual machine's CP directory entry. If your CP directory entry does not contain a XCONFIG ADRSPACE statement, then your virtual machine is not authorized to use this function to create any address spaces.

Address spaces that you create with this function exist until either your virtual machine explicitly destroys them, or until a subsystem-reset operation is performed on your virtual machine, for example by using the SYSTEM CLEAR, SYSTEM RESET, IPL, or LOGOFF command. When an address space is destroyed, if the host access list for your virtual machine or some other user's virtual machine has host access-list entries designating the address space, then those host access-list entries are set to the revoked state.

Your virtual machine must be an XC virtual machine to use this function. If your virtual machine is an XA, ESA, or Z virtual machine, then a specification exception is recognized.

### Parameters

#### *label*

is an optional assembler language label on the macro.

#### **NAME=**

specifies the address-space name to be assigned to the new address space. This operand may be specified as one of the following:

- A character string of up to 24 characters within single quotation marks.
- A label identifying a 24-byte real storage area containing the address-space name, left-justified in the 24-byte field, and the remainder of the field padded with spaces. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label is used to determine the address space containing the storage area.
- A register (in the range of 2-12, inclusive) containing the real address of a 24-byte storage area defining the address-space name, left-justified in the 24-byte field, and the remainder of the field padded with spaces. For a virtual machine in the access-register mode, the access register

corresponding to the general register is used to determine the address space containing the storage area.

In all cases, the address-space name must contain only uppercase letters (A through Z), numbers (0 through 9), and certain special characters (# \$ @ \_ -). If the name contains characters that are not allowed, then no new address space is created and return code 16 is given.

Each address space owned by your virtual machine must have a different address-space name. If the address-space name specified matches the name assigned to an address space that your virtual machine previously created, or if it matches the name *BASE* which is preassigned by CP for your virtual machine's host-primary address space, then no new address space is created and return code 4 is given.

This operand is required.

#### **SIZE=**

specifies the address of a 4-byte area in real storage that contains the size for the new address space in pages; each page is 4096 bytes. Specify this operand as a label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The minimum size of an address space is 1 page (4096 bytes), and the maximum is 524,288 pages (2 gigabytes). If the size is not in this range, then return code 20 is given. If the requested size would cause the total size of all address spaces created by your virtual machine to exceed the maximum specified for your virtual machine, then no new address space is created and return code 12 is given.

The amount of storage that CP allocates for an address space must be a multiple of 256 pages (1 megabyte). Therefore, if the value of the SIZE operand is not a multiple of 256, the value is rounded up to the next multiple of 256.

This operand is required.

#### **ASIT=**

specifies the address of an 8-byte real storage area that is set by this function to be the ASIT associated with the newly created address space. Specify this operand as a label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

This operand is required.

#### **KEY=**

specifies the address of a byte in real storage containing the storage key to be assigned to every page in the new address space. Specify this operand as a label associated with the byte in real storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the byte in real storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

Bits 0-3 of the byte contain the access-control bits of the storage key and bit 4 of the byte is the fetch-protection bit. Bits 5-7 of the byte are ignored. The reference and change bits of the storage key are always set to zero.

This operand is optional. If it is not specified, the access-control and fetch-protection bits of all pages in the newly created address space will contain zeros.

**WORKAREA=**

specifies the address of a real storage area that is used by the macro as a work area. Specify this operand as the label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the ADRSPACE DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

**Usage Notes**

1. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. Code the DEFWORKA macro at the end of your program to define any macro work areas that have not yet been defined.
3. The name specified by the NAME operand is part of the space ID for the new address space. The full space ID is *userid:name* where *userid* is the user ID for your virtual machine, and *name* is the address-space name specified by the NAME operand.

**Condition Codes and Return Codes**

On return from the CREATE function, register 15 contains one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | CREATE function status                                                                                                                                                                |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | The address space has been created as requested. The ASIT associated with the new address space has been returned.                                                                    |
| 4                                          | The specified address-space name matches the name of another address space owned by your virtual machine. No new address space has been created.                                      |
| 8                                          | Creating the new address space would cause the maximum number of address spaces allowed for your virtual machine to be exceeded. No new address space has been created.               |
| 12                                         | Creating the new address space would cause the total size of all address spaces owned by your virtual machine to exceed the maximum permitted. No new address space has been created. |
| 16                                         | The specified address-space name contains invalid characters. No new address space has been created.                                                                                  |
| 20                                         | The specified size for the new address space is out of range. No new address space has been created.                                                                                  |

## ADRSPACE DECLARE

---

### Purpose

This function defines the storage required for the WORKAREA operand of the ADRSPACE macro. You must code this function only if you need to define the macro work area outside of the program requiring it. To simplify the use of the ADRSPACE macro, do not code the ADRSPACE DECLARE function and omit the WORKAREA operand on the executable functions of the ADRSPACE macro. This allows the ADRSPACE macro to control and define the necessary data expansion through the DEFWORKA macro coded at the end of your program. See [“Coding CP Macros” on page 807](#) for additional details.

### Parameters

#### *label*

is an optional assembler language label on the macro to be assigned to the defined storage.

### Usage Notes

1. The DECLARE function does not generate any executable code. You may code it within a dummy section (DSECT) or a control section (CSECT).
2. Although a label is not required on the invocation of the DECLARE function, it may be necessary to identify the work area using the WORKAREA operand.

## ADRSAPCE DESTROY

### Purpose

This function destroys an address space previously created by your virtual machine.

If the address space to be destroyed is designated by any host access-list entries, either in your virtual machine's access list or the host access list of other virtual machines, those host access-list entries are set to the revoked state. If, when in the access-register mode, your virtual machine attempts to use a revoked host access-list entry, an addressing-capability exception will be recognized.

Your virtual machine must be an XC virtual machine to use this function. If your virtual machine is an XA, ESA, or Z virtual machine, then a specification exception is recognized.

### Parameters

#### *label*

is an optional assembler language label on the macro.

#### **ASIT=**

specifies the address of an 8-byte real storage area that contains the ASIT identifying the address space to be deleted. Specify this operand as a label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The specified ASIT must match the ASIT associated with an address space that your virtual machine previously created, otherwise return code 4 is given.

This operand is required.

#### **WORKAREA=**

specifies the address of a real storage area that is used by the macro as a work area. Specify this operand as the label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the ADRSPACE DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding the use of this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

## Usage Notes

1. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. Code the DEFWORKA macro at the end of your program to define any macro work areas that have not yet been defined.
3. The DESTROY function cannot be used to destroy the host-primary address space of your virtual machine.

## Condition Codes and Return Codes

On return from the DESTROY function, register 15 contains one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | DESTROY Status                                                                                                                                                                                                                                                              |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | The address space has been destroyed as requested.                                                                                                                                                                                                                          |
| 4                                          | The specified ASIT does not identify an existing address space that your virtual machine created. This error also includes the case of the ASIT identifying the host-primary address space of your virtual machine in an attempt to destroy the host-primary address space. |

## ADRSAPCE ISOLATE

### Purpose

This function restores to a private state an address space owned by your virtual machine by removing all references by other virtual machines to the address space.

If the address space to be isolated is designated by any entries in the host access lists of any virtual machine other than your own, those host access-list entries are set to the revoked state. If, when in the access-register mode, a virtual machine attempts to use a revoked host access-list entry, an addressing-capability exception will be recognized.

The execution of the ISOLATE request does not complete until all affected host access-list entries are set to the revoked state, and all virtual machines have completed any current storage accesses to the address space which is being isolated.

If your virtual machine is not an XC virtual machine, it can use this function to isolate its host-primary address space only.

### Parameters

#### *label*

is an optional assembler language label on the macro.

#### **ASIT=**

specifies the address of an 8-byte real storage area that contains the ASIT identifying the address space to be isolated. Specify this operand as a *label* associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The specified ASIT must match the ASIT associated with an address space that your virtual machine owns, otherwise return code 4 is given.

This operand is required.

#### **MACHINE=370**

has no supported function, because 370 virtual machines are not supported. Results are undefined if this operand is specified.

#### **WORKAREA=**

specifies the address of a real storage area that is used by the macro as a work area. Specify this operand as the *label* associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for

the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the ADRSPACE DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

## Usage Notes

1. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. Code the DEFWORKA macro at the end of your program to define any macro work areas that have not yet been defined.
3. The ISOLATE function may take significant time and processing to complete. Its use should be minimized.
4. The ISOLATE function does not affect any entries in your virtual machine's host access list.
5. When the ISOLATE function completes, it is guaranteed that the only references to the isolated address space will be those being made by your virtual machine.
6. If ADRSPACE ISOLATE is used specifying the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the request fails and return code 4 is given. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:
  - SYSTEM CLEAR
  - IPL by NSS name
  - IPL by device with the CClear option
  - SET MACHINE (to a different machine architecture)

## Condition Codes and Return Codes

On return from the ISOLATE function, register 15 contains one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | ISOLATE function status                                                                                                                                                                                                                                                                                           |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | The address space has been isolated as requested.                                                                                                                                                                                                                                                                 |
| 4                                          | The specified ASIT does not identify an existing address space that your virtual machine created, nor does it identify the host-primary address space of your virtual machine, or your virtual machine has been relocated through the VMRELOCATE command and no subsequent reset clear function has been invoked. |

## ADRSAPCE PERMIT

### Purpose

This function authorizes a virtual machine for access to an address space that your virtual machine owns. The address space for which authorization is granted can be an address space created by your virtual machine or it can be your virtual machine's host-primary address space. You can authorize other virtual machines for either read-only, or read-write access to the address space.

When another virtual machine has authorization to access one of your virtual machine's address spaces, it can use the ALSERV macro to add to its host access list an entry designating the address space, and thereby access the address space when in access-register mode. It can also access the address space using CP commands such as CP DISPLAY, CP DUMP and CP STORE (if authorized for read-write access).

The authorization granted by using this function persists until one of the following occurs:

- Your virtual machine converts the address space for which access authorization was given to a private address space by using the ISOLATE function of this macro.
- Your virtual machine destroys the address space for which authorization was granted. The address space can be explicitly destroyed through the DESTROY function of this macro, or implicitly destroyed as a part of a subsystem-reset performed on your virtual machine, for example by the SYSTEM CLEAR, SYSTEM RESET, IPL, or LOGOFF commands.
- A subsystem reset is performed on the virtual machine to which authorization was granted. For example, a subsystem reset is performed by the SYSTEM CLEAR, SYSTEM RESET, IPL, or LOGOFF commands.

The SHARE parameter must be specified on an XCONFIG ADRSPACE directory control statement in your virtual machine's CP directory entry to authorize you to use this function, otherwise return code 32 is given.

### Parameters

#### *label*

is an optional assembler language label on the macro.

**USERID=**

specifies the user ID of the virtual machine to be given access authorization. This operand may be specified as one of the following:

- A character string of up to 8 characters within single quotation marks.
- A label associated with an 8-byte real storage area containing the user ID, left-justified in the 8-byte field, and the remainder of the field padded with spaces. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label is used to determine the address space containing the storage area.
- The number of a register (in the range of 2-12, inclusive) containing the real address of an 8-byte storage area defining the user ID, left-justified in the 8-byte field, and the remainder of the field padded with spaces. For an XC virtual machine in the access-register mode, the access register corresponding to the general register is used to determine the address space containing the storage area.

The user ID specified by this operand must designate a currently logged-on or disconnected virtual machine that does not already have authorization for the address space. If the user ID is not the user ID of a currently logged-on or disconnected virtual machine, then return code 28 is given. If the user ID designates a virtual machine that already has authorization for the address space, then return code 24 is given.

The USERID and VCIT operands are mutually exclusive. However, one of them is required to identify the virtual machine which is to be given access authorization.

**VCIT=**

specifies the address of an 8-byte real storage area that contains the VCIT identifying the virtual machine to be given access authorization. Specify this operand as a label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The VCIT for a virtual machine is the ASIT value assigned to that virtual machine's host-primary address space.

The VCIT specified by this operand must designate a currently logged-on or disconnected virtual machine that does not already have authorization for the address space. If the VCIT does not identify a currently logged-on or disconnected virtual machine, then return code 28 is given. If the VCIT designates a virtual machine that already has authorization for the address space, then return code 24 is given.

The USERID and VCIT operands are mutually exclusive. However, one of them is required to identify the virtual machine which is to be given access authorization.

**ASIT=**

specifies the address of an 8-byte real storage area that contains the ASIT identifying the address space for which access authorization is to be given. Specify this operand as a label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The ASIT specified by this operand must designate an address space owned by your virtual machine, that is, either an address space that your virtual machine created, or the host-primary address space for your virtual machine. If it does not designate an address space owned by your virtual machine, return code 4 is given.

This operand is required.

**MODE=**

specifies whether the virtual machine indicated by the USERID operand is to be given read-only, or read-write access authority. If MODE=READ is specified, the virtual machine is given authority for read-only access to the address space. If MODE=WRITE is specified, the virtual machine is given authority for read-write access to the address space.

This operand is optional; the default is MODE=READ.

**MACHINE=370**

has no supported function, because 370 virtual machines are not supported. Results are undefined if this operand is specified.

**WORKAREA=**

specifies the address of a real storage area that is used by the macro as a work area. Specify this operand as the label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the ADRSPACE DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

## Usage Notes

1. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. Code the DEFWORKA macro at the end of your program to define any macro work areas that have not yet been defined.
3. The first time that your virtual machine uses the PERMIT function to grant authorization for access to a particular address space, that address space is changed from a private address space to a shareable address space. The address space remains in the shareable state until your virtual machine uses the ISOLATE function of this macro to change it back to the private state.

When the host-primary address space of your virtual machine is in the shareable state, certain operations of DIAGNOSE code X'64' are prohibited. See the usage notes for DIAGNOSE code X'64' for details.

4. Your virtual machine is implicitly authorized for read-write access to its host-primary address space and to all address spaces that it creates. This authorization cannot be changed by using PERMIT function (with the MODE=READ operand). Return code 24 is given if the PERMIT function is invoked with a USERID or VCIT designating your virtual machine.
5. The address space for which authorization is to be granted is specified by ASIT. When an address space is created using the CREATE function of this macro, the ASIT associated with the address space is returned. If authorization is to be granted to your virtual machine's host-primary address space, the ASIT associated with the host-primary space can be obtained using the QUERY function of this macro.
6. Your virtual machine cannot simply reissue the PERMIT function to change the type of access authorization that was previously granted to a particular virtual machine. To change previously-granted access authorization, your virtual machine must first use the ISOLATE function to revoke all users' access authority to the address space, and then reestablish the desired access authorization for each virtual machine by a series of PERMIT invocations.
7. If an external security manager is installed on your system, you may not be authorized to use the PERMIT function of this macro. For additional information, contact your security administrator.
8. If ADRSPACE PERMIT is used specifying the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the request fails and return code 4 is given. To avoid this situation, issue a command that initiates a reset clear function on

the user on the relocation target system. Then obtain the new ASIT value using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:

- SYSTEM CLEAR
- IPL by NSS name
- IPL by device with the CLeAr option
- SET MACHine (to a different machine architecture)

## Condition Codes and Return Codes

On return from the PERMIT function, register 15 contains one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | PERMIT function status                                                                                                                                                                                                                                                        |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | The virtual machine specified by the USERID or VCIT operand has been authorized for access to the specified address space.                                                                                                                                                    |
| 4                                          | The specified ASIT does not identify a currently existing address space that your virtual machine owns, or your virtual machine has been relocated through the VMRELOCATE command and no subsequent reset clear function has been invoked. No authorization has been granted. |
| 24                                         | The specified virtual machine was already authorized for access to the specified address space. Authorization for the address space has not been changed.                                                                                                                     |
| 28                                         | The specified user ID or VCIT does not designate a currently logged-on or disconnected virtual machine. No authorization has been granted.                                                                                                                                    |
| 32                                         | Your virtual machine is not authorized to use the PERMIT function of the ADRSPACE macro.                                                                                                                                                                                      |

## ADRSPEC QUERY

### Purpose

This function returns the ASIT and size associated with an address space your virtual machine owns or is authorized to access.

### Parameters

#### *label*

is an optional assembler language label on the macro.

#### **NAME=**

specifies the name of the address space for which information is to be returned. This operand may be specified as one of the following:

- A character string of up to 24 characters within single quotation marks.
- A label associated with a 24-byte real storage area containing the address-space name, left-justified in the 24-byte field, and the remainder of the field padded with spaces. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label is used to determine the address space containing the storage area.
- The number of a register (in the range of 2-12, inclusive) containing the real address of a 24-byte storage area defining the address-space name, left-justified in the 24-byte field, and the remainder of the field padded with spaces. For an XC virtual machine in the access-register mode, the access register corresponding to the general register is used to determine the address space containing the storage area.

In all cases the address-space name must contain only uppercase letters (A through Z), numbers (0 through 9), and certain special characters (# \$ @ \_ -). If the name contains characters that are not allowed, no information is returned, and return code 16 is given.

If the OWNER operand is not specified, then this name must match the address-space name of an address space owned by your virtual machine. If it does not, then no information is returned and return code 4 is given.

If the OWNER operand is specified, then this name must match the address-space name of an address space owned by the user ID identified by the OWNER operand. Further, if the OWNER operand does not identify your virtual machine, then the owning virtual machine must have already granted authorization to your virtual machine to access the address space. If either of these conditions is not met, then no information is returned and return code 4 is given.

This operand is required.

#### **SIZE=**

specifies the address of a 4-byte real storage area that is set by this function to the size of the named address space in pages; each page is 4096 bytes.

For a host-primary address space, this includes discontinuous storage (that is, NSS or saved segment storage located above the virtual machine's defined size). Note, if discontinuous storage is used, there may be non-addressable areas within this storage.

Specify this operand as a label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of storage area. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

You must specify SIZE or ASIT or both to identify the address space information to be returned.

#### **ASIT=**

specifies the address of an 8-byte real storage area that is set by this function to the ASIT associated with the named address space. Specify this operand as a label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

You must specify SIZE or ASIT or both to identify the address space information to be returned.

#### **OWNER=**

specifies the user ID of the virtual machine owning the address space for which information is requested. This operand may be specified as one of the following:

- An asterisk (\*) to indicate the user ID of your virtual machine.
- A character string of up to 8 characters within single quotation marks.
- A label associated with an 8-byte real storage area containing the user ID, left-justified in the 8-byte field, and the remainder of the field padded with spaces. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label is used to determine the address space containing the storage area.
- The number of a register (in the range of 2-12, inclusive) containing the real address of an 8-byte storage area defining the user ID, left-justified in the 8-byte field, and the remainder of the field padded with spaces. For an XC virtual machine in the access-register mode, the access register corresponding to general register is used to determine the address space containing the storage area.

If the OWNER operand does not identify your virtual machine, then your virtual machine must be authorized to access the specified address space; otherwise, no information is returned and return code 4 is given. The virtual machine identified by the OWNER operand authorizes access to the address space by using the PERMIT function of this macro.

This operand is optional; the default is the user ID for your virtual machine.

**MACHINE=370**

has no supported function, because 370 virtual machines are not supported. Results are undefined if this operand is specified.

**WORKAREA=**

specifies the address of a real storage area that is used by the macro as a work area. Specify this operand as the label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the ADRSPACE DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding the use of this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

**Usage Notes**

- 1. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
- 2. Code the DEFWORKA macro at the end of your program to define any macro work areas that have not yet been defined.
- 3. Your virtual machine can use the QUERY function, with the operand NAME='BASE' to determine the ASIT associated with your virtual machine's host-primary address space.

**Condition Codes and Return Codes**

On return from the QUERY function, register 15 contains one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | QUERY function status                                                                                                                                                                                                                                                   |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | The ASIT and size for the specified address space have been supplied in the locations indicated by the ASIT and the SIZE operands, respectively.                                                                                                                        |
| 4                                          | The specified address-space name does not identify either an address space that your virtual machine owns, or an address space owned by another virtual machine for which your virtual machine has been granted access authorization. No information has been returned. |
| 16                                         | The specified address-space-name contains invalid characters. No information has been returned.                                                                                                                                                                         |

## ALSERV — Access List Services

---

### Purpose

Use the ALSERV macro to add entries to, or remove entries from your virtual machine's host access list. If your virtual machine is an XC virtual machine, the host access list for your virtual machine specifies those address spaces your virtual machine can access when it is in the access-register mode. If your virtual machine is an XA, ESA, or Z virtual machine, the host access list for your virtual machine specifies those address spaces your virtual machine can access indirectly through DIAGNOSE code X'248' (Copy-to-primary service).

The following access-list services can be invoked using this macro:

#### ADD

Establish a valid host access-list entry

#### DECLARE

Define the macro work area.

#### REMOVE

Invalidate a host access-list entry

### Usage Notes

**Access Lists and Access-List Entry States:** Each virtual machine has associated with it a host-managed table called a host access list. A host access list defines the set of address spaces that are directly addressable by the virtual machine when it is in the access-register mode (for XC virtual machines) or that can be accessed using DIAGNOSE code X'248' (for XA or ESA virtual machines). A host access list contains a directory-specified number of host access-list entries (ALEs), each of which is considered to be in one of three states: unused, valid or revoked. These states have an effect on the use of the entry for addressing, and the operation of the functions of the ALSERV macro, as follows:

- An unused ALE does not designate any address space and cannot be successfully used for addressing. An unused ALE can be selected by the ADD function and then set to the valid state by that function.
- A valid ALE designates a currently-existing address space and can be successfully used for addressing when your virtual machine is in the access-register mode (or when your virtual machine uses DIAGNOSE code X'248'). A valid ALE will not be selected by the ADD function.
- A revoked ALE is an ALE that was previously valid, but now designates an address space for which your virtual machine's access has been revoked. A revoked ALE cannot be successfully used for addressing. A revoked ALE will not be selected by the ADD function.

When a virtual machine is first logged on, or after a subsystem-reset operation has been performed on a virtual machine, all of the ALEs in its host access list are in the unused state.

Transitions from one ALE state to another happen as a result of the ALSERV macro, the ADRSPACE macro, and virtual-machine subsystem reset, as described below:

- An unused ALE is set to the valid state with the ADD function of this macro. When the ALE is made valid, it is set to designate a particular address space. In addition, the ALE is assigned an ALET value that is used when in the access-register mode to select this particular ALE for addressing. The ALET value remains uniquely associated with the ALE until the ALE is placed in the unused state.

The ALET value that is assigned to the host access-list entry is returned by the ADD function of this macro. When your virtual machine is in the access-register mode (or when your virtual machine uses DIAGNOSE code X'248') and uses the ALET that selects the ALE, the storage operand associated with the ALET is considered to reside within the address space that the ALE designates.

- A valid ALE is set to the revoked state when the address space designated by the ALE is destroyed, or when access to an address space is revoked by the virtual machine that owns the address space. An address space is destroyed when its owner uses the DESTROY function of the ADRSPACE macro, or it may be destroyed when a subsystem-reset operation is performed on the virtual machine that owns the

address space. A subsystem-reset is performed, for example, by the SYSTEM CLEAR, SYSTEM RESET, LOGOFF, or IPL commands. Access to an address space can be revoked by the address space owner using the ISOLATE function of the ADRSPACE macro.

- An ALE in either the valid or revoked state is set to the unused state when the entry is removed using the REMOVE function of this macro, or when a subsystem-reset operation is performed. A subsystem-reset is performed, for example, by the SYSTEM CLEAR, SYSTEM RESET, LOGOFF, or IPL commands.

Host access lists can range in size from 6 to 1022 entries. The XCONFIG ACCESSLIST directory statement controls the size of the host access list provided for a virtual machine. If a virtual machine's CP directory entry does not contain an XCONFIG ACCESSLIST statement, then the default is that a 62-entry host access list is provided for the virtual machine.

**Access-List-Entry Tokens:** When a virtual machine is in the access-register mode, (or when a virtual machine uses DIAGNOSE code X'248'), the address space in which an operand resides is specified indirectly by an access-list-entry token (ALET). An ALET selects the host access-list entry to use; the host access-list entry in turn designates the particular address space containing the operand. The process of translating an ALET and determining which, if any, host access-list entry it selects (and hence which address space the ALET represents) is called the host-access-register translation process.

A host access-list entry that is in either the valid or revoked states is selected by a single ALET value for as long as that entry remains in either of these two states. A host access-list entry that is in the unused state is not selected by any ALET value.

When the host-access-register translation process attempts to translate an ALET to determine the host access-list entry that it selects, there are four possible results. The ALET:

- Selects a host access-list entry that is in the valid state.

This is normal completion of the host-access-register translation process. The storage operand associated with the ALET is considered to reside within the address space that the host access-list entry designates.

- Selects a host access-list entry that is in the revoked state.

A revoked host access-list entry is no longer usable for addressing; an addressing-capability exception is recognized.

- Does not select a host access-list entry

The ALET is not usable for addressing; an ALEN-translation exception is recognized.

- Is not well formed, for example, it contains invalid bit settings.

The ALET is not usable for addressing; an ALET-specification exception is recognized.

## Program Exceptions

The ALSERV macro may result in one of the following program exceptions:

| Problem Encountered                                                         | Cause                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access exception (See page <a href="#">"Access Exceptions" on page 8.</a> ) | <p>An error occurred trying to</p> <ul style="list-style-type: none"> <li>• Fetch or store the macro parameter list (in macro work area)</li> <li>• Fetch a macro operand</li> <li>• Store the ALET operand (ADD function)</li> </ul> |
| Specification exception                                                     | <ul style="list-style-type: none"> <li>• The macro work area is not doubleword aligned.</li> <li>• The parameter list generated by the macro is in error.</li> </ul>                                                                  |

## ALSERV ADD

### Purpose

This function establishes a valid ALE in your virtual machine's host access list. It selects an unused entry in the host access list, places that entry in the valid state designating a specified address space, and returns the ALET that your virtual machine can use to address the specified address space.

Your virtual machine must be authorized for the requested type of access (read-only or read-write) to the specified address space, otherwise return code 8 is given. Your virtual machine is always authorized for read-write access to the address spaces that it owns. Another virtual machine can authorize your virtual machine to access address spaces that it owns by using the PERMIT function of the ADRSPACE macro.

### Parameters

#### *label*

is an optional assembler language label on the macro.

#### **ASIT=**

specifies the address of an 8-byte area in real storage that contains the ASIT identifying the address space to be designated by the validated ALE. Specify this operand as a label associated with the area in storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the area in storage. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

This ASIT must designate a currently-existing address space that your virtual machine is authorized to access, otherwise return code 8 is given.

This operand is required.

#### **ALET=**

specifies the address of a 4-byte real storage area that is set by this function to be the ALET that your virtual machine can use to reference the address space identified by the ASIT operand. Specify the ALET operand as a label associated with the area in real storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the area in storage. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

This operand is required.

### MODE=

specifies whether the new ALE allows read-only or read-write access to the designated address space. If MODE=READ is specified, then the ALE is set to provide read-only access to the address space; an attempt to modify the designated address space using this ALE will result in a protection exception.

If MODE=WRITE is specified, then the ALE is set to provide read-write access to the address space.

Your virtual machine must be authorized for the requested type of access to the address space specified by the ASIT operand. If you request either type of ALE when you have no access authorization, or a read-write ALE when you have read-only access authorization, then return code 8 is given. Your virtual machine is always authorized for read-write access to an address spaces it owns. Your virtual machine's authorization to an address space owned by another virtual machines is established by the owning virtual machine.

This operand is optional; the default is MODE=READ.

### FAULTS=

specifies whether storage references that use the ALE are eligible for page-fault handshaking.

If FAULTS=ASYNCH is specified then storage references that use the ALE are eligible for page-fault handshaking, provided that the other conditions necessary for page-fault handshaking are satisfied. See [Page-Fault Handshaking](#) for details on these other conditions and the page-fault-handshaking process.

If FAULTS=SYNCH is specified then storage references that use the ALE are not eligible for page-fault handshaking.

This operand is optional; the default is FAULTS=SYNCH.

### MACHINE=370

has no supported function, because 370 virtual machines are not supported. Results are undefined if this operand is specified.

### WORKAREA=

specifies the address of a real storage area that is used by the macro as a work area. Specify this operand as the label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For an XC virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the ALSERV DECLARE function. See ["Coding CP Macros" on page 807](#) for additional detail regarding this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

## Usage Notes

1. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. Code the DEFWORKA macro at the end of your program to define any macro work areas that have not yet been defined.
3. The address space to be designated by the new ALE is specified by ASIT. When an address space is created using the CREATE function of the ADRSPACE macro, the ASIT associated with the address space is returned. The ASIT associated with an address space can also be obtained using the QUERY function of the ADRSPACE macro.
4. If your virtual machine invokes the ADD function more than once for the same address space (with the same or a different MODE specifications), your virtual machine's host access list will contain multiple ALEs designating that address space.

5. It is not necessary to have established the location of a page-fault handshaking token prior to establishing an ALE with the FAULTS=ASYNCH option. However, page-fault-handshaking actions will not occur for the ALE until the page-fault handshaking token is established for the virtual CPU. See [Page-Fault Handshaking](#) for details on the page-fault-handshaking process.
6. If ALSERV ADD is used specifying the ASIT of a space owned by a user that has been relocated by the VMRELOCATE command prior to a subsequent reset clear function, the request fails and return code 8 is given. To avoid this situation, issue a command that initiates a reset clear function on the user on the relocation target system. Then obtain the new ASIT value using the QUERY SPACES command or the ADRSPACE QUERY API from a program. Commands that result in a reset clear include:
  - SYSTEM CLEAR
  - IPL by NSS name
  - IPL by device with the CClear option
  - SET MACHine (to a different machine architecture)

## Condition Codes and Return Codes

On return from the ADD function, register 15 contains one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | ADD function status                                                                                                                                                                                                                                                                       |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | An ALE has been established to designate the specified address space. The ALET to use to reference the address space has been returned.                                                                                                                                                   |
| 4                                          | There are no unused entries in the host access list that can be used to establish the new ALE.                                                                                                                                                                                            |
| 8                                          | The specified ASIT does not identify a currently-existing address space for which your virtual machine is authorized for the requested type of access, or your virtual machine has been relocated through the VMRELOCATE command and no subsequent reset clear function has been invoked. |

## ALSERV DECLARE

---

### Purpose

ALSERV DECLARE defines the storage required for the WORKAREA operand of the ALSERV macro. You must code this function only if you need to define the macro work area outside of the program requiring it. To simplify the use of the ALSERV macro, don't code the ALSERV DECLARE function and omit the WORKAREA operand on the executable functions of the ALSERV macro. This allows the ALSERV macro to control and define the necessary data expansion through the DEFWORKA macro coded at the end of your program. See [“Coding CP Macros” on page 807](#) for additional details.

### Parameters

#### *label*

is an optional assembler language label on the macro to be assigned to the defined storage.

### Usage Notes

1. The DECLARE function does not generate any executable code. You may code it within a dummy section (DSECT) or a control section (CSECT).
2. Although a label is not required on the invocation of the DECLARE function, it may be necessary in order to identify the work area on the WORKAREA operand.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the ALSERV DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

## Usage Notes

1. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. Code the DEFWORKA macro at the end of your program to define any macro work areas that have not yet been defined.
3. An ALET of X'00000000' designates the host-primary address space, and does not designate any ALE. An attempt to use the REMOVE function with an ALET of X'00000000' will result in return code 12.

## Condition Codes and Return Codes

On return from the REMOVE function, register 15 contains one of the following return codes:

| <b>Return Code<br/>In Register 15<br/>(Decimal)</b> | <b>REMOVE function status</b>                                                                                                            |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                                   | The ALE designated by the ALET operand has been removed as requested, and the ALE is now in the unused state.                            |
| 4                                                   | The ALET specified by the ALET operand does not designate an ALE in either the valid or revoked states. No ALE states have been changed. |
| 12                                                  | The ALET specified by the ALET operand contains invalid bit settings. No ALE states have been changed.                                   |

## DEFWORKA – Define Macro Work Area

### Purpose

Use the DEFWORKA macro to define the work areas required for one or more CP macros contained within your program. The description of each CP macro indicates whether it supports the definition of the macro's work area through DEFWORKA.

Code DEFWORKA after the invocation of the CP macros which rely on DEFWORKA. DEFWORKA collects and defines, with proper alignment, the CP macro work areas required within your program. The macros which use DEFWORKA also support a WORKAREA operand for their executable functions, and a DECLARE function. DEFWORKA generates the work area for a CP macro which is invoked without a WORKAREA specification or a CP macro which has a WORKAREA=*label* specification, where *label* has not yet been defined through DEFWORKA or the macro's DECLARE function.

### Parameters

#### *label*

is an optional assembler language label on the macro.

### Usage Notes

1. The DEFWORKA macro does not generate any executable code. You may code it within a dummy section (DSECT) or the control section (CSECT) of your program.
2. A label coded on the DEFWORKA invocation is not used anywhere within the macro expansion.
3. For additional details on this macro see [“Coding CP Macros” on page 807](#).

## MAPMDISK – Mapping Services

---

### Purpose

Use the MAPMDISK macro to establish and remove mappings between minidisks in your virtual machine's I/O configurations and address spaces owned by your virtual machine. A mapping is an association between a set of 4K minidisk blocks and a set of address space pages that permits a virtual machine to access data residing on those 4K minidisk blocks using normal CPU instructions, such as MOVE LONG, rather than by using I/O operations such as START SUBCHANNEL or DIAGNOSE code X'A4'.

Within this description of the MAPMDISK macro, the term "block", in the phrases minidisk block, pool-relative block number, minidisk-relative block number, and device-relative block number refer to a 4K byte area of data starting on a 4K block boundary. This use of the term "block" differs from a block on a fixed block architecture (FBA) DASD. Eight contiguous blocks of size 512 bytes on an FBA DASD make one minidisk 4K block. An FBA block starts on a 4K block boundary if the number of the FBA block is evenly divisible by 8.

The following mapping-service functions can be invoked using this macro:

#### DECLARE

Define the macro work area

#### DEFINE

Establish a mapping between a range of pages in an address space, and a set of 4K blocks residing in the minidisk pool

#### IDENTIFY

Identify the minidisk pool and the pool-relative block numbers of the 4K blocks within the pool

#### REMOVE

Remove a mapping between a range of pages in an address space, and a set of 4K blocks residing in the minidisk pool

#### SAVE

Initiate a request to write ranges of mapped pages to their corresponding minidisks

### Usage Notes

Your virtual machine must be an XC virtual machine to successfully use any of the functions of this macro. If your virtual machine is an XA, ESA, or Z virtual machine, then a specification exception is recognized.

**Pool-Relative Block Numbers:** A minidisk pool is the collection of minidisks in your virtual machine's I/O configuration that will participate in mappings. For defining mappings, a 4K DASD block within the minidisk pool is designated by a 32-bit unsigned value called a pool-relative block number. The IDENTIFY function of this macro identifies the minidisk pool for your virtual machine and defines the assignment of pool-relative block numbers to 4K minidisk blocks contained in the minidisk pool.

Each pool-relative block number value is considered either assigned or unassigned. An assigned pool-relative block number is associated with a single 4K minidisk block for mapping-related operations. An unassigned pool-relative block number is not associated with any 4K minidisk block within the minidisk pool. The assigned or unassigned state of a particular pool-relative block number may change as a result of invoking the IDENTIFY function, or modifying your virtual machine's I/O configuration. See [“MAPMDISK IDENTIFY” on page 851](#) for details.

Each 4K minidisk block that can be the target of a mapping is designated by at least one pool-relative block number. Although not normally the case, a 4K minidisk block may be designated by multiple pool-relative block numbers.

**Effects of Mapping:** A mapping is an association between a page in an address space and, indirectly through a pool-relative block number, a 4K block on a minidisk in a minidisk pool. When a mapping exists between a page and a 4K block, a correlation is maintained between the contents of the page and the contents of the 4K block so data contained in the 4K block is available in the page where it can be

manipulated by using normal CPU instructions. Mappings are established by using the DEFINE function of this macro, and are removed using the REMOVE function of this macro. MAPMDISK REMOVE must be issued before exiting guest applications that use MAPMDISK; otherwise, unpredictable results might occur.

A page for which a current mapping is defined is known as a mapped page. A page that has never had a mapping defined, or one that had a mapping defined and subsequently removed, is known as an unmapped page.

A mapping is established with the DEFINE function by specifying a pool-relative block number to be assigned to a page; this pool-relative block number indirectly specifies the 4K minidisk block that is associated with the mapped page. When a mapping is established for a page, the current contents of that page may be discarded and either the contents of the associated 4K minidisk block, or binary zeros, may be made available in the mapped page. Alternatively, the current contents of the page may be retained. The specific operation depends on the options used in establishing the mapping.

Subsequently, for as long as the page remains mapped, the contents of the page can be refreshed from the associated 4K minidisk block, and the contents of the page can be stored on the 4K minidisk block as follows:

- The contents of the mapped page can be refreshed by CP at any time, except that if the mapped page has been changed, then it will not be refreshed unless the store operation, whose description follows, has been successfully performed on the page at least as recently as the time of the last change.

The refresh operation performed by CP consists of translating (through the then-current minidisk extent list) the pool-relative block number assigned to the page to determine the location of the associated 4K minidisk block and fetching the contents of the 4K minidisk block into the mapped page. As viewed by virtual machines referencing the mapped page, this refreshing operation updates the contents of the page in a page-concurrent manner.

If an error is encountered when fetching data from the 4K minidisk block, the mapped page is marked *in error* so on a subsequent reference to the page a machine check indicating a storage-error condition is recognized. The storage-error condition is identified by a machine-check-interruption code (MCIC) specifying storage error uncorrected (bit 16 of the MCIC) and storage-key error uncorrected (bit 18 of the MCIC). Usually, the condition will be presented by a processing backup machine check in which all validity bits in the MCIC are set to one and a failing-storage address and ASIT are stored. However the condition may be presented by a more severe machine check with other machine-check conditions.

- The contents of the mapped page can be stored by CP at any time. In addition, a program can use the SAVE function of this macro to request that the contents of a changed mapped page be stored.

The store operation performed by CP consists of translating (through the then-current minidisk extent list) the pool-relative block number assigned to the page to determine the location of the associated 4K minidisk block and storing the contents of the mapped page on the 4K minidisk block. The store operation is performed in a manner that maintains change integrity for the contents of the page. As viewed by virtual machines accessing the 4K minidisk block, this store operation alters the contents of the block in a block-concurrent manner.

If an error is encountered when storing data on the 4K minidisk block, a machine check indicating a storage-degradation condition is recognized if the store operation was initiated automatically by CP, or an error completion code is presented if the store operation was initiated through the SAVE function. In both cases, the contents of the mapped page are unaffected and the page is still considered to be a changed page. The storage-degradation condition is identified by a machine-check-interruption code (MCIC) specifying storage-error corrected (bit 17 of the MCIC) and storage degradation (bit 19 of the MCIC). Usually, the condition will be presented by a system recovery machine check in which all validity bits in the MCIC are set to one and a failing-storage address and ASIT are stored. However the condition may be presented by a more severe machine check with other machine-check conditions.

Except as defined above, it is unpredictable if, and when, the refresh and store operations are performed. Changes made to a 4K minidisk block that is the target of a mapping may not have an immediate, if any, effect on the data available in the corresponding mapped pages. Likewise, changes made to a mapped page may not have an immediate, if any, effect on the contents of the associated 4K minidisk block.

Because of this unpredictability, care must be taken in using I/O instructions, or I/O DIAGNOSE functions to either read from or write to a 4K minidisk block that is the target of a mapping.

If, while a page is mapped, the pool-relative block number assigned to the page becomes an unassigned pool-relative block number, then the contents of the page will eventually become unavailable. When the contents are unavailable, the mapped page is marked *in error* such that on a subsequent reference to the page a storage-error machine check will be recognized.

### Programming Notes:

1. Although data on 4K minidisk blocks is said to be available in the associated pages after some forms of the DEFINE operation are completed, no actual movement of data from the minidisk into storage occurs at the time the mapping is defined. Movement of data from the 4K minidisk block into the mapped pages is performed by CP's paging subsystem when a virtual machine makes the first reference to the mapped page.

After a mapped page is in storage, CP's paging subsystem may or may not steal the frame assigned to the mapped page. If the frame is stolen and had been changed, the changed contents of the frame are stored back on the associated 4K minidisk block. When a virtual machine makes another reference to the page, the page will be reread from the 4K minidisk block.

Since it is unpredictable if or when CP's paging subsystem steals a frame, your program cannot depend on this action for correct operation. In particular, your program cannot depend on CP's page stealing to cause changed data to be written to the associated 4K minidisk blocks; the SAVE function of this macro can be used to ensure predictable saving of changed data. It also cannot depend on CP refetching data from the minidisk to cause the data in a changed 4K block to be visible in a mapped page.

2. While a mapping exists, some of the pool-relative block numbers associated with mapped pages may become unassigned, for example if the minidisk containing the 4K block identified by the pool-relative block number is detached from the virtual machine's I/O configuration. When a pool-relative block number used in a mapping becomes unassigned, it is possible that the data contained on the 4K minidisk block that was identified by the (now-unassigned) pool-relative block number may remain visible in a mapped page for an unpredictable amount of time. This will occur if CP is currently backing the mapped page with a real frame. Eventually, any changes made on the mapped page will be discarded and the mapped page will become unaddressable when CP steals the frame backing the mapped page. If a subsequent reference is made to the mapped page, a storage-error machine check will be recognized.
3. Once a storage-degradation machine check or error completion code from the SAVE function is received, future storage-degradation machine checks for the same page are possible as long as the page remains mapped to the same 4K minidisk block. This is because the contents of the page are unaffected by the error and are still considered to be changed, so CP may try the store operation again on the page at any time. To eliminate the possibility of future storage-degradation machine checks, the mapping for the page should be removed (using the REMOVE function) or changed (using the DEFINE function) after a storage-degradation machine check or error completion code from the SAVE function is received.
4. Although the preceding section defines that the contents of a mapped page can be stored by CP on the 4K minidisk block at any time, this action will not normally occur unless the page has been changed. However, there are unusual situations that can cause CP to store the contents of a page that was never changed. Because of these unusual situations, your program cannot assume that unchanged pages will not be stored.
5. Minidisk cache should be turned off for minidisks that are only read and written via MAPMDISK and the corresponding data space. Minidisks which use a combination of data space access/MAPMDISK and virtual I/O (Diagnose and channel program) should be evaluated on an individual basis to determine if minidisk cache should remain enabled.

### Program Exceptions

The MAPMDISK macro may result in one of the following program exceptions:

| Problem Encountered                                                        | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## MAPMDISK DECLARE

---

### Purpose

This function defines the storage required for the WORKAREA operand of the MAPMDISK macro. You must code this function only if you need to define the macro work area outside of the program requiring it. To simplify using the MAPMDISK macro, do not code the MAPMDISK DECLARE function and omit the WORKAREA operand on the executable functions of the MAPMDISK macro. This allows the MAPMDISK macro to control and define the necessary data expansion through the DEFWORKA macro coded at the end of your program. See [“Coding CP Macros” on page 807](#) for additional details.

### Parameters

#### *label*

is an optional assembler language label on the macro to be assigned to the defined storage.

### Usage Notes

1. The DECLARE function does not generate any executable code. You may code it within a dummy section (DSECT) or a control section (CSECT).
2. Although a label is not required on the invocation of the DECLARE function, it may be necessary to identify the work area on the WORKAREA operand.

## MAPMDISK DEFINE

### Purpose

This function establishes a mapping between a range of pages in an address space and, indirectly through pool-relative block numbers, a set of 4K blocks residing in the minidisk pool. You must first identify the minidisk pool, using the IDENTIFY function of this macro, before using the DEFINE function.

The mapping is defined in one of two ways: by using a specified list of pool-relative block numbers (the list form), or by using a specified consecutive range of pool-relative block numbers (the range form). A mapping is defined using the list form by specifying an ordered list of pool-relative block numbers that designate the 4K blocks that are to be associated with a specified consecutive range of address-space pages. A mapping is defined using the range form by specifying a consecutive range of pool-relative block numbers that designate the 4K blocks that are to be associated with a specified consecutive range of address-space pages. For both forms, the address-space pages can be pages either in an address space that you have created, or in your host-primary address space.

For each page to be mapped by the DEFINE request, the page is unlocked (if it was locked through the LOCK command) and the specified pool-relative block number is assigned to the page. Depending on the value of the PAGEVIEW parameter, the current contents of the page are either retained or discarded as part of the DEFINE operation; if the current contents are discarded, then either binary zeros or the contents of the associated 4K minidisk block are made available in the mapped page.

If PAGEVIEW=FETCH is specified and the pool-relative block number to be assigned to a page designates a 4K block that resides on a read-only minidisk, the mapped page is host-page protected by CP so any attempt to change the mapped page (or to change the storage key for the mapped page) results in a protection exception. This protection applies even if all other protection mechanisms (low-address, key-controlled and access-list-controlled protection) would allow the virtual machine to have read-write access to the page. If the pool-relative block number assigned to the page designates a 4K block that resides on a read-write minidisk, then the page is not host-page protected; a virtual machine may change the mapped page if the other protection mechanism permit the change. If PAGEVIEW=ZERO or PAGEVIEW=RETAIN is specified and the pool-relative block number to be assigned to a page designates a 4K block that resides on a read-only minidisk, return code 36 is given.

Once a mapping is established, the mapping remains in effect and the pool-relative block number specified for a page remains assigned to the page until a new mapping is established, until the mapping

is removed with the REMOVE function of this macro, or until a subsystem-reset operation is performed on your virtual machine. The mapping remains in effect even if the extent-list defining the minidisk pool is changed after the mapping was established. MAPMDISK REMOVE must be issued before exiting guest applications that use MAPMDISK; otherwise, unpredictable results might occur.

## Parameters

### *label*

is an optional assembler language label on the macro.

### **ASIT=**

specifies the real address of an 8-byte field in storage that contains the ASIT identifying the address space to be the target of the mapping. Specify this parameter as a label associated with the field, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field in storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

If this ASIT is not associated with an address space your virtual machine created, or the host-primary address space for your virtual machine, then return code 8 is given.

This operand is required.

### **PAGECT=**

specifies the real address of a 4-byte field in storage that contains the number of consecutive pages to be mapped by this request. Specify this parameter as a label associated with the field in storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field in storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

The minimum number of pages to be mapped is 1, and the maximum number is 524,288. If this count is not in this range, then return code 4 is given.

If this value does not match the sum of the ENTCT fields in each of the mapping-list definition blocks, then return code 20 is given.

This operand is required.

### **PAGEADDR=**

specifies the real address of a 4-byte field in storage that contains the 31-bit absolute address of the first page in the consecutive range of pages to be mapped. Specify this parameter as a label associated with the field in storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field in storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

The range of pages to be mapped, from PAGEADDR to PAGEADDR+(PAGECT-1)\*4096, must be contained within the bounds of the address space designated by the ASIT operand, otherwise an addressing exception is recognized. This range must not include any saved segments, or pages locked with the LOCK function of DIAGNOSE code X'98' otherwise return code 24 is given.

Bits 20-31 of the page address must be zeros, otherwise a specification exception is recognized.

This operand is required.

### **MLDBLOCK=**

specifies the real storage address of the first mapping-list definition block in the chain of mapping-list definition blocks for this request. Specify this parameter as a label associated with the block in real storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the block in real storage. For a virtual machine in the access-register mode, the access register

corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the block.

The address of the first mapping-list definition block must be an address on a doubleword boundary, otherwise a specification exception is recognized. See [Mapping-List Format](#) for more information.

The MLDBLOCK and PRBN operands are mutually exclusive. However, one of them is required to indicate whether the pool-relative block numbers to be associated with the mapped pages are specified in a list or as a consecutive range.

#### **PRBN=**

specifies the real address of a 4-byte field in storage that contains the pool-relative-block number to be associated with the page identified by the PAGEADDR operand. Each subsequent page in the range of pages to be mapped is associated with the next higher pool-relative block number.

Specify this parameter as a label associated with the field in storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field in storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

The pool-relative block number must be less than or equal to  $2^{32}$ -PAGECT and must have been assigned by the IDENTIFY function, otherwise return code 12 is given.

The MLDBLOCK and PRBN operands are mutually exclusive. However, one of them is required to indicate whether the pool-relative block numbers to be associated with the mapped pages are specified in a list or as a consecutive range.

#### **PAGEVIEW=**

specifies the disposition of the current contents of the pages to be mapped and the type of data to be available in the mapped pages at the completion of the DEFINE request. Specify this parameter as one of the keywords FETCH, RETAIN or ZERO or as the number of a register (in the range of 2-12 inclusive) containing a parameter code in the low order byte.

If PAGEVIEW=FETCH is specified, the current contents of the pages are discarded and the contents of the associated 4K minidisk blocks are made available in the mapped pages. For the SAVE function, the pages are considered to be unchanged pages at the completion of the DEFINE operation.

If PAGEVIEW=RETAIN is specified, the current contents of the pages are retained. For purposes of the SAVE function, the pages are considered to be changed pages.

If PAGEVIEW=ZERO is specified, the current contents of the pages are discarded and the mapped pages are considered to contain binary zeros. For purposes of the SAVE function, it is unpredictable whether the pages are considered to be changed or unchanged pages at the completion of the DEFINE operation.

If PAGEVIEW=(*reg*) is specified, then bits 24-31 of the general register indicated by (*reg*) contain a code that specifies PAGEVIEW as follows:

#### **Code**

##### **PAGEVIEW meaning:**

#### **X'00'**

PAGEVIEW=FETCH

#### **X'01'**

PAGEVIEW=RETAIN

#### **X'02'**

PAGEVIEW=ZERO

#### **All Others**

Invalid

If bits 24-31 of the register contain a code listed as invalid then a specification exception is recognized. Bits 0-23 of the register are ignored.

This operand is optional; the default is PAGEVIEW=FETCH.

## WORKAREA=

specifies the address of a real storage area that is used by the macro as a work area. Specify this parameter as the label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the MAPMDISK DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

## Usage Notes

1. The macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. Code the DEFWORKA macro at the end of your program to define any macro work areas that have not yet been defined.
3. The normal method of changing data on a 4K minidisk block that is the target of a mapping is to change the contents of the associated mapped page and then use the SAVE function of this macro to cause the changed data to be stored on the 4K minidisk block.

However if the data on a 4K minidisk block must be changed by some other means, such as an I/O instruction or an I/O diagnose, and you want the changed data to be visible in a mapped page, issue DIAGNOSE code X'10' against the mapped page after the data has been changed on the 4K minidisk block. The DIAGNOSE code X'10' operation will cause the mapped page to be refreshed from the 4K minidisk block on next reference.

4. Since it is unpredictable whether mapped pages established using the PAGEVIEW=ZERO operand are considered changed or unchanged pages, your program cannot use the combination of a DEFINE request with PAGEVIEW=ZERO followed immediately by a SAVE request for the same page as a way of zeroing out the contents of the associated 4K minidisk block. The SAVE request may or may not store the page of zeros on the 4K minidisk block.

If you want the page of zeros to be stored on the associated 4K minidisk block by the SAVE request, then the page must be changed through CPU instructions before the SAVE request is issued. Note however that simply storing a byte or word of zeros into the page is insufficient because by architecture rules, the page may not be considered to be a changed page after a store operation that does not change the value in storage. Two stores into the page must be done: the first being a store of some nonzero value, and the second a store of a zero into the same location.

5. Defining a mapping using the DEFINE function changes the data that is visible in the mapped page. However, it does not change the storage key associated with the page.

**Mapping-List Format:** If the DEFINE function has been requested using a specified list of pool-relative block numbers (using the MLDBLOCK parameter), then the pool-relative block numbers to be associated with the pages to be mapped are specified by a singly-linked list of mapping-list definition blocks. This mapping is a chained structure to allow for the specification of many mapping-list entries without requiring many contiguous pages of storage for the list, while retaining the option of having a single contiguous area if desired. The real address of the first block in this singly-linked list is specified by the MLDBLOCK operand.

Each mapping-list definition block contains a header, and a contiguous table of mapping-list entries. The mapping-list definition block must be aligned on a doubleword boundary. Each mapping-list entry specifies a pool-relative block number to be associated with a page in the range of pages to be mapped.

Each mapping-list definition block must be aligned on a doubleword boundary. A mapping-list definition block has the following format:

**Note:** Field names used in the following descriptions are for reference only. You may copy these names, or use any other names, in your own code.

|    |                             |                      |
|----|-----------------------------|----------------------|
| 0  | FWDPT-ALET                  | FWDPT                |
| 8  | ENTCT                       | //////////////////// |
| 16 | ENTR1                       |                      |
| nn | Mapping-list entries (MLEs) |                      |

**FWDPT-ALET**

When the virtual machine is in the access-register mode, bytes 0-3 contain an ALET specifying the address space in which the next mapping-list definition block resides. Zeros in bytes 0-3 in conjunction with zeros in bytes 4-7 indicate that this block is the last block in the chain.

Bytes 0-3 are ignored when the virtual machine is in the primary-space mode.

**FWDPT**

Bytes 4-7 of the mapping-list definition block are the real address of the next block in the singly-linked chain. This field must specify an address on a doubleword boundary, otherwise return code 28 is given. When the virtual machine is in the primary-space mode, zeros in bytes 4-7 indicate that this block is the last block in the chain. When the virtual machine is in the access-register mode, end-of-chain is indicated by zeros in bytes 4-7 and bytes 0-3.

**ENTCT**

Bytes 8-11 of the mapping-list definition block contain a word that is the number of mapping-list entries contained in this mapping-list definition block. The minimum number of entries in a mapping-list definition block is 1, and the maximum number is 524,288. If this count is not in this range, then return code 16 is given.

If the total number of mapping-list entries in all of the extent-list definition blocks in the chain is less than the value of the page count specified by the PAGECT operand on the macro invocation, then a mapping is established only for those pages for which there is a mapping-list entry. If the total number of mapping-list entries is larger than the value of the PAGECT operand, then the extra mapping-list entries are not used. In either case, return code 20 is given.

**////**

Bytes 12-15 of the mapping-list definition block are reserved for future use and should contain binary zeros.

**ENTR1**

Starting at byte 16 of the mapping-list definition block is a contiguous table of 4-byte mapping list entries. Each mapping-list entry is a word that contains a pool-relative block number. The ENTCT field specifies how many mapping-list entries are contained in this area.

The overall structure of the mapping list chain is shown in the following diagram:

The chain of mapping-list definition blocks is processed as though it was a single, ordered list of mapping-list entries. The first mapping-list entry in the first mapping-list definition block contains the pool-relative block number to be associated with the address-space page identified by the PAGEADDR operand on the macro invocation. Each subsequent mapping-list entry in the mapping-list definition block contains the pool-relative block number to be associated with the next page in the page range. After all of the mapping-list entries in a given mapping-list definition block are processed, the first mapping-list entry of the next mapping-list definition block in the chain is processed.

## Condition Codes and Return Codes

On return from the DEFINE function, register 15 contains one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | DEFINE function status                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | The mapping has been defined as requested.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 4                                          | The page count specified by the PAGECT operand is out of range. No mapping has been defined.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 8                                          | The ASIT specified by the ASIT operand does not identify either an existing address space that your virtual machine created, or your virtual machine's host-primary address space. No mapping has been defined.                                                                                                                                                                                                                                                                                                                     |
| 12                                         | The pool-relative block number to be associated with a page is either unassigned, or would exceed $2^{32}-1$ . If the error is due to an unassigned pool-relative block number, mappings have been defined for pages up to but not including the one corresponding to this error. Register 0 contains the address of the page for which the error occurred. This page resides in the address space specified by the ASIT operand. If the error is due to $PRBN+PAGECT-1$ exceeding $2^{32}-1$ , then no mappings have been defined. |
| 16                                         | The ENTCT field in a mapping-list definition block is out of range. Register 0 contains the address of the mapping-list definition block that contains the invalid ENTCT field. In the access-register mode, access register 0 contains the ALET specifying the address space in which the mapping-list definition block resides. Mapping-list definition blocks up to but not including the one containing the error have been processed.                                                                                          |

| Return Code<br>in Register 15<br>(Decimal) | DEFINE function status                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20                                         | The page count as specified by the PAGECT operand does not match the sum of the ENTCT fields in all of the mapping-list definition blocks. If the sum of the ENTCT fields is less than the page count specified by PAGECT, then all mapping-list definition blocks have been processed; register 0 contains the address of the last mapping-list definition block. If the sum of the ENTCT fields is greater than the page count specified by PAGECT, then mapping-list definition blocks up to but not including the one that caused the error have been processed; register 0 contains the address of the mapping-list definition block that caused the error. In both cases in the access-register mode, access register 0 contains the ALET specifying the address space in which the mapping-list definition block resides. |
| 24                                         | The range of pages to be mapped includes a saved segment, or includes a page locked with the LOCK function of DIAGNOSE code X'98'. Mappings have been defined for all pages up to but not including the first page that is either in a saved segment, or that has been locked with the LOCK function of DIAGNOSE code X'98'. Register 0 contains the address of the megabyte containing the page for which the error occurred. This megabyte of storage resides in the address space specified by the ASIT operand.                                                                                                                                                                                                                                                                                                              |
| 28                                         | The FWDPT field in a mapping-list definition block does not specify an address on a doubleword boundary. Mapping-list definition blocks up to and including the one containing the error have been processed. Register 0 contains the address of the mapping-list definition block containing the invalid FWDPT field. In the access-register mode, access register 0 contains the ALET specifying the address space in which the mapping-list definition block resides.                                                                                                                                                                                                                                                                                                                                                         |
| 32                                         | No minidisk pool was previously identified through the MAPMDISK IDENTIFY function. No mapping has been defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 36                                         | PAGEVIEW=ZERO or PAGEVIEW=RETAIN was specified and a pool-relative block number designates a 4K block that resides on a read-only minidisk. Mappings have been defined for pages up to but not including the one corresponding to this error. Register 0 contains the address of the page for which the error occurred. This page resides in the address space specified by the ASIT operand.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 40                                         | When in the access-register mode, an ALET used in accessing a mapping-list definition block could not be translated because of an ALET-specification-exception condition (ALET contains invalid bit settings). Mapping-list definition blocks up to and including the one containing the error have been processed. Access register 0 and general register 0 contain the ALET and address (respectively) used in the attempt to access the mapping-list definition block.                                                                                                                                                                                                                                                                                                                                                        |
| 44                                         | When in the access-register mode, an ALET used in accessing a mapping-list definition block could not be translated because of an ALEN-translation-exception condition (ALET does not designate a valid or revoked ALE). Mapping-list definition blocks up to and including the one containing the error have been processed. Access register 0 and general register 0 contain the ALET and address (respectively) used in the attempt to access the mapping-list definition block.                                                                                                                                                                                                                                                                                                                                              |
| 48                                         | When in the access-register mode, an ALET used in accessing a mapping-list definition block could not be translated because of an addressing-capability-exception condition (ALET designates an address space for which access has been revoked). Mapping-list definition blocks up to and including the one containing the error have been processed. Access register 0 and general register 0 contain the ALET and address (respectively) used in the attempt to access the mapping-list definition block.                                                                                                                                                                                                                                                                                                                     |

If an addressing or addressing-capability exception is recognized on the DEFINE function, the operation is terminated. Those pages in the page range identified by the PAGEADDR and PAGECT parameter that are processed before the point of error have mappings established as usual. Those pages in the page range at or after the point of error remain unchanged.

## MAPMDISK IDENTIFY

### Purpose

This function identifies your virtual machine's minidisk pool and defines the assignment of pool-relative block numbers to the 4K blocks contained within the minidisk pool. You must use this function to identify the minidisk pool before you can successfully use the DEFINE function to establish mappings.

To be in a minidisk pool, a minidisk must reside on a DASD device type that is supported by CP as a paging device; this requirement is checked by the IDENTIFY function when the minidisk pool is identified. For minidisks on FBA DASD, the minidisk must start and end on 4K block boundaries (the starting FBA block number and the ending FBA block number plus one must be evenly divisible by 8); this requirement is also checked by the IDENTIFY function when the minidisk pool is identified. For minidisks on CKD DASD, the MAPMDISK functions assume that all minidisks that are part of a minidisk pool are formatted so:

- All blocks are 4K byte blocks
- Each track has consecutive record numbers starting with one
- There are no pad records.

However, these last three requirements for minidisks on CKD DASD are not checked by the IDENTIFY function. Unpredictable results may occur if these requirements are not met.

The minidisk pool is specified by an extent list, which is an ordered list of minidisk segments that comprise the minidisk pool. Each extent in the list is a contiguous range of 4K blocks on a minidisk in your virtual machine's I/O configuration. The 4K blocks contained in an extent are assigned a specified consecutive range of pool-relative block numbers that designate the blocks in mapping operations. The extent list entries must be specified with increasing, nonoverlapping ranges of pool-relative block numbers.

Your virtual machine can have at most one minidisk pool defined. If your virtual machine had previously used this function to identify a minidisk pool, and then subsequently uses the function again, the new extent list for the minidisk pool replaces the previous one.

Once a minidisk pool is identified, it remains in effect until it is redefined by a subsequent invocation of the IDENTIFY function, or until a subsystem-reset operation is performed on your virtual machine. A subsystem-reset operation deletes any minidisk pool identified for your virtual machine.

If a minidisk contained within your virtual machine's minidisk pool is subsequently detached from your virtual machine's I/O configuration, or if the minidisk is redefined to have a different device number, then the minidisk is removed from the minidisk pool, and all pool-relative block numbers corresponding to the extents that were defined for that minidisk are made unassigned pool-relative block numbers. The minidisk remains outside of the minidisk pool until it is reattached to your virtual machine's I/O configuration and another IDENTIFY operation is performed which includes one or more extents residing on the minidisk device.

## Parameters

### *label*

is an optional assembler language label on the macro.

### **EXTCT=**

specifies the real address of a 4-byte field that contains the total number of extents contained in the extent list. (See [Extent-List Format](#) for more information on the extent list.) Specify this parameter as a label associated with the field in storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field in storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The minimum number of extents is 1, and the maximum number is 65,536. If this count is not in this range, then return code 4 is given.

If this value does not match the sum of the ENTCT fields in each of the extent-list definition blocks, then return code 20 is given.

This operand is required.

### **XLDBLOCK=**

specifies the real storage address of the first extent-list-definition block in the chain of extent-list-definition blocks for this request. Specify this parameter as a label associated with the block in real storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the block in real storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

This address of the first extent-list-definition block must be an address on doubleword boundary, otherwise a specification exception is recognized. See [Extent-List Format](#) for more information.

This operand is required.

### **WORKAREA=**

specifies the address of a real storage area that is used by the macro as a work area. Specify this parameter as the label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the MAPMDISK DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

## Usage Notes

1. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. Code the DEFWORKA macro at the end of your program to define any macro work areas that have not yet been defined.
3. It is possible to specify an extent list that has *gaps* in the assignment of pool-relative block numbers, that is, has pool-relative block numbers that are not assigned to the 4K blocks in any minidisk extent. Such an assignment can be used, for example, to skip ranges of pool-relative block numbers that correspond to off-line volumes.
4. A mapping between a page and a particular 4K minidisk block is established indirectly, by a pool-relative block number which is translated as necessary by CP to determine the associated 4K minidisk

block. Because of this indirection, and the fact that a mapping association between a particular page and a particular pool-relative block number remains in effect even if the current extent-list defining the minidisk pool is changed, care must be taken when changing the extent list defining the minidisk pool. Since it is unpredictable when, and how many times, a pool-relative block number is translated by CP, unpredictable operation will result if the extent list is changed so that either a particular pool-relative block number is assigned to a different 4K minidisk block in the new extent list than it was in the old extent list, or a particular pool-relative block number is unassigned in the new extent list but was assigned in the old extent list.

5. To be successfully used for mapping, a minidisk must be formatted with certain characteristics, as stated above. Minidisks formatted using the CMS FORMAT command with the BLKSIZE 4096 or BLKSIZE 4K option meets all of these formatting requirements.
6. For a minidisk on an Extended Address Volume, the minidisk end extent must reside below cylinder 65520 to be eligible for the MAPMDISK IDENTIFY function.

**Extent-List Format:** The extent list for the minidisk pool is specified by a singly-linked chain of extent-list definition blocks. The extent-list is a chained structure to allow for the specification of many mapping-list entries without requiring many contiguous pages of storage for the list, while retaining the option of having a single contiguous area if desired. The address of the first extent-list definition block in the chain is specified by the XLDBLOCK operand on the MAPMDISK IDENTIFY macro invocation.

Each extent-list definition block begins on a doubleword boundary, and is in the following format:

**Note:** Field names used in the following descriptions are for reference only. You may copy these names, or use any other names, in your own code.

|    |                     |                                      |
|----|---------------------|--------------------------------------|
| 0  | FWDPT-ALET          | FWDPT                                |
| 8  | ENTCT               | //////////////////////////////////// |
| 10 | ENTR1               |                                      |
| nn | Extent-list entries |                                      |

#### FWDPT-ALET

When the virtual machine is in the access-register mode, bytes 0-3 contain an ALET specifying the address space in which the next extent-list definition block resides. Zeros in bytes 0-3 in conjunction with zeros in bytes 4-7 indicate that this block is the last block in the chain.

Bytes 0-3 are ignored when the virtual machine is in the primary-space mode.

#### FWDPT

Bytes 4-7 of the extent-list definition block are the real address of the next block in the singly-linked chain. This field must specify an address on a doubleword boundary, otherwise a specification exception is recognized. When the virtual machine is in the primary-space mode, zeros in bytes 4-7 indicate that this block is the last block in the chain. When the virtual machine is in the access-register mode, end-of-chain is indicated by zeros in bytes 4-7 and bytes 0-3.

#### ENTCT

Bytes 8-11 of the extent-list definition block contain a word that is the number of extent-list entries contained in this extent-list-definition block. The minimum number of entries in the extent-list definition block is 1, and the maximum number is 65,536. If this count is not in this range, then return code 16 is given.

If the sum of the ENTCT fields in all of the extent-list-definition blocks does not match the value specified for the EXTCT operand on the MAPMDISK IDENTIFY macro invocation, then return code 20 is given.

////////

Bytes 12-15 of the extent-list-definition block are reserved for future use and should contain binary zeros.

# ENTR1

Starting at byte 16 of the extent-list definition block is a contiguous table of 16-byte extent-list entries. The ENTCT field specifies how many extent-list entries are contained in this area. The format of each extent-list entry follows.

Each 16-byte extent-list entry defines a single extent in the minidisk extent list. An extent-list entry has the following format:

|   |       |          |
|---|-------|----------|
| 0 | PRBN  | MRBN     |
| 8 | COUNT | DEVNM    |
|   |       | //////// |

# PRBN

Bytes 0-3 of the extent-list entry are an unsigned word that contains the pool-relative block number to be assigned to the 4K block designated by the MRBN field. This number must be larger than the pool-relative block numbers assigned to previous extents, and must be less than or equal to  $2^{32}$ -COUNT. If this number is not greater than the pool-relative block numbers assigned to previous extents, or if this number is too large, return code 24 is given.

The 4K blocks residing on the extent defined by this extent-list entry are assigned consecutive pool-relative block numbers from PRBN to PRBN+COUNT-1, inclusive. This range of pool-relative block numbers is assigned to the 4K blocks within the extent in minidisk-relative block order.

# MRBN

Bytes 4-7 of the extent-list entry are a word that contains the minidisk-relative block number of the first 4K block of the minidisk that is included in the extent. This block number is relative to the start of the minidisk, and must be between 0 and the number of 4K blocks contained on the minidisk minus one. If the number is not in this range, return code 12 is given.

# COUNT

Bytes 8-11 of the extent-list entry are a word that contains the number of 4K blocks of the minidisk that are included in the extent. This count must be greater than or equal to 1, and the sum of MRBN and COUNT must be less than or equal to the number of 4K blocks contained on the minidisk. If either of these conditions is not met, then return code 12 is given.

# DEVNM

Bytes 12-13 of the extent-list entry are a halfword that contains the virtual device number of the minidisk on which this extent resides. This must be the device number of a minidisk in your virtual machine's I/O configuration that resides on a device type supported by CP. If the device is not a minidisk that resides on a device type supported by CP, then return code 8 is given. If the device is a minidisk residing on an FBA DASD, the minidisk must start and end on a 4K block boundary (the starting FBA block number and the ending FBA block number + 1 of the minidisk must be evenly divisible by 8). If not, return code 28 is given.

////////

Bytes 14-15 of the extent-list entry are reserved for future use and should contain binary zeros.

The overall structure of the chain of extent-list definition blocks is shown in the following diagram:

The chain of extent-list-definition blocks is processed as though it was a single, ordered list of extent-list entries. The first extent-list entry in the first extent-list-definition block is the first extent processed by the identify-pool function. Each subsequent extent-list entry in the extent-list-definition block is processed in turn. After all of the extent-list entries in a given extent-list-definition block are processed, the first entry of the next extent-list-definition block in the chain is processed.

## Condition Codes and Return Codes

On return from the IDENTIFY function, register 15 contains one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | IDENTIFY function status                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | The minidisk pool has been identified as requested.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 4                                          | The total number of extents as specified by the EXTCT operand is out of range. No new minidisk pool has been identified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 8                                          | An extent-list entry contains either (1) a device number that does not exist in the virtual machine's I/O configuration, (2) a device number for a device that is not supported for mapping operations (not a minidisk device, or a minidisk device residing on a device type not supported by CP for paging, or a virtual disk in storage), or (3) a minidisk end extent is not below cylinder 65520 on an Extended Address Volume. Register 0 contains the address of the extent-list entry that contains the invalid device number. In the access-register mode, access register 0 contains the ALET specifying the address space in which the extent-list entry resides. No new minidisk pool has been identified. |
| 12                                         | An extent-list entry contains a MRBN field that is out of range, or the sum of MRBN and COUNT is out of range, or COUNT is less than or equal to zero. Register 0 contains the address of the extent-list entry. In the access-register mode, access register 0 contains the ALET specifying the address space in which the extent-list entry resides. No new minidisk pool has been identified.                                                                                                                                                                                                                                                                                                                       |
| 16                                         | The ENTCT field in an extent-list definition block is out of range. Register 0 contains the address of the extent-list definition block containing the invalid ENTCT field. In the access-register mode, access register 0 contains the ALET specifying the address space in which the extent-list definition block resides. No new minidisk pool has been identified.                                                                                                                                                                                                                                                                                                                                                 |

| Return Code<br>in Register 15<br>(Decimal) | IDENTIFY function status                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20                                         | The total number of extents as specified by the EXTCT operand does not match the sum of the ENTCT fields in all of the extent-list-definition blocks. No new minidisk pool has been identified. If the sum of the ENTCT fields is less than the extent count specified by EXTCT, then register 0 contains the address of the last extent-list definition block. If the sum of the ENTCT fields is greater than the extent count specified by EXTCT, then register 0 contains the address of the extent-list definition block whose ENTCT field caused the sum of ENTCT fields to exceed the extent count specified by EXTCT. In both cases in the access-register mode, access register 0 contains the ALET specifying the address space in which the extent-list definition block resides. |
| 24                                         | An extent-list entry contains a PRBN field that is either too large, or not larger than the pool-relative block numbers assigned to previous extents. Register 0 contains the address of the extent-list entry containing the invalid PRBN. In the access-register mode, access register 0 contains the ALET specifying the address space in which the extent-list entry resides. No new minidisk pool has been identified.                                                                                                                                                                                                                                                                                                                                                                 |
| 28                                         | An extent-list entry contains a device number for a minidisk residing on an FBA DASD. That minidisk either does not start or does not end on a 4K block boundary. (The starting FBA block number and the ending FBA block number + 1 of the minidisk must be evenly divisible by 8). No new minidisk pool has been identified. R0 contains the address of the non-aligned minidisk. In access register mode, access register 0 contains the ALET specifying the address space in which the extent list entry resides.                                                                                                                                                                                                                                                                       |

If an addressing or addressing-capability exception is recognized on the IDENTIFY function, the operation is suppressed. No new minidisk pool is identified and the minidisk pool identified by a previous IDENTIFY request, if any, remains in effect.

If the IDENTIFY function returns a nonzero return code, the minidisk pool identified through a previous IDENTIFY request, if any, remains in effect.

## MAPMDISK REMOVE

Notes:

<sup>1</sup> The keyword parameters that follow can be specified in any order.

### Purpose

This function removes a mapping between a range of pages in an address space and a set of 4K blocks residing in the minidisk pool.

The current contents of the pages in the specified range are discarded, the pages are set to binary zeros, and are considered to be unmapped pages. If host-page protection was applied to the page by the DEFINE function (because the page was mapped onto a read-only minidisk), that host-page protection is removed. MAPMDISK REMOVE must be issued before exiting guest applications that use MAPMDISK; otherwise, unpredictable results might occur.

### Parameters

#### *label*

is an optional assembler language label on the macro.

#### **ASIT=**

specifies the real address of an 8-byte field in storage that contains the ASIT identifying the address space for which mappings are to be removed. Specify this parameter as a label associated with the field in storage, or as the number of a register (in the range 2-12, inclusive) containing the address of the field in storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

If this ASIT is not associated with an address space your virtual machine created, or with your virtual machine's host-primary address space, then return code 8 is given.

This operand is required.

#### **PAGEADDR=**

specifies the real address of a 4-byte field in storage that contains the 31-bit absolute address of the first page in the range of pages to be unmapped. Specify this parameter as a label associated with the field in storage, or as the number of a register (in the range 2-12, inclusive) containing the address of the field in storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

The range of pages to be unmapped, from PAGEADDR to PAGEADDR+(PAGECT-1)\*4096, must be contained within the bounds of the address space designated by the ASIT operand, otherwise an

addressing exception is recognized. In addition, this range must not include any unmapped pages, otherwise return code 12 is given.

Bits 20-31 of the page address must be zeros, otherwise a specification exception is recognized.

This operand is required.

**PAGECT=**

specifies the real address of a 4-byte field in storage that contains the count of pages for which a mapping is to be removed. Specify this parameter as a label associated with the field in storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

The minimum number of pages to be unmapped is 1, and the maximum number is 524,288. If this count is not in this range, then return code 4 is given.

This operand is required.

**WORKAREA=**

specifies the address of a real storage area that is used by the macro as a work area. Specify this parameter as the label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the MAPMDISK DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

## Usage Notes

1. The macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. Code the DEFWORKA macro at the end of your program to define any macro work areas that have not yet been defined.
3. Removing a mapping using the REMOVE function changes the data that is visible in the mapped page. However, it does not change the storage key associated with the page.

## Condition Codes and Return Codes

On return from the REMOVE function, register 15 contains one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | REMOVE function status                                                                                                                                                                                                  |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | The mapping has been removed from the specified range of pages.                                                                                                                                                         |
| 4                                          | The page count specified by the PAGECT operand is out of range. No mappings have been removed.                                                                                                                          |
| 8                                          | The ASIT specified by the ASIT operand does not identify either an existing address space that your virtual machine created, or the host-primary address space for your virtual machine. No mappings have been removed. |

| Return Code<br>in Register 15<br>(Decimal) | REMOVE function status                                                                                                                                                                                                                                                                                              |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12                                         | The range of pages to be unmapped includes an unmapped page. Mappings have been removed for all pages up to but not including the first unmapped page in the range. Register 0 contains the address of the page for which the error occurred. This page resides in the address space specified by the ASIT operand. |

If an addressing exception is recognized on the REMOVE function, the operation is terminated. Those pages in the page range identified by the PAGEADDR and PAGECT parameter that are processed before the point of error have mappings removed as usual. Those pages in the page range at or after the point of error remain unchanged.

## MAPMDISK SAVE

### Purpose

The SAVE function initiates an asynchronous operation that causes the contents of changed, mapped pages to be stored on the associated 4K minidisk blocks. This function provides a mechanism to commit changes made to those pages in a predictable fashion.

Your virtual machine must have read-write access to the address space containing the mapped pages.

The pages to be saved are specified in a save-list definition block. The size of the save-list definition block cannot exceed 4096 bytes. A block may be in the form of a list of address ranges or a list of individual pages, but not both. Normally, a given page is specified only once per SAVE request. However, it is not an error for a particular page to be specified multiple times in a single SAVE request, or multiple times in the same save-list definition block.

For each page to be saved by the SAVE request, a check is made to determine if the page has been changed since the last time a store operation (either as a result of the SAVE function, or performed automatically by CP) was performed on the page. If the page has changed, a store operation is initiated to save the contents of the page on the associated 4K minidisk block; unchanged pages are skipped. If a page is changed after the SAVE function is invoked but before completion of the SAVE function is signaled, it is unpredictable whether the changed data is stored as a result of the in-progress SAVE function. If the changed data is not stored, change integrity is maintained so a subsequent SAVE function request will cause the change data to be stored.

The order in which the pages are processed by the SAVE function is unpredictable.

Asynchronous completion of the SAVE operation is indicated by a save-completion external interruption being presented to the virtual machine. Upon the external interruption, a completion code is stored to indicate the success or failure of the SAVE operation. See [Notification of SAVE Completion](#) for details on the save-completion external interruption.

Multiple SAVE functions can be concurrently outstanding; each is distinguished by a user supplied token. The token is supplied on the save-completion external interruption. Uniqueness of the token is not enforced, but if the tokens are not unique your program may have difficulty determining which save operation completed.

### Parameters

#### *label*

is an optional assembler language label on the macro.

**LIST=**

specifies the real address of a save-list-definition block for this request which is in **list form**. Specify this parameter as a label associated with the block in storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the block in storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the block.

The address of the first save-list-definition block must be an address on a doubleword boundary, otherwise a specification exception is recognized. See [Save-List Format](#) for more information.

This parameter is mutually exclusive with BLOCK= and one of them must be specified.

**BLOCK=**

specifies the real address of a save-list-definition block for this request which is in **block form**. Specify this parameter as a label associated with the block in storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the block in storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the block.

The address of the first save-list-definition block must be an address on a doubleword boundary, otherwise a specification exception is recognized. See [Save-List Format](#) for more information.

This parameter is mutually exclusive with LIST= and one of them must be specified.

**ENTCT=**

specifies the real address of a 4-byte field in storage that contains the total count of entries in the save-list definition block. Specify this parameter as the label associated with the field in storage or as the number of a register (in the range of 2-12, inclusive) contains the address of the field in storage. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

The minimum number of entries is one for both forms of the macro. For the **list form** the maximum number of entries is 1018 and for the **block form** the maximum number of entries is 509. If the above counts are out of bounds then a return code of 4 is given.

**WORKAREA=**

specifies the address of a real storage area that is used by the macro as a work area. Specify this parameter as the label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the MAPMDISK DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

**Usage Notes**

1. The macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. When an error completion code is stored on external interruption code X'2603', subcode X'01', the error buffer contains the address of one of the pages for which an error was found. However, because errors may have occurred on pages other than the one identified by the address in the error buffer, and since the SAVE function processes pages in an unpredictable order, when an error completion code is stored on external interruption code X'2603', subcode X'01' it is unpredictable as to what pages have or have not been saved.

3. After an error completion code is received, the following recovery procedure can be used to bypass the error on the failing page (identified by the address in the error buffer) and complete the save process on the remaining pages:
  - a. Move the data in the failing page to some other page which is mapped to some other 4K minidisk block
  - b. Modify the save list to remove the address of the failing page and add the address of the target page from the preceding step
  - c. Reissue the SAVE request.

Pages that were not successfully saved during the first SAVE request are saved by this second SAVE request (unless there are more errors) while pages that were saved by the first request are skipped.

However, the above procedure is not sufficient to eliminate the possibility of future storage-degradation machine checks on the failing page. See Programming Note “3” on page 840 for a procedure to use to eliminate the possibility of future storage-degradation machine checks on the same page.

4. The error buffer must be in writeable storage, otherwise a protection exception is recognized.

**Save-List Format:** The pages to be saved are specified in a save-list definition block. The block contains a header, and a contiguous table of save-list entries. The block must be aligned on a doubleword boundary and cannot exceed 4096 bytes in length. The save-list entries for a particular save-list definition block are either in the format of single pages or ranges of contiguous pages:

- For single pages, the absolute address of each page to be saved is specified by a word in the list.
- For ranges of contiguous pages, each range is specified by a pair of words in the list, the first word of a pair specifies the absolute address of the start of the range and the second word of a pair specifies the number of contiguous pages to be saved.

The two types of entries cannot be mixed within a save-list definition block and the type being used for a particular block is specified on the MAPMDISK macro.

**Note:** Field names used in the following descriptions are for reference only. You may copy these names, or use any other names, in your own code.

A save-list definition has the following format:

|    |                          |          |
|----|--------------------------|----------|
| 0  | ASIT                     |          |
| 8  | TOKEN                    | Reserved |
| 10 | Reserved                 | ERRBA    |
| 18 | ENTR1                    |          |
| nn | Save-list entries (SLEs) |          |

#### ASIT

Bytes 0-7 of the save-list definition block contains the ASIT identifying the address space in which pages will be saved. If this ASIT is not associated with an address space your virtual machine created, or the host-primary address space for your virtual machine, then return code 8 is given.

#### TOKEN

Bytes 8-11 of the save-list definition block contains a 32 bit token to be associated with this save request. It is the program's responsibility to maintain uniqueness to distinguish different SAVE functions. The token is returned with external interrupt code X'2603', subcode X'01'.

#### Reserved

Bytes 12-19 of the save-list definition block are reserved for future use and should contain binary zeros.

#### ERRBA

Bytes 20-23 of the save-list definition block contain the 31-bit absolute address of an 8-byte error buffer within the host-primary address space. This field must specify a nonzero address on a

doubleword boundary, otherwise a specification exception is recognized. The error buffer is always in the host-primary address space, even when the virtual machine is in the access-register mode.

Information is provided in the error buffer when the SAVE operation completes with certain errors. See [Notification of SAVE Completion](#) for details.

### ENTR1

Starting at byte 24 of the save-list definition block is a contiguous table of save-list entries. Each save-list entry is either a:

- 4-byte word that contains the 31-bit absolute page address of an individual page to be saved.
- 8-bytes that consists of two words, the first specifying the 31-bit absolute page address of the start of a range of pages and the second specifying the count of contiguous pages to be saved.

Each entry in a save-list definition block must be of the same format, either a 4-byte individual page address or an 8-byte page range specification. The two formats cannot be mixed within the same save-list definition block. The type of format being used for a save-list entry is specified on the MAPMDISK macro.

When page ranges are specified, the total number of pages contained within the supplied ranges must be at least 1 and must not exceed 524,288. If the total number of pages contained within the specified ranges is not between these values, then return code 16 is given.

The range of pages to be mapped, from the start address to the start address+(count-1)\*4096, must be contained within the bounds of the address space designated by the ASIT in the ASIT field, otherwise an addressing exception is recognized. This also applies to the individual pages that are found outside of the same bounds.

The different structures for each type of save-list definition block follows:

Single page entries  
save-list definition  
block  
**List form**

|          |          |
|----------|----------|
| ASIT     |          |
| TOKEN    | 00000000 |
| 00000000 | ERRBA    |
| Page     | Page     |
| Page     | Page     |
| .....    |          |
| .....    |          |
| .....    |          |
| Page     | Page     |

Range of page entries  
save-list definition  
block  
**Block form**

|          |          |
|----------|----------|
| ASIT     |          |
| TOKEN    | 00000000 |
| 00000000 | ERRBA    |
| Start1   | Count1   |
| Start2   | Count2   |
| .....    |          |
| .....    |          |
| .....    |          |
| StartN   | CountN   |

## Condition Codes and Return Codes

On return from the SAVE function, register 15 contains one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | SAVE function status                                                                                                                                                                         |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | The save request has been successfully initiated. When the asynchronous request completes, the completion status will be reflected through a external interrupt code X'2603', subcode X'01'. |
| 4                                          | The ENTCT count is either zero or above a maximum of 1018 or 509 for a list of individual or range of pages, respectively. Save processing was not performed on any page.                    |

| Return Code<br>in Register 15<br>(Decimal) | SAVE function status                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8                                          | The ASIT specified by the ASIT operand does not identify either an existing address space that your virtual machine created, or your virtual machine's host-primary address space. Save processing was not performed on any page.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 16                                         | A MAPMDISK SAVE function was invoked specifying a save-list definition block in range form, and a count of 0 consecutive pages was detected. A count was greater than 524,288. The total count of all count fields is greater than 524,288. Save processing was not performed on any page. Register 0 contains the address within the save-list definition block containing the invalid count. For the case where the total count is greater register 0 contains the address of the entry that caused the overflow. In both cases in the access-register mode, access register 0 contains the ALET specifying the address space in which the save-list definition block resides. |

If an addressing exception is recognized on the SAVE function, the operation is terminated. None of the pages have been processed.

## Completion Conditions

**Notification of SAVE Completion:** When a MAPMDISK SAVE operation has completed, the virtual machine that initiated the SAVE operation is notified of the completion by a save-completion external interruption. The save-completion interruption is indicated by an external interruption code of X'2603' and a subcode of X'01'; the subcode of X'2603' is stored at location 132 on the external interruption.

The save-completion interruption is a floating interruption condition that is presented to any virtual CPU in the configuration that is enabled for the condition. The external interruption mask (bit 7 of the PSW) and subclass-mask bit 22 of control register 0 determine whether a virtual CPU is enabled for external interruption code X'2603'.

When the save-completion external interruption is presented, data is stored at real storage locations 128-133 as follows:

### Location

#### Data stored on interruption

#### 128-131

The 32 bit token specified for the SAVE operation.

#### 132

External-interruption X'2603' subcode. A value of X'01' denotes a save-completion notification.

#### 133

Bit 0 indicates whether the program-supplied error buffer contains valid data. If bit 0 is one, then the error buffer does not contain valid data. This could be due to the page being read-only or the error-buffer address being no longer addressable. If bit 0 is zero, then for completion codes X'04', through X'0C', the program-provided error buffer contains additional data related to the error.

Bits 1-7 are a completion code indicating the completion status of the MAPMDISK SAVE operation, as follows:

### Code

#### Completion status

#### X'00'

All pages were saved without errors.

#### X'04'

An attempt was made to save at least one unmapped page. All mapped pages have been saved without error. If bit 0 of byte 133 is zero, the address of one of the unmapped pages has been stored in bytes 4-7 of the program-provided error buffer.

**X'08'**

The address space containing the pages to be saved no longer exists. None of the pages have been saved. If bit 0 of byte 133 is zero, the ASIT identifying the address spaces has been stored in bytes 0-7 of the program-provided error buffer.

**X'0C'**

Paging I/O errors were detected while saving one or more pages. It is unpredictable as to whether any pages were saved successfully. If bit 0 of byte 133 is zero, the address of one of the pages for which an error was found has been stored in bytes 4-7 of the program-provided error buffer.

If both X'04' and X'0C' conditions are detected during save processing, completion code X'0C' is presented on the save-completion notification.

## PFAULT Macro -- Page-Fault Handshaking Services

---

CP manages the address spaces provided to virtual machines. This includes the host primary address space (base space) and host data spaces created by XC-mode virtual machines (ESA/XC and z/XC architecture). While managing real machine storage, CP determines what portions of virtual machine storage are allowed to be resident at any given time. If a virtual machine references a portion of an address space that is not resident in real storage, CP receives a page-fault indication. CP's usual course of action is to suspend the operation of the virtual machine, perform the paging operation, and finally resume execution of the virtual machine. The page fault and its resolution by CP are transparent to the virtual machine, except for the time delay during which the virtual machine was suspended.

It is possible that for some applications, such as servers, the delay due to synchronous page-fault resolution can be a problem. If the server implements some form of multitasking to maximize its throughput, it would want to use the delay in executing one task, for instance to wait for a host-paging I/O operation to complete, to work on another. It can do this by using support for asynchronous page-fault handling.

When a page fault occurs during a storage reference and asynchronous resolution is enabled, CP initiates the paging operation and then immediately resumes execution of the virtual machine, presenting a page-fault initiation interruption to the virtual machine as a signal that a page fault has occurred. The multitasking server in the virtual machine can then suspend its current task (the one that just encountered the page fault) and select some other task to run. The new task runs in parallel with the CP paging operation to resolve the original task's page fault.

Upon completion of the paging operation, CP presents a page-fault completion interrupt to the virtual machine. This interruption informs the server that the task that generated the page fault can now be resumed since the page it requires is now available in storage.

To use asynchronous page-fault handling, the application must do some preparation and some additional processing using CP and possibly some CMS services. To activate and be able to use page-fault notification, the application must:

1. Establish an external interrupt handler for the page fault initiation and completion signals.
2. Issue the PFAULT macro to define a TOKEN address to CP.<sup>5</sup> This TOKEN address is the location of an area in storage that the server maintains as the task ID token of the current (running) task. The server would typically set this word to the address of the task control block for the current task. When a page fault occurs, CP obtains the token for the current task from this location and supplies it in the page-fault initiation and completion notifications for the page fault just encountered. Because this token is usually the address of the task control block, the server can process the page-fault completion interrupt without having to search for the correct task control block.
3. Call the ADD function of the ALSERV macro with the FAULTS=ASYNCH operand when establishing addressability to the VM data spaces address space. Asynchronous page-fault handling is enabled independently for each entry in a virtual machine's access list. Thus, the server can use asynchronous page-fault resolution for some types of references, but not for others.<sup>6</sup>

Asynchronous page-fault handling is available for references that occur in AR mode for nonprimary address spaces and in primary-space mode or AR mode to the primary space. Asynchronous page-fault handling is typically used only for page faults that require CP to perform I/O operations to resolve. If I/O operations are not required, then the time required to perform the page fault is so short that no significant benefit can be derived by using asynchronous handling considering the overhead involved.

---

<sup>5</sup> In some limited circumstances it may be necessary to invoke a DIAGNOSE X'258' directly rather than with the preferred PFAULT macro interface.

<sup>6</sup> The primary address space does not require any additional enablement.

## Purpose

Use the PFAULT macro to enable or cancel page-fault handshaking for a virtual CPU. Page-fault handshaking allows a virtual CPU to continue execution during the time CP is resolving a host page fault. Page-fault handshaking is particularly useful for multitasking applications that can normally find some other task to run during the time that a task must be suspended while CP resolves a host page fault for it.

The following functions can be invoked with this macro:

### CANCEL

Cancel page-fault handshaking for a virtual CPU

### DECLARE

Define the macro work area

### TOKEN

Activate page-fault handshaking for a virtual CPU and establish the location of the page-fault handshaking token. When the VERSION=2 parameter is specified with the TOKEN function, host-primary address spaces are also supported.

## Usage Notes

If the VERSION=2 parameter is **not** specified with PFAULT TOKEN, then your virtual machine must be an XC virtual machine to successfully use this macro. If your virtual machine is an ESA virtual machine, then a specification exception is recognized unless VERSION=2 is specified. If the VERSION=2 parameter is specified with PFAULT TOKEN, then your virtual machine can be in any machine mode and architecture mode supported by CP.

**Page-Fault Handshaking:** If the VERSION=2 parameter is **not** specified with PFAULT TOKEN, then page-fault handshaking is applied to selected storage references made when in the access-register mode. If the VERSION=2 parameter is specified with PFAULT TOKEN, then handshaking is applied in all modes supported by CP, but storage references made while in the access-register mode still require FAULTS=ASYNCH on the appropriate ALSERV ADD macro. The handshaking process consists of the presentation of a pair of page-fault handshaking external interruptions to the virtual machine: the first interruption provides a page-fault initiation signal, and the second provides a page-fault completion signal.

Before page-fault handshaking actions can be performed for a virtual CPU, handshaking must be enabled for the virtual CPU through the TOKEN function of this macro. If the VERSION=2 parameter is **not** specified, the TOKEN function specifies the (guest) real address of a four byte area in the host-primary address space (the token location) that contains the page-fault handshaking token. If the VERSION=2 parameter is specified, the TOKEN function specifies the guest real address of an eight byte area if ARCHITECTURE=z is specified or a four byte area if ARCHITECTURE=ESA is specified. The current contents of this location (the current token) are provided in the page-fault initiation signal that indicates the start of a page-fault handshaking action, and the same value is provided in the corresponding page-fault completion signal.

The token is intended to identify the virtual machine task associated with the page fault in order to suspend that task upon page-fault initiation and to make that task eligible to run upon page-fault completion. Management of the token, including assigning token values, maintaining the appropriate relationships between the token and the current virtual machine task, and so forth is the responsibility of the program running in the virtual machine. It is expected that the token location is fixed for a virtual CPU. That is, the program should change the contents of the token location, rather than the address of the token location, whenever switching tasks to be executed by the virtual CPU.

**Programming Note:** The page-fault handshaking token is 32 bits long, or 64 bits long if the VERSION=2 with ARCHITECTURE=z parameters are specified, so that the program can use the address of the task control block as the handshaking token for the task. Assigning the token in this way allows the program to suspend and resume the task without the need for searches to find the task indicated by a page-fault initiation or page-fault completion signal.

**Conditions necessary for handshaking:** Page-fault handshaking is usually applied to a storage reference that will encounter a significant delay due to a page-fault condition, if all of the following conditions are met:

- The virtual CPU making the storage reference is enabled for page-fault handshaking external interruptions. (See [Notification of Page-Fault Handshaking](#).)
- The virtual CPU has activated page-fault handshaking. A virtual CPU activates page-fault handshaking by using the TOKEN function of this macro.
- If the VERSION=2 parameter was **not** specified with PFAULT TOKEN, then the virtual CPU is in the access-register mode, and the storage reference is through an access-list entry (ALE) that is eligible for page-fault handshaking. An ALE is made eligible for page-fault handshaking by specifying FAULTS=ASYNCH on the ALSERV ADD operation that establishes the ALE.

When the VERSION=2 parameter was specified, if the virtual machine is in XC mode and the virtual CPU is in access-register mode, then access-register-specified storage references are eligible only if the corresponding ALE has been made eligible for page-fault handshaking using FAULTS=ASYNCH on the ALSERV ADD macro. Host-primary storage references require no additional authorization.

- If VERSION=2, the bits that are on in the selection mask must be in the same state in the PSW for the virtual CPU as they are in the compare mask.

If any of these conditions are not met, then page-fault handshaking is not applied to the storage reference. The virtual CPU is suspended by CP until resolution of the page-fault condition is completed. When the resolution of the page-fault condition is completed, execution of the virtual CPU is resumed without any indication of the delay.

Under unusual circumstances, page-fault handshaking may be bypassed for a storage reference even though all of the above conditions are met.

**Handshaking process:** When a virtual CPU encounters a host page fault for which page-fault handshaking is to be applied, the following occurs:

1. The instruction that encountered the host page fault is nullified.
2. CP fetches four bytes, or eight bytes if VERSION=2 is specified with ARCHITECTURE=z, from storage at the token location in the host-primary address space.
3. CP presents a page-fault initiation signal to the virtual machine through a page-fault handshaking external interruption. The page-fault handshaking token fetched from the token location is provided in this initiation signal.
4. The page-fault initiation signal is presented to the virtual CPU that encountered the page-fault condition.
5. Normally, the virtual machine responds to the initiation signal by suspending the currently running task and switching to some other task.

Subsequently, when CP finishes resolution of the page-fault condition, it presents a page-fault completion signal to the virtual machine through a page-fault handshaking external interruption. The page-fault handshaking token provided in this completion signal is the same as that provided in the corresponding page-fault initiation signal for this host page fault. The page-fault completion signal may be presented to any virtual CPU in the configuration that is enabled for the interruption, even those which have not activated page-fault handshaking (that is, did not execute the TOKEN function of this macro).

Normally, the virtual machine responds to the completion signal by enabling the task identified by the page-fault handshaking token to run again.

**Notification of page-fault handshaking:** The page-fault initiation and page-fault completion signals described above are provided through page-fault handshaking external interruptions. A page-fault handshaking interruption is indicated by an external interruption code of X'2603' and a subcode of X'02' or X'06'; the subcode of X'2603' is stored at location 132 on the external interruption.

When the page-fault handshaking interruption is for a page-fault initiation signal, the interruption is presented to the virtual CPU encountering the host page fault condition. When the page-fault handshaking interruption is for a page-fault completion signal, it is a floating interruption condition

that is presented to any virtual CPU in the configuration that is enabled for the condition. The external interruption mask (bit 7 of the PSW) and subclass mask bit 22 of control register 0 determine whether a virtual CPU is enabled for external interruption code X'2603' (for either initiation or completion signals).

When the page-fault handshaking external interruption is presented and either the VERSION=2 parameter of PFAULT TOKEN was not in effect, or the VERSION=2 and ARCHITECTURE=ESA parameters of PFAULT TOKEN were specified, then data is stored at real storage locations 128–133 as follows:

#### Location

##### Data stored on interruption

#### 128-131

The 32-bit page-fault handshaking token retrieved from the token location at the time that page-fault handshaking action was initiated for the page fault. The same value is provided in both the page-fault initiation and page-fault completion signals for a given instance of page-fault handshaking action.

#### 132

External interruption X'2603' subcode. A value of X'02' denotes a page-fault handshaking external interruption.

#### 133

Bit 0 indicates whether the interruption is for a page-fault initiation or a page-fault completion signal. If bit 0 is zero, then the interruption is for a page-fault initiation signal. If bit 0 is one, then the interruption is for a page-fault completion signal.

The contents of bits 1-7 are unpredictable.

When the page-fault handshaking external interruption is presented and the VERSION=2 and ARCHITECTURE=z parameters of PFAULT TOKEN were in effect, then data is stored at real storage locations as follows:

#### Location

##### Data stored on interruption

#### 4536-4543

The 64-bit page-fault handshaking token retrieved from the token area at the time that page-fault handshaking action was initiated for the page fault. The same value is provided in both the page-fault initiation and page-fault completion interruptions for a given page fault.

#### 132

External interruption X'2603' subcode. In z/Architecture mode, a value of X'06' denotes a page-fault handshaking external interruption for the VERSION=2 parameter of PFAULT TOKEN.

#### 133

Bit 0 indicates whether the interruption is for a page-fault initiation or page-fault completion signal. If bit 0 is zero, then the interruption is for a page-fault initiation signal. If bit 0 is one, then the interruption is for a page-fault completion signal.

The contents of bits 1-7 are unpredictable.

## Program Exceptions

The PFAULT macro may result in one of the following program exceptions:

| Problem Encountered                                                         | Cause                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access exception (See page <a href="#">“Access Exceptions” on page 8.</a> ) | <p>An error occurred trying to</p> <ul style="list-style-type: none"> <li>• Fetch or store the macro parameter list (in macro work area)</li> <li>• Fetch a macro operand</li> <li>• Fetch from the token location specified by the ADDR operand (TOKEN function); key-controlled protection does not apply</li> </ul> |

| Problem Encountered     | Cause                                                                                                                                                                                                                                                                                                      |

| Specification exception | <ul style="list-style-type: none"><li>• If the VERSION=2 parameter of PFAULT TOKEN was not in effect, your virtual machine is not an XC virtual machine.</li><li>• The macro work area is not aligned on a doubleword boundary.</li><li>• The parameter list generated by the macro is in error.</li></ul> |

## PFAULT CANCEL

### Purpose

This function cancels page-fault handshaking for the virtual CPU that invokes the function.

The CANCEL function purges all in-progress page-fault handshaking actions that were initiated as a result of page faults encountered by the invoking virtual CPU. A page-fault handshaking action is considered to be in-progress if the page-fault initiation signal has been made pending, but the corresponding page-fault completion signal has not yet been made pending. If the page-fault completion signal has been made pending on the invoking or other virtual CPU, it remains pending.

### Parameters

#### *label*

is an optional assembler language label on the macro.

#### **WORKAREA=**

specifies the address of a real storage area that is used by the macro as a work area. Specify this operand as the label associated with the storage area, or as the number of a register (in the range 2-12 inclusive) containing the address of the storage area. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the PFAULT DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding the use of this operand.

This operand is optional; you can simplify coding of your program by omitting this operand in order to defer the definition of the macro work area to the DEFWORKA macro.

### Usage Notes

1. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. In a multiple virtual CPU environment, the CANCEL function cancels page-fault handshaking only for the virtual CPU on which it is invoked. Other virtual CPUs that have activated page-fault handshaking continue to be eligible for page-fault handshaking.

### Condition Codes and Return Codes

On return from the CANCEL function, register 15 contains one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | CANCEL function status                                                                             |
|--------------------------------------------|----------------------------------------------------------------------------------------------------|
| 0                                          | Page-fault handshaking is cancelled for the virtual CPU.                                           |
| 4                                          | Page-fault handshaking has not been activated for the virtual CPU or has been previously canceled. |

## PFAULT DECLARE

---

### Purpose

This function defines the storage required for the WORKAREA operand of the PFAULT macro. You must code this function only if you need to define the macro work area outside of the program requiring it. To simplify using the PFAULT macro, do not code the PFAULT DECLARE function and omit the WORKAREA operand on the executable functions of the PFAULT macro. This allows the PFAULT macro to control and define the necessary data expansion through the DEFWORKA macro coded at the end of your program. See [“Coding CP Macros” on page 807](#) for additional details.

### Parameters

#### *label*

is an optional assembler language label on the macro to be assigned to the defined storage.

### Usage Notes

1. The DECLARE function does not generate any executable code. You may code it within a dummy section (DSECT) or a control section (CSECT).
2. Although a label is not required on the invocation of the DECLARE function, it may be necessary to identify the work area on the WORKAREA operand.

## PFAULT TOKEN

### Purpose

This function activates page-fault handshaking for the virtual CPU that invokes the function and establishes the location of the page-fault handshaking token for that virtual CPU. It can also establish the selection and compare masks for that virtual CPU.

Once activated, page-fault handshaking remains in effect with the same page-fault handshaking token location until handshaking is cancelled using one of the following methods:

- The PFAULT CANCEL macro is issued on the virtual CPU.
- A CPU-reset operation is performed on the virtual CPU.
- A SIGP Set-Architecture instruction is performed by the virtual configuration.

### Parameters

#### *label*

is an optional assembler language label on the macro.

#### **ADDR=**

Specifies the real address where the token is located in the host-primary address space. Specify this operand as a label associated with where the token is located in real storage, or as the number of a register (in the range 2-12, inclusive) containing the real address of the token's location in real storage.

The token is a 4-byte fullword aligned field or an 8-byte doubleword aligned field when the VERSION=2 and ARCHITECTURE=z parameters are specified.

Generation of the effective address of the token location, including address wraparound, is performed at the time of the invocation of this function. The resulting effective address is stored in the parameter list and used for all subsequent page-fault handshaking actions. That is, the addressing mode in effect at the time of a page-fault initiation or page-fault completion signal has no effect on the addressing of the token location.

This operand is required.

**VERSION=2**

Enables page-fault handshaking for both 31-bit and 64-bit guests, for data spaces and for primary address space page faults.

**ARCHITECTURE=**

Specifies the architecture to be used by the macro expansion. When ARCHITECTURE=z is specified, z/Architecture instructions and 64-bit registers are used in the macro expansion. When ARCHITECTURE=ESA is specified, ESA/390 instructions and 32-bit registers are used in the macro expansion. This parameter also determines the length and alignment of the token area.

**Note:** When specifying the 'z' operand, an upper or lower case character can be used.

**SELECTMASK=**

Specifies the real address of the 64-bit selection mask. Specify this operand as a label associated with the 8-byte mask in real storage, or as the number of a register (in the range 2-12, inclusive) containing the real address of the location of the selection mask in real storage.

At the time a page-fault occurs that is eligible for page-fault handshaking, if a bit in the selection mask is zero, it causes the corresponding bit in the virtual CPU PSW at the time of the page fault to be ignored. If a bit in the selection mask is one, it causes the corresponding bit in that PSW to be selected for comparison against the corresponding bit in the compare mask.

In z/Architecture mode, all 64 bits of the mask are significant. When not in z/Architecture mode, only bits 0-32 are significant.

Generation of the effective address of the location of the selection mask, including address wraparound, is performed at the time of the invocation of this macro. The resulting effective address is used to copy an 8-byte field to the parameter area.

If this operand is not specified, a mask of all zeros is the default.

**COMPAREMASK=**

Specifies the real address of the 64-bit compare mask. Specify this operand as a label associated with the 8-byte mask in real storage, or as the number of a register (in the range 2-12, inclusive) containing the real address of the location of the compare mask in real storage.

At the time a page-fault occurs that is eligible for page-fault handshaking, if a bit in the selection mask is zero, it causes the corresponding bit in the virtual CPU PSW at the time of the page fault to be ignored. If a bit in the selection mask is one, it causes the corresponding bit in that PSW to be selected for comparison against the corresponding bit in this compare mask.

Generation of the effective address of the location of the compare mask, including address wraparound, is performed at the time of the invocation of this macro. The resulting effective address is used to copy an 8-byte field to the parameter area.

If this operand is not specified, a mask of all zeros is the default.

**WORKAREA=**

specifies the address of a real storage area that is used by the macro as a work area. Specify this operand as the label associated with the storage area, or as the number of a register (in the range 2-12 inclusive) containing the address of the storage area. For a virtual machine in access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the PFAULT DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding the use of this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

Figure 98. Page Fault Processing when VERSION=2

## Usage Notes

1. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. CP does not enforce any restriction on the contents of the page-fault handshaking token. Uniqueness of the page-fault handshaking token and maintenance of the established token location (that is, the token's relationship to a virtual machine task) is the responsibility of the virtual machine application.
3. The location of the page-fault handshaking token for a virtual CPU cannot be changed without first cancelling page-fault handshaking for the virtual CPU. To cancel page-fault handshaking for a virtual CPU, invoke the CANCEL function of this macro. A CPU reset operation also cancels page-fault handshaking.
4. Page-fault handshaking is most effective when the page containing the page-fault handshaking token is resident in host storage. Defining the token within (guest) real page zero achieves this effect because real page zero for a virtual CPU is always resident when the virtual CPU is running. Alternatively, the token can be defined outside of real page zero; the frequent references that are made to that page to maintain the handshaking token may be sufficient to keep the page resident in host storage. However, if the token is defined outside of real page zero, you may want to consider locking that page in host storage to guarantee residency.

If, at the time of a handshaking-eligible host page-fault, the page containing the page-fault handshaking token is not resident in host storage then it is unpredictable whether page-fault handshaking is applied to the page fault. Even if it is applied, the virtual CPU is delayed until CP completes page-in of the page containing the token or of the faulting page, whichever occurs sooner.

5. The PFAULT macro activates page-fault handshaking and establishes the location of a page-fault handshaking token only for the virtual CPU on which the PFAULT macro is invoked. In a multiple virtual CPU environment, activation of page-fault handshaking requires invocation of the PFAULT macro by each virtual CPU for which handshaking is desired.

Normally, each virtual CPU has a different absolute storage location for the page-fault handshaking token. Because the address of the page-fault handshaking token is a (guest) real address, this can

be achieved by defining the token at the same address within real page zero for each virtual CPU. The prefixing process transforms the real address into different (guest) absolute addresses for each virtual CPU.

6. If page fault handshaking is in effect and the virtual configuration executes a SIGP Set-Architecture instruction, page-fault handshaking is reset.
  7. Registers 2-12 inclusive may be used for the ADDR, SELECTMASK, and COMPAREMASK operands, but the value specified for ADDR must be unique. The mask parameters may specify the same register.
  8. If a bit in the compare mask is set to 1, the corresponding bit in the selection mask must also be set to 1, or a specification exception is returned.
  9. If the selection mask and the compare mask both have a 1 in bit position 15, then the program determines that the PSW must be in the problem state for an initial interruption to be presented. If the selection mask and the compare mask are both all zeros, then all page faults pass the selection test.
  10. The ARCHITECTURE parameter only indicates how the macro expands. The mode of the virtual CPU at the time the macro executes determines the size of the token area and the location in the prefix area where the interruption parameter is stored. This must match the ARCHITECTURE parameter setting or a specification exception is returned.
  11. If the mode of the virtual CPU is z/Architecture or z/XC mode, you must specify ARCHITECTURE=z if you specify VERSION=2. The token area is 8 bytes and the interruption parameter is 8 bytes, which are stored in locations 4536-4543; the subcode is X'06.'
- If the mode of the virtual CPU is ESA/390 or ESA/XC mode, you must specify ARCHITECTURE=ESA if you specify VERSION=2. In ESA/390 or ESA/XC mode, the token area is 4 bytes and the interruption parameter is 4 bytes. The information is stored in locations 128-131; the subcode is X'02.'
12. If the token area is not accessible, a program check is presented to the virtual CPU.
  13. Registers 0, 1, 14 and 15 are changed by this macro. When ARCHITECTURE=z is specified, all 64 bits of these registers may be affected.

## Condition Codes and Return Codes

On return from the TOKEN function, register 15 contains one of the following 32 bit return codes:

| Return Code<br>in Register 15<br>(Decimal) | TOKEN function status                                                                                                                      |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | Page-fault handshaking is activated for the virtual CPU.                                                                                   |
| 8                                          | Page-fault handshaking has already been activated for the virtual CPU. The established page-fault handshaking token location is unchanged. |

## REFPAGE — Page Reference Services

---

### Purpose

Use the REFPAGE macro to temporarily identify an ordered set of pages that your program will reference over a relatively short amount of time. Such an ordered set of pages is known as a page-reference pattern. Identifying your program's short-term page-reference pattern allows CP to perform some pre-fetching of pages, that is, retrieving pages into processor storage in advance of your program's need for them. This reduces the number of page faults your program encounters, and thus improves the performance of the system.

CP performs pre-fetching by using the page-reference pattern information to form logical blocks of pages. These logical blocks are sets of pages that your program will require at about the same time. When your program encounters a page fault for the first of the pages in a logical block, CP may initiate page-in of the other pages in the logical block as well. However, the logical blocks formed from the page-reference pattern are temporary. Once pages identified in a page-reference pattern have been brought into processor storage for referencing, the logical blocking created from the page-reference pattern is lost.

The following page-reference services can be invoked using the REFPAGE macro:

#### DECLARE

Define the macro work area.

#### INFORMB

Identify a regular page-reference pattern using the ***block form***.

#### INFORML

Identify a complex page-reference pattern using the ***list form***.

### Usage Notes

To successfully use any of the functions of this macro, you must be an XC virtual machine. If not, an specification exception is recognized for an ESA virtual machine.

**Specifying Page-Reference Patterns:** The REFPAGE macro provides two ways to indicate your program's page-reference pattern. They are the ***block form*** and the ***list form***.

***Block form*** is used when pages will be referenced in either ascending or descending address order and there is a regular pattern in the addresses of the pages to be referenced. The REFPAGE macro uses the concept of groups, subgroups, spans and skips to define such a regular page-reference pattern. They are defined as:

#### Group

is a page-reference pattern that consists of one or more sets of pages called *subgroups*.

#### Subgroup

is the portion of the block-form reference pattern that is treated as a single logical block when retrieving pages into processor storage. Depending on the storage demand on the z/VM system, page-in of all of the pages in the subgroup into processor storage may be initiated at the time of the first reference to a page in the subgroup.

A subgroup consists of one or more sets of contiguous pages to be referenced, called *spans*, possibly separated by sets of contiguous pages that will not be referenced, called *skips*.

#### Span

is a set of contiguous pages that will be referenced in sequential order.

#### Skip

is a set of contiguous pages, between spans, that will not be referenced.

See [Examples](#) for various examples of block-form page-reference patterns.

**List form** is the other way to indicate your program's page-reference pattern. It is used when there is no regular pattern in the addresses of the pages your program will reference but nonetheless the set of pages about to be referenced is known in advance. For example, your program may soon reference a set of pages determined from a lookup in an index. This set of references will not occur in strictly ascending or descending page address order, nor is there some regular pattern that relates one page in the pattern to the next in the pattern. An example of a non-regular reference pattern that might result is:

| Reference | Page address | Reference | Page address |
|-----------|--------------|-----------|--------------|
| 1st       | 00020000     | 6th       | 02BC3000     |
| 2nd       | 0000E000     | 7th       | 00021000     |
| 3rd       | 00DE2000     | 8th       | 00022000     |
| 4th       | 01E00000     | 9th       | 00E00000     |
| 5th       | 0000A000     | 10th      | 00023000     |

The list form of the REFPAGE macro allows the identification of this complex reference pattern by specifying the page addresses for each of the pages to be referenced, in the order in which the references will be made.

Both forms of the REFPAGE macro construct logical blocks of pages. These blocks are constructed of pages that are currently paged-out (reside on paging DASD, not in processor storage) and can span 1MB segment boundaries, but not address space boundaries. Logical blocks allow CP to bring a whole or partial block into processor storage when the virtual machine references a page in the block. However, it does not guarantee any pre-paging activity on behalf of the virtual machine. Pre-paging is dependent on system resource availability.

## Program Exceptions

The REFPAGE macro may result in one of the following program exceptions:

| Problem Encountered                                                        | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access exception (See page <a href="#">“Access Exceptions”</a> on page 8.) | <p>An error occurred trying to</p> <ul style="list-style-type: none"> <li>• Fetch or store the macro parameter list (in macro work area)</li> <li>• Fetch a macro operand</li> <li>• Fetch the page-reference list (INFORML function)</li> <li>• Access (as if a fetch) a page in a block-form reference pattern (INFORMB function); key-controlled protection does not apply; access-exception conditions other than addressing are reported as return codes</li> <li>• Access (as if a fetch) a page specified in the page-reference list (INFORML function); key-controlled protection does not apply; access-exception conditions other than addressing are reported as return codes</li> </ul> |
| Specification exception                                                    | <ul style="list-style-type: none"> <li>• Your virtual machine is an ESA virtual machine.</li> <li>• The macro work area is not aligned on a doubleword boundary.</li> <li>• The parameter list generated by the macro is in error.</li> <li>• The page-reference list is not aligned on a word boundary.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                 |

## REFPAGE DECLARE

---

### Purpose

This function defines the storage required for the WORKAREA operand of the REFPAGE macro. You must code this function only if you need to define the macro work area outside of the program requiring it. To simplify using the REFPAGE macro, do not code the REFPAGE DECLARE function and omit the WORKAREA operand on the executable functions of the REFPAGE macro. This allows the REFPAGE macro to control and define the necessary data expansion through the DEFWORKA macro coded at the end of your program. See [“Coding CP Macros” on page 807](#) for additional details.

### Parameters

#### *label*

is an optional assembler language label on the macro to be assigned to the defined storage.

### Usage Notes

1. The DECLARE function does not generate any executable code. You may code it within a dummy section (DSECT) or a control section (CSECT).
2. Although a label is not required on the invocation of the DECLARE function, it may be necessary to identify the work area on the WORKAREA operand.

## REFPAGE INFORMB

### Purpose

The **INFORMB** function identifies an ordered reference pattern in which pages will be referenced in either strictly ascending or descending address sequence and the pages to be referenced form a repeating pattern or are contiguous to each other.

### Parameters

#### *label*

is an optional assembler language label on the macro.

#### **ALET=**

specifies the real address of a 4-byte field in storage that contains the access-list-entry-token (ALET) identifying the address space for which the page-reference pattern is being defined. Specify this parameter as a label associated with the field, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

The ALET contained in the field must designate a private address space that your virtual machine owns, otherwise return code 8 is given. This ALET is always used to identify the target address space; that is, this ALET is used even when the virtual machine is in the primary-space mode.

This operand is required.

#### **ADDR=**

specifies the real address of a 4-byte field in storage that contains the 31-bit starting address in the page-reference pattern. Specify this parameter as a label associated with the field, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

The starting address is used as the lowest address in the page-reference pattern when the DIRECTION operand indicates *ascending* (the default), or is the highest address in the page-reference pattern when the DIRECTION operand indicates *descending*.

This operand is required.

#### **DIRECTION=**

specifies the real address of a 1-byte field in storage that contains an indication of the direction of the page-reference pattern. Specify this parameter as a label associated with the field, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

A value of X'01' (positive one, binary) in the field indicates an *ascending* page-reference pattern while a value of X'FF' (negative one, binary) indicates a *descending* page-reference pattern. When an ascending page-reference pattern is indicated, the starting address specified by the ADDR operand is the lowest address of the page-reference pattern. When a descending page-reference pattern is indicated, the starting address specified by the ADDR operand is the highest address of the page-reference pattern.

There is no validity checking for values other than X'01' and X'FF' in the field. Results are unpredictable if an invalid value is specified.

This operand is optional; the default is an ascending page-reference pattern.

#### **GROUP=**

specifies the real address of a 4-byte field in storage that contains the number of sub-groups in the page-reference pattern. Each subgroup constitutes a logical block of pages that is brought into processor storage as a unit. Specify this parameter as a label associated with the 4-byte field, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

The default and minimum value for this parameter is 1 and the maximum is 262,144. If the value is not within this range, then return code 20 is given.

**Note:** If GROUP operand is 1 or omitted then there will be only one logical block of pages formed. When referencing a large number of pages, there may be places in the page-reference pattern that may have long periods of computation before continuing to referencing the remainder. In these cases, a value greater than 1 should be used to allow breaking the page-reference pattern into subgroups. This allows only those pages in the subgroup that are referenced to be brought into processor storage.

This operand is optional; the default value is 1.

#### **SUBGROUP=**

specifies the real address of a 4-byte field in storage that contains the number of spans contained in each subgroup of the page-reference pattern. Specify this parameter as a label associated with the field, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

A subgroup is a logical block of pages. Subject to the storage demands on the z/VM system, CP attempts to bring all of the pages in a subgroup into processor storage when the first page in the subgroup is referenced.

The default and minimum value allowed for SUBGROUP is 1 and the maximum is 262,144. If the value is not within this range, then return code 20 is given.

If SUBGROUP operand is omitted or 1 then the SPAN operand specifies the subgroup size if the GROUP operand is greater than 1.

This operand is optional; the default value is 1.

**SPAN=**

specifies the real address of a 4-byte field in storage that contains the number of contiguous pages that will be referenced sequentially. Specify this parameter as a label associated with the field, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

The default and minimum value allowed for SPAN is 1 and the maximum is 262,144. If the value is not within this range, then return code 20 is given.

**Note:** If the operands SPAN and SUBGROUP are either omitted or 1, then there will not be any blocking of pages.

This operand is optional; the default value is 1.

**SKIP=**

specifies the real address of a 4-byte field in storage that contains the number of pages that will be skipped from the last page of a given span to the first page of the next span. Sequences of skipped pages are not brought into processor storage when referencing the subgroup. Specify this parameter as a label associated with the 4-byte field, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

The default and minimum value for SKIP is 0 and the maximum is 131,072. If the value is not in this range, then return code 20 is given.

**Note:** If SKIP is zero then all pages specified for keywords SPAN and SUBGROUP are contiguous.

This operand is optional; the default value is 0.

**WORKAREA=**

specifies the real address of a storage area that is used by the macro as a work area. Specify this parameter as the label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the REFPAGE macro DECLARE function. See [“Coding CP Macros” on page 807](#) for additional detail regarding the use of this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

**Usage Notes**

1. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. To indicate a contiguous span of pages in one logical page block set GROUP and SUBGROUP to 1 and SKIP to 0 and set SPAN to the number of contiguous pages.
3. If all the operands use their default value, there will not be any page blocking.
4. Multiple REFPAGE macro INFORMB functions can be concurrently active. If the same page(s) are specified in more than one INFORMB or INFORML request then the logical blocks of pages that result will be interleaved. The last INFORM function will be the only one with its logical block of pages intact. The other logically blocked pages are partially intact. There could be reduced expected performance depending on how the logical blocks are referenced.
5. Logical blocks are formed from pages that reside on DASD. If the pages are located in host storage, they will not be blocked.

6. CP's normal page stealing forms blocks of pages similar to those formed by REFPAGE. It is possible for a block of pages that was formed by normal page stealing to point into a REFPAGE-formed block. If a page from the steal-formed block is referenced then it is possible that part of the REFPAGE-formed block will be brought into storage.
7. The value of the keywords when multiplied together minus the value of SKIP should not exceed the maximum value of 524,288:  

$$(\text{GROUP} * \text{SUBGROUP} * (\text{SPAN} + \text{SKIP})) - (\text{SKIP}) \leq 524,288$$
8. Large numbers can cause a virtual machine to have performance problems when issuing this macro.

## Condition Codes and Return Codes

On return from REFPAGE INFORMB, register 15 will contain one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | REFPAGE macro INFORMB function status:                                                                                                                                                                                                                                                                      |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | The notification of the pending order of page references has been accepted and processed.                                                                                                                                                                                                                   |
| 8                                          | The ALET operand does not identify either an existing private address space that your virtual machine created, or your virtual machine's base address space. An address space (including the base) must be private when it is used with this function. The page-reference pattern has not been established. |
| 12                                         | A shared page was detected in the page-reference pattern.                                                                                                                                                                                                                                                   |
| 20                                         | A value was specified for either GROUP, SUBGROUP, SPAN, or SKIP that was out of range. The page-reference pattern has not been established.                                                                                                                                                                 |

## Examples

**Example 1:** This example shows how to define a logical block of pages to be brought into storage. This will allow the program to have pages *P1,P2,P3,P6,P7,P8,P11,P12,P13,P16,P17,P18* brought in with one page fault when *P1* is referenced.

```

      LA      2,STARTLOW
      REFPAGE INFORMB,ADDR=(2),GROUP=L1,SUBGROUP=L4,SPAN=L3,SKIP=L2
      .
      .
      .
L1     DC     F'1'
L2     DC     F'2'
L3     DC     F'3'
L4     DC     F'4'
STARTLOW DC    X'00012000' (Addr of P1)

```

This defines a page-reference pattern as follows:

Figure 99. Group of 1 Subgroup That Has 4 Spans of Pages

**Example 2:** This example shows how to define two logical blocks of pages to be brought into storage separately. This will allow the program to have pages *P1,P2,P3,P6,P7,P8* brought into storage for one page fault. The second subgroup will not be brought in until *P11* is referenced.

```

LA      2,STARTLOW
...
REFPAGE INFORMB,ADDR=(2),GROUP=L2,SUBGROUP=L2,SPAN=L3,SKIP=L2
...
L2      DC      F'2'
L3      DC      F'3'
STARTLOW DC      X'00012000' (Addr of P1)

```

defines a page-reference pattern as follows:

Figure 100. Group of 2 Subgroups That Have 2 Spans of Pages in Each Subgroup

**Example 3:** This example shows how to define two logical blocks of pages to be brought into storage separately in reverse order. This will allow the program to have pages *P18,P17,P16,P13,P12,P11* brought into storage for one page fault. The second subgroup will not be brought in until *P8* is referenced.

```

LA      2,STARTRIG
...
REFPAGE INFORMB,ADDR=(2),GROUP=L2,SUBGROUP=L2,SPAN=L3,
      SKIP=L2,DIRECTION=DESCEND
...
L2      DC      F'2'
L3      DC      F'3'
STARTRIG DC      X'01F12000' (Addr of P18)
DESCEND DC      X'FF'

```

defines a page-reference pattern as follows:

Figure 101. Group of 2 Subgroups That Have 2 Spans of Pages in Each Subgroup

**Example 4:**

```

LA      2,STARTLOW
...
REFPAGE INFORMB,ADDR=(2),SPAN=L18
...
L18     DC      F'18'
STARTLOW DC      X'00012000' (Addr of P1)

```

defines a page-reference pattern that has 18 contiguous pages in one logical block of pages.

Figure 102. Group of a Span of 18 Pages in One Logical Block

Example 5:

```
LA      2,STARHIG
...
REFPAGE INFORMB,ADDR=(2),SPAN=L18,DIRECTION=DESCEND
...
L18     DC      F'18'
STARHIG DC      X'01F12000' (Addr of P18)
DESCEND DC      X'FF'
```

defines a page-reference pattern that has 18 contiguous pages in one logical block of pages. The keyword DIRECTION indicates that keyword ADDR is the highest address.

Figure 103. Group of a Span of 18 Pages in One Logical Block

where each page is to be considered an individual group with a span of one without any skips.

## REFPAGE INFORML

### Purpose

The INFORML function identifies an ordered reference pattern in which there is no regular pattern or relationship among the addresses of the pages to be referenced. Instead, the page reference pattern is identified by a list of pages in the reference pattern.

### Parameters

#### *label*

is an optional assembler language label on the macro.

#### **PRLIST=**

specifies the real address of the page-reference list. Specify this parameter as a label associated with the page-reference list in storage, or as the number of a register (in the range of 2-12, inclusive) containing the address of the page-reference list. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the page-reference list.

The page-reference list specifies the absolute addresses of pages to be included in the page-reference pattern. (See [Page-Reference List Format](#) for more information on the page-reference list.) The page-reference list is processed in the order it is specified to form one or more logical blocks of pages. Pages specified by consecutive entries in the list are placed the same logical block as long as the ALETs for the entries are the same. If consecutive entries have different ALETs, the current logical block is ended and a new logical block is started. Thus, if the list contains entries with differing ALETs then multiple logical blocks are formed. Logical blocks are formed within an address space not across address spaces.

This operand is required.

#### **COUNT=**

specifies the real address of a 4-byte field in storage that contains the count of entries in the page-reference list specified by the PRLIST operand. Specify this parameter as a label associated with the field, or as the number of a register (in the range of 2-12, inclusive) containing the address of the field. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the field.

The minimum number of entries is two and the maximum number of entries is 16,384. If the count is not in this range, then return code 4 is given.

This operand is required.

**WORKAREA=**

specifies the real address of a storage area that is used by the macro as a work area. Specify this parameter as the label associated with the storage area, or as the number of a register (in the range of 2-12, inclusive) containing the address of the storage area. For a virtual machine in the access-register mode, the access register corresponding to the base register selected by the assembler for the label (label form) or the access register associated with the specified general register (register form) is used to determine the address space containing the storage area.

The storage area is defined by the DEFWORKA macro coded at the end of your program or through the REFPAGE DECLARE function. See [“Coding CP Macros” on page 807](#) for additional details regarding this operand.

This operand is optional; you can simplify coding of your program by omitting this operand to defer the definition of the macro work area to the DEFWORKA macro.

**Usage Notes**

1. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
2. The order of the entries in this list defines the order each page is planned to be referenced by the caller. If the reference order does not match their ordering in the list, performance improvements may not be realized.
3. Multiple REFPAGE macro INFORML functions can be concurrently active. If the same page(s) are specified in more than one INFORMB or INFORML request then the logical blocks of pages that result will be interleaved. The last INFORM function will be the only one with its logical block of pages intact. The other logically blocked pages are partially intact. There could be reduced expected performance depending on how the logical blocks are referenced.
4. The number of entries of 16,384 should be used with caution. Large numbers can cause a virtual machine performance problems when issuing this macro.

**Page-Reference List Format:** The list pointed to by PRLIST is a set of word pairs where each pair is an ALET and 31-bit absolute page address. Each ALET must designate a private address space that your virtual machine owns, otherwise return code 8 is given. Logical blocks are formed from each consecutive identical ALET within the list. If there are different ALETs then there will be multiple logical blocks formed. If an ALET appears twice in the list with an intervening different ALET a second logical block will be formed for the same address space.

Thus, the list of entries appears as follows:

The ALETs contained in the page-reference list are always used to identify the target address spaces; that is, they are used even when the virtual machine is in the primary-space mode.

**Condition Codes and Return Codes**

On return from REFPAGE INFORML register 15 contains one of the following return codes:

| Return Code<br>in Register 15<br>(Decimal) | REFPAGE macro INFORML function status:                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                          | The notification of the pending order of page references has been accepted and processed.                                                                                                                                                                                                                                                                                        |
| 4                                          | The value for keyword COUNT is either less than 2 or greater than the maximum of 16,384. This request was not processed.                                                                                                                                                                                                                                                         |
| 8                                          | An ALET specified within the page-reference list does not identify either an existing private address space that your virtual machine created, or your virtual machine's host-primary address space. An address space (including the base) must be private when it is used with this function. The list of pending page references may have been formed up to the ALET in error. |
| 12                                         | A shared page was detected in page-reference list.                                                                                                                                                                                                                                                                                                                               |

## VMUDQ – VM User Directory Query

### Purpose

The VMUDQ (VM User Directory Query) macro provides an application interface for making specified queries against the CP User Directory. Documented here is the LSTMDISK (List MDISK Definitions) function, which writes selected MDISK definitions from the user directory to a designated buffer.

**Note:** IBM privilege class B is needed.

### Parameters

#### **label**

is an optional assembler language label.

#### **parmlabel**

##### **(parmreg)**

specifies the address of a function parameter list held within an address space. Specify this operand as a label associated with the storage area, or as the number of a general register that is part of an address/ALET pair of the storage area.

If it is specified as the number of a general register, this register is assumed to be already loaded with the address, and the corresponding access register is assumed to be already loaded with the ALET of the target address space. If the ALET value is 0, the target address space is the user's primary address. If the virtual machine is not an XC virtual machine, the ALET value is ignored, and the target address space is the user's host-primary address space.

The parameter list is maximum of six doublewords long, and is described under [MDISK Parameter List Contents](#). It must be on a doubleword boundary and must not span a page boundary. Otherwise, a specification exception is recognized.

This operand is required.

#### **bufflabel**

##### **(buffreg)**

specifies the address of the data buffer held within an address space. Specify this operand as the label associated with the storage area, or as the number of a register that is part of an address/ALET pair of the storage area. If it is specified as the number of a general register, this is assumed to be already loaded with the address, and the corresponding access register is assumed to be already loaded with ALET of the target address space. If the ALET value is 0, the target address space is the user's host-primary address space. If the virtual machine is not an XC virtual machine, the ALET value is ignored, and the target address space is the user's host-primary address space.

This operand is required.

#### **bufflen**

##### **(lenreg)**

is the length in bytes of the allocated data buffer.

The minimum value of the length required for the data buffer is 60 bytes, otherwise, a specification exception is recognized.

This operand is required.

**MACHINE=370**

has no supported function, because 370 virtual machines are not supported. Results are undefined if this operand is specified.

**LSTMDISK Function:** This function creates a list of MDISK definitions from the CP user directory based on, or qualified by, the:

- User IDs to which the MDISK definitions belong
- Virtual devices to which the MDISK definitions are defined
- Volumes containing volsers on which MDISK definitions are found
- SSI member system or SUBCONFIG ID for which the MDISK definitions are found.

An asterisk (\*) can be used as a trailing wild card to select a wider group of definitions.

The criteria for this list are in a parameter list pointed to by the PARMADR of the macro. The list is built in the buffer defined in the macro.

**MDISK Parameter List Contents:** Figure 104 on page 890 shows the structure of the MDISK parameter list. It consists of six doublewords.

|    |                     |       |            |
|----|---------------------|-------|------------|
| 0  | Length              | Flags | ////////// |
| 8  | LSTMDISK            |       |            |
| 16 | *   userid   use*   |       |            |
| 24 | *   vdevno   vdev*  |       |            |
| 32 | *   volser   vols*  |       |            |
| 40 | *   systemid   sys* |       |            |

Figure 104. Contents of the LSTMDISK Function Parameter List

**Length**

The length is a fullword containing the length in bytes of the length field itself, the reserved field, and the parameter string that follows. The length field must be one of the following values: 16, 24, 32, 40, or 48; otherwise a specification exception is recognized.

**Flags**

contains flags as follows:

**X'80'**

Indicates that a SUBCONFIG ID should be included in the output record instead of a system name.

**////////**

is reserved for later use.

**LSTMDISK**

is the name of the function to be performed by the macro. It must be LSTMDISK; otherwise, a specification exception is recognized.

**\* | *userid* | *use*\***

selects MDISK definitions that belong to the specified user IDs. The *userid* from a USER or IDENTITY directory statement can be used. SUBCONFIG IDs cannot be specified. If you specify an asterisk (\*) alone, all MDISK definitions are retrieved. If you specify an asterisk following a set of characters, all the MDISK definitions owned by all the user IDs that begin with those characters are retrieved. The value is left-justified in the field and padded to eight characters with blanks. If you leave the field blank, an asterisk is the default.

**\* | *vdevno* | *vdev*\***

selects MDISK definitions that are defined to the specified virtual device number(s). Multiple virtual device numbers are specified by using an asterisk (\*). If you specify an asterisk (\*) alone, all MDISK definitions are selected regardless of *vdevno*. If you specify an asterisk following a set of numbers, all MDISK definitions for all the virtual devices whose addresses begin with those numbers are retrieved. A four-digit address is assumed; therefore, 000\* would mean 0000 through 000F and 04\* would mean 0400 through 04FF, and so on. The value is left-justified in the field and padded to eight characters with blanks. If you leave the field blank, an asterisk is the default.

**\* | *volser* | *vols*\***

selects MDISK definitions that are found on the volume containing the specified *volser*. If you specify an asterisk (\*) alone, all MDISK definitions are retrieved. If you specify an asterisk following a set of characters, all the MDISK definitions on the volumes with *volsers* that start with those characters are retrieved. If you leave the field is blank, an asterisk is the default. The value is left-justified in the field and padded to eight characters with blanks.

**\* | *systemid* | *sys*\***

selects MDISK definitions that are found on the specified SSI member system. An asterisk (\*) can be used as a trailing wild card to select a range of systems that begin with a common set of characters. An asterisk (\*) by itself indicates that the MDISK definitions on all member systems are to be analyzed. The value is left-justified in the field and padded to eight characters with blanks. If the field is blank, the default assumed is blank, indicating that only the MDISK definitions on the current system are to be analyzed. Specifying a system other than by an asterisk or a blank is allowed only when an SSI-enabled directory is in use.

**Output Buffer Format:** The output buffer consists of seven blank-delimited fields containing the information indicated in the following example:

```
OWNERID- VDEV VOLSER DEVTYPE- START----- SIZE----- SYSTEM
12345678 1234 123456 12345678 1234567890 1234567890 12345678
-----+-----+-----+-----+-----+-----+-----
User123 0191 ABC123 3390 0000000010 0000000200 SYSTEM1
User456 0191 CCC123 FB-512 0000000010 0000200000 SYSTEM1
User789 0222 CCC222 3380 0000000010 END SYSTEM2
UserABC 0345 000345 3390 0000000000 0000000100
```

**Notes:**

1. In the above example the "START" field may contain either the starting cylinder or block number. The "SIZE" field contains the remaining number of cylinders or blocks. The non-device specific "END" in the size field denotes the end of the volume. Also, the header lines are not part of the returned data.
2. In the above example, the first three lines of output include a system ID. A system ID indicates that the device was defined within a SUBCONFIG stanza and the device is local to a specified system. The last line of output does not include a system ID, indicating that the device was defined within an identity or user stanza and the device is global to all systems.

If an SSI-enabled or SSI-ready directory is in use, a flag can be set in the Flags field of the parameter list to cause the SUBCONFIG ID that contains the MDISK definition to be returned instead of the system name.

3. If the MDISK was defined with a size of "END", then size that will be returned in the output buffer will simply be "END".
4. Temporary disks (T-disks) and virtual disks in storage are ignored by the LSTMDISK function and are not included in the output buffer.

## Examples

1. Assume you want to create a list of all MDISK definitions in the CP user directory for the system on which you are currently running and place them in a buffer addressed by *buffaddr*. Further assume that the buffer is only 10,000 bytes long. You create the following:

label VMUDQ parmadr,buffadr,10000

2. Assume you want to create a list of MDISK definitions belonging to user DOTY with addresses in the range of 0400 through 04FF, regardless of the volume on which they reside, and place them in a buffer addressed by (*R6/AR6*), and further assume that the buffer is only 10000 bytes long as specified in (*R7*). You create the following parameter list as addressed by (*R2/AR2*).

label VMUDQ (2),(6),(7)

## Usage Notes

1. An address space is acquired in blocks of 256 pages; therefore, the number of bytes in the buffer to be passed on the call would equal:

(number pages requested+255/256) \* 1048576.

2. This macro modifies general and access registers 0, 1, 14, and 15. All others remain unchanged.
3. If *userid*, *volser*, or *systemid* contains an asterisk (\*) not used as a trailing wild card, conflicting results can occur, because an asterisk is treated as a trailing wild, card left-justified, and padded to eight characters with blanks.
4. If the MDISK was defined with a volume serial number of &SYSRES, then the value in the VOLSER output column is the value specified for the &SYSRES option when DIRECTXA created the user directory. If this option was not specified, the value +VMRES is used.
5. In an SSI-enabled directory, MDISK definitions can be global or local. A global MDISK definition is one that is included in a user or identity stanza and the minidisk being defined can be linked by virtual machines on any member system of the SSI cluster. A local MDISK definition is one that is included

in a SUBCONFIG stanza and the minidisk being defined can be linked only by virtual machines on the SSI member system to which the SUBCONFIG stanza applies. When specifying the system ID parameter (\* | *systemid* | *sys\**), you are requesting all MDISK definitions that are global and local to a particular system. If you specify a system ID that is not specified on any BUILD statements in the directory, then all global MDISK definitions are reported. If you specify a system ID that is specified on a BUILD statement in the directory, then all global MDISK definitions and local MDISK definitions for the specified system are reported.

6. If an SSI-enabled or SSI-ready directory is in use, a flag can be set in the Flags field of the parameter list to cause the SUBCONFIG ID that contains the MDISK definition to be returned instead of the system name.

## Condition Codes and Return Codes

One of the following condition codes is returned:

| Condition Code | Description                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------|
| 0              | Normal exit from VMUDQ.                                                                                                    |
| 1              | VMUDQ has detected an error.                                                                                               |
| 3              | VMUDQ has encountered a paging error while trying to access the target area in the data space or an object directory page. |

On return from the LSTMDISK function, register 15 contains one of the following return codes if the condition code is 0.

| Function | Return code in Register 15 | Description                                                                                               |
|----------|----------------------------|-----------------------------------------------------------------------------------------------------------|
| General  | X'00'                      | Successful. Register 0 contains the number of bytes moved as the result of query.                         |
|          | X'04'                      | No records were found to match the criteria specified.                                                    |
|          | X'08'                      | The buffer length supplied is insufficient. Register 0 contains the number of bytes needed for the query. |
| LSTMDISK | X'100'                     | An invalid user ID was specified.                                                                         |
|          | X'104'                     | An invalid virtual device number was specified.                                                           |
|          | X'108'                     | An invalid volume serial number was specified.                                                            |
|          | X'10C'                     | An invalid system ID was specified.                                                                       |
|          | X'110'                     | The user directory does not include SUBCONFIG information but SUBCONFIG IDs were requested.               |

## Program Exceptions

You may receive one of the following program checks if the VMUDQ input data is invalid.

| Problem Encountered                                                        | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                                                    | <p>Any of the following:</p> <ul style="list-style-type: none"> <li>• The input parameter list does not start at double-word boundary.</li> <li>• The length of buffer is less than 60 bytes, which is the minimum output buffer size.</li> <li>• The function specified is not LSTMDISK.</li> <li>• The input parameter list does cross a page boundary.</li> <li>• The length of the input parameter list is not one of the values 16, 24, 32, 40, or 48.</li> </ul> |
| Access exception (See page <a href="#">“Access Exceptions”</a> on page 8.) | <p>An error occurred trying to:</p> <ul style="list-style-type: none"> <li>• Fetch the parameter list</li> <li>• Store into the data buffer.</li> </ul>                                                                                                                                                                                                                                                                                                                |

## Part 6. Architectural Extensions and Accommodations for Virtual Machines

This part contains the following chapters:

- [Chapter 26, “Collaborative Memory Management Assist,” on page 897](#)
- [Chapter 27, “370 Accommodation Facility Overview,” on page 907](#)
- [Chapter 28, “370 Accommodation Facility Definition,” on page 915](#)
- [Chapter 29, “Store Hypervisor Information \(STHYI\) Instruction,” on page 927](#)

---

## Chapter 26. Collaborative Memory Management Assist

The collaborative memory management assist is a machine feature that allows z/Architecture guests with the appropriate support to exchange memory usage and status information with z/VM. This sharing of information provides several benefits:

- z/VM can make more effective decisions, leading to a more efficient use of available memory.
- z/VM page-write overhead is eliminated for pages that the guest has designated as unused or volatile.
- The guest can make better decisions when assigning pages.
- Guest page-clearing overhead can be eliminated for pages that z/VM has indicated contain zeros.
- z/VM can accommodate a proportionately larger number of guests for a given system paging load.

This chapter describes the EXTRACT AND SET STORAGE ATTRIBUTES instruction, the interface used by a guest to collaborate with z/VM, as well as associated changes to the virtual-machine interface. The material is an extension to the material in *z/Architecture Principles of Operation* (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>), SA22-7832.

The collaborative memory management assist provides a means for communicating state information about a 4 KB block of storage between a program running in a z/Architecture virtual machine and the z/VM control program. This sharing of state information allows the program and z/VM to make more efficient memory management decisions. The collaborative memory management assist includes the following features:

- A unique block-usage state and block-content state that are associated with each 4 KB block of main storage (that is, memory) in the virtual configuration.
- The privileged EXTRACT AND SET STORAGE ATTRIBUTES instruction which can be used to extract and optionally set the block-usage and block-content states of a 4 KB block.
- A new reason for recognizing an addressing-exception program interruption.
- The new block-volatility-exception program-interruption condition.

---

### Storage

The following is an extension to "Chapter 3. Storage", in *z/Architecture Principles of Operation*.

### Collaborative Memory Management Block State

When the collaborative memory management assist is installed, a unique block-usage state and block-content state are associated with each 4 KB block of storage that is available in the virtual-machine configuration. Block-usage states and block-content states are not part of addressable storage. The current states of a 4 KB block are extracted and optionally set by EXTRACT AND SET STORAGE ATTRIBUTES.

#### Block-usage States

Following is a description of the block-usage states that can be assigned to a 4 KB block and their meanings:

- **Stable state.** A 4 KB block in the stable block-usage state can be referenced by the program. If z/VM reclaims the real-storage page frame in which the block resides, z/VM preserves (pages out) the block contents.
- **Unused state.** A 4 KB block in the unused state should not be referenced by the program; otherwise, an addressing exception might be recognized or unpredictable results might occur. At any time the contents of a 4 KB block in the unused block-usage state can be discarded. When a block in the unused

block-usage state is discarded, the block-content state of the block is set to the logically-zero state, the reference and change bits for the block are set to zeros, and the remainder of the storage key is set to unpredictable values. (For a description of the logically-zero state, see [“Block-content States”](#) on page 898.)

- **Volatile state.** A 4 KB block in the volatile block-usage state can be referenced by the program. However, at any time the contents of a 4 KB block in the volatile block-usage state can be discarded. When a block in the volatile block-usage state is discarded, the block-content state of the block is set to the logically-zero state, the reference and change bits for the block are set to zeros, and the remainder of the storage key is set to unpredictable values. (For a description of the logically-zero state, see [“Block-content States”](#) on page 898.)

If the program references a 4 KB block that is in the volatile block-usage state and is discarded (i.e., the block is in the volatile block-usage state and the logically-zero block-content state), a block-volatility exception is recognized.

- **Potentially-volatile state.** A 4 KB block in the potentially-volatile block-usage state can be referenced by the program. Based on change indication, the block-usage state might change to the volatile or stable state as follows:

If the change bit for the 4 KB block is one, the block-usage state might be changed to the stable state.

If the change bit for the 4 KB block is zero, the contents of the block might be discarded. When a block in the potentially-volatile block-usage state is discarded, the block-usage state of the block is set to the volatile state, the block-content state of the block is set to the logically-zero state, the reference and change bits for the block are set to zeros, and the remainder of the storage key is set to unpredictable values. (For a description of the logically-zero state, see [“Block-content States”](#) on page 898).

## Block-content States

Following is a description of the block-content states that can be assigned to a 4 KB block and their meanings:

- **Resident state.** The contents of a 4 KB block in the resident block-content state are present in z/VM real storage and immediately accessible by the program.
- **Preserved state.** The contents of a 4 KB block in the preserved block-content state are not present in z/VM real storage and are preserved elsewhere. When the program references a 4 KB block in the preserved block-content state, the contents of the block are restored and the block-content state of the block is changed to the resident state.
- **Logically-zero state.** The contents of a 4 KB block in the logically-zero block-content state are not present in z/VM real storage and are known to be zero. The logically-zero block-content state in conjunction with the block-usage state of the 4 KB block indicates whether the page is accessible by the program, as follows:

If the block-usage state of the 4 KB block is the stable state and the block-content state of the block is the logically-zero state when the block is referenced by the program, the contents of the block are set to zeros and the block-content state is changed to the resident state.

If the block-usage state of the 4 KB block is the unused state and the block-content state of the block is the logically-zero state when the block is referenced by the program, an addressing exception is recognized.

If the block-usage state of the 4 KB block is the volatile state and the block-content state of the block is the logically-zero state when the block is referenced by the program, a block-volatility exception is recognized.

The program can also change the states associated with a page by using the EXTRACT AND SET STORAGE ATTRIBUTES instruction.

For 4 KB blocks that are in the stable block-usage state, the block-content state might change at any time from the resident to the preserved state or from the preserved to the resident state.

For 4 KB blocks that are in a block-usage state other than the stable state, the states associated with the block might change at any time as described under the block-usage states above.

For 4 KB blocks that are in the stable block-usage state and the logically-zero block-content state, the logically-zero state is removed when non-zero contents are stored in the block. This might occur at other times as well.

The collective term **discarded state** refers to either of two state combinations: the unused block-usage state and the logically-zero block-content state, or the volatile block-usage state and the logically-zero block-content state. Note that a discarded state need not arise from a discard action by z/VM. For example, an EXTRACT AND SET STORAGE ATTRIBUTES instruction performing a Set Unused operation on a stable logically-zero block or on a stable preserved block places that block into a discarded state.

References made by an entity other than the CPU (such as the channel subsystem) to storage in a 4 KB block that is in a discarded state are treated as if the block is not in the configuration. See [“Implications for the DIAGNOSE Instruction and Non-CPU Accesses”](#) on page 905.

As a result of the machine recognizing block-usage states, some combinations of block-usage and block-content states are not permissible. Thus, if the program executes EXTRACT AND SET STORAGE ATTRIBUTES specifying an impermissible state combination, the machine replaces the impermissible combination with a permissible combination. The table in [Figure 105 on page 899](#) summarizes which combinations are permissible and which are not. The table also shows the state combinations (in parentheses) which replace the impermissible combinations.

|                    |   | Block-Content States |                                         |                    |
|--------------------|---|----------------------|-----------------------------------------|--------------------|
|                    |   | r                    | p                                       | z                  |
| Block-Usage States | S | Y                    | Y                                       | Y                  |
|                    | U | Y                    | N(Uz) <sup>1</sup>                      | Y                  |
|                    | V | Y                    | N(Vz) <sup>2</sup>                      | Y                  |
|                    | P | Y                    | N(Sp) <sup>3</sup><br>(Vz) <sup>3</sup> | N(Vz) <sup>4</sup> |

**Legend:**

r - Resident block-content state  
p - Preserved block-content state  
z - Logically-zero content state  
S - Stable block-usage state  
U - Unused block-usage state  
V - Volatile block-usage state  
P - Potentially-volatile block-usage state

Y - Yes - permissible  
N - No - not permissible

*Figure 105. Summary of permissible collaborative memory management state combinations*

Footnotes on block/block-content state combinations shown in parentheses:

**Notes:**

1. Use of the EXTRACT AND SET STORAGE ATTRIBUTES instruction to set the block-usage state of a 4 KB block in the preserved block-content state to the unused state results in discarding the block by changing the block-usage state to the unused state and the block-content state to the logically-zero state.
2. Use of the EXTRACT AND SET STORAGE ATTRIBUTES instruction to set the block-usage state of a 4 KB block in the preserved block-content state to the volatile state results in discarding the block by

changing the block-usage state to the volatile state and the block-content state to the logically-zero state.

3. Use of the EXTRACT AND SET STORAGE ATTRIBUTES instruction to set the block-usage state of a 4 KB block in the preserved block-content state to the potentially-volatile state results in the block-usage state remaining the stable state and the block-content state remaining the preserved state, if the block has been changed, or results in discarding the block by changing the block-usage state to the volatile state and the block-content state to the logically-zero state, if the block has not been changed.
4. Use of the EXTRACT AND SET STORAGE ATTRIBUTES instruction to set the block-usage state of a block in the logically-zero block-content state to the potentially-volatile state results in changing the block-usage state to the volatile state, and the block-content state remains the logically-zero state.

## Modification of Translation Tables

When the collaborative memory management assist is installed, translation tables should reside in 4 KB blocks that are in the stable block-usage state. The results of a translation that requires a translation-table entry that resides in a 4 KB block that is not in the stable block-usage state are unpredictable.

## Assigned Storage Locations

The definitions of the assigned storage locations below are extended as indicated when the collaborative memory management assist is installed in a z/Architecture virtual machine:

### 160

(Real Address)

*Exception Access Identification:* During a program interruption due to a block-volatility exception, zeros might be stored into location 160.

### 162

(Real Address)

*Operand Access Identification:* During a program interruption due to a block-volatility exception recognized by the MOVE PAGE instruction, the contents of the R<sub>1</sub> field of the instruction are stored in bit positions 0-3 of location 162, and the contents of the R<sub>2</sub> field are stored in bit positions 4-7. If the block-volatility exception was recognized during the execution of an instruction other than MOVE PAGE, the contents of location 162 are unpredictable.

### 168-175

(Real Address)

*Translation-Exception Identification:* During a program interruption due to a block-volatility exception, bits 0-51 of the absolute address causing the exception are stored in bits 0-51 of locations 168-175. Bits 52-60 of locations 168-175 are unpredictable. If the exception was recognized during the execution of MOVE PAGE, bit 61 of locations 168-175 is set to one; otherwise, bit 61 is set to zero. Bits 62-63 of locations 168-175 are stored as zeros.

## Control

---

The following is an extension to "Chapter 4. Control" in *z/Architecture Principles of Operation*.

## Resets

The definitions of subsystem reset and clear reset are extended as indicated when the collaborative memory management assist is installed in a z/Architecture virtual machine:

### Subsystem Reset

In addition to the standard operations performed by subsystem reset, if the collaborative memory management assist is installed, then the block-usage state of all 4 KB blocks is set to the stable state.

## Clear Reset

In addition to the standard operations performed by clear reset, if the collaborative memory management assist is installed, the block-content state of all 4 KB blocks is set to the logically-zero state. Since a clear reset includes a subsystem reset, the block-usage state of all 4 KB blocks is also set to the stable state.

## Interruptions

---

The following is an extension to "Chapter 6. Interruptions" in *z/Architecture Principles of Operation*.

### Addressing Exception

z/Architecture defines a main storage location as not available in the configuration when the location is not installed, when the storage unit is not in the configuration, or when power is off in the storage unit. An address designating a storage location that is not available in the configuration is referred to as invalid. An addressing exception is generally recognized when the CPU attempts to reference a main storage location that is not available in the configuration.

When the collaborative memory management assist is installed, a main storage location is also considered not available in the configuration when the location is within a 4 KB block that is in the unused block-usage state and the logically-zero block-content state. However, addressing exceptions due to collaborative memory management block-usage and block-content states are not recognized for 4 KB blocks designated by the following instructions:

- EXTRACT AND SET STORAGE ATTRIBUTES
- INSERT STORAGE KEY EXTENDED
- SET STORAGE KEY EXTENDED
- RESET REFERENCE BIT EXTENDED

### Block-volatility Exception

A block-volatility exception is recognized when the collaborative memory management assist is installed and the CPU attempts to reference a main storage location that is within a 4 KB block that is in the volatile block-usage state and for which the contents of the block have been discarded (as indicated by the referenced block also being in the logically-zero block-content state).

The unit of operation is nullified.

When an interruption occurs, information about the 4 KB block address causing the exception is stored at real locations 168-175 and conditionally at real locations 160 and 162. See [“Assigned Storage Locations” on page 900](#) for a detailed description of this information.

Block-volatility exceptions are not recognized for 4 KB blocks that are designated by the following instructions:

- EXTRACT AND SET STORAGE ATTRIBUTES
- INSERT STORAGE KEY EXTENDED
- SET STORAGE KEY EXTENDED
- RESET REFERENCE BIT EXTENDED

When a block-volatility exception occurs during the fetching of an instruction or during the fetching of a DAT table entry associated with an instruction fetch, it is unpredictable whether the ILC is 1, 2, or 3. When the exception is associated with fetching the target of EXECUTE, the ILC is 2.

In all cases of block-volatility exceptions not associated with instruction fetching, the ILC is 1, 2, or 3, indicating the length of the instruction that caused the reference.

A block-volatility exception is indicated by a program-interruption code of 001A hex (or 009A hex if a concurrent PER event is indicated).

## Access Exceptions

The access exceptions consist of those exceptions which can be encountered while using an absolute, instruction, logical, real, or virtual address to access storage. When the collaborative memory management assist is installed, the block-volatility exception is added to the list of these exceptions, in all translation and address-space-control modes.

A block-volatility exception for a particular access (instruction, operand, ART table, or DAT table) occurs at the same priority as an addressing exception for that access.

## Control Instructions

The following is an extension to "Chapter 10. Control Instructions" in *z/Architecture Principles of Operation*.

## Program Exceptions

The descriptions of general and control instructions typically indicate the cases in which access exceptions might be recognized. In these cases, when the collaborative memory management assist is installed, block-volatility exceptions are implicitly included among the access exceptions that might be recognized, except where indicated below.

Certain control instructions might list individual exceptions in their definition, rather than the overall term "access exceptions." In those cases, except as noted in the sections below, wherever addressing exception is listed as a program exception that an instruction might recognize, a block-volatility exception is also recognized when appropriate for that access when the collaborative memory management assist is installed. For example, BRANCH AND SET AUTHORITY lists an addressing exception on the dispatchable-unit control table; it also recognizes a block-volatility exception on that table when applicable.

## Storage-key Manipulation Instructions

For the instructions INSERT STORAGE KEY EXTENDED, RESET REFERENCE BIT EXTENDED, and SET STORAGE KEY EXTENDED, a block-volatility condition is not recognized for the address specified by general register R<sub>2</sub>. Similarly, for these instructions, an addressing exception is not recognized due to the 4 KB block at the address specified by general register R<sub>2</sub> being in the unused block-usage state and logically-zero block-content state. Instead, the instruction accesses the storage key without regard to the block-usage and block-content states of this block.

## TEST PROTECTION

If the collaborative memory management assist is installed and the location designated by the first operand resides within a 4 KB block that is in both the volatile block-usage state and the logically-zero block-content state, a block-volatility exception is not recognized. Instead, the instruction is completed by setting the condition code to 3.

## EXTRACT AND SET STORAGE ATTRIBUTES

The block-usage state and the block-content state of the 4 KB block designated by the second operand are extracted into the first operand location. The block-usage state and block-content state might be optionally set based on the value of the  $M_3$  field.

Asynchronous to the execution of the instruction, either or both the block-usage state and the block-content state might be changed, as described in the “Associated Functions” on page 905.

In the 24-bit addressing mode, bits 40-51 of general register  $R_2$  designate a 4 KB block in absolute storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register  $R_2$  designate a 4 KB block in absolute storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register  $R_2$  designate a 4 KB block in absolute storage, and bits 52-63 of the register are ignored. In all addressing modes, bits 52-63 should be zero; otherwise the program might not operate compatibly in the future.

When the instruction completes, the general register designated by the  $R_1$  field contains the block-usage state and block-content state of the designated 4 KB block before any specified state change is made. The format of this register is as follows:

Bits 0-59 are not used and unpredictable. Programs that depend on the value of these bits might not operate compatibly in the future.

## Block-usage State (US)

Bits 60-61 contain a 2-bit code value indicating the block-usage state of the designated 4 KB block. Following are the meanings of each block-state code value:

### Code value

#### Meaning

- |          |                            |
|----------|----------------------------|
| <b>0</b> | Stable state               |
| <b>1</b> | Unused state               |
| <b>2</b> | Potentially-volatile state |
| <b>3</b> | Volatile State             |

## Block-content State (CS)

Bits 62-63 contain a 2-bit code value indicating the block-content state of the designated 4 KB block. Following are the meanings of each block-content state code value:

### Code value

#### Meaning

- |          |                      |
|----------|----------------------|
| <b>0</b> | Resident state       |
| <b>1</b> | (reserved)           |
| <b>2</b> | Preserved state      |
| <b>3</b> | Logically-zero state |

The  $M_3$  field designates a 4-bit operation-request code (ORC). Following are the meanings of values of this field:

| Code value | Meaning |
|------------|---------|
|------------|---------|

**0**

Extract Block Attributes. The current block-usage and block-content states of the designated 4 KB block are extracted. No change is made to either state.

**1**

Set Stable State. The current block-usage and block-content states of the designated 4 KB block are extracted. Following extraction of the states, the block-usage state is set to the stable state.

**2**

Set Unused State. The current block-usage and block-content states of the designated 4 KB block are extracted. Following extraction of the states, the following occurs:

- The block-usage state is set to the unused state.
- If the block-content state is the preserved state, the contents of the block are immediately discarded and the block-content state is set to the logically-zero state.

**3**

Set Volatile State. The current block-usage and block-content states of the designated 4 KB block are extracted. Following extraction of the states, the following occurs:

- The block-usage state is set to the volatile state.
- If the block-content state is the preserved state, the contents of the block are immediately discarded and the block-content state is set to the logically-zero state.

**4**

Set Potentially-Volatile State. The current block-usage and block-content states of the designated 4 KB block are extracted. Following extraction of the states, the following occurs:

- If the block-content state is the resident state, the block-usage state is set to the potentially-volatile state.
- If the block-content state is the preserved state and the change bit for the 4 KB block is one, the block-usage state remains the stable state and the block-content state remains the preserved state. (See Figure 105 on page 899.)
- If the block-content state is the preserved state and the change bit for the 4 KB block is zero, the contents of the block are immediately discarded and the block-usage state is set to the volatile state and the block-content state is set to the logically-zero state.
- If the block-content state is the logically-zero state, the block-usage state is set to the volatile state.

**5**

Set Stable State and Make Resident. The current block-usage and block-content states of the designated 4 KB block are extracted. Following extraction of the states, the block-content state is set to the resident state and the block-usage state is set to the stable state.

**6**

Set Stable State If Resident. The current block-usage and block-content states of the designated 4 KB block are extracted. Following extraction of the states, the block-usage state is set to the stable state only if the block-content state is the resident state.

**7-15**

Reserved. The instruction should not be issued with any of these values in  $M_3$ ; otherwise the program might not operate compatibly in the future.

When the contents of a 4 KB block are discarded, either synchronously or asynchronously, the reference and change bits in the storage key for the block are set to zeros and the values of the access-control and fetch-protection bits are changed to unpredictable values. With the exception of this case, the instruction has no effect on the reference and change bits for the block.

A serialization and checkpoint-synchronization function is performed before the operation begins and a checkpoint-synchronization function is performed again after the operation completes.

## Associated Functions

Subsequent to the execution of EXTRACT AND SET STORAGE ATTRIBUTES, either the block-content state, the block-usage state, or both, might be changed, as follows:

- If the change bit in the storage key is one for a 4 KB block in the potentially-volatile block-usage state, the block-usage state of the block might be changed to the stable state. If the change bit is zero for such a block, the contents of the block might be discarded, thereby causing the block-usage state to be changed to the volatile state, and the block-content state to be changed to the logically-zero state.
- While a 4 KB block is in the stable block-usage state, its contents are not discarded. However, the block-content state of such a block might be changed from the preserved to the resident state or from the resident state to the preserved state.
- While a 4 KB block is in the unused or volatile block-usage state, its contents might be discarded, thereby also causing the block-content state to be changed to the logically-zero state.

## Special Conditions

The  $M_3$  field must specify an ORC value in the range of 0-6; otherwise, a specification exception is recognized and no other action is taken.

The 4 KB block designated by the second operand is not subject to low-address protection or key-controlled protection. The block is subject to host page protection when  $M_3$  specifies an ORC value in the range of 1-6. That is, if the block is contained in a read-only page range of a named saved system (NSS) or discontinuous saved segment (DCSS), it is forbidden to change its block-content state.

Unlike ordinary instructions, execution of EXTRACT AND SET STORAGE ATTRIBUTES does not recognize a block-volatility condition for the address specified by general register  $R_2$ . Similarly, execution of EXTRACT AND SET STORAGE ATTRIBUTES does not recognize an addressing exception due to the 4 KB block at the address specified by general register  $R_2$  being in the unused block-usage state and logically-zero block-content state.

## Resulting Condition Codes

The code remains unchanged.

## Program Exceptions

- Addressing (operand 2)
- Operation (if the collaborative memory management assist is not installed)
- Privileged operation
- Protection (store, operand 2, due to host page protection when  $M_3$  specifies an ORC value in the range of 1-6)
- Specification

### Programming Notes:

1. After changing the state of a 4 KB block to the unused block-usage state, the program should first change the state of the 4 KB block back to the stable state before referencing the 4 KB block; otherwise, an addressing exception or unpredictable results might occur.
2. If the program changes the state of a 4 KB block to the potentially-volatile or volatile block-usage state, the program should ensure that it will not be harmed or that it can reconstruct the contents of the block if the contents of the block are discarded.

## Implications for the DIAGNOSE Instruction and Non-CPU Accesses

An access by an entity other than the CPU (such as the I/O subsystem) to a 4 KB block that is in a discarded state (that is, a block in the logically-zero block-content state and either the unused or the volatile block-usage state) is treated like an access to a block not available in the configuration. For

example, an attempt to access a CCW, IDAW, or I/O buffer contained in block in a discarded state results in a channel program check. Likewise, an access by a CPU asynchronously to an instruction, such as during the storing of an interruption parameter, treats a block in a discarded state like a block not available in the configuration.

It is unpredictable whether a synchronous access by the DIAGNOSE instruction to a block in a discarded state is treated like an access by the CPU (resulting in an addressing or block-volatility exception) or by an entity other than the CPU, as described above. In the latter case, DIAGNOSE might yield the same result (such as a particular condition code or return code) for a block in a discarded state that it would yield for a block not available in the configuration.

To avoid these consequences, the program should ensure that blocks referenced by DIAGNOSE or by non-CPU accesses are in the stable state.

## Implications for ESA/390, ESA/XC, and z/XC Guests

---

The collaborative memory management assist is available only to guests in z/Architecture mode. EXTRACT AND SET STORAGE ATTRIBUTES results in an operation exception in an ESA/390, ESA/XC, or z/XC virtual machine. Therefore, a program in such a machine can not place storage blocks into states other than the stable state.

A z/Architecture guest might share storage with an ESA/390, ESA/XC, or z/XC guest through a named saved system (NSS) or discontinuous saved segment (DCSS) or through the ADRSPACE PERMIT service. It is therefore possible for a guest not operating in z/Architecture mode to encounter storage blocks in a discarded state. A reference by such a guest to a block in a discarded state is treated as a reference to a block not available in the configuration. For example, such a reference by most instructions generates an addressing exception. A block-volatility exception is not presented to an ESA/390, ESA/XC, or z/XC guest.

## Implications for Saved Systems and Segments

---

Storage in the page ranges of an NSS or DCSS should be in the stable block-usage state at the time of the SAVESYS or SAVESEG command. Otherwise, the SAVESEG or SAVESYS operation might fail, or the contents and the block-usage and block-content states of that storage will be unpredictable when the storage is subsequently loaded into a virtual machine by IPL or DIAGNOSE X'64', respectively.

When an NSS or DCSS containing shared ranges is imbedded into virtual-machine storage, there is a single copy of the block-usage and block-content states for each block in the range. If the range is shared read-only (indicated by page descriptor code SR on DEFSEG or SAVESEG), then EXTRACT AND SET STORAGE ATTRIBUTES instructions are not permitted to change the block-usage or block-content states of blocks in this range (though the block-content state might change in normal system operation). If the range is shared read-write (page descriptor code SW or SN), then all sharing virtual machines observe and operate on a common state for the block. If one sharer issues EXTRACT AND SET STORAGE ATTRIBUTES to change the block-content state, other sharers will observe the new state through EXTRACT AND SET STORAGE ATTRIBUTES Extract, and all sharers are subject to the consequences, such as discard operations and resulting block-volatility and addressing exceptions. For proper operation, virtual machines sharing read-write storage must cooperate with regard to collaborative memory management states, just as they must cooperate with regard to storage contents and storage keys.

## Implications for the VMDUMP Command

---

When the collaborative memory management assist is used, the VMDUMP command omits, without indication, any non-stable pages in the specified range.

## Chapter 27. 370 Accommodation Facility Overview

This chapter provides an overview of the 370 Accommodation Facility. It includes background information describing why this facility is useful and introductory information describing how to use it.

### Background

One of the reasons that CMS users find it difficult to migrate from virtual machines using the System/370 architecture to virtual machines using a later architecture (370-XA, ESA/370, ESA/390, or ESA/XC,<sup>7</sup> herein called generically *ESA-family* architectures) is that they are using, and must continue to use, programs that cannot tolerate these architectures. Unlike most operating systems, CMS runs its applications in virtual machine supervisor state. This allows applications to include privileged instructions. The lack of low-level system services in older versions of CMS often forced applications to use privileged instructions to accomplish their goals. While the 370-XA architecture was defined to be highly upward compatible with the System/370 architecture *for problem-state instructions*, this does not cover all instructions used by CMS applications. Privileged instructions, the format of the Program Status Word (PSW), and interruption-parameter formats, are not upward compatible from the System/370 architecture to the ESA-family architectures.

Many CMS programs therefore exist that are restricted to running in 370 virtual machines. Many of these programs have not been converted to tolerate ESA-family architectures, so users have been prevented from using the enhancements provided by the newer architectures.

### System/370 Constraints

For CMS Level 11 and prior levels, in a 370 virtual machine, CMS could use at most 16 megabytes of storage for programs, due to the 24-bit addresses provided by the System/370 architecture.

Beginning with CMS Level 12, CMS no longer supports 370 virtual machines. Therefore, users are encouraged to migrate to ESA-family virtual machines. The 370 Accommodation Facility can help you in this migration.

### High-level Description

The 370 Accommodation Facility allows CMS applications written for 370 virtual machines to run in ESA-family virtual machines. The 370 Accommodation Facility is successful in running the majority of 370 CMS applications, but not every 370 application is guaranteed to run in ESA-family virtual machines with 370 Accommodation active.

Two levels of 370 Accommodation support are offered. The first level is provided by CP processing alone. The second level is provided by supplementing the CP processing with CMS assistance. Although the first level of support has less overhead, the second level of support is more powerful, and allows more 370 programs to run in ESA-family virtual machines. Applications that cannot run with either of these 370 Accommodation levels active must be converted to run in an ESA-family virtual machine.

A program written for System/370 may do one or more of the following that prevent it from running in an ESA-family virtual machine:

- Use instructions that exist only in the System/370 architecture. Certain privileged instructions, including I/O instructions and storage-key operations, are unique to System/370, and are replaced by new instructions in the ESA family. The instructions of most importance to CMS programs written to run in a 370 virtual machine are: SIO, TIO, SSK, ISK, DIAGNOSE code X'18', and DIAGNOSE code X'20'. Other instructions less commonly used are: SIOF, HIO, HDV, CLRIO, RRB, and the SIOF-Real subcode

<sup>7</sup> z/VM supports only ESA/390 and ESA/XC architectures for CMS. z/VM also supports z/Architecture and z/XC for z/CMS, but a virtual machine in these *z-family* architectures cannot run with 370ACCOM ON.

of DIAGNOSE code X'98'. The 370 Accommodation Facility extends the ESA-family architectures to provide these instructions.

- Load a BC-mode PSW. This is usually done either by a LOAD PSW (LPSW) instruction or by the loading of the new PSW as part of interruption processing. 370 Accommodation extends the ESA-family architectures by causing the BC-mode PSW to be translated into an equivalent ESA PSW, without interrupting the application.
- Manipulate the system mask in the PSW assuming that the PSW is a BC-mode PSW. Because CMS has not always offered ENABLE and DISABLE macros, programs often resorted to direct manipulation of the system mask using instructions like SET SYSTEM MASK (SSM) or STORE THEN OR SYSTEM MASK (STOSM). Because CMS always uses a BC-mode PSW when running in a 370 virtual machine, most programs were written to assume that mode. BC-mode PSWs are not provided in the ESA family, so such programs usually fail in these modes. 370 Accommodation extends the ESA-family architectures by causing a PSW that is manipulated in this manner to be *repaired*, without interrupting the application.
- Use the interval timer. In a System/370 virtual machine, the interval timer is a facility which allows a program to measure either elapsed time or CPU time, depending on the setting established by the CP SET TIMER command. The 370 Accommodation facility extends the ESA-family architectures to provide the interval timer.
- Use interruption parameters, having fetched them from the locations associated with BC-mode PSWs. When an interruption occurs in System/370 architecture, the machine stores the interruption parameters in different places depending on whether the PSW at the time of the interruption was a BC-mode PSW or an EC-mode PSW. 370 CMS programs that replace CMS interruption new PSWs with their own are usually written to use the interruption parameters in the BC-mode locations. Even if the BC-mode PSW that would be loaded as part of interruption processing is repaired, such *PSW-stealing* programs would fail in ESA-family virtual machines because the interruption parameters are not stored in the locations being examined by the program. 370 Accommodation extends the ESA-family architectures by recognizing that a 370 program has stolen the interruption new PSW (specifically, that the interruption new PSW designates BC mode, or in the case of I/O interruptions, that the I/O new PSW designates BC mode or is a 24-bit EC-mode PSW) and presenting interruption parameters in both System/370 BC-mode and ESA-family format and locations. The BC-mode format allows the stealing program to process the interruption. The ESA-family format allows CMS to process it in the event that the stealing program passes control to CMS, which often happens when the interruption trapped is not one that the application sought to handle. Because it is not possible to know beforehand which interruptions will be handled by 370 or by ESA-family programs, both interruption formats are stored in these cases. The additional 370 Accommodation services provided by CMS also allow CP to detect when a program has modified just the low-order three bytes or the low-order four bytes of either the I/O or the external new PSWs. Many programs do this with the intent of merely redirecting control to their own interruption handler, but should nevertheless be considered to be stealing the PSW.

## When Should 370 Accommodation be Used?

In general, 370 Accommodation should be activated to try any program that worked in a 370 virtual machine but fails in an ESA-family virtual machine. There are specific symptoms, however, that are indicative of programs that may be aided by 370 Accommodation:

- If a program issues an instruction that is not valid in a given architecture, an operation-exception program interruption occurs. This is the result that would occur if a 370 application tries to issue an instruction (for example, TIO) that does not exist in the ESA-family architectures. CMS reports this event with messages similar to the following:

```
DMSABE148T System abend 0C1 called from hhhhhhhh reason code 00000000
DMSABE141T Operation exception occurred at hhhhhh in routine ccccccc
```

The first message may not always appear.

- If a program manipulates the system mask of an ESA PSW as if it were BC mode, or loads a BC-mode PSW in an ESA-family virtual machine, a specification-exception program interruption occurs. CMS reports this event with messages similar to the following:

```
DMSABE148T System abend 0C6 called from hhhhhhhh reason code 00000000
DMSABE141T Specification exception occurred at hhhhhh in routine cccccccc
```

The first message may not always appear.

- If a program uses the interval timer, and pauses until it receives an external interruption from the interval timer, it will appear to hang.
- If a program steals the CMS I/O new PSW and then pauses until it receives a particular interruption, it may appear to hang.
- If a program steals the CMS external new PSW and then pauses until it receives a particular interruption, it may appear to hang, or it may pass an interruption on to CMS that will confuse CMS. CMS reports such an event with messages similar to the following:

```
DMSHDE744R Unexpected external interrupt detected, interrupt status consists
of: CODE=hhhh, CPUID=hhhh, PARAMETER=hhhhhhhh. Enter a
1 for ABEND or 2 for RESUME:
```

- If a program steals the CMS program-new PSW in an ESA-family virtual machine, replacing it with a BC-mode PSW, the following CP message would result if a program interruption ever occurs:

```
HCPGIR453W CP entered; program interrupt loop
```

If you see any of these symptoms when attempting to run a 370 application in an ESA-family virtual machine, 370 Accommodation should be activated to see if it helps.

## Choosing a Level of 370 Accommodation

Two levels of 370 Accommodation support are offered. In the first level, CP alone performs dynamic repair actions that allow many 370 programs to run. In the second level of support, CMS manipulates its own I/O and external new PSWs to make it easier for CP to detect PSW-stealing programs. This allows a great number of additional 370 programs to run successfully in ESA-family virtual machines.

The most important difference between the two levels of support is that when it is not needed by an application, there is no performance penalty for activating just the CP level of 370 Accommodation, but there is a performance penalty if you activate the CMS level of 370 Accommodation. To choose which level is best, you should experiment with your 370 applications. First try activating just the CP level of 370 Accommodation when you run your 370 program. If your program works, then there is no need to use the CMS level of 370 Accommodation. If your program does not work, or works except in certain circumstances, try activating the CMS level of 370 Accommodation and running the program again. If it does not work with the CP level of support, but does work when you activate the CMS level of support, then you should use the CMS level of 370 Accommodation when running that program.

## Activating 370 Accommodation

The CP level of the 370 Accommodation Facility is activated by issuing the following command:

```
CP SET 370ACCOM ON
```

You can determine the current setting by issuing the CP QUERY SET command.

The CMS level of the 370 Accommodation Facility is activated by issuing the following CMS command:

```
SET CMS370AC ON
```

When you issue the SET CMS370AC ON command, CMS will issue a CP SET 370ACCOM ON command as part of its processing. If you later issue the SET CMS370AC OFF command, CMS will restore the setting of CP SET 370ACCOM to what it was when the SET CMS370AC ON command was issued. Issue the QUERY CMS370AC command to interrogate the current setting of the CMS 370 Accommodation facility.

## 370 Accommodation Facility Overview

If you find that activating 370 Accommodation helps a 370 application to run in an ESA-family virtual machine, you must decide when to activate the facility for everyday execution of the application. You have the following choices:

1. Issue the CP SET 370ACCOM ON command or the SET CMS370AC ON command before starting the 370 application. This is the simplest approach, especially when testing the usefulness of the facility.
2. Write a *cover exec* to preserve the current 370 Accommodation setting, activate it, run the 370 application, and then restore 370 Accommodation to its original setting. A cover exec that activates just the CP level of 370 Accommodation might look like the following:

```
/* Cover exec for a 370 application */
Address Command

/* Get the current state of 370ACCOM */
Parse Value Diag(8,'QUERY SET') With '370ACCOM' accsetting . '15'x

/* Strip any trailing commas in case other parameters are */
/* someday added to the QUERY SET response. */
accsetting=Strip(accsetting,',','Trailing')

/* Activate the 370 Accommodation Facility */
If accsetting\='ON' Then 'CP SET 370ACCOM ON'

/* Run application with the arguments passed to this cover exec. */
/* (Replace 370APPL below with the name of your 370 application). */
Address CMS '370APPL' Arg(1)
retcode=rc /* Preserve return code for exit */

/* Restore 370ACCOM, if necessary */
If accsetting\='ON' Then 'CP SET 370ACCOM' accsetting

Exit retcode /* Return with return code from application */
```

There are several features of this exec worth mentioning:

- a. It makes no assumptions about the setting of 370 Accommodation when the exec is invoked. Upon exit, it is restored to whatever value it had on entry.
- b. When parsing the response to QUERY SET, it tolerates the presence of parameters after 370ACCOM.
- c. It allows arguments to be passed to the application program, and returns the application's return code upon exit.

A cover exec that activates the CMS level of 370 Accommodation might look like the following:

```
/* Cover exec for a 370 application */
Address Command

/* Get the current state of CMS370AC */
'PIPE COMMAND QUERY CMS370AC|SPEC W3|VAR accsetting'
If rc\=0 Then Exit rc

/* Activate the CMS 370 Accommodation facility */
If accsetting\='ON' Then 'SET CMS370AC ON'

/* Run application with the arguments passed to this cover exec. */
/* (Replace 370APPL below with the name of your 370 application). */
Address CMS '370APPL' Arg(1)
retcode=rc /* Preserve return code for exit */

/* Restore CMS370AC, if necessary */
If accsetting\='ON' Then 'SET CMS370AC' accsetting

Exit retcode /* Return with return code from application */
```

This cover exec assumes that the level of CMS is at least CMS Level 12.

3. Issue the CP SET 370ACCOM ON command from your PROFILE EXEC. Your PROFILE EXEC runs each time you IPL CMS. If you find that you always want to activate 370 Accommodation, then putting it in your profile can save you from worrying about each individual application. It is probably best to avoid putting a SET CMS370AC ON command in your PROFILE EXEC, due to the performance degradation it

induces. If that userid generally runs only one program, however, or if you find that you nearly always need the CMS level of 370 Accommodation, then you should consider it.

4. The systems programmer may issue the CP SET 370ACCOM ON command from the SYSPROF EXEC associated with the CMS you IPL, or perhaps an exec called from SYSPROF EXEC. The SYSPROF EXEC runs each time you IPL CMS, before your PROFILE EXEC runs. If the systems programmer believes that most users find the facility helpful, you may find that it is already active when your PROFILE EXEC runs. To determine the setting of the CP SET 370ACCOM command, issue the CP QUERY SET command after your PROFILE EXEC runs. To determine the setting of the SET CMS370AC command, issue the QUERY CMS370AC command.

There are several things to be aware of when using 370 Accommodation:

1. The 370 Accommodation Facility is automatically turned off whenever your virtual machine experiences a subsystem reset. Such a reset usually occurs during the execution of the following CP commands:

```
IPL
DEFINE STORAGE
SET MACHINE
SYSTEM RESET
SYSTEM CLEAR
DETACH CPU
```

370 Accommodation is turned off automatically in case the next operating system you IPL is not CMS. The architectural extensions that exist when 370 Accommodation is active might confuse a guest operating system, so CP turns it off.

2. It is possible, though unlikely, for a program to successfully run in an ESA-family virtual machine *before* activating 370 Accommodation, but to fail once 370 Accommodation is activated. See [“Possible Adverse Effects on a Working Program”](#) on page 912 for more information on how that can occur. If you find a program like this, you may want to consider using an alternative for activating 370 Accommodation other than including the CP SET 370ACCOM ON or SET CMS370AC ON command in your PROFILE EXEC or the SYSPROF EXEC.
3. When it is not needed by an application, there is no performance penalty for activating just the CP level of 370 Accommodation. When it is needed, there is a slight performance cost because CP is repairing conditions during execution that would otherwise result in program exceptions. The degree of the performance degradation is related to how much repair action is required. Normally, you will not notice it.

On the other hand, there may be more of a performance cost for activating the CMS level of 370 Accommodation. In order to help CP recognize programs that steal the I/O and external new PSWs, CMS changes its own I/O and external new PSWs in a way that causes CP to perform a small amount of extra processing for every I/O and external interruption reflected to the virtual machine. If your virtual machine fields a lot of these interruptions, you might notice the performance penalty. If you are running a 370 program that *does* need the CMS level of 370 Accommodation, though, the cost of having it active doesn't necessarily rise. It depends only on the frequency with which I/O and external interruptions are received.

## Running a Restricted CMS MODULE

---

The CMS GENMOD command used to have a 370 option that could be used to generate a MODULE file that CMS restricted to executing in a 370 virtual machine. This option prevented the execution of applications in ESA-family virtual machines with 370 Accommodation active.

If you have used this option, you need to do one of the following to enable your programs to run in that environment:

- Use the GENMOD command to generate a new module without using the 370 option. Your program can then run in any virtual machine architecture, so you can run it with 370 Accommodation active.

- Use the CMS SET GEN370 OFF command to cause CMS to bypass checking for that condition when loading the MODULE file. If you no longer have access to the original source program, or at least the TEXT files, this may be your only choice. If you use this method, you may consider adding this command to a *cover exec* for the application, or possibly including it in your PROFILE EXEC.

## What is Not Provided by the 370 Accommodation Facility

---

Not all programs written for a 370 CMS virtual machine run successfully in an ESA-family virtual machine with 370 Accommodation active. The following are some reasons a program may not work:

- If an application uses internal CMS fields, the application is not specifically helped by 370 Accommodation. The format and location of some internal CMS fields have changed from VM release to VM release, and if an application program depends on the layout of such a field, it may fail. Such a program may already fail in 370 virtual machines of the later CMS releases, so it is not unexpected.
- If an application makes use of instructions or architectural facilities that are not typically used by CMS or 370 CMS applications, it may not run even with 370 Accommodation active. An example of such an architectural facility is Dynamic Address Translation (DAT). If a program uses System/370 DAT, it may not work in an ESA-family virtual machine.
- If an application selectively enables for I/O interruptions by setting only some of the channel mask bits in the BC-mode PSW, or by setting specific bits in control register 2, it may not run even with 370 Accommodation active. When this kind of application runs in an ESA-family virtual machine, control register 2 is not examined; and because 370 Accommodation performs only an approximate translation of the PSW enablement, the application may not work as expected.
- If an application loads a BC-mode PSW with the problem-state bit set to one, it may not run with 370 Accommodation active. 370 Accommodation assigns a special meaning to the problem-state bit in BC-mode PSWs, and is not always able to determine whether the special meaning should apply to the PSW in which it's set.

## Possible Adverse Effects on a Working Program

---

If an application program does any of the following, it may fail in an ESA-family virtual machine with 370 Accommodation active, even though it runs when 370 Accommodation is not active. If you encounter such a program, 370 Accommodation should be set off before running the program.

1. If a program depends upon getting an operation-exception program interruption in an ESA-family virtual machine when issuing an instruction valid only on the System/370 architecture, it may fail. When 370 Accommodation is active, CP assumes the application was written to run in a 370 virtual machine, and simulates the instruction. The application may become confused when the expected program interruption does not occur. The likely result is that it will fail to exploit 31-bit addressing, even though it is running in an ESA-family virtual machine.
2. If a program depends upon getting a specification-exception program interruption when loading a BC-mode PSW in an ESA-family virtual machine, it may fail. When 370 Accommodation is active, CP assumes the application was written to run in a 370 virtual machine and translates the PSW to EC mode. The application may become confused when the expected program interruption does not occur.
3. If a program depends upon getting a specification-exception program interruption in an ESA-family virtual machine when setting unassigned bits in the PSW system mask, it may fail. When 370 Accommodation is active, CP assumes the application was written to run in a 370 virtual machine and is trying to enable for I/O interruptions in what it expects is a BC-mode PSW, and CP translates the PSW to the EC-mode equivalent. The application may become confused when the expected program interruption does not occur.

It may sound unlikely that an application would depend on any of these events, but there is a case in which it is possible. Some application programs need to know what architecture mode they are running in because sometimes different actions must be taken by the program for different architecture modes. Usually such a program determines what mode it is in by obtaining the information from CMS. That information is available from CMS using the Extract/Replace CSL service, from information in the simulated OS CVT, or from fields in NUCON. Some applications, however, were written to determine it

themselves. The usual procedure is to try something that should work in one architecture mode and fail in others. For example, the program might try loading an EC-mode, 31-bit-mode, PSW. If a specification exception program interruption occurs, then that PSW format is not valid in the current architecture, so the architecture must be System/370 architecture. If no program interruption occurs, then it must be one of the ESA-family architectures. The example just given continues to work even with 370 Accommodation active because the program interruption occurs in a 370 virtual machine, and a 370 virtual machine is not affected by 370 Accommodation.

But, suppose the program tries loading a BC-mode PSW instead. If a program interruption occurs, it knows it is using one of the ESA family architectures because a BC-mode PSW is not permitted in those architectures. If no program interruption occurs, it knows it is using the System/370 architecture. But with 370 Accommodation active, CP allows a BC-mode PSW to be loaded in an ESA-family virtual machine and silently converts it to the equivalent ESA PSW. No program interruption is presented to the application. If an application performs a test like this, it might incorrectly conclude it is in a 370 virtual machine instead of an ESA-family virtual machine. When you have such an application, 370 Accommodation should be set off before running the program. One possible sign of such an incorrect conclusion by the program would be that the program will not exploit 31-bit addressing, even when it is in an ESA-family virtual machine.

## Chapter 28. 370 Accommodation Facility Definition

This chapter provides a detailed description of the architecture changes observable in ESA-family virtual machines when the 370 Accommodation Facility is active.

### System/370 Instructions

When 370 Accommodation is active, the ESA-family virtual machines are extended to support some instructions that are normally limited to System/370 architecture. The following sections describe these additions. Except where specifically mentioned, the operation of the instructions is as defined in the *System/370 Principles of Operation*.

### System/370 I/O Instructions

The following System/370 I/O instructions are provided when 370 Accommodation is active:

- START I/O (SIO)
- START I/O FAST RELEASE (SIOF)
- TEST I/O (TIO)
- HALT I/O (HIO)
- HALT DEVICE (HDV)
- CLEAR I/O (CLRIO)
- DIAGNOSE code X'18'
- DIAGNOSE code X'20'
- DIAGNOSE code X'98', SIOF-Real subcode

These instructions operate the same under 370 Accommodation as they do for System/370, with the following changes:

- The operand System/370 I/O address is treated as an ESA-family device number.
- The addressed channel and device is available to all CPUs in the configuration. The instructions are not restricted to a single CPU as they would be in a 370 virtual machine on VM/ESA.
- The I/O address specified is not limited to X'1FFF', which is normally the case for a 370 virtual machine on VM/ESA. This has the effect of making it appear as though there are 256 channels available to the program.
- If *vestigial status* is pending at the subchannel, it is discarded before proceeding with instruction execution. For more information on this new type of status in the subchannel, see [“Vestigial Status” on page 921](#).
- If the subchannel is not enabled at the beginning of instruction execution, it becomes enabled before proceeding with instruction execution. That is, bit 8 of word 1 of the subchannel-information block associated with the subchannel is set to one.
- I/O interruptions generated from operations initiated by these instructions are masked by interruption subclass (ISC) not channel number. Whether a CPU is enabled for interruptions is determined, therefore, by bit 6 of the PSW and the interruption-subclass mask in control register 6, not channel-enablement bits in the PSW and control register 2.

For the START I/O FAST RELEASE (SIOF) and CLEAR I/O (CLRIO) instructions, it should additionally be noted that bit 0 of control register 0, the block-multiplexing-control bit, is examined during instruction execution, even though that bit position is unassigned in the ESA-family architectures.

### SET STORAGE KEY (SSK)

This instruction operates the same under 370 Accommodation as it does for System/370, with the following changes:

- This instruction operates as if bit 7 of control register 0, the System/370 storage-key-exception-control bit, were set to one. That is, bit 7 of control register 0 is not examined, and is considered to be a one during instruction execution.

### INSERT STORAGE KEY (ISK)

This instruction operates the same under 370 Accommodation as it does for System/370, with the following changes:

- This instruction operates as if bit 7 of control register 0, the System/370 storage-key-exception-control bit, were set to one. That is, bit 7 of control register 0 is not examined, and is considered to be a one during instruction execution.
- This instruction operates as if the PSW were in BC mode, with respect to determining what should be placed into bit positions 29-30 of general register R<sub>1</sub>.

### RESET REFERENCE BIT (RRB)

This instruction operates the same under 370 Accommodation as it does for System/370, with the following changes:

- This instruction operates as if bit 7 of control register 0, the System/370 storage-key-exception-control bit, were set to one. That is, bit 7 of control register 0 is not examined, and is considered to be a one during instruction execution.

## ESA-Family Instructions

---

When 370 Accommodation is active, the following ESA-family instructions are changed. Except where specifically mentioned, the operation of the instructions is as defined in the *Principles of Operation* document appropriate to the specific ESA-family architecture. References are made below to the term *vestigial status*. For more information on this new type of status in the subchannel, see [“Vestigial Status” on page 921](#).

### TEST SUBCHANNEL (TSCH)

This instruction operates normally, with the following change:

- If executed against a subchannel that has vestigial status pending, the instruction is executed as if the vestigial status were normal status. That is, the status is stored in the interruption-response block (IRB), with bit 31 of word 0, the status-pending bit, set to one. The status is then cleared, and the instruction completed with condition code 0.

### STORE SUBCHANNEL (STSCH)

This instruction operates normally, with the following change:

- If executed against a subchannel that has vestigial status pending, the instruction is executed as if the vestigial status were normal status. That is, the status is stored in the subchannel-information block (SCHIB), with bit 31 of word 0, the status-pending bit, set to one. The status remains pending as vestigial status.

### TEST PENDING INTERRUPTION (TPI)

This instruction operates normally, with the following change:

- If TPI recognizes and clears an interruption condition, it discards any vestigial status pending at the subchannel. The status in abeyance behind the vestigial status — there must be such status for

the subchannel to be interruption-pending — becomes ordinary pending status, and the subchannel becomes no longer interruption-pending.

## Discarding Vestigial Status

The following ESA-family instructions are changed to discard any vestigial status at the beginning of instruction execution. That is, if vestigial status is pending at the subchannel when any of the following instructions is executed, the vestigial status is discarded before proceeding with instruction execution. If any additional status was held in abeyance behind the vestigial status, it will become normal pending status.

- CLEAR SUBCHANNEL (CSCH)
- HALT SUBCHANNEL (HSCH)
- MODIFY SUBCHANNEL (MSCH)
- RESUME SUBCHANNEL (RSCH)
- START SUBCHANNEL (SSCH)
- DIAGNOSE code X'58'
- SSCH-Real subcode of DIAGNOSE code X'98'
- DIAGNOSE code X'A4'
- DIAGNOSE code X'A8'

## Other Instructions

---

When 370 Accommodation is active, the following instructions are changed:

### DIAGNOSE code X'28'

This instruction is provided in both System/370 virtual machines and ESA-family virtual machines. When used by System/370 programs, the Ry register contains a device address, but when used by ESA-family programs, the Ry register contains a subchannel number. Since CP does not know, when the instruction is issued, what kind of program is running, the following heuristic is used to interpret the Ry value specified by the program when 370 Accommodation is active: If the Ry value, when viewed as a System/370 device address, selects a device which exists, and at least one of the following is true, then the Ry value is interpreted as a device address. Otherwise, the Ry value is interpreted as a subchannel number.

- There is an active channel program on the device with that device address, and the channel program was started by a System/370 I/O instruction (e.g., SIO or SIOF).
- The Ry value, when viewed as a 370-XA subchannel number, does not select a subchannel with a device assigned to it.
- The Ry value, when viewed as a 370-XA subchannel number, selects a subchannel with a device assigned to it, but there is no active channel program on that device.

## The Interval Timer

---

The System/370 architecture offers a timing facility called the interval timer, which is a location in storage which is updated by the machine as time passes. When running in a System/370 virtual machine on VM/ESA, the CP SET TIMER command can be used to select whether the interval timer should be updated both when the virtual machine is running and when the virtual machine is in wait state (TIMER REAL), or just when the virtual machine is running (TIMER ON). If no use of the interval timer is intended, the CP SET TIMER OFF command can be used to disable interval timer emulation.

When 370 Accommodation is active, CP will respect the setting of the CP SET TIMER command, and will emulate the presence of an interval timer in ESA-family virtual machines. Note, however, that since this is done without the machine assistance that is normally available for System/370 virtual machines, the interval timer may not be decremented as often as prescribed by the *System/370 Principles of Operation*. On average, though, CP will update the interval timer at the proper overall rate. The observable difference

is that it may not be as smooth as it would be if machine assistance were available. For example, instead of updating the interval timer once every 1/300 of a second, it may be updated twice in 1/150 of a second, or three times in 1/100 of a second.

When 370 Accommodation is activated, the setting of CP SET TIMER is switched from OFF to either ON or REAL, depending on what it was set to before the virtual machine switched to one of the ESA family of architectures. If the System/370 architecture was not previously used, the default is ON. This is the same transition that occurs when a SET MACHINE 370 command is processed.

When an interval timer interruption becomes pending, it is masked by bit 24 of control register 0, the interval-timer subclass-mask bit in the System/370 architecture, even though that bit position is unassigned in the ESA-family architectures. When an interval-timer external interruption is reflected, the interruption condition is never combined with other external interruption conditions, even though this can occur in the System/370 architecture.

When 370 Accommodation is active, the CP SET TIMER command is available to change the type of interval-timer emulation. Normally this command is not available to ESA-family virtual machines. Similarly, the EXTERNAL INTERVAL command can be used to force an interval-timer interruption to become pending.

## PSW Conversions

---

When 370 Accommodation is active, certain events in an ESA-family virtual machine cause changes to be made to the Program Status Word (PSW), either when it is being introduced or when it is being stored. The following is a summary of the PSW conversions that can occur. They are described in more detail following the summary.

- When a BC-mode PSW is introduced, it is converted to an equivalent EC-mode PSW.<sup>8</sup>
- When an EC-mode PSW with unassigned bits set in the system mask is introduced, it is repaired by converting the system mask to the equivalent EC-mode system mask.
- When a *mapped PSW* is introduced, it is converted into an EC-mode PSW substantially equivalent to the original EC-mode PSW. For more information on this new PSW format, see [“Mapped PSWs” on page 919](#).
- When a supervisor call, external, I/O, or program interruption is being presented, and the interruption new PSW is a BC-mode PSW, or in the case of I/O interruptions, if the I/O new PSW is a BC-mode or 24-bit EC-mode PSW, the EC-mode PSW that would be stored as the interruption-old PSW is first converted to BC mode so that the interruption code can be stored as part of the old PSW. If such a conversion cannot be done without loss of information, it is converted to a mapped PSW instead.

## BC-mode PSW Conversion

When a program written for System/370 introduces a BC-mode PSW with 370 Accommodation active, it is converted to an EC-mode PSW. A BC-mode PSW is typically introduced with a LOAD PSW (LPSW) instruction or when a new PSW is loaded during the interruption processing. Commands such as CP STORE PSW and CP SYSTEM RESTART can also be used to introduce a new PSW.

However the PSW is introduced, it is converted into an EC-mode PSW using the following process:

1. The condition code is moved from bit positions 34-35 to 18-19.
2. The program mask is moved from bit positions 36-39 to 20-23.
3. Bit 6, the EC-mode I/O-enablement bit, is set to one if any of bits 0-5 are set to one.
4. Bits 0-5, 16-17, and 24-39 are set to zero.
5. Bit 12, the EC-mode bit is set to one.

When this conversion is performed, no interruption or other indication is presented to the program.

---

<sup>8</sup> PSWs in the ESA family are not called EC mode, because since only one PSW format exists, differentiation is not necessary. The term as used here refers to any PSW with bit 12 set to one.

## BC-mode System Mask Conversion

When a program written for System/370 introduces a system mask in the (EC-mode) PSW setting unassigned bits to one, the PSW is repaired. Specifically, whenever the PSW has a format error caused by an unassigned bit in the system mask being set to one, if the rest of the PSW is valid, the format error is repaired by clearing bits 0-5 of the PSW and setting bit 6, the I/O enablement bit, to one. No interruption or other indication of this repair action is presented to the program.

## Mapped PSW Conversion

When a *mapped PSW* is introduced, it is converted into an EC-mode PSW that is approximately the same as the EC-mode PSW from which the mapped PSW was originally formed. Mapped PSWs are described in detail in [“Mapped PSWs” on page 919](#). Mapped PSWs may be stored, for example, as interruption old PSWs. If an interruption handler reloads the interruption old PSW, introducing the mapped PSW as the current PSW, it is converted into an EC-mode PSW.

If the mapped PSW was unchanged from the time it was stored, then the new EC-mode PSW can differ from the original EC-mode PSW only in the following ways:

- If the original PSW had a key other than X'0' or X'E', the key has been restored to X'0' instead. Unless the program was depending upon getting an access exception for a key mismatch, this should not cause any detrimental effects. Since the original PSW had to be in supervisor state to be mapped in the first place, changing the key this way does not violate any virtual-machine protection mechanisms.
- If the original PSW was enabled for machine-check interruptions, it is now disabled.
- If the original DAT-off PSW had bit 16 set to one, it is now set to zero. Bit 16 is not significant for CMS programs that do not use DAT, so this should not be noticeable.

## PSW Conversions During Interruption Processing

When an external, supervisor call, program, or I/O interruption is being presented and the interruption new PSW is a BC-mode PSW, or in the case of I/O interruptions, if the I/O new PSW is a BC-mode or 24-bit EC-mode PSW, the EC-mode PSW that would be stored as the interruption old PSW is first converted to BC mode. This is necessary in order to store the interruption code in the old PSW, which is where 370 CMS applications expect it to be. See [“Interruption Parameters” on page 920](#) for more information on the storing of interruption parameters when 370 Accommodation is active. If the PSW cannot be converted without loss of information, it is converted to a mapped PSW instead.

Specifically, if bits 0-5, 16-17, and 24-39 in the original EC-mode PSW are all zeros, then it can be directly converted to a BC-mode PSW with no loss of information. The following describes that process:

1. The condition code is moved from bit positions 18-19 to 34-35.
2. The program mask is moved from bit positions 20-23 to 36-39.
3. Bits 18-23 are set to zero.
4. Bits 0-5, the BC-mode I/O-enablement bits for channels 0 through 5, are set to one if bit 6 was one in the original PSW.
5. Bit 12, the EC-mode bit, is set to zero.

## Mapped PSWs

If the PSW cannot be converted directly without losing information, it is transformed into a mapped PSW. This is the only condition that causes a PSW to be mapped. See [“PSW Mapping Algorithm” on page 924](#) for details of the transformation. A mapped PSW may be relied on to have the following attributes:

- Bit 6 contains the I/O enablement mask bit.
- Bit 7 contains the external enablement mask bit.
- Bit 14 contains the wait-state bit.
- Bits 16-31, when a mapped PSW is stored, contain the interruption code. When a mapped PSW is reloaded, these bits are ignored.

- Bits 32-33 contain the instruction-length code (ILC) of the instruction which caused the interruption, if appropriate for the type of interruption,
- Bits 34-35 contain the condition code.
- Bits 36-39 contain the program mask.

The PSW fields previously listed have the same bit positions in a mapped PSW as they do in a BC-mode PSW. This is appropriate since the interruption handler expects to see a BC-mode old PSW. So long as an interruption handler confines itself to changing just those bits in the interruption old PSW, the mapped PSW may be reloaded safely and still be transformed by CP back into a proper EC-mode PSW.

## Interruption Parameters

---

When a 370 CMS application replaces one of CMS's interruption new PSWs, it probably replaces it with a BC-mode PSW. A program that replaces an interruption new PSW, or even part of an interruption new PSW, is called a *PSW stealer*. When a PSW stealer's interruption handler is driven, it typically examines the interruption to see if it is one that requires special processing. If so, the processing is done, and the interrupted program is resumed. If not, the interruption is typically *passed on* to CMS by loading the PSW that was the new PSW before it was stolen. For instance, if the program is trying to use the clock comparator, it may replace CMS's external new PSW to trap interruptions due to the clock comparator before CMS sees them. If the external interruption is from the clock comparator, it is handled. If the external interruption is not from the clock comparator, it is passed on to CMS. For example, the program may be driving a particular I/O device and want to trap I/O interruptions arriving from that device before CMS sees them.

Interruption codes, such as the external interruption code and the I/O interruption code, are stored as part of the interruption old PSW in System/370 architecture when the PSW at the time of the interruption is in BC mode. In the ESA-family architectures, however, they are stored in other locations in the prefix page. A 370 program that steals a PSW probably looks for the interruption code and other parameters in the locations that are reserved for them according to the BC-mode definition instead of the EC-mode definition. When 370 Accommodation is active, CP handles the different requirements by storing interruption parameters in *both* sets of locations if the interruption new PSW is in BC mode, or in the case of I/O interruptions, if the I/O new PSW is a BC-mode or 24-bit EC-mode PSW. The parameters are put in both sets of locations rather than just in the BC-mode locations to allow CMS to find them where it expects if the PSW stealer ends up passing the interruption on to CMS for processing. Because the restart new PSW and the machine-check new PSW are not typically stolen by CMS programs, this checking is only performed for external, SVC, program, and I/O interruptions.

Because the interruption code is stored as part of the BC-mode old PSW, and these bits are already in use in an EC-mode PSW, the current (always EC-mode) PSW is converted to BC mode before storing it during interruption presentation. Because an EC-mode PSW in ESA-family architectures contains more information than a System/370 BC-mode PSW, something must be done when bits are set in the EC-mode PSW that cannot be transferred directly to a BC-mode PSW. When it is not possible to convert the BC-mode PSW into EC mode without losing information, an attempt is made to convert it into a mapped PSW. The setting of some bits causes the mapping operation to be skipped, some bits are ignored, and some bits are relocated to other positions in the new, mapped PSW. If the resulting BC-mode or mapped PSW is subsequently reloaded, an approximation of the original EC-mode PSW is restored by relocating the bits back to their original positions. See [“PSW Conversions During Interruption Processing”](#) on page 919 for general information and [“PSW Mapping Algorithm”](#) on page 924 for details of the transformation.

Along with converting the current PSW to BC mode during presentation, the new PSW is converted to EC mode, if it is not in EC mode already, as it becomes the current PSW. This procedure should allow the interruption handler to find the interruption parameters either where they belong for BC-mode PSWs or where they belong for EC-mode PSWs. An interruption presented in this way is called a *hybrid interruption*.

## Special Conditions

The following special conditions may arise during the presentation of the interruption and the storing of the interruption parameters:

- If a program loads a BC-mode PSW that exactly matches the external, SVC, or program new PSW, either all or none of the following may occur to the value in the location assigned for the corresponding old PSW:
  - The value is converted to a BC-mode or mapped PSW
  - The value is combined with the ILC (if appropriate for that type of interruption) and with the interruption code
  - The value is replaced in the old PSW location.
- The storing of the interruption old PSW may be observed to be a multiple-access reference. That is, intermediate values may be observed by other CPUs in the location assigned to hold the interruption old PSW before the final value is stored. The storing of the interruption old PSW is normally single-access and doubleword-concurrent.

## Presentation of Interruptions

---

Under 370 Accommodation, when an external, I/O, program, or SVC interruption is to be presented, the corresponding interruption new PSW is first fetched and examined. When this interruption new PSW is an EC-mode PSW, the interruption is presented as an ESA-family interruption; when the interruption new PSW is a BC-mode PSW, the interruption is presented as a hybrid interruption. In the case of I/O interruptions, if the I/O new PSW is a 31-bit EC-mode new PSW, the interruption is presented as an ESA-family interruption; when the I/O new PSW is a BC-mode or 24-bit EC-mode PSW, the interruption is presented as a hybrid interruption. A hybrid interruption differs from an ESA-family interruption in the following ways:

- Before being stored as the interruption old PSW, the PSW at the time of the interruption is transformed into an equivalent BC-mode PSW, if possible. Otherwise, the PSW is transformed into a mapped PSW. See [“PSW Conversions During Interruption Processing”](#) on page 919 for information about this PSW conversion.
- In addition to storing interruption parameters according to the ESA-family of architectures, parameters are stored according to System/370 BC mode. For external, SVC, and program interruptions, the interruption code appears both in its ESA-family architecture location and in bytes 2-3 of the interruption old PSW. For I/O interruptions, the device number is stored in bytes 2-3 of the I/O old PSW, and an ESA-family I/O interruption code (including the subchannel ID and the subchannel's interruption parameter) is stored in its usual location.
- In System/370 architecture, a side effect of an I/O interruption is to clear the status pending at the subchannel. In ESA-family architectures, the subchannel remains status-pending until TSCH is executed (or the status is cleared another way). Under 370 Accommodation, a hybrid I/O interruption differs from both of these: a copy of the status is stored as the System/370 channel-status word (CSW), but the subchannel remains status-pending with *vestigial status* until some other event clears the vestigial status (see [“Vestigial Status”](#) on page 921).

When 370 Accommodation is active, all I/O interruptions store a System/370 CSW. If the interruption is not a hybrid interruption, this is the only way in which the interruption differs from a normal ESA-family I/O interruption. Specifically, if the I/O interruption is not a hybrid interruption, no device number is stored in the I/O old PSW, and the subchannel remains status-pending with *normal* (not vestigial) status.

## Vestigial Status

---

When a hybrid I/O interruption is presented, the pending interruption condition is cleared at the subchannel, and subchannel status is stored in the form of a System/370 channel-status word (CSW). This status also remains pending in the subchannel as vestigial status. Vestigial status is handled as follows:

1. If TSCH or STSCH is executed against a subchannel that has vestigial status pending, the instruction is executed as if the vestigial status were normal pending status. That is, TSCH stores the status (with the status-pending bit on) in the IRB, clears it, and completes with condition code 0. STSCH stores the status (with status-pending on) in the SCHIB but leaves it pending as vestigial status.

2. If CSCH, HDV, HIO, HSCH, MSCH, RSCH, SIO, SIOF, SSCH, TIO, DIAGNOSE code X'18', DIAGNOSE code X'20', DIAGNOSE code X'58', DIAGNOSE code X'98' SIOF-Real and SSCH-Real subcode, DIAGNOSE code X'A4', or DIAGNOSE code X'A8' is executed against a subchannel that has vestigial status pending, the vestigial status is discarded and the instruction thereafter executes normally.
3. If additional status is presented (either intermediate or primary status following intermediate status, or secondary status following primary status, or unsolicited status) while vestigial status is pending at the subchannel, then the subchannel becomes interruption-pending. The additional status is held in abeyance in the channel subsystem until the vestigial status is cleared. Such status is never merged with the vestigial status, even for combinations for which the ESA-family architectures would permit merging.

In such a case, when the interruption subsequently occurs for this subchannel, any vestigial status that is still pending at that time is discarded, and the status in abeyance becomes ordinary pending status. The interruption is then presented as having arisen from this (formerly abeyant) status. Presentation of this interruption follows standard 370-Accommodation rules: it is presented as a ESA-family or hybrid interruption according to the I/O new PSW. Note that if a hybrid interruption is presented, the new (formerly abeyant) status itself becomes vestigial status.
4. TPI does not present an I/O-interruption code designating a subchannel that has only vestigial status pending because, by definition, such a subchannel is not interruption-pending. However, as noted above, the arrival of subsequent status for a subchannel that has vestigial status pending makes that subchannel interruption-pending again. In that case, TPI can recognize and clear that interruption condition. If TPI presents an I/O-interruption code designating a subchannel with status in abeyance behind vestigial status, then the vestigial status is discarded during the execution of TPI. The abeyant status becomes ordinary pending status; and the subchannel becomes no longer interruption-pending.

### Programming Notes:

1. Discarding the vestigial status on SIO, SIOF, or SSCH usually makes the subchannel idle and allows the new I/O request to proceed. However, if subsequent status was held in abeyance behind the vestigial status, then the status in abeyance becomes normal (not vestigial) pending status when the original vestigial status is discarded. This newly pending status may prevent execution of a new start function.
2. A consequence of the handling of status that the device presents while vestigial status is pending in the subchannel is that 370 Accommodation will not work reliably in conjunction with a PSW-stealing program in a virtual multiprocessor environment when more than one CPU is simultaneously enabled for the same interruption subclass. As long as only one processor remains enabled for interruptions from a subchannel, the program that receives a hybrid I/O interruption is guaranteed that the status remains available to TSCH provided that the TSCH is executed before the CPU next enables for interruptions from that subchannel. When multiple CPUs are enabled for the same subclass, the status made vestigial by presentation of an interruption on one CPU may be prematurely cleared by presentation on another CPU of an interruption arising from subsequent status.

### Notes on the Definition of Vestigial Status:

1. The handling of vestigial status when additional status arrives (described in case [“3” on page 922](#)) is done for the following reasons:
  - a. A program that processes the interruption according to the ESA-family architectures must be able to retrieve the first status report through TSCH. Thus, the arrival of additional status after the hybrid interruption is presented but before the program reaches its TSCH must not cause the vestigial status to be discarded.
  - b. Conversely, a program that processes the interruption according to the System/370 architecture must be allowed to receive the second status report. That is, the vestigial status must not postpone presentation of the second status indefinitely because this could result in a *hang* condition: A program written for System/370 will use the status logged in the CSW and will never issue TSCH. When this program is finished with the CSW, it will simply reenables I/O interruptions. At that time, the vestigial status can safely be discarded and the second status report presented.

The critical dependency here is that an ESA-family program will issue TSCH before enabling for I/O interruptions. ESA-family programs that delay the TSCH beyond the point of reenabling may fail

under 370 Accommodation because a second incoming status report will clear the vestigial status before it can be presented to TSCH.

2. Merging of vestigial status with subsequent status is prohibited because such merging would not preserve the behavior desired for 370 Accommodation. If status were merged, then the single resulting status report would have to be classified as either vestigial or ordinary status, and neither is correct. Making the merged status vestigial prevents the subsequent status from being presented in the form of a System/370 CSW. Programs written for System/370 will never process the second status condition. Conversely, making the merged status ordinary status may cause the first status condition to be presented redundantly in CSW form, so that programs written for System/370 will process the same status indication twice.

Forbidding merging has the additional benefit of simplifying the 370 Accommodation environment by ensuring that when status is presented in a CSW, a subsequent TSCH will present identical status. Thus, System/370 and ESA-family programs will see the same sequence of status reports.

## The CMS 370 Accommodation Facility

When the SET CMS370AC ON command is used to activate the CMS level of 370 Accommodation, the following actions are taken by CMS:

- The current setting of the CP 370 Accommodation facility is interrogated and preserved for restoration when the CMS 370 Accommodation facility is turned off again.
- The CP SET 370ACCOM ON command is issued to turn on the CP 370 Accommodation facility.
- The CMS I/O and external new PSWs are replaced with BC-mode PSWs which direct interruption processing to *glue* code.
- When the glue code gets control on an I/O or external interruption, it converts the old PSW associated with the interruption from a BC mode or mapped PSW to the original EC-mode PSW that was in effect at the time of the interruption. Control is then passed to the normal CMS interruption handler by loading the interruption new PSW that was in effect before the SET CMS370AC ON command was issued.

### Notes on the Definition:

1. The intent of these actions is to allow CP and CMS to better handle 370 programs which steal only part of the interruption new PSW. Consider a program which overlays just the low-order three bytes of the I/O new PSW. The original I/O new PSW used by CMS is a 31-bit EC-mode PSW. If an application overlays just the low-order three bytes, the result will still be a 31-bit EC-mode PSW. Loading such a PSW during the reflection of an I/O interruption does not trigger CP's hybrid-interruption processing, so the application's interruption handler will not find the interruption parameters in the locations it expects. Moreover, the application's interruption handler will receive control in 31-bit mode, which is likely to cause it to fail, as 370 programs normally expect to run in 24-bit mode. Finally, if the instruction address in the original CMS I/O new PSW is above the 16-megabyte line, the resulting PSW has an instruction address which points neither to the CMS interruption handler nor to the application's interruption handler. Clearly a failure is very likely if control is passed to an unintentional location in storage.
2. Now consider the same scenario, having issued the SET CMS370AC ON command before running the 370 program. Now when the 370 program executes, the I/O new PSW is in BC mode, which in fact is what the application was coded to expect. When an I/O interruption occurs, hybrid interruption processing is performed by CP because the new PSW is in BC mode. This allows the application's interruption handler to find the interruption parameters in the locations it expects. The application's interruption handler will also receive control in 24-bit mode, which is what it expects. Since the CMS glue code is guaranteed to reside below the 16-megabyte line, there's no danger of an incorrect instruction address being formed when the I/O new PSW is modified.
3. If the application's interruption handler loads the original CMS I/O new PSW that it found, it would pass control to the glue code. The glue code will convert the I/O old PSW back into its original EC-mode form, because that's what the CMS interruption handler expects to find, and then pass control to the I/O interruption handler by loading the original 31-bit EC-mode PSW. This allows the CMS I/O interruption handler to be entered in the addressing mode it expects, with an interruption old

PSW in the form it expects. The pending status which caused the I/O interruption is still pending as vestigial status, and is thus available to be drained by the TSCH instruction in the CMS I/O interruption handler.

If the SET CMS370AC OFF command is issued, CMS restores its I/O and external new PSWs to their original values, and sets the CP 370 Accommodation facility to what it was when SET CMS370AC ON was issued. **It is very important that the CP SET 370ACCOM OFF command not be issued when SET CMS370AC ON is in effect.** This would leave CMS with BC-mode I/O and external new PSWs without the CP facility active to convert them into EC mode when an interruption occurs. CMS will probably fail soon after receiving the next I/O or external interruption.

Although the CMS 370 Accommodation facility is very useful for running certain types of PSW-stealing applications, it should be noted that since it causes CMS to run with BC-mode I/O and external new PSWs, it generates some additional overhead due to the extra CP processing involved with hybrid interruptions. This extra processing will occur even when you are not running a 370 application program. If possible, it is best to limit your use of the CMS 370 Accommodation facility to when you need it for a particular 370 application program instead of running with it active all of the time.

## PSW Mapping Algorithm

“PSW Conversions During Interruption Processing” on page 919 describes a case when it is necessary to convert, when using 370 Accommodation, an EC-mode PSW to a BC-mode PSW. If that is not possible without losing information, the EC-mode PSW is converted instead into a mapped PSW. This section describes the details of that conversion. This information is presented for diagnostic purposes only.

If an EC-mode PSW cannot be converted directly to a BC-mode PSW without losing information, it is transformed according to the following table:

| Table 211. Converting an EC-mode PSW to a mapped PSW. This table shows what happens to each bit of an ESA-family EC-mode PSW as it gets converted to a mapped PSW during interruption presentation. This conversion only occurs for PSWs that cannot be converted without loss of information. |                          |                                 |                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bit Positions in Original EC-mode PSW                                                                                                                                                                                                                                                          | Meaning in EC-mode PSW   | Bit Positions in New Mapped PSW | Explanation                                                                                                                                                                                                                                                                             |
| 0                                                                                                                                                                                                                                                                                              | Unassigned               | N/A                             | A 1 in this position will prevent conversion.                                                                                                                                                                                                                                           |
| 1                                                                                                                                                                                                                                                                                              | PER                      | 13                              | This bit position is vacated in order to free up contiguous bits for the addressing mode and high-order bits of the instruction address.                                                                                                                                                |
| 2-4                                                                                                                                                                                                                                                                                            | Unassigned               | N/A                             | A 1 in any of these positions will prevent conversion.                                                                                                                                                                                                                                  |
| 5                                                                                                                                                                                                                                                                                              | DAT                      | N/A                             | A 1 in this position will prevent conversion.                                                                                                                                                                                                                                           |
| 6                                                                                                                                                                                                                                                                                              | I/O enablement           | 6                               | This bit is left in this position in case it is manipulated by the interruption handler.                                                                                                                                                                                                |
| 7                                                                                                                                                                                                                                                                                              | External enablement      | 7                               | This bit is left in this position in case it is manipulated by the interruption handler.                                                                                                                                                                                                |
| 8-11                                                                                                                                                                                                                                                                                           | Key                      | 11                              | CMS typically uses only keys X'0' and X'E' in the PSW. These values will be converted to B'0' and B'1', respectively. Any other PSW key will be converted to B'0'.                                                                                                                      |
| 12                                                                                                                                                                                                                                                                                             | EC mode                  | N/A                             | A 0 in this position will prevent conversion. Bit 12 of the new mapped PSW will be set to 0 to indicate BC mode. This guarantees that the mapped PSW has an early format error associated with it, which in turn ensures that CP will be notified if this mapped PSW is ever re-loaded. |
| 13                                                                                                                                                                                                                                                                                             | Machine-check enablement | N/A                             | This bit will be ignored in the EC-mode PSW. When the mapped PSW is later re-loaded, the machine-check enablement bit will be set to 0.                                                                                                                                                 |
| 14                                                                                                                                                                                                                                                                                             | Wait state               | 14                              | This bit is left in this position in case it is manipulated by the interruption handler.                                                                                                                                                                                                |
| 15                                                                                                                                                                                                                                                                                             | Problem state            | N/A                             | A 1 in this position will prevent conversion. Bit 15 of the new PSW will be set to 1 to indicate the PSW is a <i>mapped</i> PSW.                                                                                                                                                        |

*Table 211. Converting an EC-mode PSW to a mapped PSW.* This table shows what happens to each bit of an ESA-family EC-mode PSW as it gets converted to a mapped PSW during interruption presentation. This conversion only occurs for PSWs that cannot be converted without loss of information. (continued)

| Bit Positions in Original EC-mode PSW | Meaning in EC-mode PSW                                | Bit Positions in New Mapped PSW | Explanation                                                                                                                                                                                         |
|---------------------------------------|-------------------------------------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16                                    | Address-space control for ESA or Z; unassigned for XC | N/A                             | A 1 in this position will be ignored. If the virtual machine is in ESA mode or Z mode, the bit is not effective anyway (PSW bit 5 is off). If the virtual machine is in XC mode, the bit must be 0. |
| 17                                    | Address-space control for ESA or Z; AR-mode for XC    | 10                              | This bit is preserved because if the virtual machine is in XC mode, this bit position indicates access-register mode.                                                                               |
| 18-19                                 | Condition code                                        | 34-35                           | Relocate to positions assigned for this field in a BC-mode PSW.                                                                                                                                     |
| 20-23                                 | Program mask                                          | 36-39                           | Relocate to positions assigned for this field in a BC-mode PSW.                                                                                                                                     |
| 24-31                                 | Unassigned                                            | N/A                             | A 1 in any of these positions will prevent conversion.                                                                                                                                              |
| 32                                    | Addressing mode                                       | 0                               |                                                                                                                                                                                                     |
| 33-37                                 | Bits 1-5 of instruction address                       | 1-5                             |                                                                                                                                                                                                     |
| 38-39                                 | Bits 6-7 of instruction address                       | 8-9                             |                                                                                                                                                                                                     |
| 40-63                                 | Bits 8-31 of instruction address                      | 40-63                           |                                                                                                                                                                                                     |

The following table shows the converse, which is where each bit of the resulting mapped PSW originates:

*Table 212. Constructing a mapped PSW.* This table shows where each bit of the resulting mapped PSW originates, when an ESA-family EC-mode PSW is converted to a mapped PSW during interruption presentation. This conversion only occurs for PSWs that cannot be converted without loss of information.

| Bit Positions in Resulting Mapped PSW | Meaning in BC-mode PSW   | Bit Positions in Original EC-mode PSW | Explanation                                                                                                                                                                                     |
|---------------------------------------|--------------------------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                     | Channel 0                | 32                                    | Addressing mode bit of original EC-mode PSW                                                                                                                                                     |

| 34-35                                 | Condition code           | 18-19                                 |                                                                                                                                                                                                 |
| 36-39                                 | Program mask             | 20-23                                 |                                                                                                                                                                                                 |

*Table 212. Constructing a mapped PSW.* This table shows where each bit of the resulting mapped PSW originates, when an ESA-family EC-mode PSW is converted to a mapped PSW during interruption presentation. This conversion only occurs for PSWs that cannot be converted without loss of information. (*continued*)

| Bit Positions in Resulting Mapped PSW | Meaning in BC-mode PSW           | Bit Positions in Original EC-mode PSW | Explanation |
|---------------------------------------|----------------------------------|---------------------------------------|-------------|
| 40-63                                 | Bits 8-31 of instruction address | 40-63                                 |             |

When a mapped PSW is loaded, it is converted back into an approximation of the original EC-mode PSW from which it was formed. This conversion takes place whenever the loaded PSW has bit 15 set to one, and bits 1-5, 8-9, and 12 set to zero. Any other loaded PSW with bit 12 set to zero is treated like a normal BC-mode PSW.

done for access to pages of the buffer beyond the last page updated by the response. The remaining bits of general register  $R_1$  should be zeros in order for the program to operate compatibly in the future.

General register  $R_2$  contains the guest logical address of a response buffer, which must be on a 4 KB boundary or a specification exception is recognized. For function codes 0, 1, 3 and 5 the response buffer is 4 KB in length. For function codes 2, 4 and 6 the length is as specified in  $R_1$ .

Function codes 3, 5 and 6 require an additional parameter that identifies the object for which that information is requested. Guest general register  $R_{1+1}$  must contain the guest logical address of a buffer on a doubleword boundary containing the search key. The key value is an 8-byte value containing a string of up to 8 EBCDIC characters, left-aligned and padded on the right with blanks. If the buffer is not aligned on a doubleword boundary a specification exception is recognized.

Input addresses are guest logical addresses with the same meaning as described for DIAGNOSE codes. See Chapter 1, “The DIAGNOSE Instruction in a Virtual Machine,” on page 3.

When the instruction completes with condition code 3,  $R_{2+1}$  contains the following return code. The return code is stored in bits 0-31 in ESA/390 or ESA/XC mode, or bits 0-63 in z/Architecture or z/XC mode. The response buffer is unmodified except as noted below.

| Return Code in $R_{2+1}$ | Meaning                                                                                                                                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'04'                    | Unsupported function code                                                                                                                                                                                             |
| X'08'                    | Not authorized for the function code                                                                                                                                                                                  |
| X'0C'                    | Missing or invalid name                                                                                                                                                                                               |
| X'10'                    | Specified name is unknown                                                                                                                                                                                             |
| X'14'                    | Response buffer is too small. The minimum required size is returned in response buffer field INFCRQSZ. Values are also provided in INFCVRSN, INFCHDLN and INFCTOTL. Other response buffer contents are unpredictable. |

When the instruction completes with condition code 0, general register  $R_{2+1}$  contains a return code of 0 indicating that the instruction completed successfully. The return code is stored in bits 0-31 in ESA/390 or ESA/XC mode, or bits 0-63 in z/Architecture or z/XC mode. The contents of the buffer beyond the reported length of the response are unpredictable.

Unless otherwise stated:

- All character strings returned in the response buffer are left-justified EBCDIC padded on the right with blanks (X'40') and without a terminating null character. This is referred to as "EBCDIC format" in the response buffer.
- All numeric values are unsigned binary values.

Programs written to use HCPINFBK COPY on one release of z/VM can be executed on a new release of z/VM without change. To exploit the function provided by a follow-on release, examine your program for necessary changes. A program will be able to use the contents of the response buffer without change as long as the following are all true:

- Offset fields are used to locate the contents of sections of the response buffer.
- Length fields are used to determine whether fields are included in the response buffer.
- Count fields are used to determine how many of a repeated section are included in the response buffer.
- Validity bits are used to determine whether values of certain fields are meaningful. If the validity bit is off, then the values of the specified fields could not be determined.

## Function Code X'0000' - Processor Capacity Information

Function code X'0000' returns information on capacity of general-purpose processors (CPs), z Integrated Information Processor (zIIP), and Integrated Facility for Linux processors (IFLs), including current CPU

resources available at the machine, logical partition, hypervisor, and guest levels, as well as any caps that restrict the guest's use of these resources. This information enables an application to determine the maximum capacity of CPs, zIIPs, and IFLs available to software running in the issuing virtual machine.

When function code X'0000' is specified, general register R<sub>2</sub> contains the guest logical address of a 4 KB response buffer, which must be on a 4 KB boundary or a specification exception is recognized.

When the instruction completes with condition code 3, the response buffer located by the guest logical address in R<sub>2</sub> is unchanged. When the instruction completes with condition code 0, CPU capacity information will be stored into the buffer at the guest logical address specified by register R<sub>2</sub>.

The response buffer returns one section of data for each of the following:

- The Header section. See [“Function Code X'0000' Response Header \(INFOHDR DSECT\)”](#) on page 929.
- The Machine section. See [“Function Code X'0000' Response Machine Section \(INFOMAC DSECT\)”](#) on page 931.
- The Partition section. See [“Function Code X'0000' Response Partition Section \(INFOPAR DSECT\)”](#) on page 933.

The response buffer returns up to three sections of data for each of the following:

- The Hypervisor section. See [“Function Code X'0000' Response Hypervisor Section \(INFOHYP DSECT\)”](#) on page 935.
- The Guest section. See [“Function Code X'0000' Response Guest Section \(INFOGST DSECT\)”](#) on page 937.

Multiple levels can be reported for the Hypervisor and Guest sections when, for example, z/VM is run as a guest of z/VM. A maximum of three levels of Hypervisor and Guest sections are reported. When more than three levels exist, the three levels closest to the hardware that support the STHYI instruction are returned in the buffer. These sections are numbered 1-3, starting with the level that is closest to the hardware. The remaining unused area in the 4 KB response buffer is cleared (set to 0).

Each Hypervisor section in the function code 0 response contains a mask of the supported function codes. When running a hypervisor second level or higher, a complete response for function code 0 is available only if all hypervisor levels support function code 0.

## Function Code X'0000' Response Buffer Format (INFOHDR)

INFOHDR DSECT in HCPINFBK COPY of HCPGPI MACLIB describes the response buffer format and might include information regarding usage of the fields in the DSECT.

The header section is placed at the beginning of the response buffer and identifies the location and length of all other sections. Valid sections have nonzero offset and length values in the header. Each section provides information about the validity of fields within that section.

The validity bits, not these flags, should be used to determine if a field is valid. X'80' INFGPDU Global Performance Data unavailable X'40' INFSTHYI One or more hypervisor levels below this level does not support the STHYI instruction. When this flag is set the value of INFGPDU is not meaningful because the state of the Global Performance Data setting cannot be determined. X'20' INFVSI Virtualization stack is incomplete. This bit indicates one of 2 cases: 1. One or more hypervisor levels do not support STHYI. For this case INFSTHYI will also be set. 2. There were more than 3 levels of guest/hypervisor information to report. X'10' INFBASIC Execution environment is not within a logical partition. |

## Function Code X'0000' Response Guest Section (INFOGST DSECT)

All counts of CPs, IFLs, and zIIPs and capacity values are based on quantities of cores when multithreading is enabled. While virtual CPUs are thread dispatched they have the potential of consuming an entire core. Therefore virtual CP, IFL, and zIIP counts are counts of virtual CPUs but treated as counts of cores.

## Common Header Section (INFCHDR)

This common header (INFCHDR) is imbedded at the start of the response buffer for function codes X'0001' through X'0006'. The common header includes information about the size of the response, as well as list designation fields used to locate and traverse a list that may be included in the response.

## Common Header Format (INFCHDR DSECT)

| Hex  | Dec | Type/Val                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Lng | Label (dup)  | Comments                                                                                                                                                         |                                                                                       |

## Function Code X'0001' - Hypervisor Environment Information

Function code X'0001' returns hypervisor environment information including current CPU resources and utilization information available at the machine, logical partition, hypervisor, and guest levels. This information enables an authorized application to perform CPU performance monitoring and management of guests of the z/VM system.

Use of this function code is authorized in the user directory by OPTION STHYI-UTIL.

When the instruction completes with condition code 3, the response buffer located by the guest logical address in  $R_2$  is unchanged. When the instruction completes with condition code 0, CPU capacity and utilization information will be stored into the buffer at the guest logical address specified by register  $R_2$ . This response buffer contains information as described by HCPINFBK COPY in HCPGPI MACLIB. Refer to the INF1BK DSECT.

The response buffer returns one section of data for each of the following:

- The Header section. See [“Function Code X'0001' Response Header \(INF1BK DSECT\)”](#) on page 942.
- The Machine section. See [“Function Code X'0001' Response Machine Section \(INF1MAC DSECT\)”](#) on page 945.
- The Partition section. See [“Function Code X'0001' Response Partition Section \(INF1PAR DSECT\)”](#) on page 946.

The response buffer returns up to three sections of data for each of the following:

- The Hypervisor section. See [“Function Code X'0001' Response Hypervisor Section \(INF1HYP DSECT\)”](#) on page 951.
- The Guest section. See [“Function Code X'0001' Response Guest Section \(INF1GST DSECT\)”](#) on page 954.

Multiple levels can be reported for the Hypervisor and Guest sections when, for example, z/VM is run as a guest of z/VM. A maximum of three levels for Hypervisor and Guest sections is reported. When more than three levels exist, the three levels closest to the hardware that support the STHYI instruction are returned in the buffer. These sections are numbered 1-3, starting with the level reported which is closest to the hardware. The contents of the remaining unused area in the 4 KB response buffer are unpredictable.

If the guest issuing the STHYI is not authorized the STHYI instruction completes with CC3 and RC=8.

When running z/VM second level or higher, a complete response for function code 1 is available only if all hypervisor levels support function code 1 and the guest at each layer is authorized for function code 1.

## Function Code X'0001' Response Buffer Format (INF1BK)

INF1BK DSECT in HCPINFBK COPY of HCPGPI MACLIB describes the response buffer format and might include information regarding usage of the fields in the DSECT.

The version number (INF1VRSN) in the function code X'0001' response header can be used to clearly identify whether the function code is at the required service level and can be used by applications to show actual and required version in messages when required support is missing.

The header section is placed at the beginning of the response buffer and identifies the location and length of all other sections. Valid sections have nonzero offset and length values in the header. Each section provides information about validity of fields within that section.

The list designation fields in the common header are stored as zeroes.

### Function Code X'0001' Response Header (INF1BK DSECT)

| Hex  | Dec Type/Val                                                                                                                                                                                                                                                                                                                                                              | Lng Label (dup)                        | Comments                                                                                                                                                                                              |

|      | One to three levels of hypervisors and guests may be reported. When the guest is running second level or higher, hypervisor/guest section 1 is filled in by the hypervisor running closest to the hardware, with its guest filling in the next section, etc. for a maximum of 3 levels.                                                                                   |                                        |                                                                                                                                                                                                       |
|      | The format of this response buffer is determined by the hypervisor closest to the LPAR. When running directly in a partition, there is only one level of hypervisor involved in constructing the response so the version is the same for all sections. However when running second level the version of this block is generally determined by the first level hypervisor. |                                        |                                                                                                                                                                                                       |
|      | The formats of the pairs of hypervisor and guest sections may differ. The specified version number describes the format of that section.                                                                                                                                                                                                                                  |                                        |                                                                                                                                                                                                       |

|      | Entitlement values are current values for the partition. Share of extra capacity varies over time. The sum of the calculated values at each hiperdispatch interval and the count of those intervals are provided so an average between two STHYI invocations can be calculated. INF1PENC, INF1PENI, INF1PSXCA, INF1PSXCA, INF1PSXIA, INF1PSXCC and INF1PSXIC are monotonically increasing for the life of the system. |             |                                                                                                                                                                                                                                                                              |

| The values in these fields are the aggregate of individual online processors. When a processor is varied online, the value is reset. The length of the interval is determined from the INF1YUTOD value delta. INF1YUTOD is set from the TOD clock at the start of the calculation of these values. |              |             |                                                                                                                                                            |

## Function Code X'0002' - Guest List

Function code X'0002' returns a list of logged on guests. Guest virtual machines in the process of logging on, logging off, being forced, or relocating to this system are excluded. Guests enabled for shutdown signals appear in the output during the shutdown signal timeout interval until the actual logoff process begins.

Use of this function code is authorized in the user directory by OPTION STHYI-GUEST.

When function code X'0002' is specified, general register  $R_2$  contains the guest logical address of a response buffer, which must be on a 4 KB boundary or a specification exception is recognized. The size of the response buffer as an unsigned number of 4 KB pages must be specified in general register  $R_1$  (bits 0-15 in ESA/390 or ESA/XC mode, or bits 32-47 in z/Architecture or z/XC mode). If the value is zero, then a specification exception is recognized. No checking is done for address wrapping. No checking is done for access to pages of the buffer beyond the last page of the actual response data.

When the instruction completes with condition code 0, a list of logged on guests will be returned in the buffer at the guest logical address specified by register  $R_2$ .

The possible nonzero return codes for this function code are:

### CC=3 RC=4

Unsupported function code. Buffer is unchanged.

### CC=3 RC=8

Not authorized for the function code. Buffer is unchanged.

### CC=3 RC=20

Response buffer is too small. INFCRQSZ specifies required buffer size. Values are also provided in INFCVRSN, INFCHDLN and INFCTOTL. Other response buffer contents are unpredictable.

## Function Code X'0002' Response Buffer Format (INF2BK)

INF2BK DSECT in HCPINFBK COPY of HCPGPI MACLIB describes the response buffer format and might include information regarding usage of the fields in the DSECT.

The common header section (INFCHDR DSECT) is placed at the beginning of the response buffer and identifies the length of the response.

The common header includes list designation fields for the following:

- List of logged on guests mapped by INF2GST DSECT

Valid lists have nonzero count, offset and length values in the header.

The version number (INF2VRSN) in the function code X'0002' response header can be used to clearly identify whether the function code is at the required service level and can be used by applications to show actual and required version in messages when required support is missing.

## Function Code X'0003' - Designated Guest Information

Function code X'0003' returns guest CPU resource information useful to an authorized application performing CPU performance monitoring and management.

Use of this function code is authorized in the user directory by OPTION STHYI-GUEST.

When function code X'0003' is specified, general register  $R_2$  contains the guest logical address of a 4 KB response buffer, which must be on a 4 KB boundary or a specification exception is recognized.

This function code provides information for the Guest specified in the 8-byte buffer located at the guest logical address in  $R_{1+1}$ . If the buffer is not aligned on a doubleword boundary a specification exception is recognized.

When the instruction completes with condition code 3, the response buffer located by the guest logical address in  $R_2$  is unchanged. When the instruction completes with condition code 0, guest information will be stored into the buffer at the guest logical address specified by register  $R_2$ .

The possible nonzero return codes for this function code are:

### CC=3 RC=4

Unsupported function code. Buffer is unchanged.

### CC=3 RC=8

Not authorized for the function code. Buffer is unchanged.

### CC=3 RC=12

Missing or invalid guest name. Buffer is unchanged.

### CC=3 RC=16

Named guest is not logged on. Buffer is unchanged.

## Function Code X'0003' Response Buffer Format (INF3BK)

INF3BK DSECT in HCPINFBK COPY of HCPGPI MACLIB describes the response buffer format and might include information regarding usage of the fields in the DSECT.

The common header section (INFCHDR DSECT) is placed at the beginning of the response buffer and identifies the length of the response.

The list designation fields in the common header are stored as zeroes.

The guest information follows the common header at INF3GSTI and is mapped by INF3GST DSECT.

The high-frequency counters starting at field INF3GIWSC report data collected when Monitor high-frequency sampling is active. The values are reset to zero when Monitor commands are issued that deactivate high-frequency sampling, and remain zero while it is inactive. MONITOR SAMPLE RATE is used to set the frequency of the guest state sampling which should be more frequent than the sampling interval. The high-frequency sampling is activated using MONITOR SAMPLE ENABLE USER for the users of interest.

The version number (INF3VRSN) in the function code X'0003' response header can be used to clearly identify whether the function code is at the required service level and can be used by applications to show actual and required version in messages when required support is missing.

**Function Code X'0003' Response Header (INF3BK DSECT)**

| These counts are the number of times that CP and IFL CPUs of the guest are observed in each state. These counts are reset to zero when Monitor commands are issued that disable high-frequency sampling. Otherwise they are monotonically increasing values. INF1YMONH provides the high-frequency sampling interval for the state testing. For each virtual CPU type, the order of the count fields is the order that the states are tested so that if a vCPU is in multiple states, it is counted with the first state that matches so that it is counted in one and only one state. The one exception is that when a guest is on the dormant list and SVM wait they are counted in both INF3GDLSC and INF3GDSSC for virtual CPs and for IFLs, both INF3GDLSC and INF3GDSSI. The values are aggregate values for all guest virtual CPUs of that type. See Monitor record MRUSEINT D4 R4 for additional information. |              |              |  |                                                                                                                             |

## Function Code X'0004' - Resource Pool List

Function code X'0004' returns a list of defined resource pools.

Use of this function code is authorized in the user directory by OPTION STHYI-RESPOOL.

When function code X'0004' is specified, general register R<sub>2</sub> contains the guest logical address of a response buffer, which must be on a 4 KB boundary or a specification exception is recognized. The size of the response buffer as an unsigned number of 4 KB pages must be specified in general register R<sub>1</sub> (bits 0-15 in ESA/390 or ESA/XC mode, or bits 32-47 in z/Architecture or z/XC mode). If the value is zero, then a specification exception is recognized. No checking is done for address wrapping. No checking is done for access to pages of the buffer beyond the last page of the actual response data.

When the instruction completes with condition code 0, a list of defined Resource Pools will be returned in the buffer at the guest logical address specified by register R<sub>2</sub>.

The possible nonzero return codes for this function code are:

| Function code X'0004' Response Buffer |             |             |                                                                                           |

## Function Code X'0005' - Designated Resource Pool Information

Function code X'0005' returns a resource pool description for the specified resource pool.

Use of this function code is authorized in the user directory by OPTION STHYI-RESPOOL.

When function code X'0005' is specified, general register  $R_2$  contains the guest logical address of a 4 KB response buffer, which must be on a 4 KB boundary or a specification exception is recognized.

This function code provides information for the resource pool specified in the 8-byte buffer located at the guest logical address in  $R_{1+1}$ . If the buffer is not aligned on a doubleword boundary a specification exception is recognized.

When the instruction completes with condition code 3, the response buffer located by the guest logical address in  $R_2$  is unchanged. When the instruction completes with condition code 0, guest CPU resource information will be stored into the buffer at the guest logical address specified by register  $R_2$ .

The possible nonzero return codes for this function code are:

**CC=3 RC=4**

Unsupported function code. Buffer is unchanged.

**CC=3 RC=8**

Not authorized for the function code. Buffer is unchanged.

**CC=3 RC=12**

Missing or invalid Resource Pool Name. Buffer is unchanged.

**CC=3 RC=16**

Named Resource Pool does not exist. Buffer is unchanged.

## Function Code X'0005' Response Buffer Format (INF5BK)

INF5BK DSECT in HCPINFBK COPY of HCPGPI MACLIB describes the response buffer format and might include information regarding usage of the fields in the DSECT.

The common header section (INFCHDR DSECT) is placed at the beginning of the response buffer and identifies the length of the response.

The list designation fields in the common header are stored as zeroes.

The resource pool information follows the common header as described by the INF5BK DSECT.

The version number (INF5VRSN) in the function code X'0005' response header can be used to clearly identify whether the function code is at the required service level and can be used by applications to show actual and required version in messages when required support is missing.

### Function Code X'0005' Response Header (INF5BK DSECT)

## Special Conditions, Exceptions, and Usage Notes

### Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

- The  $R_1$  or  $R_2$  field designates an odd-numbered register.
- The  $R_1$  and  $R_2$  fields designate the same register.
- The response buffer is not on a 4 KB boundary.
- For function codes 2, 4 and 6, the value for the number of pages is zero.
- For function codes 3, 5 and 6, if the search key buffer address specified in  $R_{1+1}$  is not aligned on a doubleword boundary.

### Program Exceptions

- Access (store, response buffer). When an access exception occurs while storing into any part of the response buffer, the contents of any accessible portion of the response buffer are unpredictable. This is true even if the exception is defined to suppress or nullify execution of the instruction.
- Operation (if the store-hypervisor-information facility is not installed)
- Specification

### Usage Notes

1. Support for function codes 1-6 is available on z/VM 6.4 with APAR VM66105, or on later releases of z/VM. Each Hypervisor section in the function code 0 response contains a mask of the supported function codes and a mask of function codes that the guest is authorized to use. When the response to function code 0 is too short to contain the masks, then only function code 0 is supported and authorized.
2. DirMaint support for the user directory options for STHYI authorization is provided with APAR VM66109 for function level 640, or with later releases of z/VM.
3. Running z/VM second level or higher, a complete response for function code 1 requires that all hypervisor levels support function code 1, and the guest at each level is authorized for function code 1 by that hypervisor level.
4. Use of the STHYI instruction within a transaction will cause the transaction to abort with either a restricted-instruction transaction-abort code or a transaction-constraint exception.
5. If the partition where z/VM is running has Global Performance Data off, function codes 0 and 1 will not be able to return certain information because it is not available to z/VM. Validity bits will be off for sets of information that are not available. The state of the validity bits should be checked before the contents of any associated fields are used to ensure the contents are valid.
6. All pages of the response buffer must be resident in guest memory for the STHYI instruction to complete. A guest access exception is presented each time a page of the buffer is found to be non-resident, and the instruction must be re-executed completely. Therefore performance might be improved by ensuring each 4 KB block of the response buffer is initialized before issuing STHYI.

7. Use of STHYI in an SSI cluster may encounter problems if members do not have the same level of support. For example:
  - If a member that is authorized for STHYI function codes 1-6 is relocated to a member that does not support those function codes and then is relocated back to a member that does have the support, they will no longer be authorized.
  - Guest initial share settings reported by STHYI function code 1 and function code 3 are not accurate if the guest had at any time relocated to a member without support for those function codes.
8. Counts of dedicated cores in the machine and partition layers refer to cores in use in dedicated partitions. The counts of dedicated cores in the hypervisor and guest layers refer to processors dedicated to guest virtual CPUs. z/VM hypervisors no longer support dedication of processors to guest virtual CPUs as of 7.1.0.
9. zIIP support necessary for z/OS guests running zCX is added by APAR VM66329. When zCX is running in a z/OS guest of z/VM, there are two layers of hypervisor. For correct reporting of zIIP configuration information, the zIIP validity bits must be on in each reported layer. Fields were not added for counts of dedicated zIIP cores in the hypervisor and guest layers because guest dedication is no longer supported.
10. In most cases, virtual CPUs are dispatched on processors of a matching CPU type. z/VM CPUAFFINITY settings could change the dispatch type of a specialty CPU type so that they are dispatched on CPs. In either case, for each CPU type the dispatch type field indicates on which processor type the virtual CPUs are dispatched. However, z/OS supports a spillover function that allows virtual zIIPs to be dispatched on CP processors (general CPUs) if zIIP processors are unavailable. In this case, the dispatch type will be INFGPUCZCP indicating that the virtual CPUs may be dispatched on either zIIP or CP processors.
11. Resource pool related fields are used to report z/OS tenant resource group settings when the hypervisor is zCX.

## Chapter 30. Store System Information (STSI) Instruction

The Store System Information (STSI) instruction provides information about the level or components of a system configuration. Information can be provided for up to three levels of configuration:

1. The basic machine, which is the machine as if it were operating in the basic mode.
2. A logical partition, which is provided if the machine is operating in the LPAR, or logically partitioned mode.
3. A virtual machine, which is provided by a hypervisor that is run either by the basic machine or in a logical partition.

A virtual machine can use the STSI instruction to receive details about the configuration in which it is running. Using function codes and selectors, the virtual machine can request SYSIB 3.2.2 to get information about the hypervisor. The instruction and the general format of the response is described in *IBM z/Architecture Principles of Operation*. However, because the hypervisor provides the SYSIB 3.2.2 response, details of the SYSIB 3.2.2 response vary by the type of hypervisor.

When the STSI instruction is executed in a z/VM virtual machine that requests SYSIB 3.2.2, the first virtual-machine description block (VMDB) in the response contains the following information that is specific to the z/VM hypervisor:

| Table 213. z/VM-specific responses for SYSIB 3.2.2 |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Field                                              | Length (bytes) | z/VM response                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Virtual-Machine Name                               | 8              | The virtual-machine name is the userid of the virtual machine.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Control-Program Identifier                         | 16             | <p>The first 8 bytes contain the string "z/VM", padded with blanks on the right.</p> <p>The next 8 bytes contain a level ID, padded with blanks on the right. The level ID is of the format <i>v.r.m</i>, where:</p> <ul style="list-style-type: none"> <li>• <i>v</i> = Version</li> <li>• <i>r</i> = Release</li> <li>• <i>m</i> = Modification level</li> </ul> <p>Each component of the level is a decimal number of 1-2 digits. The components are separated by a period.</p> <p>Example:</p> <pre>z/VM    7.3.0</pre> |
| EVMNE (Extended VM-Name Encoding)                  | 1              | The EVMNE field is zero, which indicates that no extended VM name is provided.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Universally-Unique Identification (UUID)           | 16             | The universally-unique-identification field is zero, which indicates that no UUID is provided.                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Note:** The description applies only to the first virtual-machine description block in the response. If the response contains additional blocks from nested levels of hypervisors, then the content of those blocks is determined by the corresponding hypervisors.

---

## Part 7. Symptom Record Reporting

This part contains the following chapter:

- [Chapter 31, “Symptom Record Reporting,” on page 977](#)

---

## Chapter 31. Symptom Record Reporting

This document, with its emphasis on application programming, describes symptom record reporting within this chapter as well as in the material covering DIAGNOSE code X'94' on [“DIAGNOSE Code X'94' – VMDUMP and Symptom Record Service”](#) on page 113. For more information on the VMDUMP command, refer specifically to [z/VM: CP Commands and Utilities Reference](#), and for more information about symptom records, see [z/VM: System Operation](#) and [z/VM: Dump Viewing Facility](#).

---

### Reporting Software Error Symptoms (Symptom Records)

DIAGNOSE code X'94' provides a mechanism by which a program running in a virtual machine may provide a symptom record to be recorded by CP, either with or independent of, a virtual machine dump. Refer to Chapter 22, [“Symptom System Service \(\\*SYMPTOM\)”](#) on page 771 for details on how symptom records are recorded by CP.

The program-created symptom record contains a description of some programming failure, along with a description of the environment in which the failure occurred. The format of this information is indicated in the ADSR macro, which is in HCPGPI MACLIB. CP uses the same format to document symptom record information.

The VM Dump Tool's VMDUMPTL command and SYMPTOM subcommand can be used to view symptom record information. For more information on this command and subcommand, see [z/VM: VM Dump Tool](#).

---

### The Format of the Symptom Record

The symptom record consists of six sections that are structured according to the format shown in the ADSR macro. These sections are numbered 1 through 5, including an additional section that is numbered 2.1. Because sections 2.1, 3, 4, and 5 of the symptom record are variable in length, they do not need to be sequentially ordered within the record. In section 2, the application (the program running in the virtual machine) supplies the offset and the length of the nonfixed sections. The purpose of each section, including material showing its format, is described in the following sections.

#### Section 1 (Environmental Data)

Section 1 contains the record header with basic environmental data. The application initializes this area to binary zeros and stores the characters *SR* in the record header. The environmental data of section 1 is filled in automatically when DIAGNOSE code X'94' SR processing is invoked. The environmental data that is stored in this section provides a system context within which the software errors can be viewed. Section 1 includes items such as the:

- CPU model and serial number
- Date and time, with a time zone conversion factor
- Customer-assigned system name
- Product ID of the control program.

#### Section 2 (Control Data)

Section 2 contains control information with the lengths and offsets of the sections that follow. The application must initialize the control information before invoking DIAGNOSE code X'94'. Section 2 immediately follows section 1 in the symptom record structure.

### Section 2.1 (Component Data)

Section 2.1 contains the name of the component in which the error occurred, as well as other specific component-related data. The application must also initialize section 2.1 before invoking the DIAGNOSE code.

### Section 3 (Primary SDB—Structured Data Base—Symptoms)

Section 3 contains the **primary symptom string** of problem symptoms, which may be used to perform tasks such as duplicate problem recognition. When an application detects an error, it must store a string of symptoms in section 3, and this string becomes the primary symptom for the error. This string should be a unique and complete description of the error. All incidences of that error should produce the same string in section 3. When problems are analyzed, problems that have identical strings in section 3 represent the same error. Note that an application does not store any primary symptom string or invoke DIAGNOSE code X'94' unless it detects an error in its own processing.

### Section 4 (Secondary SDB Symptoms)

Section 4 contains an optional **secondary symptom string**. The purpose of the secondary string is to provide additional symptoms that may supplement the symptoms in section 3.

### Section 5 (Free-Format Data)

Section 5 contains logical segments of optional problem-related data to aid in problem diagnosis. However, the data in section 5 is not in the SDB format, which is found only in sections 3 and 4. Each logical segment in section 5 is structured in a **key-length-data** format.

### Symptom Strings — SDB Format

The symptom strings placed in sections 3 and 4 of the symptom record must be in the SDB (structured database) format. In this format, the individual symptoms in sections 3 and 4 of the symptom record consist of a prefix and its associated data. Examples of typical prefixes are:

**Prefix**

**Data**

**PIDS/**

A component name

**RIDS/**

A routine name

**AB/**

An abend code

**PRCS/**

A return code

### Notes for Applications Using DIAGNOSE Code X'94' SR Option

This section contains programming notes on how the various fields of the ADSR data area (symptom record) are set. Some fields of this area must be set by the caller of the DIAGNOSE code, and other fields are set by the system when the application invokes the DIAGNOSE code. The fields that the caller must always set are indicated by an RC code in the following sections. The fields that are set by CP are indicated by an RS code.

The RA code designates certain flag fields that need to be set only when certain kinds of alterations and substitutions are made in the symptom record after the incident occurs. These alterations and substitutions must be obvious to the user who interprets the data. Setting these flag fields is the responsibility of the program that alters or substitutes the data. If a program changes a symptom record that has already been recorded, it should set the appropriate RA-designated flag-bit fields as an indication of how the record has been altered.

The remaining fields, those not marked by RC, RS, or RA, are optionally set by the caller of DIAGNOSE code X'94'. When DIAGNOSE code X'94' is invoked, it checks that all the required input fields in the symptom record are set by the caller. If the required input fields are not set, DIAGNOSE code X'94' issues appropriate return and reason codes.

## Programming Notes for Section 1

Notes in this section pertain to the following fields, which are in section 1 of the ADSR data area.

|    |           |            |          |
|----|-----------|------------|----------|
| 0  | ADSRID    | ADSRCPM    | ADSRCPS- |
| 8  | -ADSRCPS  | ADSRGMT    |          |
| 10 | ADSRTIME  | ADSRTOOD - |          |
| 18 | -ADSRTOOD | ADSRDATE - |          |
| 20 | -ADSRDATE | ADSRSID -  |          |
| 28 | -ADSRSID  | ADSRSYS    | ADSRCML- |
| 30 | -ADSRCML  | FL1        | FL2      |
| 38 | ADSRDTP   |            |          |

|          |                                         |      |
|----------|-----------------------------------------|------|
| ADSRID   | Record header (SR)                      | (RC) |
| ADSRCPM  | CPU model number                        |      |
| ADSRCPS  | CPU serial number                       |      |
| ADSRGMT  | Local time zone conversion factor       |      |
| ADSRTIME | Time stamp                              | (RS) |
| ADSRTOOD | Time stamp (HHMMSSSTH)                  |      |
| ADSRDATE | Date (YYMMDD)                           |      |
| ADSRSID  | Customer-assigned system/node name      | (RS) |
| ADSRSYS  | Product ID of the base system (BCP)     | (RS) |
| ADSRCML  | Feature and level of Symrec Service     | (RS) |
| ADSRTRNC | Truncated flag                          | (RS) |
| ADSRPMOD | Section 3 modified flag                 | (RA) |
| ADSRSGEN | Surrogate record flag                   | (RA) |
| ADSRSMOD | Section 4 modified flag                 |      |
| ADSRNOTD | ADSRTOOD and ADSRDATE not-computed flag | (RS) |

## Symptom Record Reporting

|          |                         |      |
|----------|-------------------------|------|
| ADSRASYN | Asynchronous event flag | (RA) |
| ADSRDTP  | Name of dump            |      |

**Notes:**

1. The application invoking DIAGNOSE code X'94' must provide the space for the entire symptom record, and must initialize that space to binary zeros. The application must also store the value *SR* into *ADSRID*.
2. DIAGNOSE code X'94' stores the TOD clock value into *ADSRTIME* when the incident occurs. However, it does not compute *ADSR TOD* and *ADSRDATE* when the incident occurs, but afterward, when it formats the output. When the incident occurs, DIAGNOSE code X'94' also sets *ADSRNOTD* to 1 as an indication that *ADSR TOD* and *ADSRDATE* have not been computed.
3. DIAGNOSE code X'94' stores the customer-assigned system node name into *ADSRSID*.
4. DIAGNOSE code X'94' stores the first four digits of the base control program component ID into *ADSRSYS*.
5. If DIAGNOSE code X'94' truncates the symptom record, it sets *ADSRTRNC* to 1. This can happen when the size of the symptom record provided by the invoking application exceeds 3500 decimal bytes.
6. *ADSRSGEN*, if 1, indicates that the symptom record was not provided as *first time data capture* by the invoking application. Another program created the symptom record. The identification of the other program might be included with other optional information, for example, in section 5.
7. If some application creates the record asynchronously, that application should set *ADSRASYN* to 1. This means that the data is derived from sources outside the normal execution environment, such as human analysis or some type of machine post-processing.

## Programming Notes for Section 2

Notes in this section pertain to the following fields, which are in section 2 of the ADSR data area.

|    |          |          |           |           |
|----|----------|----------|-----------|-----------|
| 40 | ADSRARID | ADSRL    | ADSRCS1   | ADSRCS0   |
| 48 | ADSRDBL  | ADSRDB0  | ADSRROSL  | ADSRROSA  |
| 50 | ADRRONL  | ADSRRONA | ADSRRIISL | ADSRRIISA |
| 58 | ADSRRES  |          |           |           |
| 60 | Reserved |          |           |           |

|          |                                 |      |
|----------|---------------------------------|------|
| ADSRARID | Architectural level designation | (RS) |
| ADSRL    | Length of section 2             | (RC) |
| ADSRCSL  | Length of section 2.1           | (RC) |
| ADSRCSO  | Offset of section 2.1           | (RC) |
| ADSRDBL  | Length of section 3             | (RC) |
| ADSRDBO  | Offset of section 3             | (RC) |
| ADSRROSL | Length of section 4             |      |

|           |                         |
|-----------|-------------------------|
| ADSRROSA  | Offset of section 4     |
| ADSRRONL  | Length of section 5     |
| ADSRRONA  | Offset of section 5     |
| ADSRRIISL | Length of section 6     |
| ADSRRIISA | Offset of section 6     |
| ADSRRES   | Reserved for system use |

**Notes:**

1. The invoking application must ensure that the actual lengths of supplied data agree with the lengths indicated in the ADSR data area. The application should not assume that DIAGNOSE code X'94' validates these lengths and offsets.
2. The lengths and offsets in section 2 are intended to make the indicated portions of the record indirectly addressable. Invoking applications should not depend on the sections following one another, and thus should not use computed absolute offsets into the data area.
3. The value of the ADSRARID field is the architectural level at which the DIAGNOSE code X'94' SR support is operating. This field is supplied by DIAGNOSE code X'94'.
4. Section 2 has a fixed length of 48 bytes. Optional fields (not marked with RC, RS, or RA) contain binary zeros when the invoking application provides no values for them.

**Programming Notes for Section 2.1**

Notes in this section pertain to the following fields, which are in section 2.1 of the ADSR data area.

|          |                                |      |
|----------|--------------------------------|------|
| ADSRC    | C'SR21' Section 2.1 Identifier | (RC) |
| ADSRCL   | Architectural level of record  | (RC) |
| ADSRCID  | Component identifier           |      |
| ADSRFLC  | Component status flags         |      |
| ADSRNIBM | Non-IBM program flag           | (RC) |
| ADSRVL   | Component release level        | (RC) |
| ADSRPTF  | Service level                  |      |
| ADSRPID  | PID number                     | (RC) |

|          |                      |      |
|----------|----------------------|------|
| ADSRPIDL | PID release level    | (RC) |
| ADSRCDSC | Text description     |      |
| ADSRRET  | Return code          | (RS) |
| ADSRREA  | Reason code          | (RS) |
| ADSRPRID | Problem identifier   |      |
| ADSRSSID | Subsystem identifier |      |

### Notes:

1. This section has a fixed length of 100 bytes, and cannot be truncated. Optional fields (not marked with RC, RS, or RA) appear as binary zeros, if no values are provided.
2. ADSRCRL is the architectural level of the record. Note that ADSRARID (section 2) is the architectural level of DIAGNOSE code X'94'.
3. ADSRCID is the component ID of the application that incurred the error.

Under some circumstances, there can be more than one component ID involved. For ADSRCID, select the component ID that is most indicative of the source of the error. Additional and clarifying data (such as, another component ID involved) is optional, and may be placed in optional entries, such as ADSRCDSC of section 2.1, section 4, or section 5.

ADSRCID is not a required field in this section, although it is required in section 3 after the PIDS/ prefix of the symptom string. Repeating this value in section 2.1 is desirable but not required. Where the component ID is not given in section 2.1, this field must contain binary zeros.

4. ADSRNIBM is a flag indicating that a non-IBM program originated the symptom record.
5. ADSRLVL is the release level of the component indicated in ADSRCID, or zero if ADSRCID is zero.
6. ADSRPTF is the service level. It may differ from ADSRLVL because the program may be at a higher level than the release. ADSRPTF can contain any number indicative of the service level. For example, a PTF, FMID, APAR number, or user modification number. This field is not required, but it should be provided if possible.

ADSRPID is the program identification number assigned to the program that incurred the error. When the symptom record is being created by an IBM program, ADSRPID must be provided only if it does not have an assigned component ID. Therefore, ADSRCID contains binary zeros if ADSRPID is provided.

7. ADSRPIDL is the release level of the program designated by ADSRPID.
8. ADSRCDSC is a 32-byte area that contains text, and it is only provided at the discretion of the reporting component. It provides clarifying information.
9. ADSRRET is the return code, and ADSRREA is the reason code from the execution of DIAGNOSE code X'94'. DIAGNOSE code X'94' places these values in registers 0 and 15 and in these two fields as part of its execution. The fields are right-justified, and identical to the contents of registers 0 and 15.
10. ADSRPRID is a value that can be used to associate the symptom record with other symptom records. This value must be in EBCDIC, but it is not otherwise restricted.
11. ADSRSSID is the name of a subsystem. A zero value is interpreted as no name.

### Programming Notes for Section 3

Section 3 of the symptom record contains the primary symptoms associated with the error, and is provided by the application that incurred the error, or by some program that acts on its behalf. The internal format of the data in section 3 is the SDB format, with a blank separating each entry. Once this data has been passed to DIAGNOSE code X'94' by the invoker, it may not be added to or modified without setting ADSRPMOD (in Section 1) to 1. The data in this section is EBCDIC, and no binary zeros may appear. The symptoms are in the form K/D where K is a keyword of one to eight characters and D is at least one character. D can only be an alphanumeric or @, \$, and #.

**Notes:**

1. The symptom K/D can have no imbedded blanks, but the pound sign, #, can be used to substitute for desired blanks. Each symptom (K/D combination) must be separated by at least one blank. The first symptom may start at ADSRRSCS with no starting blank, but the final symptom must have at least one trailing blank. The total length of each symptom (K/D combination) cannot exceed 15 characters.
2. This section is provided by the component that reports the failure to the system.
3. The PIDS/ entry is required, with the component ID following the slash, from all programs that originate a symptom record and have a component ID assigned. Further, it must be identical to the value in ADSRCID (section 2.1) if that is provided. (ADSRCID is not a required field).

**Programming Notes for Section 4**

Section 4 of the symptom record contains the secondary symptoms associated with the error incident, and it is provided by the application that incurred the error, or by some program that acts in its behalf. The internal format of the data in section 4 is the SDB format, with a single blank separating each entry. Once this data has been passed to DIAGNOSE code X'94' by the invoker, it may not be added to or modified without setting ADSRSMOD to 1.

**Programming Notes for Section 5**

Section 5 of the symptom record contains logical segments of data that are provided by the application or by some program that acts in its behalf. The application stores data in section 5 before DIAGNOSE code X'94' is invoked.

**Notes:**

1. The first segment must be stored at symbolic location ADSR5ST. In each segment, the first two characters are a hex key value, and the second two characters are the hexadecimal length of the data string, which must immediately follow the 2-byte length field. Adjacent segments must be packed together. The length of section 5 is in the ADSRRONL field in section 2, and this field should be correctly updated as a result of all additions or deletions to section 5.
2. There are 64K key values grouped in 13 ranges representing 13 potential categories. The data type (that is, hexadecimal, EBCDIC, and so forth) of section 5 is indicated by the category of the key value. Thus, the key value indicates both the user category and the data type that are associated with the information in section 5. Because the component ID is a higher order qualifier of the key, it is only necessary to control the assignment of keys within each component ID or, if a component ID is not assigned, within each PID number.

## Appendix A. Data Areas Used by DIAGNOSE Codes

This appendix contains descriptions of data areas and control blocks referred to by DIAGNOSE codes X'14', X'24', X'D8', X'B4' and X'B8', and X'210'.

### Data Areas Used by DIAGNOSE Codes X'24' and X'210'

The following information is returned as output from DIAGNOSE codes X'24' and X'210'. Information returned from DIAGNOSE code X'210' only is indicated by an asterisk (\*). Symbolic names can be used by including DEVTYPE\$ COPY from the HCPGPI library in your program.

**Note:** DIAGNOSE code X'24' will no longer be upgraded for new device support. Applications using DIAGNOSE code X'24' should use DIAGNOSE code X'210' to take advantage of new device support. z/VM includes DIAGNOSE code X'24' primarily for VM/SP, VM/SP HPO, and VM/ESA (370 Feature) compatibility.

### CP370 Device Classes

These are the virtual and real device classes returned in byte 0 of Ry and Ry+1, respectively, for DIAGNOSE code X'24' and bytes 4 and 8, respectively, of the VRDCBLOK for DIAGNOSE code X'210'.

|          |     |       |                                  |
|----------|-----|-------|----------------------------------|
| CLASTERM | EQU | X'80' | TERMINAL DEVICE CLASS            |
| CLASGRAF | EQU | X'40' | GRAPHICS DEVICE CLASS            |
| CLASURI  | EQU | X'20' | UNIT RECORD INPUT DEVICE CLASS   |
| CLASURO  | EQU | X'10' | UNIT RECORD OUTPUT DEVICE CLASS  |
| CLASTAPE | EQU | X'08' | MAGNETIC TAPE DEVICE CLASS       |
| CLASDASD | EQU | X'04' | CKD DIRECT ACCESS STORAGE DEVICE |
| CLASSPEC | EQU | X'02' | SPECIAL DEVICE CLASS             |
| CLASFBA  | EQU | X'01' | FIXED BLOCK STORAGE DEVICE CLASS |

### CP370 Device Types

These are the virtual and real device types within each class returned in byte 1 of Ry and Ry+1, respectively, for DIAGNOSE code X'24' and bytes 5 and 9, respectively, of the VRDCBLOK for DIAGNOSE code X'210'.

Codes for devices that are marked with an asterisk (\*) are returned only by using DIAGNOSE code X'210'.

#### CLASTERM (Terminals):

|          |       |                                    |
|----------|-------|------------------------------------|
| TYPBSC   | X'80' | BISYNC LINE FOR 3270 REMOTE        |
| TYP2700  | X'40' | 2700 BISYNC LINE                   |
| TYP2955  | X'40' | 2955 COMMUNICATIONS LINE           |
| TYPTELE2 | X'20' | TELEGRAPH TERM CONTROL TYPE II     |
| TYPTTY   | X'20' | TELETYPE TERMINAL                  |
| TYP2741  | X'18' | 2741 COMMUNICATIONS TERMINAL       |
| TYPIBM1  | X'10' | IBM TERMINAL CONTROL TYPE I        |
| TYP\$DLC | X'08' | synchronous data link control(ICA) |
| TYP3210  | X'00' | 3210 CONSOLE                       |
| TYP3215  | X'00' | 3215 CONSOLE                       |
| TYP2150  | X'00' | 2150 CONSOLE                       |
| TYP1052  | X'00' | 1052 CONSOLE                       |

#### CLASGRAF (Graphics Devices):

|         |        |                             |
|---------|--------|-----------------------------|
| TYPHFGD | X'.C0' | 5080 HIGH FUNCTION GRAPHICS |
| TYP2250 | X'.80' | 2250 DISPLAY UNIT           |
| TYP3277 | X'.04' | 3277 DISPLAY STATION        |
| TYP3138 | X'.04' | 3138 DISPLAY CONSOLE        |
| TYP3148 | X'.04' | 3148 DISPLAY CONSOLE        |
| TYP3158 | X'.04' | 3158 CONSOLE                |
| TYP3284 | X'.02' | 3284 PRINTER                |
| TYP3286 | X'.02' | 3286 PRINTER                |
| TYP3287 | X'.02' | 3287 PRINTER                |

|         |        |                      |
|---------|--------|----------------------|
| TYP3288 | X'.02' | 3288 PRINTER         |
| TYP3278 | X'.01' | 3278 DISPLAY STATION |

#### CLASURI (Unit Record Input Devices):

|          |        |                  |
|----------|--------|------------------|
| TYP3505  | X'.84' | 3505 CARD READER |
| TYP2540R | X'.82' | 2540 CARD READER |
| TYP2501  | X'.81' | 2501 CARD READER |

#### CLASURO (Unit Record Output Devices):

|          |        |                           |
|----------|--------|---------------------------|
| TYP3525  | X'.84' | 3525 CARD PUNCH           |
| TYP2540P | X'.82' | 2540 CARD PUNCH           |
| TYP3820  | X'.4F' | 3820 PRINTER              |
| TYPAFP1  | X'.4E' | ADVANCED FUNCTION PRINTER |
| TYP38008 | X'.4D' | 3800 MODEL 8 PRINTER      |
| TYP4248  | X'.4B' | 4248 PRINTER              |
| TYP4245  | X'.4A' | 4245 PRINTER              |
| TYP38003 | X'.49' | 3800 MODEL 3 PRINTER      |
| TYPVAFP  | X'.48' | VAFP PRINTER              |
| TYP3262  | X'.47' | 3262 PRINTER MODEL 5      |
| TYP3800  | X'.45' | 3800 MODEL 1 PRINTER      |
| TYP3203  | X'.43' | 3203 PRINTER              |
| TYP3211  | X'.42' | 3211 PRINTER              |
| TYP1403  | X'.41' | 1403 PRINTER              |

#### CLASTAPE (Tape Devices):

|           |        |                 |
|-----------|--------|-----------------|
| TYP3422   | X'.82' | 3422 TAPE DRIVE |
| * TYP3490 | X'.81' | 3490 TAPE DRIVE |
| TYP3420   | X'.10' | 3420 TAPE DRIVE |
| TYP3430   | X'.02' | 3430 TAPE DRIVE |
| TYP3480   | X'.01' | 3480 TAPE DRIVE |
| TYP3424   | X'.42' | 3424 TAPE DRIVE |
| TYP3590   | X'.83' | 3590 TAPE DRIVE |
| TYP9348   | X'.44' | 9348 TAPE DRIVE |

#### CLASDASD (DASD Devices):

|           |        |                                |
|-----------|--------|--------------------------------|
| * TYP3390 | X'.82' | 3390 DISK STORAGE FACILITY     |
| * TYP9345 | X'.81' | 9345 DISK STORAGE FACILITY     |
| TYP3380   | X'.20' | 3380 DISK STORAGE FACILITY     |
| TYP3330   | X'.10' | 3330 DISK STORAGE FACILITY     |
| TYP3333   | X'.10' | 3333 DISK STORAGE FACILITY     |
| TYP3350   | X'.08' | 3350 DISK STORAGE FACILITY     |
| TYP3375   | X'.04' | 3375 DISK STORAGE FACILITY     |
| TYP2305   | X'.02' | 2305 FIXED HEAD STORAGE DEVICE |
| TYP3340   | X'.01' | 3340 DISK STORAGE FACILITY     |

#### CLASFBA (FBA Devices):

|         |        |                         |
|---------|--------|-------------------------|
| TYP3370 | X'.02' | FBA Disk Storage Device |
| TYP9336 | X'.40' | FBA Disk Storage Device |
| TYP9332 | X'.08' | FBA Disk Storage Device |
| TYP9335 | X'.04' | FBA Disk Storage Device |
| TYPFBA  | X'.00' | FBA Disk Storage Device |

#### CLASSPEC (Special Devices):

|           |        |                                  |
|-----------|--------|----------------------------------|
| TYPCTCA   | X'.80' | CHANNEL TO CHANNEL ADAPTER       |
| TYP3704   | X'.40' | 3704 PROGRAMMABLE COMM. CTL UNIT |
| TYP3705   | X'.40' | 3705 PROGRAMMABLE COMM. CTL UNIT |
| * TYP0SA  | X'.20' | OPEN SYSTEMS ADAPTER DEVICE      |
| * TYP9033 | X'.08' | 9033 DYNAMIC SWITCH              |
| * TYP9032 | X'.02' | 9032 DYNAMIC SWITCH              |
| TYPUNSUP  | X'.01' | DEVICE UNSUPPORTED BY VM/370     |

## CP370 Device Features

These are the real device feature codes returned in byte 3 of Ry+1 for DIAGNOSE code X'24' and byte 11 of the VRDCBLOK for DIAGNOSE code X'210'.

Codes for features that are marked with an asterisk (\*) are returned only by using DIAGNOSE code X'210'.

### Terminals:

|         |       |                                 |
|---------|-------|---------------------------------|
| FTRDIAL | X'01' | 3275 WITH SWITCHED LINE SUPPORT |
| FTR3270 | X'02' | 3270 MODE, VIRTUAL 3215 DEVICE  |

### Graphics Devices:

|          |       |                         |
|----------|-------|-------------------------|
| FTR0PRDR | X'80' | OPERATOR ID CARD READER |
|----------|-------|-------------------------|

### Unit Record Output Devices:

|          |       |                                       |
|----------|-------|---------------------------------------|
| FTRUCS   | X'01' | UCS FEATURE                           |
| FTR4WCGM | X'80' | 3800, 4 Writable Generation Char Mods |
| FTREXTSN | X'40' | IS ALSO USED FOR A 3800 PRINTER       |

### Tape Devices:

|            |       |                              |
|------------|-------|------------------------------|
| FTR7TRK    | X'80' | 7-TRACK FEATURE              |
| FTRDLNS    | X'40' | DUAL DENSITY FEATURE         |
| FTRTRANS   | X'20' | TRANSLATE FEATURE            |
| FTRDCONV   | X'10' | DATA CONVERSION FEATURE      |
| * FTRCMPCT | X'08' | 3480 DATA COMPACTION FEATURE |

### DASD Devices:

|           |       |                                                  |
|-----------|-------|--------------------------------------------------|
| FTRRPS    | X'80' | ROTATIONAL POSITIONAL SENSING (RPS)              |
| FTRFH     | X'80' | FIXED HEAD DEVICE                                |
| FTREXTSN  | X'40' | EXTENDED SENSE BYTES (24 BYTES)                  |
| * FTRDYNP | X'40' | DYNAMIC PATHING                                  |
| FTR2311T  | X'20' | TOP HALF OF 2314 USED AS 2311                    |
| SYSVIRT   | X'20' | DEVICE IS A 3330V 'SYSVIRT'                      |
| * FTRVUA  | X'20' | 3330V THAT MAY BE DEDICATED TO A VIRTUAL MACHINE |
| FTR2311B  | X'10' | BOTTOM HALF OF 2314 USED AS 2311                 |
| FTR35MB   | X'08' | 35 MB DATA MODULE MOUNTED (3340)                 |
| FTR70MB   | X'04' | 70 MB DATA MODULE MOUNTED (3340)                 |
| FTRRSRL   | X'02' | RESERVE/RELEASE ARE VALID CCW OP CODES           |
| VIRTUAL   | X'01' | DEVICE IS A 3330V 'VIRTUAL'                      |
| FTRVIRT   | X'01' | 3330 VIRTUAL (MSS) VOLUME                        |
| * FTRCOMP | X'01' | 3350 in 3330 COMPATIBLE MODE                     |

### Special Devices:

|            |       |                                         |
|------------|-------|-----------------------------------------|
| FTR3088    | X'40' | CTCA IS TYPE 3088                       |
| FTRTYP1    | X'10' | TYPE ONE CHANNEL ADAPTER (3704/5)       |
| FTRTYP4    | X'10' | TREAT AS TYPE1 CHAN ADAPT (370X)        |
| FTR3088    | X'40' | CTCA IS TYPE 3088                       |
| * FTRTERM  | X'80' | Unsupported Terminal Device             |
| * FTRGRAF  | X'40' | Unsupported Graphic Display             |
| * FTRSP00L | X'20' | Unsupported Unit Record Spooling Device |
| * FTRTAPE  | X'08' | Unsupported Tape Device                 |
| * FTRDASD  | X'04' | Unsupported DASD Device                 |
| * FTRSWCH  | X'01' | Unsupported Dynamic Switch              |

## CP370 Virtual Device Status

This is the virtual device status returned in byte 2 of Ry for DIAGNOSE code X'24' and byte 6 of the VRDCBLOK for DIAGNOSE code X'210'.

|       |                             |
|-------|-----------------------------|
| X'20' | VIRTUAL DEVICE IS BUSY      |
| X'04' | VIRTUAL DEVICE IS NOT READY |
| X'01' | DEVICE IS DEDICATED         |

CP370 Virtual Device Flags

These are the virtual device flags returned in byte 3 of Ry for DIAGNOSE code X'24' and byte 7 of the VRDCBLOK for DIAGNOSE code X'210'.

|         |                                                                 |
|---------|-----------------------------------------------------------------|
| X'80'   | DASD - READ ONLY                                                |
| X'80'   | IF VIRTUAL 270X, LINE ENABLED                                   |
| X'40'   | IF DASD, TDISK OR VIRTUAL DISK IN STORAGE SPACE ALLOCATED BY CP |
| X'40'   | IF VIRTUAL 270X, LINE CONNECTED                                 |
| X'10'   | IF CONS/SPOOLING, PROCESSING 1ST CCW                            |
| X'08'   | IF DASD, VIRTUAL DISK IN STORAGE SPACE ALLOCATED BY CP          |
| X'02'   | IF DASD, RESERVE/RELEASE ARE VALID CCW OP CODES                 |
| * X'01' | DEVICE SUPPORTS MIDAWS                                          |

Data Areas Used by DIAGNOSE Codes X'14' and X'D8'

You might need to refer to one of the following data areas when using DIAGNOSE code X'14' or X'D8':

- SFBLOK — VM/SP 370 spool file control block
- SPLINK — VM/SP 370 spool file data block
- Extended spool file block for DIAGNOSE code X'D8'.

SFBLOK - VM/SP 370 Spool File Control Block

SFBLOK is in HCPGPI MACLIB as SFBLOK COPY.

NAME: SFBLOK  
DESCRIPTIVE NAME: VM/SP 370 SPOOL FILE CONTROL BLOCK  
DSECT NAME - SFBLOK  
FUNCTION: THIS DSECT IS USED TO WHEN SPOOL FILES ARE TO BE  
TRANSLATED TO VM/SP FORMAT. (IT IS ANALOGOUS TO  
THE VM/XA SPFBK.)  
CREATED BY:  
HCPSPXSB FOR SPFBK TO SFBLOK TRANSLATIONS. THIS IS  
DONE FOR DIAGNOSE X'14' AND \*SPL OUTPUT.  
DELETED BY:  
NOT APPLICABLE

## SPLINK - VM/SP 370 Spool File Data Block

SPLINK is in HCPGPI MACLIB as SPLINK COPY.

NAME: SPLINK  
DESCRIPTIVE NAME: VM/SP 370 SPOOL FILE DATA BLOCK  
DSECT NAME - SPLINK  
FUNCTION: THIS DSECT WHEN SPOOL FILES NEED TO BE TRANS-  
LATED TO VM/SP FORMAT. (IT IS ANALOGOUS TO  
THE VM/XA SPDBK.)  
CREATED BY:  
HCPSXSPL FOR DIAGNOSE X'14' AND \*SPL OUTPUT.  
DELETED BY:  
NOT APPLICABLE

## External Attribute Buffer Used by DIAGNOSE Codes X'B4', X'B8', and X'290'

The external attribute buffer (XAB) is a control block that contains data you create to specify additional information about a print file. Each print file has its own XAB, and CP has the facilities to maintain XABs.

### Suggested Format for an External Attribute Buffer

Figure 106 on page 995 shows the suggested format for data contained in an external attribute buffer. The basic design of the format is to create or locate a specific block without affecting other blocks within the XAB.

Figure 106. Suggested Format of an External Attribute Buffer

#### Lx

is the length of a block. This is a 2-byte field that specifies the total number of bytes for this block.

#### 00

is reserved.

#### Hx

is the length of the header. This is a 2-byte field that specifies the total number of bytes used for header information. The value is the size of the header + 2 (for the size of the Hx field itself).

#### header

is the header data. This is a variable size field which identifies the block.

For multiple independent blocks to be contained in the XAB, it is necessary for each block to have a unique header.

- The first part of the header should be a name or character string that uniquely identifies who or what is defining the block. For example, a company name or trademark.
- The second part of the header should be the name of the product associated with the company or trademark.
- The third part of the header should be the name of the block.
- The fourth part of the header should be format level for the block. If a change is made to a defined block, it is reflected in the format level for that block.

The following are examples of headers.

Blocks defined for products from IBM might use a header like:

```
IBM - VM - BLOCK XYZ - LEVEL 0.0.0
```

And if IBM changed this block, the header might look like:

```
IBM - VM - BLOCK XYZ - LEVEL 1.0.0
```

Blocks defined for products from company JJKLL might use a header like:

```
JJKKLL - PROD1 - BLOCK OPQ - LEVEL 0.0.0
```

### **data**

is the actual data for the block. This is a variable size field.

**Note:** CP has no restrictions on the content of an XAB except that the total size of the XAB cannot exceed 32KB-1 bytes (32,767 bytes). Although CP does not check to see that the standard format has been followed, we recommend that each user of an XAB use the suggested format for multiple uses of the XAB.

## Appendix B. Sample Programs Using DASD Block I/O System Service

Following are two sample programs using the DASD Block I/O system service (\*BLOCKIO). The first program verifies writing to a DASD device using \*BLOCKIO and the second program verifies reading a DASD device using \*BLOCKIO. Both programs use CMS IUCV support. For more information on CMS IUCV support, see [z/VM: CMS Macros and Functions Reference](#) and [z/VM: CMS Application Development Guide for Assembler](#).

Also, for more information on \*BLOCKIO itself, see [Chapter 14, “DASD Block I/O System Service \(\\*BLOCKIO\),”](#) on page 719.

**Note:** These programs work, however, they could be easily enhanced. They are presented as samples and should be viewed as such.

### Write Program

```
*****
*
*   SAMPLE PROGRAM ID - BLKWRITE
*
*   TYPE SYSTEM - CPIUCV/BLOCKIO
*
*   PURPOSE OF SAMPLE PROGRAM -
*       VERIFY WRITING TO A DASD DEVICE USING THE
*       CP BLOCK I/O INTERFACE
*
*   METHOD -
*       CONNECTION IS MADE TO A DASD DEVICE THRU BLOCK
*       I/O. THE ENDING BLOCK NUMBER IS OBTAINED AND A LOOP
*       IS SET UP TO START WRITING AT BLOCK 1 THRU THE ENDING
*       BLOCK.
*
*   EXPECTED RESULTS (NORMAL) -
*       MSGS - CONNECTION COMPLETE
*             - SEND DONE
*
*   EXPECTED RESULTS (ABNORMAL) - ANYTHING OTHER THAN ABOVE.
*
*   EXECUTION INSTRUCTIONS: BEFORE LOADING AND STARTING THE
*       FOLLOWING STEPS MUST BE PREFORMED:
*
*       - FORMAT THE DASD(512,1K,2K,OR 4K)
*       - ISSUE THE RESERVE COMMAND FOR THE DASD
*       - ISSUE 'FILEDEF BLKPGM DISK XXX' WHERE XXX
*         IS THE VIRTUAL ADDRESS OF THE DASD
*
*   NOTE: THIS PROGRAM CAN BE RUN AGAINST ALL DASD
*         AND ALL BLOCKSIZES.
*

## Read Program

```

*****
*
*   SAMPLE PROGRAM ID - BLKREAD
*
*   TYPE SYSTEM - CPIUCV/BLOCKIO
*
*   PURPOSE OF SAMPLE PROGRAM -
*           VERIFY READING A DASD DEVICE USING THE
*           CP BLOCK I/O INTERFACE
*
*   METHOD -
*           CONNECTION IS MADE TO A DASD DEVICE THRU BLOCK
*           I/O.THE ENDING BLOCK NUMBER IS OBTAINED AND A LOOP
*           IS SET UP TO START READING AT BLOCK 1 THRU THE ENDING
*           BLOCK.THE FINAL BLOCK IS WRITTEN OUT.
*
*   EXPECTED RESULTS (NORMAL) -
*           MSGS - CONNECTION COMPLETE
*                 - SEND DONE
*                 - THE FINAL BLOCK OF DATA(F'S INS THIS CASE)
*
*   EXPECTED RESULTS (ABNORMAL) - ANYTHING OTHER THAN ABOVE.
*
*   EXECUTION INSTRUCTIONS: BEFORE LOADING AND STARTING THE
*           FOLLOWING STEPS MUST BE PREFORMED:
*
*           - FORMAT THE DASD(512,1K,2K,OR 4K)
*           - ISSUE THE RESERVE COMMAND FOR THE DASD
*           - ISSUE 'FILEDEF BLKPGM DISK XXX' WHERE XXX
*             IS THE VIRTUAL ADDRESS OF THE DASD

## Appendix C. DIAGNOSE Code X'68' and VMCF

---

### DIAGNOSE Code X'68'

---

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'68' to initiate a function of the Virtual Machine Communication Facility (VMCF).

**Note:** VMCF is maintained in z/VM only for compatibility; all new programs should use APPC/VM for communication. See the appendixes in the *VM/ESA V2.4: Conversion Guide and Notebook* (<https://www.ibm.com/pubs/hcse9a10.pdf>), GC24-5839 for information on how to migrate your programs to APPC/VM or IUCV.

VMCF provides virtual machines with the ability to send data to, and receive data from, any other virtual machine.

VMCF is made up of control functions, data transfer functions, the VMCPARM parameter list, a special external interrupt (code X'4001') to asynchronously alert virtual machines to pending messages, and an external interrupt message header (VMCMHDR) to pass control information to another user.

See “The Virtual Machine Communication Facility” on page 1005 for more information on VMCF protocol and details of VMCF functions.

**Notes:**

1. Before you can use any other VMCF function, you must use the AUTHORIZE function for communications. Before you can communicate with another user, that user must also have used the AUTHORIZE function.
2. In an XC virtual machine, DIAGNOSE code X'68' may not be issued in access-register mode.

**Entry Values:**

**Rx**

Contains the address of a parameter list (VMCPARM). The address of VMCPARM must be in guest real storage in the host-primary address space and must be doubleword-aligned. (See “The VMCPARM Parameter List” on page 1016 for the format of VMCPARM and a description of the contents of each of its fields.) One of the entries in this parameter list is a subcode, specifying the particular request being initiated. The functions and their subcodes are listed under the description of the VMCPFUNC field.

**Ry**

Not used.

**Exit Values:**

**Ry**

Contains the return code upon successful or unsuccessful completion of DIAGNOSE code X'68' function invocation. For a list of VMCF return codes and their meanings, see Table 214 on page 1004 or Table 219 on page 1023. Note that return codes also are found in Final Response Interrupts in the VMCMEFLG field. See Table 220 on page 1026.

### Usage Notes

1. Rx and Ry can be any general register, R0 through R15. They may also be the same register.
2. You may not be authorized to issue this DIAGNOSE code if an external security manager is installed on your system. For additional information, contact your security administrator.

## Responses

**Return Codes:** The virtual machine initiating a VMCF request receives a return code that may be returned in the general register specified as Ry in the DIAGNOSE instruction or in VMCMEFLG upon receiving an interrupt associated with a data transfer operation. The return code indicates successful completion of the request or error conditions associated with the request.

Upon completion of DIAGNOSE code X'68', the following return codes may be received:

*Table 214. VMCF Return Codes from DIAGNOSE code X'68'*

| Return Code in Ry | Meaning                                                                                                                                                                                                                                                                                                                                    |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')         | Successful completion of a request                                                                                                                                                                                                                                                                                                         |
| 1 (X'01')         | Invalid buffer address or length                                                                                                                                                                                                                                                                                                           |

| 16 (X'10')        | Incorrect length                                                                                                                                                                                                                                                                                                                           |
| 17 (X'11')        | Destructive overlap. A virtual machine executed a RECEIVE or REPLY function and specified a receive buffer address that overlapped the source virtual machine send data address or specified a reply data address that overlapped the source virtual machine reply buffer address.                                                         |
| 18 (X'12')        | User not authorized for priority messages                                                                                                                                                                                                                                                                                                  |
| 19 (X'13')        | Data transfer error                                                                                                                                                                                                                                                                                                                        |
| 20 (X'14')        | Cancel-busy. A virtual machine attempted to cancel a message being processed. If this is a SEND/RECV request and the RECEIVE function is in process, repeated retries may cancel the REPLY function.                                                                                                                                       |

**Program Exceptions:** These program exceptions can occur if the DIAGNOSE X'68' is given incorrect input data:

| Problem Encountered                                                   | Cause                                                                                    |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| Special-operation exception                                           | DIAGNOSE code X'68' cannot run in an XC virtual machine that is in access register mode. |
| Privilege-operation exception                                         | The virtual machine is in the problem state.                                             |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch the parameter list.                                    |

## The Virtual Machine Communication Facility

**Note:** VMCF is maintained in z/VM only for compatibility; all new programs should use APPC/VM for communication. See [VM/ESA V2.4: Conversion Guide and Notebook](#) (<https://www.vm.ibm.com/pubs/hcse9a10.pdf>), GC24-5839 for information on how to migrate your programs to APPC/VM or IUCV.

The Virtual Machine Communication Facility (VMCF) is part of the CP component of VM. VMCF provides virtual machines with the ability to send data to and receive data from any other virtual machine.

VMCF is made up of five data transfer functions, seven control functions, a special external interrupt (code X'4001') to asynchronously alert virtual machines to pending messages, and an external interrupt message header to pass control information (and data, at times) to another user.

VMCF is implemented by means of functions invoked using the DIAGNOSE instruction code X'68' and a special 40-byte parameter list called VMCPARM. (VMCPARM DSECT is in HCPGPI MACLIB.) A VMCF function is indicated by a particular function subcode in the VMCPFUNC field in the parameter list.

**Note:** Before you can use any other VMCF function, you must use the AUTHORIZE function for communications. Before you can communicate with another user, that user must also have used the AUTHORIZE function.

A special external interrupt (code X'4001') notifies one virtual machine of a pending transfer of data. This interrupt is also used to synchronize sending and receiving of data.

Along with this interrupt, the virtual machine receives a message header that is logged into a preassigned virtual storage area called VMCMHDR. (VMCMHDR DSECT is in HCPGPI MACLIB.) This message header is used to define the type of request and to provide data transfer information, such as length of data. The message header is also used to notify the originator of a transaction of the success or failure of the transaction. In this case, the message header includes such information as residual counts and data transfer return codes.

See [Table 215 on page 1005](#) for a list of the VMCF functions and a brief description of each. The functions are described in detail starting on page [“Descriptions of VMCF Functions” on page 1011](#).

Messages and data are directed to other virtual machines logically through the user ID. The amount of data that can be moved in a single transfer is limited only by the sizes of virtual machine storage of the respective virtual machines. Use of real storage is minimal. Only 1 real storage page per virtual machine (a total of 2 pages, 1 for the sender and 1 for the receiver) needs to be locked during the data transfer.

The special message facility (MSG) uses VMCF to send messages from 1 virtual machine storage area to another virtual machine storage area. For a description of the special message facility and how it uses VMCF, see [Appendix D, “The Special Message Facility,” on page 1027](#).

[Table 215 on page 1005](#) describes the purpose of each function.

*Table 215. Virtual Machine Communication Facility (VMCF) Functions*

| Function    | Type    | Description                                                                                                                                                                           |
|-------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AUTHORIZE * | Control | Initializes VMCF for a given virtual processor. Once AUTHORIZE is executed, the virtual processor can execute other VMCF functions and receive messages or requests from other users. |

Table 215. Virtual Machine Communication Facility (VMCF) Functions (continued)

| Function      | Type          | Description                                                                                                                       |
|---------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------|
| UNAUTHORIZE * | Control       | Terminates VMCF activity on a virtual processor                                                                                   |
| SEND          | Data Transfer | Directs a message or block of data to another virtual machine                                                                     |
| SEND/RECV     | Data Transfer | Directs a message or block of data to another virtual machine, and requests notification of a reply                               |
| SENDX         | Data Transfer | Directs data to another virtual machine on a faster but more restrictive protocol than the SEND function                          |
| RECEIVE       | Data Transfer | Allows you to accept selective messages or data sent through a SEND or SEND/RECV function                                         |
| SETLIMIT      | Control       | Allows you to set the maximum number of outgoing messages that you can have pending.                                              |
| CANCEL        | Control       | Cancels a message or data transfer directed to another user but not yet accepted by that user                                     |
| REPLY         | Data Transfer | Allows you to direct data back to the originator of a SEND/RECV function, simulating full duplex communication                    |
| QUIESCE *     | Control       | Temporarily rejects further SEND, SENDX, SEND/RECV, or IDENTIFY requests from other users to the virtual machine                  |
| RESUME *      | Control       | Resets the status set by the QUIESCE function and allows execution of subsequent requests from other users to the virtual machine |
| IDENTIFY      | Control       | Notifies another user that your virtual machine is available for VMCF communication                                               |
| REJECT        | Control       | Allows you to reject specific SEND or SEND/RECV requests pending for your virtual machine                                         |

\*These functions have different meanings in a virtual MP environment. For more information about a virtual MP environment, see [“VMCF in an MP Environment”](#) on page 1022.

## Using the Virtual Machine Communication Facility

The following discussion presents ideas and suggestions for using the Virtual Machine Communication Facility (VMCF).

### VMCF Applications

The VM system with VMCF provides the user with the potential to apply new and different techniques to current applications.

#### *Resource Sharing*

VMCF provides a clear and concise method for sharing and serializing resources between virtual machines. The resources can range from multi-write minidisks to entire processors. The control functions for resource sharing (such as resource management, serialization) can be contained in a virtual machine.

#### *Virtual Extensions to VM*

It is conceivable that functions could be added to VM without altering the control program (CP). A special privilege class virtual machine could be used to provide additional functions to nonprivilege class

users using the VMCF interface. Similarly, CMS capabilities could be expanded (or at least appear to be expanded) by linking CMS with other virtual machines.

### ***Program Testing***

The program testing capabilities offered by VMCF can range from device simulation to teleprocessing network simulation. In particular, VMCF can be used to provide external interactions from one virtual machine to another. A simulated teleprocessing network could be constructed with virtual machines. Each virtual machine would effectively become a node within the network. The network structure could range from a simple tree type structure to a complicated multi-path mesh type structure. The program logic within each node virtual machine would be the same logic as required for a real teleprocessing node. In theory, a reasonably complicated structure could be simulated without requiring the physical hardware.

The significant testing capability provided by VMCF is the ability to link the test system with test/simulation routines in another virtual machine.

### ***Intra-Virtual Machine Communication***

Although the VMCF interface is intended for communication from one virtual machine to another, it can also be used to communicate within a single virtual machine (wrap connection). The VMCF interface could conceivably be used to link one or more operating system tasks that are logically separated by the software. This would allow task-to-task communication rather than virtual machine-to-virtual machine communication.

### **Security and Data Integrity**

The VMCF interface provides the following security aids:

- The user doubleword in the external interrupt message header can be used to contain a security code to prevent unwarranted users from accessing a shared database or other confidential information.
- The AUTHORIZE SPECIFIC option allows a user to restrict messages sent to his virtual machine. This option is useful when worker machines are to communicate only with a host machine. The worker machines can AUTHORIZE SPECIFIC with the host and prevent unwarranted users from clogging their message queues.
- The design of VMCF prevents malicious users from intercepting transactions in process for other users (for example, user D cannot execute a RECEIVE, REPLY, REJECT or CANCEL to a message sent to user B from user A).

The VMCF support module is designed so a user is always informed of conditions that could threaten the integrity of his own data. The user is notified either with a DIAGNOSE code X'68' return code or data transfer error code. There is no internal buffering of user data within the control program (CP). A message is always retained by either the SOURCE or TARGET virtual machine. If a SEND type request fails, the SOURCE still has a copy of the original message. If a TARGET REPLY fails, the TARGET user still has a copy of the REPLY data. The DIAGNOSE return code or data transfer error code can indicate to a user that a transaction failed. It is up to the user to preserve the associated transaction data. A VMCF user should consider the following notes:

1. The buffer used for SOURCE data in a SEND, SENDX or SEND/RECV request should not be freed or reused until the final response external interrupt is received by the SOURCE.
2. The buffer used for TARGET data in a REPLY function can be reused by the TARGET after the DIAGNOSE instruction (REPLY) has successfully completed.
3. The user parameter list, VMCPARM, may be re-used upon completion of the DIAGNOSE instruction. At that point the VMCPARM data has been copied to a VMCF control block by the control program. A user should, however, maintain queues of VMCPARM data to associate an external interrupt message header, VMCMHDR, with a particular request.
4. A user should always interrogate the DIAGNOSE return code or data transfer error code for possible error conditions. It is the user's responsibility to determine the types and extent of error recovery. The DIAGNOSE return code 19 (X'13') for a SOURCE SEND, SEND/RECV or SENDX request indicates that

an error was associated with the TARGET user and for a TARGET RECEIVE or REPLY request indicates that an error was associated with the SOURCE user. The user who receives this return code does not have to invoke error recovery for himself but only be aware that the transaction did not complete successfully because of an error associated with the other user.

## Performance Considerations

There are several factors that can affect the performance of VMCF:

- It is to a user's benefit to have the user parameter list, VMCPARM, in the same 4K page as the DIAGNOSE code X'68' instruction. This may eliminate a paging operation.
- User support modules using the VMCF interface should be written as reentrant modules and be contained within a CP shared segment whenever possible. This helps reduce CP paging overhead.
- For applications that involve serial message processing, the SENDX function is the most efficient. The SENDX function eliminates the need for the TARGET to do a RECEIVE operation.

**Note:** Overall system VM performance is not affected when VMCF is not being used by an installation.

## General Considerations

The SENDX function is a fast way to transfer messages or data and can be used in place of the CP MSG command where the message length exceeds the capacity of the terminal input line. Its use is somewhat restricted in that the maximum data length must be agreed upon by all VMCF users and then remains fixed unless renegotiated.

The SEND and SEND/RECV functions are better suited to transfer high volume database type information. This type of data transfer requires the flexibility of a wide range of data lengths along with rigorous management and control techniques.

The QUIESCE function allows a virtual machine to stop receiving messages. The virtual machine can process those messages already stacked and then use the RESUME function to continue reception. The QUIESCE function also allows a virtual machine to process all queued messages prior to terminating VMCF operation.

The user parameter list, VMCPARM, is designed so it can be used for any function by simply varying the contents of its fields.

Users should keep copies of VMCPARMs for all requests made through the SEND, SEND/RECV, or SENDX functions. When a final response interrupt is received and the interrupt message header indicates no data transfer errors, the corresponding VMCPARM copy can be released. If a data transfer error is indicated, the copy can be used to reinitiate the transaction.

## VMCF Protocol

VMCF provides four types of protocol:

- SEND
- SEND/RECV
- SENDX
- IDENTIFY.

The protocol used to communicate between two virtual machines depends on the application of VMCF and conventions established by virtual machine users authorized to use VMCF. A virtual machine must invoke the AUTHORIZE function before it is allowed to use any of the other functions.

The types of transactions that virtual machines can be involved in are described by a series of VMCF protocols. In these protocols the originating virtual machine is called the *source* virtual machine. The destination virtual machine is called the *target* virtual machine.

The protocol for a transaction remains in effect for the duration of the transaction.

## The SEND Protocol

The SEND protocol defines a one-way transfer of data from source virtual machine storage to target virtual machine storage. The SEND protocol uses the SEND and RECEIVE functions, as described in [Figure 107 on page 1009](#). The source virtual machine first transfers data to the target virtual machine. This is done by executing the SEND function which specifies the user ID of the target virtual machine, a message ID, and the address and length of the data being sent. The target virtual machine receives an external interrupt from CP notifying it of the data transfer request. The target virtual machine can then respond through the RECEIVE function. The RECEIVE request specifies the address and the length of the TARGET buffer that is to receive the data and causes the data to be transferred from source virtual machine storage to target virtual machine storage. When the data transfer is complete, the source virtual machine receives an external interrupt from CP, indicating that the transaction is complete and that the target virtual machine has received the data.

All virtual machines authorized to use VMCF can send data using this protocol.

The amount of data transferred is limited only by virtual machine storage size. Data is transferred in blocks of up to 2K (when necessary) and only one real page frame is locked during the data transfer operation.

Figure 107. The SEND Protocol

## The SEND/RECV Protocol

The SEND/RECV protocol defines a transaction calling for two-way transfer of data, as described in [Figure 108 on page 1010](#). The SEND/RECV protocol uses the SEND/RECV, RECEIVE, and REPLY functions.

The source virtual machine initiates the transaction using the SEND/RECV function. Using an external interrupt, CP notifies the target virtual machine that there is a message waiting. The target virtual machine uses the RECEIVE function to cause the data to be transferred from the source virtual machine's storage to the target virtual machine storage. The target virtual machine now uses the REPLY function to cause data to be transferred from its storage to the source virtual machine's storage. When the REPLY function completes processing, CP causes an external interrupt in the source virtual machine, notifying it that the transaction is complete.

The SEND/RECV request requires that the source virtual machine specify the address and length of the data to be transferred and the address where data is expected from the REPLY function. (Both addresses are in source virtual machine storage.) These addresses, along with the length of the data to be transferred, are specified through the VMCPARM parameter list. See [“The VMCPARM Parameter List” on page 1016](#).

When RECEIVE is issued by the target virtual machine in response to the SEND/RECV request, VMCPARM contains the address in target virtual machine storage where data is to be received. Finally, when the REPLY request is issued, VMCPARM contains the address in the target virtual machine storage from which data is to be transferred.

Figure 108. The SEND/RECV Protocol

## The SENDX Protocol

The SENDX protocol defines a transaction calling for an expedited one-way transfer of data. [Figure 109 on page 1011](#) shows the SENDX protocol visually. SENDX differs from the SEND protocol in that the target virtual machine need not issue the RECEIVE function; data is transferred from source virtual machine storage to target virtual machine storage at the same time the external interrupt from CP notifies the target virtual machine of the transaction. Data sent by the source virtual machine is placed in the external interrupt buffer of the target virtual machine.

Virtual machines using the SENDX protocol are responsible for specifying the user ID for the target virtual machine, a message ID, the address and length of the data being sent, and the external interrupt buffer address and data length for the target virtual machine. A virtual machine to be used as a target virtual machine with the SENDX protocol must specify this information through VMCPARM when that virtual machine issues the AUTHORIZE function. The data length specified must be at least as long as the maximum amount of data to be transferred during a transaction; it need not be limited to the usual 40-byte external interrupt buffer. Effective use of the SENDX protocol requires that VMCF users agree on a maximum size for SENDX data and then issue the AUTHORIZE function with the appropriate external interrupt buffer size.

If the target virtual machine has not provided enough SENDX buffer area in the external interrupt buffer, CP notifies the source virtual machine that the transaction was not completed.

When a SENDX data transfer is complete, CP directs a response external interrupt to the source virtual machine, notifying it that the transaction is complete.

Figure 109. The SENDX Protocol

## The IDENTIFY Protocol

The IDENTIFY protocol defines a means for virtual machines to identify themselves to other virtual machines by passing user-defined control information through a standard VMCF message header. [Figure 110 on page 1011](#) shows the IDENTIFY protocol visually.

When the IDENTIFY function is issued, CP directs an external interrupt to the target virtual machine. Along with the external interrupt, the target virtual machine receives a standard VMCF message header that contains user-defined information. The IDENTIFY protocol does not cause a response external interrupt to be directed to the source virtual machine.

Figure 110. The IDENTIFY Protocol

## Descriptions of VMCF Functions

There are two types of VMCF functions:

- Control functions
- Data transfer functions.

### The Control Functions

The VMCF control functions allow efficient management of data transfer operations from your virtual machine console. The control functions are:

- AUTHORIZE
- UNAUTHORIZE
- CANCEL
- QUIESCE
- RESUME
- IDENTIFY

- REJECT.

### ***AUTHORIZE: DIAGNOSE Code X'68' Subcode X'0000'***

AUTHORIZE enables VMCF for a virtual machine; once an AUTHORIZE has been executed, the virtual machine can execute other VMCF functions and receive messages and data from other authorized VMCF virtual machines. It is possible to specify three options with the AUTHORIZE function: SPECIFIC, PRIORITY, and VMCPMSG.

The SPECIFIC option authorizes communication with a specific virtual machine. Any messages sent to the virtual machine from other than the specified virtual machine will be rejected. The SPECIFIC option can be used in an application where virtual machines desire to communicate with a host virtual machine but not among themselves. Under the special message facility, CP is authorized with every virtual machine that is to receive messages sent with the SMSG command. Virtual machines that are to receive messages must authorize themselves. The VMCPMSG option allows a virtual machine to receive special messages.

The PRIORITY option allows a virtual machine to authorize the receipt of priority messages. A virtual machine is allowed to send priority messages to another virtual machine only if the other virtual machine is authorized to receive priority messages. A priority message is queued ahead of nonpriority messages and therefore accepted first.

When you execute the AUTHORIZE function, you must specify the address and length of the external interrupt buffer for your virtual machine. The buffer must be large enough to contain a fixed message header (40 bytes). The message header identifies messages sent by other virtual machines or responses to messages you might send to your own virtual machine.

If you are going to accept SENDX-type communications, you must specify the size of the external interrupt buffer as 40 plus the maximum size of SENDX data that you plan to accept. This has the effect of authorizing SENDX protocol. That is, a virtual machine may receive data along with the external interrupt in its external interrupt buffer. When a virtual machine sends data to another virtual machine through the SENDX function the data must fit in that virtual machine's external interrupt buffer or the function is rejected. It is recommended that you specify a buffer length of 280 bytes.

Any AUTHORIZE options in effect can be reset or changed by executing the AUTHORIZE function again. If there are errors during execution of the AUTHORIZE function, a virtual machine's authorization status is not changed.

### ***UNAUTHORIZE: DIAGNOSE Code X'68' Subcode X'0001'***

UNAUTHORIZE terminates VMCF activity for a virtual machine. The UNAUTHORIZE function causes any stacked or queued messages associated with the virtual machine to be purged. A virtual machine should execute the QUIESCE function before executing UNAUTHORIZE if messages that are already queued are to be handled. When a virtual machine executing UNAUTHORIZE has pending final response external interrupts, the interrupts are purged. If a virtual machine has pending SEND external interrupts from another source virtual machine, a RESPONSE interrupt is reflected to the source indicating that the virtual machine is no longer available.

### ***CANCEL: DIAGNOSE Code X'68' Subcode X'0006'***

CANCEL cancels a message or data transfer pending for but not accepted by another VMCF virtual machine. A virtual machine can CANCEL messages it originates with SEND, SENDX, or SEND/RECV functions. A message cannot be cancelled if any of the following conditions exist and the request was:

- SENDX or IDENTIFY and the target had already received the SEND external interrupt.
- SEND and the target had already executed the RECEIVE or REJECT functions.
- SEND/RECV and the target had already executed the REPLY or REJECT functions.

If the original request was SEND/RECV and the target virtual machine had executed the RECEIVE function but not the REPLY, the REPLY can be cancelled. A virtual machine is notified of this condition with a DIAGNOSE return code. (For a description of the return codes, see [Table 217 on page 1019.](#))

***QUIESCE: DIAGNOSE Code X'68' Subcode X'0008'***

QUIESCE temporarily rejects SEND, SENDX, SEND/RECV, or IDENTIFY requests from other virtual machines. QUIESCE allows a virtual machine to receive any stacked or queued messages but reject further SEND, SENDX, IDENTIFY, or SEND/RECV requests from other virtual machines. QUIESCE can be used to indicate to other virtual machines that the virtual machine is in QUIESCE status, authorized for communication but not able to accept messages at this time (for example, entering slowdown, my buffers are full, try again later). The IDENTIFY function could be used to inform other virtual machines that a particular user is no longer in QUIESCE status. You should execute the QUIESCE function before executing the UNAUTHORIZE function to avoid losing messages (see [“UNAUTHORIZE: DIAGNOSE Code X'68' Subcode X'0001'”](#) on page 1012). A virtual machine can reset the QUIESCE status (exit slowdown) by executing the RESUME function. (See [“RESUME: DIAGNOSE Code X'68' Subcode X'0009'”](#) on page 1013.) A virtual machine in QUIESCE status may continue to send messages to other virtual machines. QUIESCE status for a virtual machine only affects messages sent from other virtual machines.

***RESUME: DIAGNOSE Code X'68' Subcode X'0009'***

RESUME cancels the QUIESCE status, allowing your virtual machine to resume reception of VMCF requests from other virtual machines. You can use the IDENTIFY function to inform other virtual machines that your virtual machine is no longer in QUIESCE status. (See [“IDENTIFY: DIAGNOSE Code X'68' Subcode X'000A'”](#) on page 1013.)

***IDENTIFY: DIAGNOSE Code X'68' Subcode X'000A'***

IDENTIFY notifies another virtual machine that your virtual machine is available for VMCF communication. Use the IDENTIFY function after issuing the AUTHORIZE function or after your virtual machine has been in the VMCF QUIESCE state and you have issued the RESUME function. IDENTIFY causes an external interrupt to be stacked for a specified virtual machine. The virtual machine executing the IDENTIFY function specifies the user ID of the user to receive the external interrupt. The external interrupt identifies the virtual machine executing the IDENTIFY function. The IDENTIFY function is provided to inform a host or controller virtual machine that a virtual machine is activated (logged on) and ready for VMCF communication. The IDENTIFY function can also be used to inform other virtual machines that your virtual machine has exited QUIESCE state. There is no response external interrupt associated with the IDENTIFY function.

The IDENTIFY function can also be used to pass virtual machine defined control information. The fields in the VMCF parameter list, VMCPARM, not used by the IDENTIFY function may be used to contain additional virtual machine data.

***REJECT: DIAGNOSE Code X'68' Subcode X'000B'***

REJECT selectively rejects pending SEND or SEND/RECV requests from other VMCF virtual machines. REJECT causes a response external interrupt to be reflected to the originator of a message. The external interrupt indicates to the originator that the message was rejected. (See VMCMRJCT on page [“The External Interrupt Message Header \(VMCMHDR\)”](#) on page 1021.) The user doubleword within the external interrupt header may tell a user why the message was rejected. (See VMCPUSE on page [“The VMCPARM Parameter List”](#) on page 1016 and VMCMUSE on page [“The External Interrupt Message Header \(VMCMHDR\)”](#) on page 1021.) When the user of a virtual machine executes the REJECT function, he specifies within the VMCF parameter list, VMCPARM, the message ID of the message to be rejected. A virtual machine cannot reject a message sent with the SENDX function since the message is received at the same time the external interrupt is received. The REJECT function can be executed as response to either SEND or SEND/RECV requests.

**The Data Transfer Functions**

The data transfer functions are:

- SEND
- SEND/RECV
- SENDX

- RECEIVE
- REPLY
- SETLIMIT

These operations involve the movement of data from one virtual machine storage to another virtual machine storage.

### ***SEND: DIAGNOSE Code X'68' Subcode X'0002'***

SEND directs a message or block of data to another virtual machine. Specify the virtual address and length of data to be sent within the user parameter list, VMCPARM. Also, specify in the parameter list a message ID to be associated with the message and the user ID of the user to receive the message data. You can also send a doubleword of data to be transmitted within the external interrupt message header (refer to the section [“VMCF User Doubleword” on page 1022](#)). If the SEND function is executed with a data length of 0, only the user doubleword is transmitted to the target virtual machine. The target virtual machine can then respond with a RECEIVE function (0 length) and pass back a doubleword of data to the source virtual machine. The external interrupt message header identifies the SEND request. When the target virtual machine executes a RECEIVE function, the message is transmitted from the source virtual machine storage to the target virtual storage. There is no internal buffering of data within the control program (CP). When the data transfer function is complete, the source virtual machine receives a response external interrupt indicating that the SEND request is complete. The target virtual machine receives a DIAGNOSE code X'68' return code indicating that the RECEIVE function is complete. The return code can indicate error conditions associated with the RECEIVE function or normal completion.

The target virtual machine has the option to reject a message rather than execute the RECEIVE function. (See [“REJECT: DIAGNOSE Code X'68' Subcode X'000B'” on page 1013](#).) The source virtual machine may cancel a SEND request before the target virtual machine has executed a RECEIVE function or REJECT function. (See [“CANCEL: DIAGNOSE Code X'68' Subcode X'0006'” on page 1012](#).)

If you are executing the SEND function, you may specify the PRIORITY option. The PRIORITY option causes the external interrupt for the target virtual machine to be queued ahead of all other nonpriority external interrupts. If there are other PRIORITY external interrupts pending for the target virtual machine, the queuing is done in a first-in-first-out manner. That is, PRIORITY interrupts are queued FIFO among themselves but ahead of all nonpriority interrupts.

### ***SEND/RECV: DIAGNOSE Code X'68' Subcode X'0003'***

SEND/RECV provides the capability to both send and receive data in a single VMCF transaction. The SEND/RECV function causes an external interrupt to be queued for the target virtual machine. When the target virtual machine receives the external interrupt, it can respond with the RECEIVE function. The RECEIVE function causes data to be transferred from the source virtual storage to target virtual storage. The target virtual machine can then respond with a REPLY function. The REPLY function causes data to be transferred from specified target virtual storage to a reply buffer in the source virtual storage. The source virtual machine then receives a response external interrupt indicating that the SEND/RECV request is complete.

When the source virtual machine executes the SEND/RECV function it specifies the address and length of both the SEND buffer and reply buffer. The address and length specifications are contained within the user parameter list, VMCPARM. The user parameter list also contains a message ID and user ID of the user to receive the data. (See the [“The VMCPARM Parameter List” on page 1016](#).)

The source virtual machine can cancel a previously executed SEND/RECV request provided the target virtual machine has not yet executed the REPLY or REJECT function. If the target virtual machine has already executed the RECEIVE function, only the REPLY can be cancelled. (See [“CANCEL: DIAGNOSE Code X'68' Subcode X'0006'” on page 1012](#).)

The target virtual machine can execute the REJECT function in response to the SEND/RECV request and cause the entire operation to be terminated. (See [“REJECT: DIAGNOSE Code X'68' Subcode X'000B'” on page 1013](#).)

The target virtual machine can respond to a SEND/RECV request with the REPLY function without executing the RECEIVE function. This has the effect of informing the source virtual machine that the target virtual machine cannot accept data but that it can send data. The source virtual machine could have executed the SEND/RECV function only as a means to solicit data from the target virtual machine. The application of this protocol is up to VMCF users. The user doubleword can be used as a means to control such an application. (See [“VMCF User Doubleword”](#) on page 1022.)

You can execute a SEND/RECV request using the PRIORITY option. The PRIORITY option causes the target external interrupt for the SEND/RECV request to be queued ahead of any other nonpriority external interrupts. Response external interrupts directed to the source of a PRIORITY message are also queued in priority order.

### ***SENDX: DIAGNOSE Code X'68' Subcode X'0004'***

SENDX directs data to another virtual machine through a faster but more restrictive protocol than the SEND function. SENDX function data reaches the target virtual machine at the same time the SEND external interrupt reaches the target. To use the SENDX function, the target virtual machine must have an external interrupt buffer large enough to contain both the standard message header and the data. The size of the external interrupt buffer is specified when you execute the AUTHORIZE function. Attempts to execute SENDX are rejected when the target virtual machine's external interrupt buffer is not large enough to contain the data. After the target virtual machine receives the SEND external interrupt and data, a response external interrupt is directed to the source virtual machine. The SENDX function eliminates the need for a target virtual machine to execute a RECEIVE function.

A SENDX request can be cancelled by the source virtual machine provided the SENDX external interrupt has not yet been reflected to the target virtual machine. (See [“CANCEL: DIAGNOSE Code X'68' Subcode X'0006”](#) on page 1012.)

Specify the SENDX buffer address and length in the user parameter list, VMCPARM. The message ID and user ID of the target virtual machine are also specified in VMCPARM.

The SENDX function can be executed with the PRIORITY option allowing the SEND external interrupt to be queued ahead of all nonpriority external interrupts for the target virtual machine.

A SENDX request cannot be rejected by the target virtual machine since the message is received at the same time the external interrupt is received.

You can execute the SENDX function with a 0 data length causing only the message header and user doubleword to be transmitted.

### ***RECEIVE: DIAGNOSE Code X'68' Subcode X'0005'***

RECEIVE allows you to selectively accept messages or data sent through the SEND or SEND/RECV functions. You must specify in the user parameter list, VMCPARM, the virtual address and length of the RECEIVE buffer. The parameter list also contains the message ID of the message to be received and user ID of the virtual machine that originated the SEND or SEND/RECV request. When a virtual machine has more than one message pending, the RECEIVE function can be executed to select messages in any order by message ID.

You can execute the REJECT function to reject messages sent by other virtual machines. The REJECT function terminates the SEND or SEND/RECV request. (See [“REJECT: DIAGNOSE Code X'68' Subcode X'000B”](#) on page 1013.)

You can execute the RECEIVE function in response to a SEND/RECV request and then execute a REJECT function rather than a REPLY. The user doubleword passed back with the REJECT function could indicate RESEND, for example, if the original data was not received correctly (depending on how you want to use the protocol).

### ***REPLY: DIAGNOSE Code X'68' Subcode X'0007'***

REPLY allows you to direct data back to the sender of a SEND/RECV function. This simulates full duplex communication. The REPLY function is used with the SEND/RECV function. A user who receives a SEND/RECV external interrupt normally responds by executing the RECEIVE function. The RECEIVE function

causes data to be transferred from the source virtual storage to the target virtual storage. The target virtual machine can then respond with the REPLY function causing data to be transferred from specified target virtual storage to the source virtual storage. The REPLY function causes a response external interrupt to be reflected to the source virtual machine.

The user parameter list, VMCPARM identifies the virtual buffer address and length of reply data. When the REPLY function is executed, the user parameter list, VMCPARM, also contains the message ID and the user ID of the virtual machine to receive the reply.

The REPLY function can be executed with a 0 data length indicating no response. You can transmit a reply, 0 length or otherwise, using the user doubleword.

A reply can be executed in response to a SEND/RECV request without executing the RECEIVE function. This indicates that you do not want to receive the message but may want to send a reply. A reply of 0 length could be executed simply to terminate the SEND/RECV request. The application of the REPLY function is a user decision. It must be used to terminate a SEND/RECV request, however, unless the REJECT function is executed. (See [“REJECT: DIAGNOSE Code X'68' Subcode X'000B'”](#) on page 1013.) The reply is complete when the source virtual machine receives the external interrupt response.

A REPLY function cannot be executed in response to a SEND request, this is a protocol violation.

### ***SETLIMIT: DIAGNOSE Code X'68' Subcode X'000C'***

SETLIMIT determines the maximum number of VMCF messages that a virtual machine can have outstanding (that is, sent but not received, cancelled, or rejected) at any one time. When a virtual machine uses the AUTHORIZE function, the message limit is set to the default value of 50. Thereafter, the SETLIMIT function can be used to change the limit at any time. If the limit value is specified as zero, the limit is set to the default value of 50. Only the low-order halfword of the specified limit is used, so the maximum value that can be set is 65535.

If a virtual machine sets its maximum number of messages to a value less than its current number of outstanding outgoing VMCF messages, the user is not allowed to send additional messages until the number outstanding is reduced to less than the limit.

## **Invoking VMCF Functions**

VMCF functions are invoked by means of:

- DIAGNOSE code X'68' subcodes
- The VMCPARM parameter list
- External interrupt code X'4001'
- The external interrupt message header (VMCMHDR).

### **DIAGNOSE Code X'68'**

All VMCF functions are invoked from within assembler language programs by means of DIAGNOSE code X'68'. For more information, see [“DIAGNOSE Code X'68'”](#) on page 1003.

### **The VMCPARM Parameter List**

The Rx register of DIAGNOSE code X'68' contains the address of a parameter list, VMCPARM. This parameter list specifies the VMCF function to be executed, along with other information required by VMCF to execute that function. The address of VMCPARM must be doubleword-aligned and must be in second level storage (the storage that appears real to the virtual machine).

The following is the format of the VMCPARM parameter list, provided as VMCPARM COPY in the HCPGPI macro library:

VMCPARM DSECT

|    |          |       |          |          |
|----|----------|-------|----------|----------|
| 0  | V*1      | ///// | VMCPFUNC | VMCPMID  |
| 8  | VMCPUSER |       |          |          |
| 10 | VMCPVADA |       |          | VMCPLENA |
| 18 | VMCPVADB |       |          | VMCPLENB |
| 20 | VMCPUSE  |       |          |          |

**V\*1 (VMCPFLG1)**

is a flag byte used to specify options associated with a particular function. This flag byte can be set to the following values:

**VMCPAUTS (X'80')**

indicates, for the AUTHORIZE function, an AUTHORIZE SPECIFIC request. When this bit is set, the VMCPUSER field must contain the user ID of the target virtual machine. The target virtual machine is the receiving virtual machine. The status of the specified target virtual machine is not checked by the control program (CP) at this time.

**VMCPPRTY (X'40')**

indicates, for SEND, SEND/RECV, SENDX, and IDENTIFY requests, a priority message request. For an AUTHORIZE request, it indicates an AUTHORIZE PRIORITY request. You cannot send priority messages to another virtual machine unless that virtual machine has been authorized for priority messages. The send and response external interrupts for a priority message are queued ahead of pending nonpriority external interrupts.

**VMCPSMSG (X'20')**

indicates that the virtual machine is authorized to receive special messages. This bit can be turned either on or off by the SET MSG ON command.

Bits 3 through 7 are reserved for IBM use.

**VMCPFUNC**

Contains the halfword DIAGNOSE code X'68' subcode that defines the VMCF function being requested as shown in Table 216 on page 1017.

Table 216. VMCF Function Codes for DIAGNOSE Code X'68'

| Field Attributes in the DSECT | Hexadecimal Code | Function    |
|-------------------------------|------------------|-------------|
| VMCPAUTH                      | X'0000'          | AUTHORIZE   |
| VMCPAUT                       | X'0001'          | UNAUTHORIZE |
| VMCPSEND                      | X'0002'          | SEND        |
| VMCPSEN                       | X'0003'          | SEND/RECV   |
| VMCPSENX                      | X'0004'          | SENDX       |
| VMCPRECV                      | X'0005'          | RECEIVE     |
| VMCPCANC                      | X'0006'          | CANCEL      |
| VMCPREPL                      | X'0007'          | REPLY       |
| VMCPQUIE                      | X'0008'          | QUIESCE     |
| VMCPRESM                      | X'0009'          | RESUME      |
| VMCPIDEN                      | X'000A'          | IDENTIFY    |
| VMCPRJCT                      | X'000B'          | REJECT      |
| VMCPSETL                      | X'000C'          | SETLIMIT    |

**VMCPMID**

contains a unique message identifier associated with a transaction. The source virtual machine must originate the message ID for SEND, SEND/RECV, and SENDX requests. The message ID is used by the target virtual machine (along with VMCPUSER) to respond to the source request with a RECEIVE, REPLY, or REJECT request. The message ID allows the target virtual machine to selectively Receive,

REPLY, or REJECT messages when more than one message is enqueued. The message ID is used by both the source and target as a unique identification for all messages. You may send messages with the same message ID to multiple users; you cannot send multiple messages with the same message ID to one user. Once a transaction is completed, however, the message ID may be reused.

This field is also used to specify the message limit for the SETLIMIT function.

#### **VMCPUSER**

specifies the user ID of the target virtual machine for SEND, SEND/RECV, SENDX, IDENTIFY, and CANCEL requests, and the user ID of the source virtual machine for RECEIVE, REPLY, and REJECT requests. The target virtual machine uses this field in combination with the message ID (VMCPMID) to respond to source requests. When the original source parameter list VMCPARM is passed to the target as the message header VMCMHDR, the user ID is changed from target to source.

This field is also used to specify the specific user ID for an AUTHORIZE SPECIFIC request.

#### **VMCPVADA**

contains one of the following addresses, depending upon which VMCF function is requested for:

- SEND, SEND/RECV, and SENDX requests, the address of the source virtual machine data.
- RECEIVE requests, the address of a target virtual machine receive buffer.
- REPLY requests, the address in target virtual machine storage where reply data is located.
- An AUTHORIZE request, the address of the virtual machine external interrupt buffer.

All of these addresses are in guest absolute addresses in the host-primary address space.

For the AUTHORIZE function, the interrupt buffer is checked during execution of DIAGNOSE code X'68' for storage-protection violations. All storage-protection mechanisms applicable to synchronous stores are enforced. Subsequently, when each interrupt is presented, the buffer is again checked for key-controlled protection according to the PSW key at the time of the AUTHORIZE. If this check fails, the interruption is discarded and, if it was not a final response or IDENTIFY interrupt, then a final response interrupt indicating a data transfer error (VMCMEFLG=19) is presented to the sender.

For functions other than AUTHORIZE, the PSW key at the time of the DIAGNOSE code X'68' instruction is used to enforce key-controlled protection when data is transferred. Low-address protection, fetch-protection override, and storage-protection override do not apply.

The length of the associated data or buffer is specified in the VMCPLENA field.

#### **VMCPLENA**

contains the length of the data sent by a user, the length of a receive buffer, or the length of an external interrupt buffer, whichever is specified in the field VMCPVADA. The size of the value specified in VMCPLENA is restricted only by virtual machine storage size.

The target virtual machine can use the value in this field as the data length for Receive operations.

#### **VMCPVADB**

contains the address of a source virtual machine's reply buffer for a SEND/RECV request. The address is a guest absolute address in the host-primary address space. When the target virtual machine issues a REPLY in response to a SEND/RECV from the source virtual machine, the reply data is moved in this buffer. The length of the reply buffer is contained in the field VMCPLENB.

The PSW key at the time of the DIAGNOSE code X'68' instruction is used to enforce key-controlled protection when data is transferred. Low-address protection, fetch-protection override, and storage-protection override do not apply.

#### **VMCPLENB**

specifies the length of the source virtual machine's reply buffer. The target virtual machine uses this field to determine the maximum length of the reply. A corresponding field within the response message header contains a residual data count. The source virtual machine uses this residual count to determine the length of the target reply. The original reply buffer length (less the residual count) is the length of the reply from the target virtual machine.

**VMCPUSE**

contains the VMCF user doubleword. The user doubleword is transmitted to the target virtual machine in the send message header for SEND, SEND/RECV, SENDX, and IDENTIFY requests. For RECEIVE, REPLY, and REJECT requests, the user doubleword is transmitted to the source virtual machine within the response message header. The target virtual machine can transmit the user doubleword to the source virtual machine with REJECT or REPLY requests only if the original request was a SEND/RECV. The user doubleword is transmitted only with requests that result in send or response external interrupts.

See Table 217 on page 1019 for a summary of the VMCPARM fields required for execution of each of the VMCF functions. Possible return codes (in decimal) associated with each function are also listed. For a list of the return codes, hexadecimal values, and their meanings, see “Responses” on page 1004.

| <b>Note:</b> Fields within the user parameter list that are not used by a particular function may be used to contain additional user data. The data, however, can only be passed to the target virtual machine by the source virtual machine. The reply buffer address and length fields (VMCPVADB + VMCPLINB) may be used to transmit additional user data for SEND and SENDX requests. All fields except VMCPFLG1, VMCPFUNC, and VMCPUSER may be used to pass control information with an IDENTIFY request. |                                                                                                                                                                                               |                                          |

## External Interrupt Code X'4001'

External interruption code X'4001' is a special interrupt code recognized by CP as part of a VMCF transaction. Just as virtual machines use the DIAGNOSE instruction to communicate with CP, so too CP uses this interrupt code to communicate with virtual machines. External interrupt code X'4001' and DIAGNOSE code X'68' provide the mechanism VMCF uses to synchronize message processing.

## The External Interrupt Message Header (VMCMHDR)

Associated with external interruption code X'4001' is a storage area referred to as the external interruption message header. The external interrupt message header (VMCMHDR) contains the control information required to send and receive messages. The fields within the message header are, for the most part, a copy of VMCPARM parameter list fields.

CP passes the external interruption buffer (containing the external interruption message header) to the user's interruption handler for processing. The user must specify the address and length of this buffer when he executes the AUTHORIZE function. This address must be in second-level storage (the storage that appears real to the virtual machine). Then, when the user sends or receives messages, CP knows the address of the buffer and passes it to the appropriate interruption handler routine.

Fields VMCMFUNC through VMCMUSE correspond to the fields VMCPFUNC through VMCPUSE in the VMCMHDR DSECT parameter list transmitted by the source virtual machine. The VMCMHDR COPY file is provided in the HCPGPI macro library.

The format of the message header and optional SENDX data buffer is:

### VMCMHDR DSECT

|    |                                    |     |          |          |
|----|------------------------------------|-----|----------|----------|
| 0  | V*1                                | V*2 | VMCMFUNC | VMCM MID |
| 8  | VMCMUSER                           |     |          |          |
| 10 | VMCMVADA                           |     |          | VMCMLENA |
| 18 | VMCMVADB                           |     |          | VMCMLENB |
| 20 | VMCMUSE                            |     |          |          |
| 28 | VMCMBUF<br>Optional Message Buffer |     |          |          |

### V\*1 (VMCMSTAT)

is a status byte associated with the message header. The bits within the status byte are defined as follows:

#### VMCMRESP (X'80')

indicates final external interrupt (transaction complete).

#### VMCMRJCT (X'40')

is set in a response external interrupt to indicate that the target virtual machine rejected the message by means of the REJECT function.

#### VMCMPRTY (X'20')

is set in both send and response external interrupts to indicate a priority message.

### V\*2 (VMCMEFLG)

contains a data transfer error code indicating success or errors associated with a data transfer operation. This is only valid for Final Response Interrupts.

### VMCMFUNC

contains the subcode of the original request. The target virtual machine uses this field to determine the type of request. The possible subcodes are shown in [Table 218 on page 1021](#).

Table 218. VMCMFUNC Subcodes - DIAGNOSE Code X'68'

| Field Attributes in the DSECT | Hexadecimal Code | Function  |
|-------------------------------|------------------|-----------|
| VMCPSEND                      | X'0002'          | SEND      |
| VMCPSENH                      | X'0003'          | SEND/RECV |
| VMCPSENX                      | X'0004'          | SENDX     |
| VMCPIDEN                      | X'000A'          | IDENTIFY  |

### VMCM MID

contains the message ID associated with the original source request.

**VMCMUSER**

contains the user ID of the source virtual machine for send external interrupts and the user ID of the target virtual machine for response external interrupts.

**VMCMVADA**

contains the address of the original send data for SEND requests.

**VMCMLENA**

indicates the length of send data for send external interrupts. It indicates a data transfer residual count for response external interruptions.

**VMCMVADB**

contains the address of the reply buffer for SEND/RECV requests.

**VMCMLENB**

contains the length of the source virtual machine reply buffer for SEND/RECV external interrupts; contains the residual reply count for response external interrupts. The target virtual machine uses this field to determine the maximum length of the reply; the source virtual machine uses this field to determine the length of the target virtual machine reply data.

**VMCMUSE**

contains the user doubleword, which is transmitted to the target virtual machine with send external interrupts and to the source virtual machine with response external interrupts.

**VMCMBUF**

This is the optional data buffer used by the SENDX function. The data sent with the SENDX function is moved into this buffer. The buffer size is specified when a virtual machine executes the VMCF AUTHORIZE function.

## VMCF User Doubleword

VMCF provides a doubleword for user data that can be transmitted within the external interrupt message header. A user supplies the doubleword of data within the parameter list (VMCPARM) for certain VMCF requests (SEND, SENDX, SEND/RECV, RECEIVE, REPLY, IDENTIFY, and REJECT). You can use the user doubleword in any manner you desire. The doubleword is transmitted within the external interrupt message header for both send and response external interrupts.

The user doubleword can be used for control information in a user-defined higher level protocol. That is, you could have your own message headers defined within the data transmitted from one virtual machine to another. The user doubleword could be used to control such a protocol.

The user doubleword can also be used as a security code or provide additional information for functions such as IDENTIFY and REJECT. You can specify a 0 data length for any VMCF transaction. The effect of this is that only the external interrupt message header with user doubleword is transmitted or received.

## VMCF in an MP Environment

VMCF includes support for a virtual multiprocessor (MP) environment. If you use VMCF, but do not use virtual multiprocessing, you are not impacted by this support. The following list is intended to provide some guidance on using VMCF in a virtual MP environment:

- As long as one processor in a virtual configuration has authorized for VMCF, any virtual processor within the virtual configuration can invoke VMCF functions.
- If you run with multiple virtual processors defined and only one virtual processor has issued a VMCF AUTHORIZE, note the following:
  - The virtual processor that issued the AUTHORIZE will be presented with all VMCF external interrupts if enabled. The buffer length may be changed on subsequent AUTHORIZE commands issued by the one authorized virtual processor. Any virtual processor in the complex can invoke VMCF functions.
  - All other VMCF functions will remain the same.
- If you run with multiple virtual processors defined and two or more virtual processors have issued a VMCF AUTHORIZE, note the following:

- The VMCF functions of QUIESCE and RESUME apply to the entire virtual processor complex.
- Any processor in a virtual MP complex can issue a VMCF function as long as at least one processor in the virtual MP complex has issued a VMCF AUTHORIZE. Multiple virtual processors may AUTHORIZE.
- The external interrupt buffer length (VMCPLNA) on the first VMCF AUTHORIZE in a virtual MP complex is the required length for all other interrupt buffers defined in that virtual MP complex by subsequent AUTHORIZES. If a subsequent AUTHORIZE on another virtual processor is issued with an interrupt buffer length that does not match the length defined in the initial AUTHORIZE, a return code of 1 is received from the AUTHORIZE command. The buffer length for the virtual MP complex can be changed after the entire MP complex unauthorizes, or when one processor remains authorized and that processor issues another authorize with a new length (this corresponds to a non-MP environment).
- Each processor that has issued a VMCF AUTHORIZE in the virtual MP complex has its own interrupt buffer.
- In the virtual MP environment, VMCF interrupts are treated as "floating" external interrupts. Any virtual processor that issued an AUTHORIZE and has enabled for VMCF external interrupts may receive a VMCF interrupt.
- The type of authorization is complex-wide for all processors that issue an AUTHORIZE, and is of the type of the last AUTHORIZE issued. For example, if the last AUTHORIZE issued is an AUTHORIZE SPECIFIC, then all processors in the virtual MP complex are authorized specific. AUTHORIZE PRIORITY and authorization for SMSG are treated the same way.
- UNAUTHORIZE is a processor-specific function. The entire complex is not unauthorized until the last authorized processor issues an UNAUTHORIZE.
- CMS can only handle VMCF interrupts on its base processor, that is, the IPLed processor. Therefore, in order to run a CMS VMCF application, the application must first issue VCPUSELECT VM\_CPU\_BASE\_ONLY.
- Regardless of the number of virtual processors defined, the message limit established by the SETLIMIT function (see “SETLIMIT: DIAGNOSE Code X'68' Subcode X'000C'” on page 1016) applies to all processors collectively.

## DIAGNOSE Code X'68' Return Codes

The virtual machine initiating a VMCF request receives a return code in the general purpose register specified as Ry in the DIAGNOSE instruction. The return code indicates successful completion of the request or error conditions associated with the request. Table 219 on page 1023 is a description of all possible return codes returned to a virtual machine executing DIAGNOSE code X'68'.

Table 219. DIAGNOSE Code X'68' Return Codes

| Return Code | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')   | The normal response. Indicates successful completion of a request or successful initiation of a request. For example, for an AUTHORIZE request, 0 indicates that the AUTHORIZE function is complete; for a SEND request, 0 indicates that the SEND was successfully initiated. The SEND request, of course, would not be complete until the final RESPONSE external interrupt was received by the source virtual machine. |

Table 219. DIAGNOSE Code X'68' Return Codes (continued)

| Return Code | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 (X'01')   | Invalid virtual buffer address or length. A virtual machine tried to execute a VMCF function but specified an invalid address or length: <ul style="list-style-type: none"> <li>• External interrupt buffer not within virtual storage.</li> <li>• External interrupt buffer address not doubleword aligned.</li> <li>• Message data or buffer not within virtual storage.</li> <li>• External interrupt buffer less than the standard message header length.</li> <li>• In a virtual MP complex, if this is not the first AUTHORIZE, this return code may indicate that your interrupt buffer length does not match the initial length on the first AUTHORIZE.</li> </ul> |
| 2 (X'02')   | Invalid function code. A virtual machine tried to execute a VMCF function but specified an unsupported subcode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3 (X'03')   | Protocol violation. A virtual machine tried to execute a function which would violate the defined protocol: <ul style="list-style-type: none"> <li>• Cancel a message it did not originate.</li> <li>• Reply to a message not sent via SEND/RECV.</li> <li>• Executed more than one RECEIVE to a SEND or SEND/RECV request.</li> </ul>                                                                                                                                                                                                                                                                                                                                     |
| 4 (X'04')   | Source virtual machine not authorized. A virtual machine tried to execute a function (other than AUTHORIZE) but was not authorized to use VMCF (had not successfully executed the AUTHORIZE function).                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 5 (X'05')   | User not available. A virtual machine tried to execute a function and specified a virtual machine currently not available for VMCF communication: <ul style="list-style-type: none"> <li>• Not logged on.</li> <li>• Not authorized for VMCF communication.</li> <li>• Virtual machine authorized SPECIFIC for some other virtual machine.</li> </ul>                                                                                                                                                                                                                                                                                                                      |
| 6 (X'06')   | Protection violation. A virtual machine tried to execute a VMCF function that would result in a STORE or FETCH protection violation. The virtual machine specified a data or buffer address that contained a storage key other than its current PSW key (assume the key was nonzero). This return code is also set if a virtual machine tries to receive data in a CP-owned shared segment.                                                                                                                                                                                                                                                                                |
| 7 (X'07')   | SENDX data too large. A virtual machine tried to execute a SENDX request but specified a SENDX data length larger than the target virtual machine external interrupt buffer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 8 (X'08')   | Duplicate message. A virtual machine tried to execute a SEND-type function and specified a message ID and virtual machine user ID for which there was already an active message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 9 (X'09')   | Target virtual machine in QUIESCE status. A virtual machine tried to execute a SEND-type function and specified a target virtual machine user ID of a virtual machine in QUIESCE status.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 10 (X'0A')  | Message limit exceeded. A virtual machine tried to execute a SEND function but already had the maximum number of messages active as specified by the SETLIMIT function, or the partner virtual machine has as many active incoming messages as are allowed by the MAXVMCFI limit in his directory. The virtual machine should clear any pending RESPONSE external interrupts or CANCEL previously sent messages to continue processing.                                                                                                                                                                                                                                    |

Table 219. DIAGNOSE Code X'68' Return Codes (continued)

| Return Code | Meaning                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11 (X'0B')  | REPLY cancelled. The source virtual machine executed a CANCEL to a previous SEND/RECV request. The target virtual machine had already RECEIVED the message but had not yet executed a REPLY. The target virtual machine REPLY in this case is cancelled. The target virtual machine receives return code 12 - X'0C' - (message not found) when it executes the REPLY function.                        |
| 12 (X'0C')  | Message not found. A virtual machine tried to execute a function and specified a message ID and virtual machine user ID for a message that does not exist. The message may have existed at one time but could have been cancelled by the originator.                                                                                                                                                  |
| 13 (X'0D')  | Synchronization error. The target virtual machine tried to respond to a message for which it had not yet received the SEND external interrupt. This condition can occur if the target virtual machine is anticipating certain messages but does not wait for the SEND external interrupt.                                                                                                             |
| 14 (X'0E')  | CANCEL too late. A virtual machine tried to CANCEL a message that had already been processed. The target virtual machine had already responded with RECEIVE or REJECT (SEND request) or REPLY or REJECT (SEND/RECV request). This return code is also set if a virtual machine tries to CANCEL a SENDX request for which the target virtual machine had already received the SEND external interrupt. |
| 15 (X'0F')  | Paging I/O error. A virtual machine tried to execute a function which resulted in an uncorrectable paging I/O error. This is a hardware failure.                                                                                                                                                                                                                                                      |
| 16 (X'10')  | Incorrect length. A virtual machine executed a RECEIVE or REPLY function and specified a RECEIVE buffer length less than the source virtual machine SEND data length or a REPLY data length larger than the source virtual machine reply buffer length. The source virtual machine receives a data transfer return code identifying the condition.                                                    |
| 17 (X'11')  | Destructive overlap. A virtual machine executed a RECEIVE or REPLY function and specified a RECEIVE buffer address which overlapped the source virtual machine SEND data address or a REPLY data address that overlapped the source virtual machine reply buffer address. This condition can occur only when a virtual machine is sending messages to itself (a wrap connection).                     |
| 18 (X'12')  | User not authorized for PRIORITY messages. A virtual machine tried to send a PRIORITY message to a virtual machine that was not authorized to accept PRIORITY messages (that is, had not executed the AUTHORIZE function with the PRIORITY option).                                                                                                                                                   |
| 19 (X'13')  | Data transfer error. A virtual machine executed a request that resulted in a data transfer error condition associated with the other virtual machine. The return code is returned to the target virtual machine to indicate that the transaction did not complete successfully.                                                                                                                       |
| 20 (X'14')  | CANCEL - busy. A virtual machine tried to cancel a message being processed. If this is a SEND/RECV request and the RECEIVE function is in process, repeated retries may cancel the REPLY function.                                                                                                                                                                                                    |

## Data Transfer Error Codes

When a virtual machine executes a SEND, SENDX, or SEND/RECV function, the normal DIAGNOSE return code is 0, indicating that the request was successfully initiated. However, when the actual data transfer takes place, errors can occur. All errors occurring at data transfer time are communicated to the source virtual machine in the Final Response external interrupt message header, VMCMHDR. [Table 220 on page](#)

1026 shows error codes indicating conditions that are possible after the SENDX, SEND, or SEND/RECV request is initiated. The error codes correspond to DIAGNOSE return code numbers.

*Table 220. DIAGNOSE Code X'68' Data Transfer Error Codes*

| Error Code | Meaning                                                                                                                                                                                                                                                                                                   |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')  | The normal response (no errors).                                                                                                                                                                                                                                                                          |
| 1 (X'01')  | Invalid buffer address or length. The SEND and/or RECEIVE buffers used for a data transfer operation are not within the virtual machine's virtual storage. The beginning and ending addresses were valid when a request was initiated but all addresses are not valid.                                    |
| 5 (X'05')  | User not available. The target virtual machine executed the UNAUTHORIZE function, executed the AUTHORIZE SPECIFIC function again, or implicitly reset his virtual machine after the source virtual machine request was initiated.                                                                         |
| 6 (X'06')  | Protection violation. The storage key for a virtual machine's SEND or RECEIVE buffer did not match its PSW key at the time the transfer was initiated (assume the key was nonzero). This error code is also set if a virtual machine tries to RECEIVE data into a CP-owned shared segment.                |
| 7 (X'07')  | SENDX data is too large. The target virtual machine executed AUTHORIZE again and specified an external interrupt buffer size less than the buffer size at the time a SENDX function was executed. The SENDX data no longer fits in the target virtual machine buffer.                                     |
| 15 (X'0F') | Paging I/O error. An uncorrectable paging I/O error occurred during the data transfer operation trying to fetch a virtual machine SEND or RECEIVE buffer. This is a hardware failure.                                                                                                                     |
| 16 (X'10') | Incorrect length. The target virtual machine executed a RECEIVE function with a data length (VMCPLNA) smaller than the original SEND data length or a REPLY function with a REPLY data length larger than the source virtual machine reply buffer length. The data is transferred for the smaller length. |
| 17 (X'11') | Destructive overlap. A virtual machine was communicating with itself in a wrap connection and his SEND or RECEIVE buffers overlapped one another (intra-virtual machine communication).                                                                                                                   |
| 19 (X'13') | Data transfer error. A data transfer error occurred which was associated with the other virtual machine. The transaction did not complete successfully.                                                                                                                                                   |

## Appendix D. The Special Message Facility

The Special Message Facility enables a virtual machine to send messages to another virtual machine by issuing the CP SMSG command. The Special Message Facility may be used with the Virtual Machine Communication Facility (VMCF) or with the Inter-User Communications Vehicle (IUCV). However, the sending virtual machine does not need to perform the initialization required by VMCF or IUCV. Initialization is handled by CP and is described later in this topic.

To send a message, a virtual machine need only prepare the message text and issue the class G SMSG command. Parameters on the SMSG command identify the user ID of the receiving virtual machine and specify the message text. The format of the message text must be acceptable to the receiving virtual machine. The SMSG command is described in the *z/VM: CP Commands and Utilities Reference*.

**For VMCF:** Before the receiving virtual machine can receive special messages through VMCF, it must:

- Enable itself to receive external interrupts.
- Set bit 31 of control register 0 to a value of 1.
- Authorize itself by issuing DIAGNOSE code X'68', AUTHORIZE. The parameter list, VMCPARM, specified with DIAGNOSE code X'68' must contain a pointer to an external-interrupt buffer, should specify a buffer length of 280 bytes, and must have the special message flag (VMCPSMSG) turned on.

Note that you may receive a message, *Message too large*, if you issue the SMSG command from a 3279 or 3287 Model 5 terminal to send a message longer than what the receiving virtual machine has specified.

- Turn on this special message flag (VMCPSMSG) by setting VMCPSMSG to a value of B'1' or by issuing the class G command, SET SMSG ON. For information on using DIAGNOSE code X'68', see [“DIAGNOSE Code X'68”](#) on page 1003, and [“The Virtual Machine Communication Facility”](#) on page 1005.

To understand how a special message is presented to the receiving virtual machine through VMCF, see [“The SENDX Protocol”](#) on page 1010.

**For IUCV:** Before the receiving virtual machine can receive special messages through IUCV, it must do the following:

- Enable itself to receive external interrupts
- Set bit 30 of control register 0 to a value of 1
- Issue the IUCV DECLARE BUFFER function
- Issue the IUCV CONNECT function to the CP Message System Service
- Turn on the special message flag by issuing the class G command SET SMSG IUCV.

When VMCF or IUCV message are no longer required, reset the corresponding bit in the contents of control register 0. The IUCV mask is set and cleared by CMS support for IUCV and APPC/VM, and should be used to receive special messages through IUCV.

When a virtual machine no longer wishes to accept special messages, it may turn off the special message flag by issuing the command SET SMSG OFF. To resume receiving messages, the virtual machine may issue the command SET SMSG ON or SET SMSG IUCV. CP sends an error message to any virtual machine that tries to send a special message to another virtual machine that is not accepting special messages.

Special messages are queued only as long as the virtual machine is logged on. If the virtual machine sets SMSG off or logs off, this queue of SMSGs is lost. A system IPL also loses this queue of messages for the virtual machine.

CP handles VMCF/IUCV initialization and special message processing as follows. When the SMSG command is issued, CP verifies that no invalid options were specified and that a valid user ID was specified. CP also verifies that the receiving virtual machine is accepting special messages. CP then obtains storage for the message, builds the appropriate parameter list, and sends the message to the receiving virtual machine.

## Appendix E. Logical Device Support Facility

The Logical Device Support Facility allows an application running in a virtual machine to create within CP one or more logical devices. 3270 extended data streams are supported to enable logical devices to utilize full color, programmed symbol sets, and extended highlighting capabilities. 3284, 6, 7, 8, 9 logical printer devices are supported to allow the presentation of status from a logical device printer. Applications are allowed to create logical 328x printers in addition to logical 327x display devices. Except for the logical device support facility, CP is unaware of the fact that this device has no real existence and is driven by the application program. In particular, CP sees it as a local 3270 device. Any output directed to a logical device is redirected to the virtual machine for which the device was created. The virtual machine can also transfer data to CP to be entered as input from a specific logical device, as if it were interactively produced on a real terminal.

The logical device support facility is made up of two data transfer functions, four control functions, a special external interrupt (code X'2402'), and an external control word for passing control information with the external interrupt.

To implement this facility, functions are invoked using DIAGNOSE code X'7C'. Registers Rx, Rx+1, Ry, and Ry+1 indicate the function, logical device identification, and other function-dependent information.

A special interrupt code (X'2402') notifies a virtual machine of pending logical device status for a logical device created for that virtual machine. Along with this interrupt, the virtual machine receives a control word at a virtual storage location indicating the ID of the associated logical device and the reason for the interrupt.

See [Table 221 on page 1029](#) for a summary of logical device support facility functions. More complete information about each of these functions is included under [“Logical Device Support Facility Functions” on page 89](#).

Data is directed to a logical device using the logical device ID. This ID is assigned by CP during execution of the INITIATE function. Data transfer takes place within CP at a channel command level. I/O directed to a logical device proceeds within CP through the normal path for a local device up to the point where the I/O is to be started. At that point, control passes to the logical device support modules to process the CCW string. Channel commands requiring interaction cause external interrupts to the virtual machine for which the associated logical device was created.

The format of data from the virtual machine must conform to 3270 architecture for local devices.

The default maximum number of logical devices for the system is 4096. The maximum number of logical devices allowed may be changed with the CP command SET MAXLDEV. There is no limit to the number of hosts as long as the number of logical devices does not exceed the system limit.

*Table 221. Summary of Logical Device Support Facility Functions*

| Function      | Description                                                               |
|---------------|---------------------------------------------------------------------------|
| INITIATE      | Initiate logical device communications                                    |
| ACCEPT        | Transfer data written to logical device to virtual machine storage.       |
| PRESENT       | Transfer data from virtual machine to CP as input from logical device.    |
| TERMINATE     | Drop a specific logical device.                                           |
| TERMINATE ALL | Drop all logical devices created for this virtual machine.                |
| STATUS        | Allows status to be returned to CP after an ACCEPT function is performed. |

The VM/Pass-Through Facility licensed program is an example of an application using the logical device support facility. Through the combined support of these two facilities, a z/VM user attached to system

## Logical Device Support Facility

A through a 3270 Display Station can access z/VM system B as though the display station were locally attached to system B.

## Appendix F. Reserved DIAGNOSE Codes

### Attention:

This appendix contains information that is NOT Programming Interface information. These DIAGNOSE codes are reserved for IBM use.

### DIAGNOSE Code X'40' – Clean-Up After Virtual IPL by Device

**Privilege class:** Any

**Addressing Mode:** 24-bit or 31-bit

This code is valid only during virtual IPL, and is for system use only. Other use may cause unpredictable results.

**Entry Values:** The Rx and Ry fields are used together to specify flag fields, and do not specify general registers. A value of X'00' in the RxRy field requests the IPL clean-up function. A value of X'FF' in the RxRy field requests relocation of the IPL simulator to another page in storage.

#### RxRy field=X'00'

When the simulation of the IPL function is complete, DIAGNOSE code X'40' with RxRy code X'00' is issued to cause CP to clean up the page in the virtual machine's storage that was used to contain the IPL simulator.

#### RxRy field=X'FF'

HCPVMI resides in a page in virtual machine storage and simulates the virtual IPL function. If a CCW is going to write into the page occupied by HCPVMI, DIAGNOSE X'40' with RxRy code X'FF' is issued to move the IPL simulator to another page in storage. CP relocates the virtual machine's registers and the PSW to the new page.

### Usage Note

If DIAGNOSE X'40' is issued with an RxRy field having a value other than X'00' or X'FF', a specification exception is reflected to the virtual machine.

### Responses

None.

### DIAGNOSE Code X'E0' – System Trace File Interface

**Privilege Class:** Any

DIAGNOSE X'E0' provides a virtual machine access to system trace files. The WRITE function of DIAGNOSE X'E0' is a programming interface for customers. For more information see [“DIAGNOSE Code X'E0' – System Trace File Interface”](#) on page 170. The remaining functions allow the owner of a system trace file to read trace blocks sequentially from the file. These functions are not programming interfaces for customers. The TRACERED command of the Dump Viewing Facility is the preferred interface for reading system trace files.

To use the open, read, and close subcodes of this DIAGNOSE code, the virtual machine must be authorized using the TRSAVE command. The virtual machine can process (open, read, or close) system trace files if a TRSAVE command was issued to specify its user ID as the receiver. It can also process these trace files if it is the default receiver for a file that is completed. In this case, it is the owner of the file.

The virtual machine can use this facility to read system trace files created by the following in various combinations:

## DIAGNOSE X'E0'

- The Monitor Call Class 10 interface
- The DIAGNOSE Code X'E0' write interface
- The TRSOURCE command
- The TRSAVE command.

The TRSOURCE command supports the definitions and control of I/O, data, and guest tracing, while TRSAVE specifies where the TRSOURCE and CPTRACE data is to be stored. The Monitor Call interface is only one of the ways data can be collected. Refer to the description in this manual for further details on the Monitor Call Class 10 interface.

Event trace records are formatted by CP into blocks that have the header format described below.

Entry values:

### Rx

Contains the guest real address of a 4-character spool ID (SPID) of a system trace file that it owns.

**Note:** For the READ function, Rx cannot be specified as register 15.

### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the spool ID. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the spool ID is in the host-primary address space.

### Ry

Is the DIAGNOSE subcode that specifies the function requested.

#### Value

##### Operation performed

#### X'00000008'

Open (read only)

#### X'0000000C'

Read

#### X'00000010'

Close (read only)

**Note:** Do not specify Ry as register 15 for the close operation.

### Rx+1

For the READ function, contains the address of the buffer into which to read the next block of data. The first two bytes of this buffer must contain the length of the buffer. The length must be a multiple of 4KB.

### Ax+1

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the buffer to receive the data. If Rx+1 designates general register 0 (when Rx is general register 15), if Ax+1 contains X'00000000', or if the virtual machine is not in XC mode, the buffer is in the host-primary address space.

Exit values:

On return from the DIAGNOSE processor, a return code is set in the Ry+1 register. The return codes are right-justified in the register and padded with zeros. Only the rightmost byte value is given below.

Unsupported subcode:

| Return Code | Meaning         |
|-------------|-----------------|
| 48 (X'30')  | Invalid subcode |

Program Exceptions:

| Problem Encountered     | Cause             |
|-------------------------|-------------------|
| Specification exception | Ry is register 15 |

## Subcode X'00000008' – Open (read-only)

The system trace file indicated by Rx is opened if the virtual machine is the owner of this file. The virtual machine is the owner of a system trace file if its ID was designated as the trace receiver ('TO userid') on the TRSAVE command used to start the trace.

Entry values:

### Ry+1

On return, contains the return code from this DIAGNOSE open operation.

Exit values:

On return from the DIAGNOSE processor, a return code is set in the Ry+1 register. The return codes are right-justified in the register and padded with zeros. Only the rightmost byte value is given below.

| Return Code | Meaning                                                                                                                                                                                                                                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')   | Successful open of trace data defined by TRSOURCE                                                                                                                                                                                                                                                                                              |
| 4 (X'04')   | Successful open of CP system trace data                                                                                                                                                                                                                                                                                                        |
| 8 (X'08')   | Buffer too small for block                                                                                                                                                                                                                                                                                                                     |
| 12 (X'0C')  | I/O error                                                                                                                                                                                                                                                                                                                                      |
| 16 (X'10')  | Invalid spool ID                                                                                                                                                                                                                                                                                                                               |
| 20 (X'14')  | File not found                                                                                                                                                                                                                                                                                                                                 |
| 24 (X'18')  | File in use                                                                                                                                                                                                                                                                                                                                    |
| 36 (X'24')  | Protection exception condition                                                                                                                                                                                                                                                                                                                 |
| 44 (X'2C')  | Invalid spool ID address                                                                                                                                                                                                                                                                                                                       |

## Subcode X'0000000C' – Read

The next block of trace data is read from the file into the buffer provided by the virtual machine. When an end-of-file is reached, the files are not closed. To close them, the virtual machine must issue a DIAGNOSE code X'E0' CLOSE. If the buffer size specified is insufficient to read the next block of data, an error code is returned to the virtual machine and the file is positioned to reread the same block. The Blength field in the truncated record can be used to determine the required buffer size except for blocks containing CP trace table entries which are always 4096 bytes long.

## DIAGNOSE X'E0'

Exit values:

On return from the DIAGNOSE processor, a return code is set in the Ry+1 register. The return codes are right-justified in the register and padded with zeros. Only the rightmost byte value is given below.

| Return Code | Meaning                                                                                                                                                                                                                                                                                                                                        |

## Subcode X'00000010' – Close (read-only)

When reading a file, close is used to close an open file. Note that when an end-of-file is reached on a read operation, the file is not closed. To close the file, issue DIAGNOSE code X'E0' CLOSE.

Exit values:

On return from the DIAGNOSE processor, a return code is set in the Ry+1 register. The return codes are right-justified in the register and padded with zeros. Only the rightmost byte value is given below.

| Return Code | Meaning                        |
|-------------|--------------------------------|
| 0 (X'00')   | Successful close               |
| 12 (X'0C')  | I/O error                      |
| 16 (X'10')  | Invalid spool ID               |
| 20 (X'14')  | File not opened                |
| 36 (X'24')  | Protection exception condition |
| 44 (X'2C')  | Invalid spool ID address       |

| Return Code | Meaning                                                                                                                                                                                                                                                                                                                                |

See <a href="#">“Access Exceptions” on page 8</a> for more information.                                                                                                             |
| 64 (X'40')  | ALEN-translation exception condition: For an XC virtual machine in access-register mode, Ax contains an ALET that cannot be translated. See <a href="#">“Access Exceptions” on page 8</a> for more information.                                                                                                                        |
| 68 (X'44')  | Addressing-capability exception condition: For an XC virtual machine in access-register mode, Ax contains an ALET that designates an address space for which your virtual machine's access has been revoked. (See usage note <a href="#">“5” on page 1035</a> and <a href="#">“Access Exceptions” on page 8</a> for more information.) |

## Usage Notes

1. In order for CP trace entry data to be independent of the TRSOURCE trace entry data, the DIAGNOSE OPEN differentiates between the two types and sets a return code to identify which type of data the file contains. If RC=X'00', a TRSOURCE trace file was opened; if RC= X'04', a CP system trace file was opened.
2. Multiple files may be opened simultaneously for reading by a user. Only one file is open for write for an IO, DATA, or individual trace ID. There is one system trace file open for each guest virtual machine in the enabled trace ID.
3. If an I/O error occurs on a DIAGNOSE read request, CP does not attempt to close the file, and RC=X'0C' is returned to the caller.
4. An RC=X'38' (severe error) probably is caused by a programming error. Contact your IBM service representative.
5. An addressing-capability exception condition (RC=X'44') can occur after reading has begun.

## Trace Block Containing CP Trace Table Entries

The following diagram describes the format of a block of trace data collected from CP trace tables as a result of a TRSAVE FOR CP ON command.

### Time-of-day clock

Is the 8-byte time-of-day clock.

### Verification string

Is the 24-character string *CP TRACE SERVICE TOOLS\_\_*.

### Time Zone Differential

Is the fullword time-of-day clock time zone differential.

### Trace Entries

Are trace table entries.

## DIAGNOSE Code X'214' – Pending Page Release

**Privilege class:** Any

**Addressing Mode:** 24-bit or 31-bit

# DIAGNOSE X'214'

DIAGNOSE X'214' is used by CMS storage manager to establish and cancel pending page releases. Prior to VM/ESA Release 1.1, DIAGNOSE X'10' was used for this purpose. Unlike DIAGNOSE X'10', DIAGNOSE X'214' allows CP to delay or omit the reclamation of host resources. DIAGNOSE X'10' is intended for general use while DIAGNOSE X'214' is not.

**Attention:** DIAGNOSE X'214' is not intended for use in access-register mode in an XC virtual machine. To do so yields unpredictable results.

DIAGNOSE X'214' will fail if executed when VMRELOCATION is in progress.

Entry Values:

### Rx, Rx+1

Represents an even-odd register pair. The third byte of the odd register always contains a function code. For certain function codes the Rx and Rx+1 registers identify a range of pages. In these cases, bits 1-19 of the even register (Rx) designates the first page in the range and bits 1-19 of the odd register (Rx+1) designates the last page in the range. These page addresses are guest absolute addresses in the host-primary space.

### Ry

For function code X'01' and X'03' (see below), Ry may designate a register that contains a guest key value in bits 24-28. When Ry designates register 0 the operand is ignored as are the contents of GPR 0.

| Function Code | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00'         | Establish Pending Release (EPR). EPR is used to establish pending releases for the range of pages designated by bits 1-19 of Rx and bits 1-19 of Rx+1. It permits CP to reclaim any resources backing the pages whenever CP may see fit as long as the page release remains pending.                                                                                                                                                                               |
| X'01'         | Cancel Pending Release (CPR). CPR is used to cancel any pending releases that may be in effect for the pages within the range specified in bits 1-19 of Rx and bits 1-19 of Rx+1. Optionally, if Ry designates a GPR other than GPR0, CP will set the guest keys for the specified range. It will use bits 24-27 of the contents of Ry to set the access key and bit 28 to set the fetch protect bit. The state of the reference and change bits is unpredictable. |
| X'02'         | Cancel All Pending Releases (CAPR). CAPR is used to cancel all pending releases for this guest. For a CAPR, only the function code is examined. The contents of Rx, Ry, and bits 0-23 of Rx+1 are ignored.                                                                                                                                                                                                                                                         |
| X'03'         | Cancel Pending Release and Validate (CPRV). CPRV is identical to CPR except that CP is notified of the CMS storage manager's intention to immediately reference the final page of the specified range. CP therefore will respond to CPRV by validating that page (if not currently valid) before returning to the guest.                                                                                                                                           |
| Other         | Reserved for future IBM use. The guest receives a specification exception if the function code is <i>other than</i> X'00', X'01', X'02', or X'03'.                                                                                                                                                                                                                                                                                                                 |

### Rx, Rx+1 contents for CPR(V) and EPR:

### Ry contents (if Ry does not designate GPR 0) for CPR(V):

The condition code is set to 1 if key action was requested by a CPR(V) (i.e. Ry was not specified as 0) and the keys were not all successfully set. Otherwise, the condition code is set to zero.

## Responses

**Program Exceptions:** You may receive one of the following program checks if the DIAGNOSE X'214' input data is invalid:

| Problem Encountered     | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception | <p>Any of the following:</p> <ul style="list-style-type: none"> <li>Rx is not even register</li> <li>In an MP virtual machine, the issuer was not running on the base processor</li> <li>Function code is invalid</li> <li>Function code is not CAPR (X'02') and address in Rx (starting address) is greater than address in Rx+1 (ending address)</li> <li>Function code is not CAPR (X'02') and address in Rx or Rx+1 is not in range of guest's real storage.</li> </ul> |

## DIAGNOSE Code X'23C' – Address Space Services

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE X'23C' is invoked from the guest ADRSPACE macro to perform address space management functions. For more information on the functions of the ADRSPACE macro, including a description of the possible return codes and program exceptions, refer to [“ADRSPACE – Address Space Services” on page 811](#).

### Notes:

- This DIAGNOSE code is reserved for IBM use; it is not a supported programming interface. It is included here to be used only in the diagnosis task. The supported method of invocation for the address-space services is the ADRSPACE macro.
- You may not be authorized to issue function X'03' of this DIAGNOSE code if an external security manager is installed on your system. For additional information, contact your security administrator.

The following address-space service functions can be invoked using this DIAGNOSE code:

- Create space
- Destroy space
- Query space
- Permit access
- Isolate space.

Entry Values:

**Rx**

The real address of a function parameter list, the format of which is determined by the function code in the parameter list. The parameter list is built by the ADRSPACE macro expansion in the macro's work area.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the parameter list. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the parameter list is in the host-primary address space.

Exit Values:

**Ry**

On return, contains a return code, as stated in under the address-space service functions of the ADRSPACE macro starting at [“ADRSPACE — Address Space Services” on page 811](#).

## Create-Space Function

This function creates a new address space and returns the ASIT associated with the new address space.

Your virtual machine must be an ESA/XC or z/XC virtual machine to use this function.

For the create-space function, the Rx register contains the real address of a doubleword-aligned parameter list in the following format:

**DSSDIAGC**

Bytes 0 and 1 of the parameter list contain the hexadecimal DIAGNOSE code, X'023C'.

**DSSFCODE**

Bytes 2 and 3 of the parameter list contain the hexadecimal function code for the DIAGNOSE. A function code of X'0000' indicates the create-space function.

**DSSDWLEN**

Bytes 4 and 5 of the parameter list contain the length of the parameter list in doublewords.

**DSSVERSN**

Bytes 6 and 7 of the parameter list contain a version code of X'0001'.

**Reserved-Z**

Bytes 16 through 23, and bytes 53 through 55 of the parameter list are reserved and contain binary zeros.

**DSSPACNM**

Bytes 24 through 47 of the parameter list contain the address-space name to be assigned to the new address space.

**DSSPAGCT**

Bytes 48 through 51 of the parameter list contain a fullword that is the size of the new address space in pages; each page is 4096 bytes.

**DSSSKEY**

Bits 0 through 4 of byte 52 of the parameter list contain the access-control and fetch-protection bits of the storage keys for the new address space. Bits 0 through 3 designate the access-control bits, and bit 4 is the fetch-protection bit.

Bits 5 through 7 of byte 52 of the parameter list are reserved and contain binary zeros.

**DSSASIT**

Bytes 56 through 63 of the parameter list are set by CP to be the ASIT associated with the newly-created address space.

Bytes 8 through 15 of the parameter list are ignored.

**Destroy-Space Function**

This function destroys an address space previously created by your virtual machine.

Your virtual machine must be an ESA/XC or z/XC virtual machine to use this function.

For the destroy-space function, the Rx register contains the real address of a doubleword-aligned parameter list in the following format:

|     |                                              |
|-----|----------------------------------------------|
| Dec |                                              |
| 00  | DSSDIAGC    DSSFCODE    DSSDWLEN    DSSVERSN |
| 08  | ////////////////////////////////////         |
| 16  | Reserved-Z                                   |
| 24  | ////////////////////////////////////         |
| 32  | ////////////////////////////////////         |
| 40  | ////////////////////////////////////         |
| 48  | //////////    Reserved-Z                     |
| 56  | DSSASIT                                      |

**DSSDIAGC**

Bytes 0 and 1 of the parameter list contain the hexadecimal DIAGNOSE code, X'023C'.

**DSSFCODE**

Bytes 2 and 3 of the parameter list contain the hexadecimal function code for the DIAGNOSE. A function code of X'0001' indicates the destroy-space function.

**DSSDWLEN**

Bytes 4 and 5 of the parameter list contain the length of the parameter list in doublewords.

**DSSVERSN**

Bytes 6 and 7 of the parameter list contain a version code of X'0001'.

**Reserved-Z**

Bytes 16 through 23 and bytes 52 through 55 of the parameter list are reserved and contain binary zeros.

**DSSASIT**

Bytes 56 through 63 of the parameter list contain the ASIT associated with the address space to be deleted.

Bytes 8 through 15 and 24 through 51 of the parameter list are ignored.

**Query-Space Function**

This function returns the ASIT and size associated with an address space your virtual machine owns or is authorized to access.

For the query-space function, the Rx register contains the real address of a doubleword-aligned parameter list in the following format:

|     |                                              |
|-----|----------------------------------------------|
| Dec |                                              |
| 00  | DSSDIAGC    DSSFCODE    DSSDWLEN    DSSVERSN |
| 08  | DSSUSRID                                     |
| 16  | Reserved-Z                                   |
| 24  | DSSPACNM                                     |
| 32  |                                              |
| 40  |                                              |
| 48  | DSSPAGCT    Reserved-Z                       |
| 56  | DSSASIT                                      |

## DIAGNOSE X'23C'

### DSSDIAGC

Bytes 0 and 1 of the parameter list contain the hexadecimal DIAGNOSE code, X'023C'.

### DSSFCODE

Bytes 2 and 3 of the parameter list contain the hexadecimal function code for the DIAGNOSE. A function code of X'0002' indicates the query-space function.

### DSSDWLEN

Bytes 4 and 5 of the parameter list contain the length of the parameter list in doublewords.

### DSSVERSN

Bytes 6 and 7 of the parameter list contain a version code of X'0001'.

### DSSUSRID

Bytes 8 through 15 of the parameter list contain the user ID of the virtual machine owning the address space for which data is requested. The user ID can be from one to eight characters long; if it is less than eight characters long, it must be left-justified in the field, and the remainder of the field padded with spaces. If this field contains binary zeros, your virtual machine is the owner of the address space.

### Reserved-Z

Bytes 16 through 23 and bytes 52 through 55 of the parameter list are reserved and contain binary zeros.

### DSSPACNM

Bytes 24 through 47 of the parameter list contain the name of the address space for which information is to be returned.

### DSSPAGCT

Bytes 48 through 51 of the parameter list are set by CP to be a fullword that is the size of the named address space in pages; each page is 4096 bytes.

### DSSASIT

Bytes 56 through 63 of the parameter list are set by CP to be the ASIT associated with the named address space.

## Permit-Access Function

This function authorizes a virtual machine to use the add-ALE function of DIAGNOSE X'240' to add to its host access list an ALE designating an address space owned by your virtual machine.

For the permit-access function, the Rx register contains the real address of a doubleword-aligned parameter list in the following format:

|     |                                                              |
|-----|--------------------------------------------------------------|
| Dec |                                                              |
| 00  | DSSDIAGC    DSSFCODE    DSSDWLEN    DSSVERSN                 |
| 08  | DSSUSRID/DSSVCIT                                             |
| 16  | Reserved-Z                                                   |
| 24  | ////////////////////////////////////                         |
| 32  | ////////////////////////////////////                         |
| 40  | ////////////////////////////////////                         |
| 48  | ////////////////////////////////    r    TYPFG    Reserved-Z |
| 56  | DSSASIT                                                      |

### DSSDIAGC

Bytes 0 and 1 of the parameter list contain the hexadecimal DIAGNOSE code, X'023C'.

### DSSFCODE

Bytes 2 and 3 of the parameter list contain the hexadecimal function code for the DIAGNOSE. A function code of X'0003' indicates the permit-access function.

### DSSDWLEN

Bytes 4 and 5 of the parameter list contain the length of the parameter list in doublewords.

### DSSVERSN

Bytes 6 and 7 of the parameter list contain a version code of X'0001'.

**DSSUSRID/DSSVCIT**

Bytes 8 through 15 of the parameter list contain either the user ID or the VCIT of the virtual machine that is to be given access authorization. When this field contains a user ID, the user ID can be from one to eight characters long; if it is less than eight characters long, it must be left-justified in the field, and the remainder of the field padded with spaces. Whether this field contains a user ID or a VCIT is indicated by bit 4 of byte 53 (DSSTYPFG) as described below.

**Reserved-Z**

Bytes 16 through 23, byte 52, bits 1 through 7 of byte 53, and bytes 54 and 55 of the parameter list are reserved and contain binary zeros.

**DSSTYPFG**

Bit 0 of byte 53 of the parameter list controls whether the virtual machine specified in the DSSUSRID field is to be given read-only or read-write access authority. If this bit is zero, the virtual machine is given authority for read-only access to the address space. If this bit is 1, the virtual machine is given authority for read-write access to the address space.

Bit 4 of byte 53 of the parameter list controls whether the field at bytes 8 through 15 of the parameter list is interpreted as containing the user ID or the VCIT of the virtual machine to be permitted. If this bit is zero, bytes 8 through 15 of the parameter list are treated as the user ID of the virtual machine to be permitted. If this bit is one, bytes 8 through 15 of the parameter list are treated as the VCIT of the virtual machine to be permitted.

**DSSASIT**

Bytes 56 through 63 of the parameter list contain the ASIT associated with the address space for which access authorization is to be given.

Bytes 24 through 51 of the parameter list are ignored.

## Isolate-Space Function

This function restores to a private state an address space owned by your virtual machine.

For the isolate-space function, the Rx register contains the real address of a doubleword-aligned parameter list in the following format:

**DSSDIAGC**

Bytes 0 and 1 of the parameter list contain the hexadecimal DIAGNOSE code, X'023C'.

**DSSFCODE**

Bytes 2 and 3 of the parameter list contain the hexadecimal function code for the DIAGNOSE. A function code of X'0005' indicates the isolate-space function.

**DSSDWLEN**

Bytes 4 and 5 of the parameter list contain the length of the parameter list in doublewords.

**DSSVERSN**

Bytes 6 and 7 of the parameter list contain a version code of X'0001'.

**Reserved-Z**

Bytes 16 through 23 and bytes 52 through 55 of the parameter list are reserved and contain binary zeros.

**DSSASIT**

Bytes 56 through 63 of the parameter list contain the ASIT associated with the address space to be isolated.

Bytes 8 through 5 and bytes 24 through 51 of the parameter list are ignored.

## Responses

**Program Exceptions:** The program exceptions for DIAGNOSE X'23C' are the same as those documented for the [“ADRSPACE — Address Space Services”](#) on page 811.

## DIAGNOSE Code X'240' – Access List Services

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE X'240' is invoked from the guest ALSERV macro to perform access-list management functions.

### Notes:

1. This DIAGNOSE code is reserved for IBM use; it is not a supported programming interface. It is included here to be used only in the diagnosis task. The supported method of invocation of the access-list services is the guest ALSERV macro. For more information on the ALSERV macro, refer to [“ALSERV — Access List Services”](#) on page 829.
2. This DIAGNOSE code does not support HyperPAV alias devices.

The following access-list service functions can be invoked using this DIAGNOSE code:

- Add-ALE
- Remove-ALE.

Entry Values:

### Rx

Real address of a function parameter list, the format of which is determined by the function code in the parameter list. The parameter list is built by the ALSERV macro expansion in the macro's work area.

### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the parameter list. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the parameter list is in the host-primary address space.

Exit Values:

### Ry

On return, the Ry register contains a return code, as stated in the access-list services described under the [“ALSERV — Access List Services”](#) on page 829.

## Add-ALE Function

This function establishes a valid ALE in your virtual machine's host access list.

For the add-ALE function, the Rx register contains the real address of a doubleword-aligned parameter list in the following format:

|     |          |          |          |            |
|-----|----------|----------|----------|------------|
| Dec |          |          |          |            |
| 00  | ALSDIAGC | ALSFCODE | ALSDWLEN | ALSVERSN   |
| 08  | ALSASIT  |          |          |            |
| 16  | ALSALET  |          | TYPFG    | Reserved-Z |

Where:

### ALSDIAGC

Bytes 0-1 of the parameter list contain the hexadecimal diagnose code, X'0240'.

**ALSFCODE**

Bytes 2-3 of the parameter list contain the hexadecimal function code for the diagnose. A function code of X'0000' indicates the add-ale function.

**ALSDWLEN**

Bytes 4-5 of the parameter list contain the length of this parameter list in doublewords.

**ALSVERSN**

Bytes 6-7 of the parameter list contain a version number of X'0001'.

**ALSASIT**

Bytes 8-15 of the parameter list contain the ASIT associated with the address space to be designated by the new ALE.

**ALSALET**

Bytes 16-19 of the parameter list are set by CP to be the ALET that your virtual machine can use to reference the address space specified by the ALSASIT field.

**ALSTYPFG**

Bit 0 of byte 20 of the parameter list controls whether the new ALE allows read-only or read-write access to the designated address space. If this bit is zero, then the ALE is set to provide read-only access to the address space. If this bit is one, then the ALE is set to provide read-write access to the address space.

If the ALSASIT field specifies an address space owned by another virtual machine, then that virtual machine must have authorized your virtual machine for the requested type of access.

Bit 1 of byte 20 of the parameter list controls whether page-fault handshaking is to be activated. If this bit is zero, then page-fault handshaking should not be activated. If this bit is one then, whenever the address of a page-fault handshaking token is established for the virtual CPU, page-fault handshaking should be activated to notify both initiation of a page fault and completion of a page fault.

The address space is eligible for page-fault handshaking while a page-fault handshaking token is established for the virtual CPU until the address space is either explicitly or implicitly removed.

**Reserved-Z**

Bits 2-7 of byte 20, and bytes 21-23 of the parameter list are reserved and contain binary zeros.

## Remove-ALE Function

This function sets a specified ALE in your virtual machine's host access list to the unused state. For the remove-ALE function, the Rx register contains the real address of a doubleword-aligned parameter list in the following format:

|     |                                      |          |            |          |
|-----|--------------------------------------|----------|------------|----------|
| Dec |                                      |          |            |          |
| 00  | ALSDIAGC                             | ALSFCODE | ALSDWLEN   | ALSVERSN |
| 08  | //////////////////////////////////// |          |            |          |
| 16  | ALSALET                              |          | Reserved-Z |          |

Where:

**ALSDIAGC**

Bytes 0-1 of the parameter list contain the hexadecimal diagnose code. A specification exception is recognized if this field is not X'0240'.

**ALSFCODE**

Bytes 2-3 of the parameter list contain the hexadecimal function code for the diagnose. A function code of X'0001' indicates the remove-ALE function.

**ALSDWLEN**

Bytes 4-5 of the parameter list contain the length of the parameter list in doublewords.

**ALSVERSN**

Bytes 6-7 of the parameter list contain a version number of X'0001'.

**ALSALET**

Bytes 16-19 of the parameter list contain an ALET which designates the ALE to be removed.

## DIAGNOSE X'244'

### Reserved-Z

Bytes 20-23 of the parameter list are reserved and contain binary zeros.

Bytes 8-15 are ignored.

## Responses

**Program Exceptions:** The program exceptions for DIAGNOSE X'240' are the same as those documented for the ALSERV macro; refer to [“ALSERV — Access List Services”](#) on page 829 for more information.

## DIAGNOSE Code X'244' – Mapping Services

---

**Privilege Class:** Any (XC virtual machines only)

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE X'244' is invoked from the guest MAPMDISK macro to perform mapping-service functions.

**Note:** This diagnose is reserved for IBM use; it is not a supported programming interface. The information is included here to be used only in the diagnosis task. The supported method of invocation for the mapping services is the MAPMDISK macro. For more information on the MAPMDISK macro, refer to [“MAPMDISK — Mapping Services”](#) on page 838.

The following mapping-service functions can be invoked using this DIAGNOSE:

- Identify-pool
- Define-mapping
- Remove-mapping
- Save-list.

Entry Values:

### Rx

Address of a function parameter list, the format of which is determined by the function code in the parameter list. The parameter list is built by the MAPMDISK macro expansion in the macro's work area.

### Ax

Is used only in access-register mode. Ax contains the ALET for the address space containing the parameter list.

When Rx is general register 0, Ax is not examined. The ALET is assumed to be X'00000000', which indicates the host-primary address space.

Exit Values:

### Ry

On return, register Ry contains a return code, as stated in the mapping-service functions described under the [“MAPMDISK — Mapping Services”](#) on page 838.

### Ry+1

On an error return, register Ry+1 contains the address of the parameter, definition block, or entry where the error was encountered.

### Ay+1

Is used only in access-register mode. Ay+1 contains the ALET for the address space containing the address returned in Ry+1.

## Identify-pool Function

This function identifies the minidisk pool that will participate in mappings, and defines the assignment of pool-relative block numbers to the blocks contained in the minidisk pool. For the identify-pool function, register Rx contains the real address of a doubleword-aligned parameter list in the following format:

|     |                                      |          |                                  |          |
|-----|--------------------------------------|----------|----------------------------------|----------|
| Dec |                                      |          |                                  |          |
| 00  | MPLDIAGC                             | MPLFCODE | MPLDWLEN                         | MPLVERSN |
| 08  | //////////////////////////////////// |          |                                  |          |
| 16  | Reserved-Z                           |          | //////////////////////////////// |          |
| 24  | MPLEXTCT                             |          | Reserved-Z                       |          |
| 32  | MPLXLDAL                             |          | MPLXLDBA                         |          |

Where:

#### **MPLDIAGC**

Bytes 0-1 of the parameter list contain the hexadecimal diagnose code, X'0244'.

#### **MPLFCODE**

Bytes 2-3 of the parameter list contain the hexadecimal function code for the diagnose. A function code of X'0000' indicates the identify-pool function.

#### **MPLDWLEN**

Bytes 4-5 of the parameter list contain the length of this parameter list in doublewords.

#### **MPLVERSN**

Bytes 6-7 of the parameter list contain a version code of X'0001'.

#### **Reserved-Z**

Bytes 16-19 and 28-31 of the parameter list are reserved and contain binary zeros.

#### **MPLEXTCT**

Bytes 24-27 of the parameter list contains the total number of extents in the extent list.

#### **MPLXLDAL**

Bytes 32-35 of the parameter list contain the ALET for the address space containing the first extent-list definition block in the chain of extent-list definition blocks. The contents of this field are ignored in primary space mode.

#### **MPLXLDBA**

Bytes 36-39 of the parameter list contain the address of the first extent-list definition block in the chain of extent-list definition blocks for this request.

Bytes 8-15 and bytes 20-23 of the parameter list are ignored.

## Define-mapping Function

This function establishes a mapping between a range of pages in an address space, and, indirectly via pool-relative block numbers, a set of blocks residing in the minidisk pool.

For the define-mapping function, register Rx contains the address of a doubleword-aligned parameter list in the following format:

|     |            |          |                   |            |
|-----|------------|----------|-------------------|------------|
| Dec |            |          |                   |            |
| 00  | MPLDIAGC   | MPLFCODE | MPLDWLEN          | MPLVERSN   |
| 08  | MPLALET    |          |                   |            |
| 16  | Reserved-Z |          | MPLSPAGE          |            |
| 24  | MPLPAGCT   | C ///    | VIEW              | Reserved-Z |
| 32  | MPLMLDAL   |          | MPLMLDBA/MPLSPRBN |            |

Where:

#### **MPLDIAGC**

Bytes 0-1 of the parameter list contain the hexadecimal diagnose code, X'0244'.

#### **MPLFCODE**

Bytes 2-3 of the parameter list contain the hexadecimal function code for the diagnose. A function code of X'0001' indicates the define-mapping function.

#### **MPLDWLEN**

Bytes 4-5 of the parameter list contain the length of this parameter list in doublewords.

#### **MPLVERSN**

Bytes 6-7 of the parameter list contain a version code of X'0001'.

**MPLASIT**

Bytes 8-15 of the parameter list contain the ASIT associated with the address space that is to be the target of the mapping.

**Reserved-Z**

Bytes 16-19, bits 1-7 of byte 28, and bytes 30-31 are reserved and contain binary zeros.

**MPLSPAGE**

Bytes 20-23 of the parameter list contain the absolute address of the first page in the consecutive range of pages to be mapped.

**MPLPAGCT**

Bytes 24-27 of the parameter list contains the number of consecutive pages to be mapped by this request.

**C**

Bit 0 of byte 28 of the parameter list controls whether the pool-relative block numbers to be associated with the mapped pages are specified as a consecutive range, or by a list.

If this bit is zero, then the mapping is to be established using a specified list of pool-relative block numbers. If this bit is one, then the mapping is to be established using a consecutive range of pool-relative block numbers.

**VIEW**

Byte 29 of the parameter list contains the page view codes.

A value of binary 0 indicates that the current contents of the pages are discarded and the contents of the associated minidisk blocks are made available in the mapped pages. A value of binary 1 indicates the current contents of the pages are retained.

A value of binary 2 indicates the current contents of the pages are discarded and the mapped pages are considered to contain binary zeros.

**MPLMLDAL**

When bit 0 of byte 28 is zero, bytes 32-35 contain the ALET of the address space containing the first mapping list definition block. This field is ignored if the virtual machine is in primary space mode or if the pages are to be mapped to consecutive block numbers.

**MPLMLDBA**

When the C field (bit 0 of byte 28) is zero, bytes 36-39 of the parameter list contain the address of the first mapping list definition block in the chain of mapping definition blocks for this request.

**MPLSPRBN**

When the C field (bit 0 of byte 28) is one, bytes 36-39 of the parameter list contain the pool-relative block number to be associated with the page identified by the MPLSPAGE field. Each subsequent page in the range of pages to be mapped is associated with the next larger pool-relative block number.

**Remove-mapping function**

This function removes a mapping between a range of pages in an address space, and a set of blocks residing in the minidisk pool.

For the remove-mapping function, register Rx contains the address of a doubleword-aligned parameter list in the following format:

|     |            |          |                                      |          |
|-----|------------|----------|--------------------------------------|----------|
| Dec |            |          |                                      |          |
| 00  | MPLDIAGC   | MPLFCODE | MPLDWLEN                             | MPLVERSN |
| 08  | MPLASIT    |          |                                      |          |
| 16  | Reserved-Z |          | MPLSPAGE                             |          |
| 24  | MPLPAGCT   |          | Reserved-Z                           |          |
| 32  | Reserved-Z |          | //////////////////////////////////// |          |

Where:

**MPLDIAGC**

Bytes 0-1 of the parameter list contain the hexadecimal diagnose code, X'0244'.

**MPLFCODE**

Bytes 2-3 of the parameter list contain the hexadecimal function code for the diagnose. A function code of X'0002' indicates the remove-mapping function.

**MPLDWLEN**

Bytes 4-5 of the parameter list contain the length of this parameter list in doublewords.

**MPLVERSN**

Bytes 6-7 of the parameter list contain a version code of X'0001'.

**MPLASIT**

Bytes 8-15 of the parameter list contain the ASIT associated with the address space that is the target of the mapping.

**Reserved-Z**

Bytes 16-19 and bytes 28-35 of the parameter list are reserved and must be zeros.

**MPLSPAGE**

Bytes 20-23 of the parameter list contain the address of the first page in the range of pages for which the mapping is to be removed.

**MPLPAGCT**

Bytes 24-27 of the parameter list contains the count of pages for which the mapping is to be removed.

Bytes 36-39 of the parameter list are ignored.

## Save-list Function

This function saves a specified range of pages in an address space.

For the save-list function, register Rx contains the address of a doubleword-aligned parameter list in the following format:

|     |            |          |            |            |
|-----|------------|----------|------------|------------|
| Dec |            |          |            |            |
| 00  | MPLDIAGC   | MPLFCODE | MPLDWLEN   | MPLVERSN   |
| 08  | Reserved-Z |          | Reserved-Z |            |
| 16  | Reserved-Z |          | Reserved-Z |            |
| 24  | MPLENTCT   |          | B          | Reserved-Z |
| 32  | MPLSLDAL   |          | MPLSLDBA   |            |

Where:

**MPLDIAGC**

Bytes 0-1 of the parameter list contain the hexadecimal diagnose code, X'0244'.

**MPLFCODE**

Bytes 2-3 of the parameter list contain the hexadecimal function code for the diagnose. A function code of X'0003' indicates the save-list function.

**MPLDWLEN**

Bytes 4-5 of the parameter list contain the length of this parameter list in doublewords.

**MPLVERSN**

Bytes 6-7 of the parameter list contain a version code of X'0001'.

**Reserved-Z**

Bytes 8-23, 29-31, and bits 1-7 of byte 28 of the parameter list are reserved and contain binary zeros.

**MPLENTCT**

Bytes 24-27 of the parameter list contain the total count of entries in the SLDBK.

**B**

when bit 0 of byte 28 is one it indicates that the SLDBK is in **block form**.

If bit 0 of byte 28 is zero then the SLDBK is in the **list form**.

**MPLSLDAL**

Bytes 32-35 contain the ALET of the first save-list definition block. This field is ignored if the virtual machine is in primary space mode.

**MPLSLDBA**

bytes 36-39 of the parameter list contain the address of the first save-list definition block in the chain of save-list definition blocks for this request.

The format of the save-list definition block chain is described in [“MAPMDISK SAVE” on page 860](#).

**Responses**

**Program Exceptions:** The program exceptions for DIAGNOSE X'244' are the same as those documented for the MAPMDISK macro at [“MAPMDISK — Mapping Services” on page 838](#).

**DIAGNOSE Code X'254' – Access Real Subsystem**

---

**Privilege Class:** Any, with the LIBRARY CTL option of the STDEVOPT directory control statement.

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'254' to issue a limited set of channel programs to select tape control unit subsystems. DIAGNOSE X'254' provides a virtual machine with asynchronous access to a subsystem even if all devices in that subsystem are dedicated to other virtual machines or CP. The initiating virtual machine is not required to have a device from the target subsystem in its virtual configuration.

Function Codes:

**X'00'**

Open CP Connection

**X'01'**

Close CP Connection

**X'02'**

Perform I/O

Entry Values:

**Rx**

is a general register that contains the guest real address of the Access Real Subsystem Parameter List (HCPARSPL). The ARSPL must be on a doubleword boundary.

**Ry**

is a general register. It is not examined as input. Rx and Ry can be the same register.

Exit Values:

**Ry**

contains a return code indicating the result of the request. Refer to [“Responses” on page 1054](#) for a description of the possible values.

The entire ARSPL may be replaced in guest storage upon completion of a Diagnose X'254' function.

**Hardware Specifications****Tape Subsystems**

Select tape subsystems are supported by this DIAGNOSE. A small subset of CCWs are supported. The intent is to give a virtual machine the ability to issue library function CCWs to a tape library subsystem without requiring that the virtual machine acquire a dedicated tape drive from the library.

***Supported TAPE Subsystems***

- 3490 controller subsystems
- 3590 controller subsystems
- 3494 library subsystems
- 3495 library subsystems

## ***Subsystem Identifiers***

### **Controller**

Subsystem ID can be found in bytes 112 - 125 of the response to the Read Configuration Data CCW. Bytes 112 - 113 are the Token NED's Plant of Manufacture, and bytes 114 - 125 are the Token NED's Sequence Number.

### **Library**

Subsystem ID can be found in bytes 80 - 93 of the response to the Read Configuration Data CCW. Bytes 80 - 81 are the Library NED's Plant of Manufacture, and bytes 82 - 93 are the Library NED's Sequence Number.

The Subsystem ID will be needed as input to execute all functions of this DIAGNOSE.

## ***Supported CCWs***

- Channel Path Nop
- Perform Subsystem Function
- Read Subsystem Data
- Read Configuration Data
- Read Device Characteristics
- Sense Id

## ***Further Restrictions***

- The MAINTCCW option of the OPTION directory control statement is required to issue the Pin and Unpin orders of the Perform Subsystem function CCW.
- Because this DIAGNOSE allows I/O to be issued to a drive that may be dedicated to another VM guest, or may be shared by another real host, I/O issued by this DIAGNOSE is subject to Dynamic Partitioning (DP) Unit Checks. If a DP Unit Check occurs and the DIAGNOSE user has not indicated a specific drive to issue the I/O on, VM will attempt to find another drive in the specified subsystem. If VM receives DP Unit Checks from all available drives, VM will reflect the last Unit Check to the DIAGNOSE user. If VM starts I/O to another drive because of a previous DP Unit Check and receives a non-DP error, the non-DP error will be reflected to the DIAGNOSE user. Use the Dynamic Partitioning Override bit to avoid DP Unit Checks on applicable CCW orders.
- Use of a CCW order in a way that produces an unsolicited interrupt accompanied by an attention message is not advised. This diagnose will have no knowledge of the interrupt message pair when presented by the subsystem. The interrupt message pair will be presented to the virtual machine that has dedicated to it the device that reflected the interrupt message pair, or VM will throw away the interrupt message pair if the associated device isn't attached to a guest. Leave off the Message Required bit associated with any applicable orders to avoid unsolicited interrupts and attention messages.
- When using this DIAGNOSE to issue I/O to a tape library subsystem, the Library Manager must be online when the first device on a controller in the library subsystem is defined and varied on (for example, VM initialization). VM will not be able to access devices on a controller if the Library Manager was offline because VM will have no knowledge of the Library Subsystem ID. You can correct this situation by deleting all RDEVs (for example, DELETE RDEVICE command) for devices on a controller and then recreating and varying on the RDEVs (for example, SET RDEVICE and VARY commands) when the Library Manager is online. This restriction does not apply to the Controller Subsystem ID.
- The Open CP Connection function will not be allowed for a tape library subsystem that has an active DIAGNOSE X'254' environment on a controller subsystem that is part of the library subsystem. Use the Open function consistently on either a library subsystem or a controller subsystem. An active environment on a library subsystem will give access to all controller subsystems in the library. See [“Open CP Connection” on page 1049](#) for details on the DIAGNOSE X'254' environment.

## **Open CP Connection**

This function establishes the necessary environment to invoke subsequent functions of this DIAGNOSE.

The function code for this request is X'00'. The ARSPL is defined as follows:

**Diagnose Number**

(Input) Byte 0 of word 0 starts a halfword field that defines the DIAGNOSE number. The field must contain the halfword X'0254'.

**Function Code**

(Input) Byte 2 of word 0 is a 1-byte field that defines the function code of this request. The byte must contain X'00'.

**Parameter List Length**

(Input) Byte 3 of word 0 is a 1-byte field that defines the length, in bytes, of the ARSPL. Because the ARSPL is a fixed size, the byte must contain X'58'.

**Subsystem ID**

(Input) Byte 0 of word 2 starts a 14-byte field that defines the Subsystem ID of the subsystem that will be the target of subsequent DIAGNOSE X'254' requests. The contents of the field must be right justified and padded on the left with binary zeros, if necessary, to fill all 14 bytes. Refer to [“Hardware Specifications” on page 1048](#) for more information on subsystem identifiers.

**Hardware Flags**

(Input) Byte 0 of word 6 is a 1-byte field containing a set of flags related to the hardware in the subsystem. The following table describes all defined flag bits, all other bits are reserved and must contain binary zeros.

Table 222. Hardware Flags

| Bit | Description                                                                                                                                                                                                                                                                           |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Indicates the type of tape subsystem specified by the Subsystem ID field. If 1, the Subsystem ID represents a tape library subsystem. If 0, a tape controller subsystem is assumed.                                                                                                   |
| 1   | Indicates whether VM should ignore the Plant of Manufacture bytes in the Subsystem ID field if applicable for the hardware. If 1, the Plant bytes, if applicable, will be ignored. If 0, the Plant bytes, if applicable, will be included in VM's search for the specified subsystem. |

**Reserved**

The remaining fields in the block are reserved and must contain binary zeros.

**Usage Notes:**

1. The subsystem must be supported by this DIAGNOSE and must not be defined to CP as 'unsupported'. Refer to [“Hardware Specifications” on page 1048](#) for a list of supported subsystems.
2. A given Subsystem ID can have only one active DIAGNOSE X'254' environment at a time among all users on a VM system.

## Close CP Connection

This function removes the environment established by the Open CP Connection function of this DIAGNOSE.

The environment established by the Open CP Connection function remains in effect until you explicitly terminate the environment using this function or until an I/O reset is performed for the virtual machine, for example by the SYSTEM RESET, IPL, or LOGOFF commands.

This function, as well as an I/O reset, will terminate any pending DIAGNOSE X'254' I/O on the subsystem.

The function code for this request is X'01'. The ARSPL is defined as follows:

### Diagnose Number

(Input) Byte 0 of word 0 starts a halfword field that defines the DIAGNOSE number. The field must contain the halfword X'0254'.

### Function Code

(Input) Byte 2 of word 0 is a 1-byte field that defines the function code of this request. The byte must contain X'01'.

### Parameter List Length

(Input) Byte 3 of word 0 is a 1-byte field that defines the length, in bytes, of the ARSPL. Because the ARSPL is a fixed size, the byte must contain X'58'.

### Subsystem ID

(Input) Byte 0 of word 2 starts a 14-byte field that defines the Subsystem ID of the subsystem that will have its DIAGNOSE X'254' environment removed. The contents of the field must be right justified and padded on the left with binary zeros, if necessary, to fill all 14 bytes.

### Hardware Flags

(Input) Byte 0 of word 6 is a 1-byte field containing a set of flags related to the hardware in the subsystem. The following table describes all defined flag bits, all other bits are reserved and must contain binary zeros.

Table 223. Hardware Flags

| Bit | Description                                                                                                                                                                                                                                                                           |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Indicates the type of tape subsystem specified by the Subsystem ID field. If 1, the Subsystem ID represents a tape library subsystem. If 0, a tape controller subsystem is assumed.                                                                                                   |
| 1   | Indicates whether VM should ignore the Plant of Manufacture bytes in the Subsystem ID field if applicable for the hardware. If 1, the Plant bytes, if applicable, will be ignored. If 0, the Plant bytes, if applicable, will be included in VM's search for the specified subsystem. |

### Reserved

The remaining fields in the block are reserved and must contain binary zeros.

Perform I/O

This function allows the issuer to issue select channel programs to a subsystem. Refer to [“Hardware Specifications”](#) on page 1048 for a list of supported CCWs.

The function code for this request is X'02'. The ARSPL is defined as follows:

Diagnose Number

(Input) Byte 0 of word 0 starts a halfword field that defines the DIAGNOSE number. The field must contain the halfword X'0254'.

Function Code

(Input) Byte 2 of word 0 is a 1-byte field that defines the function code of this request. The byte must contain X'02'.

Parameter List Length

(Input) Byte 3 of word 0 is a 1-byte field that defines the length, in bytes, of the ARSPL. Because the ARSPL is a fixed size, the byte must contain X'58'.

Subsystem ID

(Input) Byte 0 of word 2 starts a 14-byte field that defines the Subsystem ID of the subsystem that will be the target of the DIAGNOSE X'254' I/O request. The contents of the field must be right justified and padded on the left with binary zeros, if necessary, to fill all 14 bytes.

Device Number

(Input) Byte 2 of word 5 starts a halfword field that defines the Real Device Number of the device that will be the target of the DIAGNOSE X'254' I/O request. The device must be a member of the subsystem specified by the Subsystem ID and its number must be in the range X'0000' - X'FFFF'. This field is optional, and VM will choose the device from the specified subsystem if omitted as indicated in the I/O Request Flags field.

Hardware Flags

(Input) Byte 0 of word 6 is a 1-byte field containing a set of flags related to the hardware in the subsystem. The following table describes all defined flag bits, all other bits are reserved and must contain binary zeros.

Table 224. Hardware Flags

| Bit | Description                                                                                                                                                                                                                                                                           |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Indicates the type of tape subsystem specified by the Subsystem ID field. If 1, the Subsystem ID represents a tape library subsystem. If 0, a tape controller subsystem is assumed.                                                                                                   |
| 1   | Indicates whether VM should ignore the Plant of Manufacture bytes in the Subsystem ID field if applicable for the hardware. If 1, the Plant bytes, if applicable, will be ignored. If 0, the Plant bytes, if applicable, will be included in VM's search for the specified subsystem. |

**I/O Request Flags**

(Input) Byte 1 of word 6 is a 1-byte field containing a set of flags for the I/O request. The following table describes all defined flag bits, all other bits are reserved and must contain binary zeros.

Table 225. I/O Request Flags

| Bit | Description                                                                                                                                                                                     |
|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Indicates the format of the CCWs which make up the channel program. If 1, format-1 CCWs are specified. If 0, format-0 CCWs are specified.                                                       |
| 1   | Indicates whether the device number is indicated in the ARSPL Device Number field. If 1, the device is specified. If 0, the Device Number field is ignored and the device will be chosen by VM. |

**Storage Key**

(Input) Bits 0-3 of byte 2, word 6 contain the Storage Protection Key for fetching all CCWs and CCW related output data, and for storing all CCW related input data. The key is matched against the appropriate guest real storage key during all CCW related storage references. Bits 4-7 of byte 2, word 6 are reserved and must contain binary zeros.

**Interruption Parameter**

(Input) Byte 0 of word 7 starts a fullword field that defines user data to be stored at guest real storage locations 128-131 upon presentation of the Access Real Subsystem External Interruption at the completion of the I/O request. Refer to [“Access Real Subsystem External Interruption”](#) on page 1056 for a complete description.

**Channel Program Address**

(Input) Byte 0 of word 8 starts a fullword field that designates the location of the channel program's first CCW in guest absolute storage. If format-0 CCWs have been specified in the I/O Request Flags, then bits 0 thru 7 of the Channel Program Address must be binary zeros. If format-1 CCWs have been specified, then bit 0 must be zero. Also, the three rightmost bits of the Channel Program Address must be binary zeros. This indicates that the first CCW is on a doubleword boundary.

**CCW Address at Interrupt**

(Output) Byte 0 of word 9 starts a fullword field that designates the guest absolute address of the last executed CCW + 8 in the channel program.

**Device Status**

(Output) Byte 0 of word 10 is a 1-byte field identifying the conditions in the device, that is, the device in the subsystem to which the I/O was issued, when the channel program ended. The conditions that this byte can represent are defined in the *IBM ESA/390 Common I/O-Device Commands*, SA22-7204.

**Subchannel Status**

(Output) Byte 1 of word 10 is a 1-byte field identifying the conditions in the subchannel when the channel program ended. The conditions that this byte can represent are defined in Enterprise Systems Architecture/390 Principles of Operation ([publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf](http://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf)) and z/Architecture Principles of Operation (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>).

**Residual Count**

(Output) Byte 2 of word 10 starts a halfword field that identifies the Residual Count from the channel program's ending CCW as defined in Enterprise Systems Architecture/390 Principles of Operation ([publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf](http://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf)) and z/Architecture Principles of Operation (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>).

**Sense Count**

(Output) Byte 0 of word 11 starts a halfword field that defines the number of bytes of sense data present if Unit Check is indicated in the Device Status field.

**Sense Data**

(Output) Byte 0 of word 14 starts a 32-byte field that contains the sense data, as limited by the Sense Count field, if Unit Check is indicated in the Device Status field.

**Reserved**

The remaining fields in the block are reserved and must contain binary zeros.

**Usage Notes:**

1. The guest will receive control back after the I/O request has been accepted. If an error prevents acceptance of the I/O, the error will be indicated by the DIAGNOSE condition code and return code. The completion of any I/O performed will be reflected to the guest by an external interruption. The results of the I/O can be found by first examining the external interruption status and then, if appropriate, the output fields of the ARSPL. Refer to [“Access Real Subsystem External Interruption”](#) on page 1056 for a complete description of the external interruption.
2. It is possible that queued or started I/O could be ended by the Close CP Connection function of this DIAGNOSE. This could happen if the Close CP Connection function is processed before the I/O is complete. The Access Real Subsystem External Interruption will indicate this condition if it occurs. It is also possible that a virtual machine I/O reset (for example, caused by SYSTEM RESET, IPL, or LOGOFF commands) could end queued or started I/O before it is complete. In this case, there will be no indication that the I/O was ended because the virtual machine ends up being reset.
3. Unsupported CCWs will receive an indication of Unit Check in the Device Status field and Command Reject in the Sense Data field.
4. The Interruption Parameter field can be used to associate an Access Real Subsystem External Interruption with a particular invocation of the Perform I/O function. Refer to [“Access Real Subsystem External Interruption”](#) on page 1056 for more details.

**Responses**

**Condition Codes and Return Codes:** Upon completion of DIAGNOSE X'254', control is returned to the issuer with a condition code and return code set to indicate the status of the requested function. The return code is set in Ry.

*Table 226. General condition code descriptions for all functions*

| Condition Code | Description                   |
|----------------|-------------------------------|
| 0              | Function was successful.      |
| 2              | Subsystem is busy.            |
| 3              | Subsystem is not operational. |

*Table 227. Condition codes and return codes for the Open CP Connection function*

| Condition Code | Return Code in Ry | Description                                                                                                      |
|----------------|-------------------|------------------------------------------------------------------------------------------------------------------|
| 0              | 0 (X'00')         | Initialization of the DIAGNOSE X'254' environment for the specified subsystem has completed successfully.        |
| 2              | 32 (X'20')        | The issuer already has a DIAGNOSE X'254' environment active for the specified subsystem.                         |
| 2              | 36 (X'24')        | Another user currently has a DIAGNOSE X'254' environment active for the specified subsystem.                     |
| 2              | 40 (X'28')        | A CP Close Connection Function is currently pending for the specified subsystem.                                 |
| 3              | 52 (X'34')        | The specified subsystem is not known in VM's real I/O configuration or is not supported by VM for this DIAGNOSE. |
| 3              | 60 (X'3C')        | Reserved.                                                                                                        |
| 3              | 64 (X'40')        | Reserved.                                                                                                        |
| 3              | 255 (X'FF')       | An unexpected error occurred. The error is unrecoverable. It will be accompanied by a soft abend.                |

Table 228. Condition codes and return codes for the Close CP Connection function

| Condition Code | Return Code in Ry | Description                                                                                                                                 |
|----------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | 0 (X'00')         | The active DIAGNOSE X'254' environment has been successfully deleted. Any pending DIAGNOSE X'254' I/O to the subsystem has been terminated. |
| 2              | 40 (X'28')        | A CP Close Connection Function is currently pending for the specified subsystem.                                                            |
| 3              | 120 (X'78')       | A DIAGNOSE X'254' environment was not previously established for the specified subsystem using the Open CP Connection function.             |
| 3              | 255 (X'FF')       | An unexpected error occurred. The error is unrecoverable. It will be accompanied by a soft abend.                                           |

Table 229. Condition codes and return codes for the Perform I/O function

| Condition Code | Return Code in Ry | Description                                                                                                                                                     |
|----------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | 0 (X'00')         | The I/O request has accepted.                                                                                                                                   |
| 2              | 40 (X'28')        | A CP Close Connection Function is currently pending for the specified subsystem.                                                                                |
| 3              | 120 (X'78')       | A DIAGNOSE X'254' environment was not previously established for the specified subsystem using the Open CP Connection function.                                 |
| 3              | 148 (X'94')       | VM is unable to find an available device. Either the specified device or all devices associated with the specified subsystem are offline, or they do not exist. |
| 3              | 255 (X'FF')       | An unexpected error occurred. The error is unrecoverable. It will be accompanied by a soft abend.                                                               |

**Program Exceptions:** DIAGNOSE X'254' may result in one of the following program exceptions:

| Problem Encountered            | Cause                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Addressing exception           | The ARSPL is not within addressable guest real storage.                                                                                                                                                                                                                                                                                                                                     |
| Operand exception              | Any of the following: <ul style="list-style-type: none"> <li>The ARSPL Channel Program Address does not indicate a CCW that is on a doubleword boundary.</li> <li>Bits required to be binary zero are set in the high-order byte of the ARSPL Channel Program Address.</li> <li>Bits required to be binary zero are set in the ARSPL byte containing the Storage Protection Key.</li> </ul> |
| Privileged-operation exception | The guest is not authorized to issue this DIAGNOSE.                                                                                                                                                                                                                                                                                                                                         |
| Protection exception           | The ARSPL is store or fetch protected.                                                                                                                                                                                                                                                                                                                                                      |

| Problem Encountered     | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Access Real Subsystem External Interruption

An Access Real Subsystem External Interruption is generated if a Perform I/O function request has completed at a device.

The external interruption is a floating interruption condition and is presented to the first virtual CPU in the virtual configuration that is enabled for the interruption. The condition is cleared once the interruption is presented or if a virtual machine reset occurs, for example, by the SYSTEM RESET, IPL, or LOGOFF commands.

The subclass mask to enable for the interruption is bit 22 of control register 0.

The Access Real Subsystem condition is indicated by an external interruption code of X'2603' stored at guest real locations 134-135, and a subinterruption code of X'04' stored at guest real location 132. The Interruption Parameter, as specified in the ARSPL on the Perform I/O request, is stored at guest real locations 128-131. In addition, one of the following status codes will be stored at guest real location 133.

*Table 230. Perform I/O function completion status codes*

| Code  | Meaning                                                                                                                                                                                                                                                          |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00' | The I/O completed as indicated in the updated ARSPL.                                                                                                                                                                                                             |
| X'01' | The updated ARSPL could not be stored into guest storage. The results of the I/O operation are indeterminate.                                                                                                                                                    |
| X'02' | The user-specified or VM chosen device became unavailable after the I/O request was queued to be issued to the device. Retry the request to see if the user specified device is now available or if VM can find a different device in which to issue the I/O on. |
| X'03' | The I/O, which was queued but not yet started, was terminated due to a Close CP Connection function request.                                                                                                                                                     |
| X'04' | The I/O, which was already started at the device but not yet complete, was terminated due to a Close CP Connection function request.                                                                                                                             |
| X'05' | A missing interrupt condition was detected. The I/O request may or may not have been started.                                                                                                                                                                    |
| X'FF' | An unexpected error occurred. The error is unrecoverable. It will be accompanied by a soft abend.                                                                                                                                                                |

## DIAGNOSE Code X'25C' – Directory Query

**Privilege Class: B**

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE code X'25C' is a privileged function provided to allow applications access to the data in the CP user directory. Applications should use the VMUDQ macro to invoke the functions contained herein. For more information on the VMUDQ macro, refer to [“VMUDQ – VM User Directory Query” on page 889](#).

Entry Values:

**Rx**

contains the address of the parameter list.

**Ax**

is used only in access-register mode in an XC virtual machine. Ax contains the ALET of the address space containing the parameter list.

**Ry**

contains the address of the data buffer. Register 0 selects the virtual machine's primary address space.

**Ay**

contains the ALET of the address space.

**Ry+1**

contains the size of the data buffer in bytes.

Exit Values:

**Rx**

is modified to contain the length in bytes of the results of the query if successful or the number of bytes needed for the query if the buffer length is not sufficient. Otherwise, it remains unchanged.

**Rx+1**

might or might not be used. See the description of the function in the [Table 231 on page 1058](#) for details.

**Ry and ARy**

remains unchanged, describing the location of the data buffer.

**Ry+1**

is modified to contain the length in bytes of the results of the query.

Table 231. DIAGNOSE X'25C' Function List

| Function | Description and Parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LSTMDISK | <p>Creates a list of MDISK definitions based on, or qualified by, the owners to which they belong, virtual device number, serial number of the volume, and the SSI member on which they reside. An asterisk (*) can be used as a trailing wild card to select a wider group of definitions. The list is built in the buffer provided by the caller.</p> <p><b>Input Parameter List:</b> Consists of six doublewords as shown in the following example:</p> <pre> 0  *-----*      Length             ////////// Reserved //////////   8   -----*-----*-----*-----*-----*-----*-----*-----*-----*                          LSTMDISK                                       16                       * userid use*                                 24                       * vdevno vdev*                               32                       * volser vols*                               40                       * systemid sys*                                   -----*-----*-----*-----*-----*-----*-----*-----*-----* </pre> <p>The parameter list is a maximum of six doublewords long. It must be on a doubleword boundary and must not span a page boundary.</p> <p><b>length</b><br/>The length is a fullword containing the length in bytes of the length field itself, the reserved field, and the parameter string that follows. The length field must be one of the following values: 16, 24, 32, 40, or 48.</p> <p><b>LSTMDISK</b><br/>is the name of the function to be performed by the DIAGNOSE. The function must be LSTMDISK.</p> <p><b>*   <i>userid</i>   <i>use</i>*</b><br/>selects MDISK definitions that belong to the specified user IDs. The user ID from a USER or IDENTITY directory statement can be used. SUBCONFIG IDs cannot be specified. Definitions belonging to multiple owner ID's are selected by the use of an asterisk (*). An asterisk (*) by itself indicates that all definitions are to be analyzed regardless of <i>userid</i>. An asterisk (*) used as a trailing wild card selects definitions that belong to a group of <i>userids</i> that begin with the specified character combination. The value is left-justified in the field and padded to eight characters with blanks. The default assumed if the field is blank is an asterisk (*).</p> <p><b>*   <i>vdevno</i>   <i>vdev</i>*</b><br/>selects MDISK definitions that are defined to the specified virtual device numbers. Multiple <i>vdevnos</i> are specified by the use of the asterisk (*). An asterisk (*) by itself causes all MDISK definitions to be selected regardless of <i>vdevno</i>. An asterisk (*) used as a trailing wild card causes selection of MDISK definitions found on the selected virtual devices where the combined value indicates a range of addresses beginning with a common value. A four-digit address is assumed; therefore, 000* would mean 0000 through 000F, and 04* would mean 0400 through 04FF. The value is left-justified in the field and padded to eight characters with blanks. The default assumed if the field is blank is an asterisk (*).</p> |

Table 231. DIAGNOSE X'25C' Function List (continued)

| Function              | Description and Parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LSTMDISK<br>(cont'd.) | <p><b>*   volser   vols*</b><br/>selects MDISK definitions that are found on the volume containing the specified volume serial number. An asterisk (*) can be used as a trailing wild card to select a range of <i>volser</i>s that begin with a common set of characters. An asterisk (*) by itself indicates that the definitions on all the volumes are to be analyzed. The value is left-justified in the field and padded to eight characters with blanks. The default assumed if the field is blank is an asterisk (*).</p> <p><b>*   systemid   sys*</b><br/>selects MDISK definitions that are found on the specified SSI member system. An asterisk (*) can be used as a trailing wild card to select a range of systems that begin with a common set of characters. An asterisk (*) by itself indicates that the MDISK definitions on all member systems are to be analyzed. The value is left-justified in the field and padded to eight characters with blanks. If the field is blank, the default assumed is blank, indicating that only the MDISK definitions on the current system are to be analyzed. Specifying a system other than by an asterisk or a blank is allowed only when an SSI-enabled directory is in use.</p> <p><b>Output Buffer Format:</b> Consists of seven blank-delimited fields containing the information indicated in the example below:</p> <pre> OWNERID- VDEV VOLSER DEVTYPE- START----- SIZE----- System 12345678 1234 123456 12345678 1234567890 1234567890 12345678 -----+-----+-----+-----+-----+-----+----- User123 0191 ABC123 3390 0000000010 0000000200 User456 0191 CCC123 FB-512 0000000010 0000200000 User789 0222 CCC222 3380 0000000010 END UserABC 0223 ABC223 3370 0000000000 0000200000 SYSTEMABC </pre> <p><b>Notes:</b></p> <ol style="list-style-type: none"> <li>1. In the above example the "START" field can contain either the starting cylinder or block number. The "SIZE" field contains the remaining number of cylinders or blocks. The non-device specific "END" in the size field denotes the end of the volume. Also, the header lines are not part of the returned data.</li> <li>2. If the MDISK was defined with a size of "END", then the size returned in the output buffer is simply "END".</li> <li>3. Temporary disks (T-disks) and virtual disks in storage are ignored by the LSTMDISK function and are not included in the output buffer.</li> <li>4. If the MDISK is defined within a SUBCONFIG stanza, the system ID to which the MDISK is restricted is included in the output buffer. If the MDISK is defined within a user or identity stanza, then no system ID is specified because the MDISK is not restricted to a particular system.</li> </ol> |

## Usage Notes

1. The application programmer uses the VMUDQ macro to invoke this DIAGNOSE because this DIAGNOSE code is reserved for IBM use.
2. An address space is acquired in blocks of 256 pages; therefore the number of bytes in the buffer to be passed on the call would equal:

```
(number pages requested+255/256) * 1048576.
```

3. In an SSI-enabled directory, MDISK definitions can be global or local. A global MDISK definition is one that is included in a user or identity stanza and the minidisk being defined can be linked by virtual machines on any member system of the SSI cluster. A local MDISK definition is one that is included

in a SUBCONFIG stanza and the minidisk being defined can be linked only by virtual machines on the SSI member system to which the SUBCONFIG stanza applies. When specifying the system ID parameter (\* | *systemid* | *sys\**), you are requesting all MDISK definitions that are global and local to a particular system. If you specify a system ID that is not specified on any BUILD statements in the directory, then all global MDISK definitions are reported. If you specify a system ID that is specified on a BUILD statement in the directory, then all global MDISK definitions and local MDISK definitions for the specified system are reported.

## Responses

Condition codes and return codes are described in [Table 232 on page 1060](#) and [Table 233 on page 1060](#).

*Table 232. DIAGNOSE X'25C'—Condition codes*

| Condition Code | Meaning                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | A normal exit from DIAGNOSE X'25C'. The guest Ry+1 register contains the return code.                                                     |
| 1              | DIAGNOSE code X'25C' has detected an error.                                                                                               |
| 3              | DIAGNOSE code X'25C' has encountered a paging error while trying to access the target area in the data space or an object directory page. |

*Table 233. Diagnose X'25C' - Return codes*

| Function | Return Code in Ry+1 | Description                                                                                                          |
|----------|---------------------|----------------------------------------------------------------------------------------------------------------------|
| General  | X'00'               | Successful. The guest Rx register contains the length of bytes moved as the result of the query.                     |
|          | X'04'               | No records were found to match criteria specified.                                                                   |
|          | X'08'               | The buffer length supplied is insufficient. The guest Rx register contains the number of bytes needed for the query. |
| LSTMDISK | X'100'              | An invalid user ID was specified.                                                                                    |
|          | X'104'              | An invalid virtual device number was specified.                                                                      |
|          | X'108'              | An invalid volume serial number was specified.                                                                       |
|          | X'10C'              | An invalid system ID was specified.                                                                                  |

**Program Exceptions:** The program exceptions for DIAGNOSE X'25C' are the same as those documented for the VMUDQ macro; refer to [“VMUDQ – VM User Directory Query” on page 889](#) for more information.

## DIAGNOSE Code X'264' – CP Communication

**Privilege Class:** ANY

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE code X'264' defines an area in which CP stores notification of certain events.

Entry Values:

**Rx, Rx+1, Ry+1**

Depends on the subcode specified in Ry (see description below).

**Ry**

Function subcode.

**Program Exceptions:** CP returns a specification exception if the subcode specified in the Ry register is invalid.

## Subcode X'00000000'—Establish CP communication area

Table 234. CP Subfunctions

| Name     | Bits # | Definition                                                                                                                                                |
|----------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| CPCRECON | 0      | Set to one (1) when a RECONNECT of the virtual machine occurs                                                                                             |
| CPCFSLM  | 1      | Set to one (1) when a virtual line-mode write has completed successfully and set to zero (0) when a virtual full-screen write has completed successfully. |
| CPCSHORT | 2      | Set to one (1) when the virtual machine default date format is SHOrtdate.                                                                                 |
| CPCFULL  | 3      | Set to one (1) when the virtual machine default date format is FULLdate.                                                                                  |
| CPCISO   | 4      | Set to one (1) when the virtual machine default date format is ISODate.                                                                                   |

Entry Values:

### Rx

Contains the guest absolute address of CP communication area in the host-primary space. The communication area must not be in read-only storage and must not cross a page boundary. Key-controlled protection and low-address protection do not apply to references to the communication area.

### Rx+1

Contains the size of CP communication area in fullwords

Usage Notes:

1. Once established, the CP communication area remains active until the virtual configuration is reset or until DIAGNOSE X'264' function subcode X'00000004' removes it.
2. The communication area may become inaccessible or read-only as, for example, through DIAGNOSE X'64'. As long as this prevails, the area is not updated.
3. The guest should use Compare and Swap when modifying the CP communication area.
4. Only bits defined within the established CP communication area are updated.

Program Exceptions:

| Problem Encountered     | Cause                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception | Any of the following: <ul style="list-style-type: none"> <li>• The CP communication area is not aligned on a fullword boundary.</li> <li>• The CP communication area crosses a page boundary.</li> <li>• The CP communication area is already active for the virtual configuration.</li> <li>• The size, in fullwords, in the Rx+1 register is not positive.</li> </ul> |
| Addressing exception    | The address of the CP communication area is not valid.                                                                                                                                                                                                                                                                                                                  |
| Protection exception    | The specified communication area is in read-only storage.                                                                                                                                                                                                                                                                                                               |

## Subcode X'00000004'—Remove CP communication area

Entry Values:

**Rx**

Not used.

**Rx+1**

Not used.

**Ry+1**

Not used.

**Usage Note:** If the CP communication area has not been established, no error is presented.

**Responses:** None.

## DIAGNOSE Code X'278' – Extract XLINK Control Blocks

**Privilege Class:** G

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE code X'278' extracts XLINK Control Block data from CP and returns it to a virtual machine.

**Note:** This DIAGNOSE is reserved for IBM use. It is not a supported programming interface. It is included here only for diagnostic purposes.

Entry Values:

**Rx**

Request flags in byte 0; bytes 1 through 3 must be zero.

**X'80'**

DXLSYINR — Request for System Include list

**X'40'**

DXLSYEXR — Request for System Exclude list

**X'20'**

DXLDTABR — Request for Device Table

**X'10'**

DXLVLINR — Request for Volume Include list

**X'08'**

DXLVLEXR — Request for Volume Exclude list

All undefined bits must be 0; otherwise, a specification exception occurs.

**Ry**

Address of doubleword-aligned parameter list, HCPDXLPL. Bit 0 of Ry must be zero.

**Ay**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the override parameter list file name. If Ry designates general register 0, if Ay contains X'00000000', or if the virtual machine is not in XC mode, the override parameter list file name is in the host-primary address space.

Exit Values: The following are normal exit situations.

| Condition Code | Meaning                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------|
| 0              | Normal completion. The response area was large enough for the data, and DXLDLEN and DXLDATA have been updated. |
| 3              | The response area was not large enough for the data. DXLDLEN has been updated, but DXLDATA is unpredictable.   |

On entry, the parameter list must be filled in as follows:

DXLHDR

|   |         |          |         |          |
|---|---------|----------|---------|----------|
| 0 | DXLPLID | //////// | DXLBLEN | //////// |
|---|---------|----------|---------|----------|

#### DXLHDR

indicates the beginning of the input fields.

#### DXLPLID

is a halfword identifier for the parameter list. This field must contain the value X'0278'.

#### DXLBLEN

is a halfword containing the number of doublewords available in the DXLPL area. The DXLPL area comprises both the header and the response area. This value must be at least 1.

Between the parameter list and the response area, there is a field set by CP:

#### DXLDLEN

is a halfword containing the actual number of doublewords of DXLPL into which results have been (or will be) placed. This number includes one doubleword for the header. If the guest condition code is 0, then DXLDATA contains data. If the guest condition code is 3, then the contents of DXLDATA are unpredictable.

DXLHDR

|   |          |          |          |         |
|---|----------|----------|----------|---------|
| 0 | //////// | //////// | //////// | DXLDLEN |
|---|----------|----------|----------|---------|

The response area, DXLDATA, immediately follows DXLDLEN:

DXLDATA

|    |                                        |          |          |          |
|----|----------------------------------------|----------|----------|----------|
| 8  | DXLSYINO                               | DXLSYINC | DXLSYINL | //////// |
| 10 | DXLSYEXO                               | DXLSYEXC | DXLSYEXL | //////// |
| 18 | DXLVLINO                               | DXLVLINC | DXLVLINL | //////// |
| 20 | DXLVLEXO                               | DXLVLEXC | DXLVLEXL | //////// |
| 28 | DXLDTABO                               | DXLDTABC | DXLDTABL | //////// |
| 30 | Response information at offsets above. |          |          |          |

where:

#### DXLDATA

is the data from CP, consisting of the fields listed below. Only the fields pertaining to the data items requested in Rx are meaningful; the contents of the other fields are unpredictable.

#### DXLSYINR

XLINK included system names:

##### DXLSYINO

shows the offset, in doublewords, from the beginning of the parameter list to the system include list. DXLSYINO is two bytes long.

##### DXLSYINC

shows the number of entries in the system include list. DXLSYINC is two bytes long.

##### DXLSYINL

is the length of each entry in bytes. DXLSYINL is two bytes long.

The last two bytes of the field are reserved.

The response for each entry will be the following:

Eight-byte system name

#### DXLSYEXR

XLINK excluded system names:

##### DXLSYEXO

shows the offset, in doublewords, from the beginning of the parameter list to the system exclude list. DXLSYEXO is two bytes long.

**DXLSYEXC**

shows the number of entries in the system exclude list. DXLSYEXC is two bytes long.

**DXLSYEXL**

is the length of each entry in bytes. DXLSYEXL is two bytes long.

The last two bytes of the field are reserved.

The response for each entry will be the following:

Eight-byte system name

**DXLVLINR**

XLINK volume include list:

**DXLVLINO**

shows the offset, in doublewords, from the beginning of the parameter list to the volume include list. DXLVLINO is two bytes long.

**DXLVLINC**

shows the number of entries in the volume include list. DXLVLINC is two bytes long.

**DXLVLINL**

is the length of each entry in bytes. DXLVLINL is two bytes long.

The last two bytes of the field are reserved.

The response for each entry will be the following:

Six-byte volume serial pattern

Two-byte cylinder number

Two-byte track number

Two-byte record length

Two-byte records

**DXLVLEXR**

XLINK volume exclude list:

**DXLVLEXO**

shows the offset, in doublewords, from the beginning of the parameter list to the volume exclude list. DXLVLEXO is two bytes long.

**DXLVLEXC**

shows the number of entries in the volume exclude list. DXLVLEXC is two bytes long.

**DXLVLEXL**

is the length of each entry in bytes. DXLVLEXL is two bytes long.

The last two bytes of the field are reserved.

The response for each entry will be the following:

Six-byte volume serial pattern

**DXLDTABR**

XLINK device table:

**DXLDTABO**

shows the offset, in doublewords, from the beginning of the parameter list to the device table. DXLDTABO is two bytes long.

**DXLDTABC**

shows the number of entries in the device table. DXLDTABC is two bytes long.

**DXLDTABL**

is the length of each entry in bytes. DXLDTABL is two bytes long.

The last two bytes of the field are reserved.

The response for each entry will be the following:

One-byte device type (from HCPDVTYP)  
 One-byte model/etc. information  
 Two-byte cylinder number  
 Two-byte track number  
 Two-byte record length  
 Two-byte records

## DIAGNOSE Code X'280' – Set POSIX IDs - security values

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE code X'280' securely sets POSIX security values for one of the family of `exec()` functions. If the file to be processed is not a `set_UID` or `set_GID` file, it sets the saved set-IDs to the effective ID values. If the file is a `set_UID` or `set_GID` file, it communicates with the server and then sets the effective and saved set-IDs to the specified values.

Entry Values:

### Rx

is the general register that contains the guest real address of the `exec()` parameter list (HCPEXCBK). The EXCBK must be on a doubleword boundary.

The entire EXCBK may be replaced in guest storage when this function completes.

### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the `exec()` parameter list (HCPEXCBK). If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the `exec()` parameter list is in the host-primary address space.

### Active Process ID

The active process is specified in the active process ID (PID) field in the POSIX communication area. (Before DIAGNOSE X'280' is used, DIAGNOSE X'2A4' must have been issued in this virtual configuration to define the communication area and allocate one or more PIDs.)

Exit Values:

### Ry

Contains the return code indicating the result of this request. Refer to [“Responses” on page 1068](#) for a description of the possible values of this field. Ry cannot be the same register as Rx.

**Format of the DIAGNOSE X'280' parameter list - HCPEXCBK:** The EXCBK consists of two major sections: the header, and the function-specific section. The function-specific section is mapped

differently for each function, and may include both fixed-length and variable length portions. For upward compatibility, the field EXCFFXLN, the length of the fixed-length portion of the function-specific section, must be filled in during the execution-time creation of the block. Any subsequent references to the variable-length portion must always be based on the address of the beginning of the block plus the lengths of the header and the fixed-length portion of the function-specific section.

The format of the header is:

|   |          |          |          |          |
|---|----------|----------|----------|----------|
| 0 | EXCDIAGC | EXCFUNCD | EXCDWLEN | //////// |
| 8 | EXCFFXLN |          | //////// |          |

## Function EXCSETID - Request changes in POSIX security values for an exec() function call

This function is called when the virtual configuration's POSIX security values must be changed on behalf of one of the *exec()* functions.

Format of the HCPEXCBK for function EXCSETID

|     |    |          |          |          |          |
|-----|----|----------|----------|----------|----------|
| Dec | 0  | EXCDIAGC | EXCFUNCD | EXCDWLEN | //////// |
|     | 8  | EXCFFXLN |          | //////// |          |
|     | 10 | //////// |          | EXCTPNLN |          |
|     | 18 | EXCTPN   |          |          |          |
|     | 58 | EXCLOCLU |          |          |          |
|     | 68 | EXCMODE  |          |          |          |
|     | 70 | EXCSRET  |          | EXCSREAS |          |
|     | 78 | EXCNUID  |          | EXCNGID  |          |
|     | 80 | EXCOBJLN |          | EXCOBJTK |          |

Input:

### EXCDIAGC

is a halfword field containing the hexadecimal DIAGNOSE code, X'0280'.

### EXCFUNCD

is a halfword field containing the function code. For this function, EXCFUNCD must contain the value of EXCSETID (0).

### EXCDWLEN

is an unsigned halfword field containing the length of this parameter list in doublewords. The length must include the length of the header, the length of the fixed-length section, and the length of any specified variable-length sections. It must be no more than one page (512 doublewords) in length.

### EXCFFXLN

is an unsigned fullword field containing the length in bytes of the fixed-length portion of the function-specific area of the control block. This area starts immediately after the header, and includes the fields up to, but not including, the beginning of the object token length field (EXCOBJLN).

### Reserved header fields

The rest of the fields in the header are reserved and must contain binary zeros.

### EXCTPNLN

is an unsigned fullword field containing the length in bytes of the TPN specified in EXCTPN. The minimum TPN length is 1 byte, and the maximum length is 64 bytes.

### EXCTPN

is a 64-byte field containing the resource name of the server in which the object to be executed resides. The TPN may be between 1 and 64 bytes in length and must be left-justified.

**EXCLOCLU**

is a 16-byte field containing the locally-known LName of the target server. This field contains 2 8-byte parts: the luname qualifier (EXCLUQUL), and the target luname (EXCLUTGT), and must follow the rules for specifying a locally-known luname for a global resource.

**EXCMODE**

is an 8-byte field containing the SNA modename.

**EXCSRET**

is an unsigned fullword field set by this function to contain the return code set by the server.

**EXCSREAS**

is an unsigned fullword field set by this function to contain the reason code set by the server.

**EXCNUID**

is an unsigned fullword field set by this function. If the function completed successfully, the field contains the current effective UID.

**EXCNGID**

is an unsigned fullword field set by this function. If the function completed successfully, the field contains the current effective GID.

**EXCOBJLN**

is an unsigned fullword field containing the length of the object token data (in bytes). The value in this field must include the length of this field and the length of the object token specified in EXCOBJTK, and thus must be at least equal to the length of this field. The maximum value for this field is EXCOBJMX bytes.

EXCOBJLN must immediately follow the fixed-length portion of this function's information.

**EXCOBJTK**

is a variable-length character field containing the token representing the file to be executed. The token must be left-justified.

**Reserved**

The rest of the fields in this block are reserved and should contain binary zeros.

All other flag bits must be binary zeros.

All other fields of the parameter list are reserved and should contain binary zeros. If they do not, the results of DIAGNOSE X'280' are unpredictable.

Output: See return codes.

## Function EXCSSID - Request changes in saved set-IDs for an exec() function call

This function is called when an application in a virtual machine performs an `exec()` function call, and only the saved set-ID values must be changed.

Format of the HCPEXCBK for function EXCSSID

|     |    |          |          |          |          |
|-----|----|----------|----------|----------|----------|
| Dec | 0  | EXCDIAGC | EXCFUNCD | EXCDWLEN | //////// |
|     | 8  | EXCFFXLN |          | //////// |          |
|     | 10 | EXCSSUID |          | EXCSSGID |          |
|     | 18 | //////// |          |          |          |

Input:

**EXCDIAGC**

is a halfword field containing the hexadecimal DIAGNOSE code, X'0280'.

**EXCFUNCD**

is a halfword field containing the function code. For this function, EXCFUNCD must contain the value of EXCSSID (1).

**EXCDWLEN**

is an unsigned halfword field containing the length of this parameter list in doublewords. The length must include the length of the header and the length of the fixed-length section. It must be no more than one page (512 doublewords) in length.

**EXCFFXLN**

is an unsigned fullword field containing the length in bytes of the fixed-length portion of the function-specific area of the control block. This area starts immediately after the header, and includes the fields up to and including field EXCSSGID (the end of the parameter list for this function).

**Reserved header fields**

The rest of the fields in the header are reserved and must contain binary zeros.

**EXCSSUID**

is an unsigned fullword field set by this function. If the function completed successfully, the field contains the current saved set-UID.

**EXCSSGID**

is an unsigned fullword field set by this function. If the function completed successfully, the field contains the current saved set-GID.

**Reserved**

The rest of the fields in this block are reserved and should contain binary zeros.

All other fields of the parameter list are reserved and should contain binary zeros. If they do not, the results of DIAGNOSE X'029C' are unpredictable.

Output: See return codes.

## Responses

Upon completion of DIAGNOSE code X'280', control is returned to the invoker with a condition code set to indicate the status of both input parameter list processing and the function requested. A return code in Ry further defines that status.

The condition code and the return code in Ry supersede all other status information, including that in the return and reason code fields in the EXCBK. Those fields are set by the server, but are only valid if the return code in Ry indicates that they should be checked for further information.

Table 235 on page 1068 contains a general description of each of the condition codes.

*Table 235. DIAGNOSE X'280' condition codes*

| Condition Code | Meaning                                                                          |
|----------------|----------------------------------------------------------------------------------|
| 0              | Function completed successfully.                                                 |
| 1              | Function failed. HCPEXCBK indicates the return and reason codes from the server. |
| 2              | Function failed. The return code in Ry indicates the reason for the failure.     |

Return codes and their corresponding condition codes for the function to set POSIX security values for an `exec()` function call are listed in Table 236 on page 1068.

| <i>Table 236. Condition codes and return codes for changing effective and saved set-IDs.</i> |                   |           |          |                                                        |
|----------------------------------------------------------------------------------------------|-------------------|-----------|----------|--------------------------------------------------------|
| Condition Code                                                                               | Return Code in Ry |           |          | Description                                            |
|                                                                                              | Decimal value     | Hex value | Symbol   |                                                        |
| 0                                                                                            | 0                 | X'00'     | EXCOK    | The function completed successfully.                   |
| 2                                                                                            | 4                 | X'04'     | EXCIDIAG | The DIAGNOSE code specified in EXCIDIAGC is incorrect. |

Table 236. Condition codes and return codes for changing effective and saved set-IDs. (continued)

| Condition Code | Return Code in Ry |           |          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------|-------------------|-----------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | Decimal value     | Hex value | Symbol   |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 2              | 8                 | X'08'     | EXCBDFUN | The function code specified in EXCFUNCD is incorrect.                                                                                                                                                                                                                                                                                                                                                                                            |

| 2              | 40                | X'28'     | EXCNORES | The resource was not found.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 2              | 44                | X'2C'     | EXCNORPY | The request was terminated because the server did not reply within the allotted time.                                                                                                                                                                                                                                                                                                                                                            |
| 2              | 48                | X'30'     | EXCNOSRV | The server is unable to handle a request for POSIX security values for one or more of the following reasons: <ul style="list-style-type: none"> <li>• the server has not identified itself as prepared to handle a request for POSIX security values</li> <li>• the server is not permitted to set POSIX security values.</li> </ul>                                                                                                             |

*Table 236. Condition codes and return codes for changing effective and saved set-IDs. (continued)*

| Condition Code | Return Code in Ry |           |          | Description                                                                                                |
|----------------|-------------------|-----------|----------|------------------------------------------------------------------------------------------------------------|
|                | Decimal value     | Hex value | Symbol   |                                                                                                            |
| 2              | 52                | X'34'     | EXCSVREJ | The server rejected the request.                                                                           |
| 1              | 56                | X'38'     | EXCSVERR | The server has returned an error condition. Refer to the return and reason codes in the EXCBK for details. |
| 2              | 60                | X'3C'     | EXCSVINV | The information the server returned was invalid.                                                           |
| 2              | 64                | X'40'     | EXCUAUTH | The user is not permitted to have his POSIX security values set.                                           |
| 2              | 68                | X'44'     | EXCESMRJ | The External Security Manager rejected the specified POSIX security values.                                |
| 2              | 72                | X'48'     | EXCNOCOM | There is no POSIX communication area defined.                                                              |
| 2              | 76                | X'4C'     | EXCNPROC | There is no valid active POSIX process for which to change the POSIX security values.                      |
| 2              | 80                | X'50'     | EXCTERM  | The request was terminated at the user's request (for example, by an exigent command).                     |
| 2              | 255               | X'FF'     | EXCFATAL | An unrecoverable error occurred while processing the DIAGNOSE and a soft abend dump may have been taken.   |

Return codes and their corresponding condition codes for the function to set saved set-IDs for an `exec()` function call are listed in [Table 237 on page 1070](#).

*Table 237. Condition codes and return codes for changing saved set-IDs only.*

| Condition Code | Return Code in Ry |           |          | Description                                           |
|----------------|-------------------|-----------|----------|-------------------------------------------------------|
|                | Decimal value     | Hex value | Symbol   |                                                       |
| 0              | 0                 | X'00'     | EXCOK    | The function completed successfully.                  |
| 2              | 4                 | X'04'     | EXCIDIAG | The DIAGNOSE code specified in EXCDIAGC is incorrect. |
| 2              | 8                 | X'08'     | EXCBDFUN | The function code specified in EXCFUNCD is incorrect. |
| 2              | 12                | X'0C'     | EXCNZERO | Reserved fields do not contain binary zeros.          |

| 2              | 72                | X'48'     | EXCNOCOM | There is no POSIX communication area defined.                                                                                                                                                                                                                                                                                                                                                                                                     |
| 2              | 76                | X'4C'     | EXCNPROC | There is no valid active POSIX process for which to change the POSIX security values.                                                                                                                                                                                                                                                                                                                                                             |
| 2              | 255               | X'FF'     | EXCFATAL | An unrecoverable error occurred while processing the DIAGNOSE and a soft abend dump may have been taken.                                                                                                                                                                                                                                                                                                                                          |

**Program Exceptions:** One of the following program exceptions may be reflected to the issuing virtual machine indicating guest or host error conditions. In all cases, no meaningful return code is given, and the guest instruction (Diagnose) is nullified, suppressed, or terminated according to the architecture.

DIAGNOSE code X'280' may result in one of the following program exceptions:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                               |

| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | Attempt to fetch from or store into the HCPEXCBK failed.<br><br>Regardless of the value of EXCDWLEN, an access exception may be recognized for a minimum of one doubleword at the EXCBK address. Conversely, an access exception may not be recognized for the portion of the operand beyond the length supported by CP for the function requested. |

## DIAGNOSE Code X'29C' – Set-POSIX-IDs Services

**Privilege Class:** Any

## Addressing Mode: 24-bit or 31-bit

DIAGNOSE X'29C' specifies one of several function codes that designate Set-POSIX-IDs services. The services alter the user IDs (UIDs) and group IDs (GIDs) of the active POSIX process. DIAGNOSE code X'29C' uses the parameter list (SPXBK) to receive input data and, depending on the function requested, to return results. The SPXBK and the codes named below are defined in member HCPSPXBK and HCPOM1 MACLIB.

Any virtual machine can use this diagnose. However certain operations are privileged and require either permission from an External Security Manager (ESM) or authorization in the CP directory.

The following Set-POSIX-IDs services can be invoked using this DIAGNOSE code:

- Set user IDs (UIDs) for the active process — function code SPXFUSER (0)
- Set group IDs (GIDs) for the active process — function code SPXFGRP (1)
- Change the active process' GIDs to designate another group to which the logged-on user belongs — function code SPXFNGRP (2)
- Change the active process' supplementary group id list — function code SPXFSGID (3)

Entry Values:

### Rx

The real address of a function parameter list (SPXBK) in guest storage. The SPXBK must be on a doubleword boundary. The format of the parameter list is determined by the function code which is also in the parameter list. The SPXBK contains all the input parameters.

### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the parameter list. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the parameter list is in the host-primary address space.

### Active Process ID

The active process is specified in the active process ID (PID) field in the POSIX communication area. (Before DIAGNOSE X'29C' is used, DIAGNOSE X'2A4' must have been issued in this virtual configuration to define this area and to allocate one or more PIDs.)

Exit Values:

### Ry

On return, contains a return code. Ry can not be the same as Rx.

Format of the HCPSPXBK:

|     |          |        |          |        |        |
|-----|----------|--------|----------|--------|--------|
| Dec |          |        |          |        |        |
| 0   | SPXDIAGC | SPXFCD | SPXDWLEN | :FLAGS | :RSVD1 |
| 8   | SPXUID   |        | SPXGID   |        |        |
| 16  | SPXGNAME |        |          |        |        |

## Function SPXFUSER - Set User IDs (UIDs) for the Active Process

This function sets the effective user ID (UID) for the active POSIX process to a given user ID. For a process with appropriate privileges, this function optionally sets the real and saved set-user-IDs for the process to that same user ID as well.

Input:

### SPXDIAGC

Contains the hexadecimal DIAGNOSE code, SPXDIAGV (value X'029C').

### SPXFCD

Contains the function code, SPXFUSER (value 0).

### SPXDWLEN

Contains the length of this parameter list in doublewords. this value must be at least 2.

**SPXFLAGS**

Contains flags as follows:

**SPXALLID**

(bit 1) If this bit is on and the active process has appropriate privileges, set all three UID(s) (real, effective, and saved set). If this bit is off, only the effective UID is changed.

If the process is not authorized, this bit is ignored. Only the effective UID is changed.

All other flag bits must be binary zeros.

**SPXRSVD1**

Reserved for IBM used; must contain binary zeros.

**SPXUID**

Value to which this process' UID(s) are to be changed. If this process does not have appropriate privileges, then this must be the process' current real or saved set-UID.

All other fields of the parameter list are reserved and should contain binary zeros. If they do not, the results of DIAGNOSE X'029C' are unpredictable.

Output: See return codes.

**Return Codes for Set User IDs for the Active Process:****SPXEOK (0)**

Effective UID has been changed. Real and saved set-UIDs have not been changed.

**SPXEOKAL (10)**

Real, effective, and saved set-UIDs have been changed (not presented unless SPXALLID is specified).

**SPXECODE (1)**

Incorrect value in SPXDIAGC.

**SPXEFUNC (2)**

Invalid function code in SPXFCODE.

**SPXELEN (3)**

Length in SPXDWLEN is below the minimum allowed.

**SPXEFLAG (4)**

Invalid option flags in SPXFLAGS or SPXRSVD1 field is nonzero.

**SPXEPXCA (11)**

POSIX communication area has not been defined.

**SPXEAPID (12)**

Active PID in POSIX communication area is not a PID allocated to the requesting virtual configuration.

**SPXEID (8)**

External Security Manager (ESM) has rejected the specified UID as invalid.

**SPXEAUTH (5)**

Active process not authorized to change to specified UID.

**SPXENFND (6)**

Specified user ID or user name not found in user database.

**SPXEDBAS (9)**

User database is invalid or inaccessible.

See Program Exceptions and Machine Checks for possible guest interruptions.

**Note:** When an External Security Manager (ESM) is not installed or defers the decision to CP, CP will consider a process to have appropriate privileges to change all IDs (SPXALLID) and to set IDs to a value other than the real or saved set-ID if and only if the process' effective UID is 0.

## Function SPXFGRP - Set Group IDs (GIDs) for the Active Process

This function sets the effective group ID (GID) for the active POSIX process to a given group ID. For an authorized process, this function optionally sets the real and saved set-group-IDs for the process to that same group ID as well.

Input:

### **SPXDIAGC**

Contains the hexadecimal DIAGNOSE code, SPXDIAGV (value X'029C').

### **SPXFCODE**

Contains the function code, SPXFGRP (value 1).

### **SPXDWLEN**

Contains the length of this parameter list in doublewords. This value must be at least 3.

### **SPXFLAGS**

Contains flags as follows:

#### **SPXALLID**

(bit 1) If this bit is on and the active process has appropriate privileges, set all three GIDs (real, effective, and saved set-ID). If this bit is off, only the effective GID is changed.

If the process does not have appropriate privileges, this bit is ignored. Only the effective GID is changed.

#### **SPXNAMIN**

(bit 2) If this bit is on, set the GID(s) to the GID associated with the group name specified in SPXGNAME.

#### **SPXIDIN**

(bit 3) If this bit is on, set the GID(s) to the value specified in SPXGID.

Exactly one of SPXNAMIN and SPXIDIN must be set. All other flag bits not listed must be binary zeros.

### **SPXRSVD1**

Reserved for IBM use; must contain binary zeros.

### **SPXGID**

Value to which this process' GID(s) are to be changed when SPXNAMIN is on. If this process does not have appropriate privileges, then this must be the process' current real or saved set-GID. This field is ignored when SPXNAMIN is off.

### **SPXGNAME**

Group name to whose GID this process' GID(s) are to be changed, when SPXNAMIN is on. If this process does not have appropriate privileges, then this name must correspond to the process' current real or saved set-GID. This field is ignored when SPXNAMIN is off.

All other fields of the parameter list are reserved and should contain binary zeros. If they do not, the results of DIAGNOSE X'029C' are unpredictable.

Output: See return codes.

Return Codes for Set Group IDs for the Active Process:

#### **SPXEOK (0)**

Effective GID has been changed. Real and saved set-GIDs have not been changed.

#### **SPXEOKAL (10)**

Real, effective, and saved set-GIDs have been changed (not presented unless SPXALLID is specified).

#### **SPXECODE (1)**

Incorrect value in SPXDIAGC.

#### **SPXEFUNC (2)**

Invalid function code in SPXFCODE.

#### **SPXELEN (3)**

Length in SPXDWLEN is below the minimum allowed.

**SPXEFLAG (4)**

Invalid option flags in SPXFLAGS or SPXRSVD1 field is nonzero.

**SPXEPXCA (11)**

POSIX communication area has not been defined.

**SPXEAPID (12)**

Active PID in POSIX communication area is not a PID allocated to the requesting virtual configuration.

**SPXEID (8)**

External Security Manager (ESM) has rejected the specified GID as invalid.

**SPXEAUTH (5)**

Active process not authorized to change to specified group.

**SPXENFND(6)**

Specified group ID or group name not found in group database.

**SPXEDBAS (9)**

Group database is invalid or inaccessible

See Program Exceptions and Machine Checks for possible guest interruptions.

**Notes:**

1. When an External Security Manager (ESM) is not installed or defers the decision to CP, CP will consider a process to have appropriate privileges to change all IDs (SPXALLID) and to set IDs to a value other than the real or saved set-ID if and only if the process' effective user ID (UID) is 0.
2. This function does not change any supplementary group IDs of the process.

## Function SPXFNGRP – Change to a New Group

This function changes the real, effective and saved set-group-IDs (GIDs) for the active POSIX process to a specified GID or to the GID associated with a specified group name, or resets them to their database value. If a GID or group name is specified, the requesting virtual configuration's login name must be a member of the specified group.

Input:

**SPXDIAGC**

Contains the hexadecimal DIAGNOSE code, SPXDIAGV (value X'029C').

**SPXF CODE**

Contains the function code, SPXFNGRP (value 2).

**SPXDWLEN**

Contains the length of this parameter list in doublewords. This value must be at least 3.

**SPXFLAGS**

Contains flags as follows:

**SPXNAMIN**

(bit 2) If this bit is on, set the real, effective and saved set-GIDs to the GID associated with the group name specified in SPXGNAME.

**SPXIDIN**

(bit 3) If this bit is on, set the real, effective and saved set-GIDs to the value specified in SPXGID.

All other flag bits must be binary zeros.

It is not valid to set both SPXIDIN and SPXNAMIN on. If both SPXIDIN and SPXNAMIN are off, then the real, effective and saved-set GIDs will be reset to the GID assigned to the user in the user's database entry.

**SPXRSVD1**

Reserved for IBM use; must contain binary zeros.

**SPXGID**

Value to which this process' GIDs are to be changed when SPXIDIN is on. The virtual configuration's user name must be a member of a group with which this GID is associated. If more than one group is assigned to this GID, it is unpredictable which of them is considered to be associated with the GID. This field is ignored when SPXIDIN is off.

**SPXGNAME**

Group name to whose GID this process' GIDs are to be changed, when SPXNAMIN is on. The virtual configuration's login name must be a member of this group. This field is ignored when SPXNAMIN is off.

All other fields of the parameter list are reserved and should contain binary zeros. If they do not, the results of a DIAGNOSE X'029C' are unpredictable.

Output:

When return code is SPXEOK:

SPXGID is set to the new value of the real, effective, and save-set GIDs. (This is the unchanged input value if SPXIDIN was on, or the GID corresponding to SPXGNAME if SPXNAMIN was on, or the database value if both flags were off.)

Return Codes for Change to a New Group:

**SPXEOK (0)**

Real, effective and saved set-GIDs have been set as requested. SPXGID contains the GID value to which they were set.

**SPXECODE (1)**

Incorrect value in SPXDIAGC.

**SPXEFUNC (2)**

Invalid function code in SPXFCODE.

**SPXELEN (3)**

Length in SPXDWLEN is below the minimum allowed.

**SPXEFLAG (4)**

Invalid option flags in SPXFLAGS or SPXRSVD1 field is nonzero.

**SPXEPXCA (11)**

POSIX communication area has not been defined.

**SPXEAPID (12)**

Active PID in POSIX communication area is not a PID allocated to the requesting virtual configuration.

**SPXEID (8)**

External Security Manager (ESM) has rejected the specified GID as invalid.

**SPXENFND (6)**

Specified group ID or group name not found in group database.

**SPXEAUTH (5)**

Requesting login name is not a member of the specified group.

**SPXEDBAS**

Group database is invalid or inaccessible.

See Program Exceptions and Machine Checks for possible guest interruptions.

**Notes:**

1. If a user belongs to more than {NGROUPS\_MAX} groups, or the database has changed since the process was created, or an External Security Manager (ESM) authorizes the request, then function SPXFNGRP may be issued specifying a group which is not in the process' supplementary GID list. If CP performs the authorization checks, the only requirement is that the user be a member of the specified group. An ESM may have additional or different authorization rules.
2. This function does not change any supplementary group IDs of the process.

## Function SPXFSGID — Change the supplementary group ID list

This function changes supplementary group ID list (SGID list) for the active POSIX process to the list specified. This function is used in conjunction with function codes 0 and 1 or 2 to change the identity of the active process to that of a particular user. The active process must have appropriate privileges to use this function.

Input:

### **SPXDIAGC**

Contains the hexadecimal DIAGNOSE code, SPXDIAGV (value X'029C').

### **SPXFCODE**

Contains the function code, SPXFSGID (value 3).

### **SPXDWLEN**

Contains the length of this parameter list in doublewords. This value must be at least 3.

### **SPXFLAGS**

Must contain binary zeros.

### **SPXRSVD1**

Reserved for IBM use; must contain binary zeros.

### **SPXSGCNT**

Contains the size of the SGID-list area in units of 4 bytes, or zero if the SGID list is to be cleared. Note: the SGID list for the active process will contain only the effective GID if the count is specified as zero. To return the SGID list to its database values, the DIAGNOSE issuer must request that information from the database via DIAGNOSE code X'2A0' and then explicitly set the values via this function code.

### **SPXSGAL**

When SPXSGCNT is not zero, contains the ALET for the address space in which the SGID-list area resides. This field is used only by XC virtual machines in access-register mode.

### **SPXSGAD**

When SPXSGCNT is not zero, contains the address of the SGID-list area. It is unpredictable whether this address is treated as guest real or guest absolute.

All other fields of the parameter list are reserved and should contain binary zeros. If they do not, the results of a DIAGNOSE code X'029C' are unpredictable.

Output:

When return code is SPXEOK:

The active processes's SGID list is set to that specified on this diagnose.

Return Codes for Change the Supplementary Group ID List:

### **SPXEOK (0)**

The active processes's supplementary group ID list has been changed as requested.

### **SPXECODE (1)**

Incorrect value in SPXDIAGC.

### **SPXEFUNC (2)**

Invalid function code in SPXFCODE.

### **SPXELEN (3)**

Length in SPXDWLEN is below the minimum allowed.

### **SPXEFLAG (4)**

Invalid option flags in SPXFLAGS or SPXRSVD1 field is nonzero.

### **SPXEAUTH (5)**

The user is not authorized to perform this function.

### **SPXEPXCA (11)**

POSIX communication area has not been defined.

**SPXEAPID (12)**

Active PID in POSIX communication area is not a PID allocated to the requesting virtual configuration.

**SPXERRCP (13)**

Active PID in POSIX communication area is not a PID allocated

See Program Exceptions and Machine Checks for possible guest interruptions.

## Responses

**Program Exceptions and Machine Checks:** One of the following Program Exceptions or Machine Checks may be reflected to the issuing virtual machine indicating guest or host error conditions. In all cases, no meaningful return code is given, and the guest instruction (Diagnose) is nullified, suppressed, or terminated according to the architecture.

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                            |

## DIAGNOSE Code X'2A0' – Query POSIX IDs

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE code X'2A0' specifies one of several function codes that designate Query-POSIX-ID services. DIAGNOSE code X'2A0' uses the parameter list (QPXBK) to receive input data and return output data. Optionally the services return information to another guest-specified data area.

Any virtual machine can use this DIAGNOSE. However functions which interrogate information about other users or groups may require permission from an External Security Manager (ESM), if any, or authorization in the CP directory or system configuration definition.

The following Query-POSIX-ID data functions can be invoked using this DIAGNOSE code:

- Query process attributes — function code QPXFPROC (value 0)
- Query the user database — function code QPXFUSER (value 1)
- Query the group database — function code QPXFGRP (value 2)
- Query the supplementary group IDs (SGIDs) for the active process or for a given user name — function code QPXFSGID (value 3)
- Query POSIX configuration information — function code QPXFCNF (value 4)

Entry Values:

**Rx**

The real address of a function parameter list (QPXBK) in guest storage. The QPXBK must be on a doubleword boundary. The format of the parameter list is determined by the function code. The QPXBK contains all the input parameters.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the parameter list. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the parameter list is in the host-primary address space.

**Active Process ID**

The active process is specified in the active process ID (PID) field in the POSIX communication area. (Before DIAGNOSE code X'2A0' is used, DIAGNOSE code X'2A4' must have been issued in this virtual configuration to define this area and to allocate one or more PIDs.)

Exit Values:

**Rx**

The real address of the function parameter list supplied as input. If sufficient length (QPXDWLEN) is specified, the parameter list output area contains the values of the DIAGNOSE function. The format of this output parameter list is function dependent.

**Ry**

On return, contains a return code. Ry can not be register 15 and can not be the same as Rx.

**Ry+1**

On return, contains additional information based on the function requested. Ry+1 can not be same as Rx.

## Function QPXFPROC - Query Process Attributes

This function returns the real, effective, and saved set IDs of the active POSIX process or of a specified process within the requesting virtual configuration (specified by a process ID (PID)).

Format of the HCPQPXBK for Query Process Attributes:

|     |                                      |        |                                      |       |       |
|-----|--------------------------------------|--------|--------------------------------------|-------|-------|
| Dec |                                      |        |                                      |       |       |
| 0   | QPXDIAGC                             | QPXFCD | QPXDWLEN                             | FLAGS | RSVD1 |
| 8   | QPXPID                               |        | //////////////////////////////////// |       |       |
| 16  | //////////////////////////////////// |        |                                      |       |       |
| 24  | QPXRUID                              |        | QPXRGID                              |       |       |
| 32  | QPXEUID                              |        | QPXEGID                              |       |       |
| 40  | QPXSSUID                             |        | QPXSSGID                             |       |       |

Input:

**QPXDIAGC**

Contains the hexadecimal DIAGNOSE code, QPXDIAGV (value X'02A0').

**QPXFCD**

Contains the function code, QPXFPROC (value 0).

**QPXDWLEN**

Contains the length of this parameter list in doublewords. This value must be at least 6.

**QPXFLAGS**

Contains flags as follows:

**QPXIDIN**

(bit 0) If this bit is on then report on the process whose PID is specified in QXPID. If it is off then report on the active process.

All other flag bits must be binary zeros.

**QPXRSVD1**

Reserved for IBM use; must contain binary zeros.

**QXPID**

Contains the process ID (PID) of the target process. This PID must have been allocated to the requesting virtual configuration (with DIAGNOSE code X'2A4'). QXPID is used only if QPXIDIN is on.

All fields of the parameter list not listed by name are reserved and should contain binary zeros. If they do not, the results of DIAGNOSE code X'2A0' are unpredictable.

Output: When the return code is QPXEOK, the following information is returned:

**QXRUID**

Set to the real user ID of the target process.

**QXRUID**

Set to the real group ID of the target process.

**QPXEUID**

Set to the effective user ID of the target process.

**QPXEGID**

Set to the effective group ID of the target process.

**QPXSUID**

Set to the saved set-user-ID of the target process.

**QPXSUID**

Set to the saved set-group-ID of the target process.

**Ry+1**

Set to the meaningful length of the QPXBK in bytes (the offset just beyond the last output field in).

Return Codes for Query Process Attributes:

**QPXEOK (0)**

Output fields have been set.

**QPXECODE (1)**

Incorrect value in QPXDIAGC.

**QPXEFUNC (2)**

Invalid function code in QPXFCODE.

**QPXELEN (3)**

Length in QPXDWLEN is below the minimum allowed.

**QPXEFLAG (4)**

Invalid option flags in QPXFLAGS or QPXRSVD1 field is nonzero.

**QPXEPXCA (10)**

POSIX communication area has not been defined.

**QPXEAPID (11)**

Active PID in POSIX communication area is not a PID allocated to the requesting virtual configuration.

**QPXENFND (6)**

Process id QXPID was not found. (The PID does not exist or was not allowed to the requesting virtual configuration.)

See Program Exceptions and Machine Checks for possible guest interruptions.

## Function QPXFUSER - Query the User Database

This function gets the POSIX attributes of a user. You can specify the user by POSIX user ID (UID) or user name.

To be authorized to obtain a user database entry, either:

- the ESM must grant the requestor authority to read the entry, or
- the ESM must not be installed or must defer authorization to CP, and
  - the UID in the entry must match the active process's real or effective UID, or

- the active process's effective UID must be 0, or
- the requesting VM user ID must have the attribute POSIXOPT QUERYDB ALLOW, either through a statement in its CP directory entry or through a setting, specified or defaulted, in the system configuration file, which is not overridden in the directory entry, or
- the requesting VM user ID is requesting information about themselves.

Format of the HCPQPXBK for Query the User Database:

|     |          |          |                                      |       |       |
|-----|----------|----------|--------------------------------------|-------|-------|
| Dec |          |          |                                      |       |       |
| 0   | QPXDIAGC | QPXFCDCE | QPXDWLEN                             | FLAGS | RSVD1 |
| 8   | QPXUID   |          | QPXGID                               |       |       |
| 16  | QPXUNAME |          |                                      |       |       |
| 24  | QPXGNAME |          |                                      |       |       |
| 32  | QPXUDBAL |          | QPXUDBAD                             |       |       |
| 40  | QPXUDBSZ |          | //////////////////////////////////// |       |       |

Input:

#### **QPXDIAGC**

Contains the hexadecimal DIAGNOSE code, QPXDIAGV (value X'02A0').

#### **QPXFCDCE**

Contains the function code, QPXFUSER (value 1).

#### **QPXDWLEN**

Contains the length of this parameter list in doublewords. This value must be at least 6.

#### **QPXFLAGS**

Contains flags as follows:

##### **QPXIDIN**

(bit 0) If this bit is on then report on the UID specified in QPXUID.

##### **QPXNAMIN**

(bit 1) If this bit is on then report on the user name specified in QPXUNAME.

If neither of these flags are set, information is returned on the current POSIX process environment.

If no process environment has been established, information is returned on the default POSIX environment for the issuing user ID, or for the alternate user ID if one has been established.

#### **QPXRSVD1**

Reserved for IBM use; must contain binary zeros.

#### **QPXUID**

Contains the search argument user ID. QPXUID is used only if QPXIDIN is on.

#### **QPXUNAME**

Contains the search argument user name. QPXUNAME is used only if QPXNAMIN is on.

#### **QPXUDBAL**

When QPXUDBSZ is not zero, contains the ALET for the address space in which a user-database information area resides. This field is used only in XC virtual machine access-register mode.

#### **QPXUDBAD**

When QPXUDBSZ is not zero, contains the address of a user-database information area. It is unpredictable whether this address is treated as guest real or guest absolute.

#### **QPXUDBSZ**

Contains the size of the user-database information area in bytes, or zero if user-database information is not to be returned.

All fields of the parameter list not listed by name are reserved and should contain binary zeros. If they do not, the results of DIAGNOSE code X'2A0' are unpredictable.

Output:

When the return code is QPXEOK, the following information is returned in the parameter list and user-database area:

**QPXUID**

Set to the user ID corresponding to the given QPXUNAME when QPXNAMIN is on. Set to the user ID corresponding to the current user name when QPXIDIN and QPXNAMIN are off and no POSIX environment exists.

**QPXGID**

Set to the primary group ID assigned to this user.

**QPXUNAME**

Set to the user name corresponding to the given QPXUID when QPXIDIN is on. Set to the user name corresponding to the given QPXUNAME when QPXNAMIN is on; in this case, the input QPXUNAME and the output QPXUNAME can be different. Set to the user name corresponding to the current user's UID when QPXIDIN and QPXNAMIN are off and a POSIX environment exists.

**QPXGNAME**

Set to the primary group name assigned to this user.

When QPXUDBSZ is not zero, the user-database information area contains the following data in immediate succession.

***iwdir length***

Four-byte field containing the length of the user's initial working directory.

***iwdir***

Contains the user's initial working directory. It is a variable-length string of characters from 0 to 1023 bytes long.

***iupgm length***

Four-byte field containing the length of the user's initial user program. It immediately follows the end of IWDIR.

***iupgm***

Contains the user's initial user program, a variable-length string of characters from 0 to 1023 bytes long.

***fsroot length***

Four-byte field containing the length of the user's file system root. It immediately follows the end of the IUPGM.

***fsroot***

Contains the name of a user's file system root, a variable-length string of characters from 0 to 1023 bytes long.

***ffffff***

Contains a four-byte value X'FFFFFFFF' as end-of-data delimiter.

These string values are not null-terminated; that is, they do not end in the null character (X'00'). String values not specified in the user database entry are returned as null strings (length zero).

When the return code is QPXEOLEN, the following information is returned:

**Ry + 1**

Set to the actual length required for the user-database area, in bytes.

When the return code is not QPXEOK, the contents of any portion of the user-database information area which is not subject to an access exception are unpredictable.

Return Codes for Query the User Database:

**QPXEOK (0)**

Output fields have been set.

**QPXECODE (1)**

Incorrect value in QPXDIAGC.

**QPXEFUNC (2)**

Invalid function code in QPXFCODE.

**QPXELEN (3)**

Length in QPXDWLEN is below the minimum allowed.

**QPXEFLAG (4)**

Invalid option flags in QPXFLAGS, or QPXRSD1 field is nonzero.

**QPXEPXCA (10)**

POSIX communication area has not been defined.

**QPXEAPID (11)**

Active PID in POSIX communication area is not a PID allocated to the requesting virtual configuration.

**QPXEAUTH (5)**

Requestor is not authorized to obtain requested information.

**QPXENFND (6)**

Specified UID or UNAME is not found in user database.

**QPXEOLEN (7)**

User-database information area size specified in QPXUDBSZ is too small to contain the information.

The actual length required, in bytes, is returned in register Ry+1.

**QPXEOADR (8)**

The ALET or address range of the user-database information area is invalid, or the designated area is protected against storing.

**QPXEDBAS (9)**

The user database contents are invalid or inaccessible.

See Program Exceptions and Machine Checks for possible guest interruptions.

**Notes:**

1. If the QPXIDIN flag is on, the information returned is from a random CP directory entry or External Security Manager (ESM) entry which contains a UID matching the specified UID. If there is more than one such entry, it is unpredictable which one is returned.
2. If the named user has no UID defined in the CP directory entry or the ESM user database, the default value 4294967295 (X'FFFFFFFF') is returned in the QPXUID field.
3. If the named user has no GID defined in the CP directory entry or the ESM user database, the default value 4294967295 (X'FFFFFFFF') is returned in the QPXGID field.
4. If both QPXIDIN and QPXNAMIN are OFF, this command can be used to query information about yourself without starting the POSIX environment.

## Function QPXFGRP - Query the Group Database

This function gets the attributes of a given group ID (GID) or POSIX group name, and optionally, a list of its members.

To be authorized to obtain a group database entry, either

- the ESM must grant the requestor authority to read the entry, or
- the ESM must not be installed or must defer authorization to CP, and
  - the active process's effective UID must be 0, or
  - the active process's real or effective GID must match the GID of the designated group, or
  - the requesting user name must be a member of the designated group, or

## DIAGNOSE X'2A0'

- the requesting VM user ID must have the attribute POSIXOPT QUERYDB ALLOW, either through a statement in its CP directory entry or through a setting, specified or defaulted, in the system configuration file, which is not overridden in the directory entry.

Format of the HCPQPBK for Query the Group Database:

|     |    |                                             |          |          |       |       |
|-----|----|---------------------------------------------|----------|----------|-------|-------|
| Dec | 0  | QPXDIAGC                                    | QPXFCDCE | QPXDWLEN | FLAGS | RSVD1 |
|     | 8  | //////////////////////////////////// QPXGID |          |          |       |       |
|     | 16 | ////////////////////////////////////        |          |          |       |       |
|     | 24 | QPXGNAME                                    |          |          |       |       |
|     | 32 | QPXUNMAL                                    |          | QPXUNMAD |       |       |
|     | 40 | QPXUNMSZ                                    |          | QPXUNMCT |       |       |

Input:

### QPXDIAGC

Contains the hexadecimal DIAGNOSE code, QPXDIAGV (value X'02A0').

### QPXFCDCE

Contains the function code, QPXFGRP (value 2).

### QPXDWLEN

Contains the length of this parameter list in doublewords. This value must be at least 6.

### QPXFLAGS

Contains flags as follows:

#### QPXIDIN

(bit 0) If on then report on the group with GID as specified in QPXGID.

#### QPXNAMIN

(bit 1) If on then report on the group name specified in QPXGNAME.

Exactly one of these bits must be set. All other flag bits must be binary zeros.

### QPXRSVD1

Reserved for IBM use; must contain binary zeros.

### QPXGID

Contains the search argument group id. QPXGID is used only if QPXIDIN is on.

If there are multiple groups associated with this GID, then it is unpredictable which of them is considered the designated group.

### QPXGNAME

Contains the search argument group name. QPXGNAME is used only if QPXNAMIN is on.

### QPXUNMSZ

Contains the size of the member-list area in units of 8 bytes, or zero if no member list is to be returned.

### QPXUNMAL

When QPXUNMSZ is not zero, contains the ALET for the address space in which the member-list area resides. This field is used only by XC virtual machines in access-register mode.

### QPXUNMAD

When QPXUNMSZ is not zero, contains the address of the member-list area. It is unpredictable whether this address is treated as guest real or guest absolute.

All fields of the parameter list not listed by name are reserved and should contain binary zeros. If they do not, the results of DIAGNOSE code X'02A0' are unpredictable.

Output:

When the return code is QPXEOK, the following information is returned in the parameter list and member-list area:

**QPXGID**

Set to the group ID corresponding to the given QPXGNAME when QPXNAMIN is on, unchanged otherwise.

**QPXGNAME**

Set to the group name corresponding to the given QPXGID when QPXIDIN is on, unchanged otherwise.

**QPXUNMCT**

Set to the actual count of members in the group.

When QPXUNMSZ is not zero, an array of user names which belong to the designated group is stored in the member-list area. Each name is left-justified and blank-padded to 8 bytes.

When the return code is QPXEOLEN, the following information is returned in the parameter list:

**QPXUNMCT**

Set to the actual length required for the member-list area in units of 8 bytes.

When the return code is not QPXEOK, the contents of any portion of the member-list area which is not subject to an access exception is unpredictable.

Return Codes for Query the Group Database:

**QPXEOK (0)**

Output fields have been set.

**QPXECODE (1)**

Incorrect value in QPXDIAGC.

**QPXEFUNC (2)**

Invalid function code in QPXFCODE.

**QPXELEN (3)**

Length in QPXDWLEN is below the minimum allowed.

**QPXEFLAG (4)**

Invalid option flags in QPXFLAGS or QPXRSD1 field is nonzero.

**QPXEPXCA (10)**

POSIX communication area has not been defined.

**QPXEAPID (11)**

Active PID in POSIX communication area is not a PID allocated to the requesting virtual configuration.

**QPXEAUTH (5)**

Requestor is not authorized to obtain requested information.

**QPXENFND (6)**

Specified group ID or group name not found in group database.

**QPXEOLEN (7)**

Value in QPXUNMSZ is not zero but is smaller than the number of members in the group. The member-list area is too small. Output fields have been set.

**QPXEOADR (8)**

The ALET or address range of the member-list area is invalid, or the designated area is protected against storing.

**QPXEDBAS (9)**

The group database contents are invalid or inaccessible.

See Program Exceptions and Machine Checks for possible guest interruptions.

## Function QPXFSGID - Query the Supplementary Group IDs

This function gets the number, and optionally the list, of supplementary group IDs (SGIDs) currently associated with the active POSIX process, or associated with the given user name in the user database.

## DIAGNOSE X'2A0'

A process is always authorized to obtain its own SGID list. To be authorized to obtain a SGID list for a user name either

- the ESM must grant the requestor authority to obtain the list, or
- the ESM must not be installed or must defer authorization to CP, and
  - the UID in the entry must match the active process's real or effective UID, or
  - the active process's effective UID must be 0, or
  - the requesting VM user ID must have the attribute POSIXOPT QUERYDB ALLOW, either through a statement in its CP directory entry or through a setting, specified or defaulted, in the system configuration file, which is not overridden in the directory entry.

Format of the HCPQPXBK for Query the Group Database:

|     |    |                                  |                                  |          |       |       |
|-----|----|----------------------------------|----------------------------------|----------|-------|-------|
| Dec | 0  | QPXDIAGC                         | QPXFCDL                          | QPXDWLEN | FLAGS | RSVD1 |
|     | 8  | //////////////////////////////// | //////////////////////////////// |          |       |       |
|     | 16 | QPXUNAME                         |                                  |          |       |       |
|     | 24 | //////////////////////////////// |                                  |          |       |       |
|     | 32 | QPXGIDAL                         |                                  | QPXGIDAD |       |       |
|     | 40 | QPXGIDSZ                         |                                  | QPXGIDCT |       |       |

Input:

### QPXDIAGC

Contains the hexadecimal DIAGNOSE code, QPXDIAGV (X'02A0').

### QPXFCDL

Contains the function code, QPXFSGID (value 3).

### QPXDWLEN

Contains the length of this parameter list in doublewords. This value must be at least 6.

### QPXFLAGS

Contains flags as follows:

#### QPXNAMIN

(bit 1) If on then report the information from the user database on the user name specified in QPXUNAME. If off then report the current attributes of the active process.

All other flag bits must be binary zeros.

### QPXRSVD1

Reserved for IBM use; must contain binary zeros.

### QPXUNAME

Contains the search argument user name. QPXUNAME is used only if QPXNAMIN is on.

### QPXGIDSZ

Contains the size of the SGID-list area in units of 4 bytes, or zero if no SGID list is to be returned.

### QPXGIDAL

When QPXGIDSZ is not zero, contains the ALET for the address space in which the SGID-list area resides. This field is used only by XC virtual machines in access-register mode.

### QPXGIDAD

When QPXGIDSZ is not zero, contains the address of the SGID-list area. It is unpredictable whether this address is treated as guest real or guest absolute.

All fields of the parameter list not listed by name are reserved and should contain binary zeros. If they do not, the results of DIAGNOSE code X'02A0' are unpredictable.

Output:

When the return code is QPXEOK, the following information is returned in the parameter list and SGID-list area:

**QPXGIDCT**

Set to the actual count of SGIDs stored in the SGID-list area or count of SGIDs assigned if QPXGIDSZ=0.

When QPXGIDSZ is not zero, an array of 4-byte unsigned supplementary group IDs assigned to the designated process or user is stored in the SGID-list area.

When the return code is QPXEOADR, the contents of any portion of the SGID-list area which is not subject to an access exception is unpredictable.

Return Codes for Query the Supplementary Groups IDs:

**QPXEOK (0)**

Output fields have been set.

**QPXECODE (1)**

Incorrect value in QPXDIAGC.

**QPXEFUNC (2)**

Invalid function code in QPXFCODE.

**QPXELEN (3)**

Length in QPXDWLEN is below the minimum allowed.

**QPXEFLAG (4)**

Invalid option flags in QPXFLAGS or QPXRSD1 field is nonzero.

**QPXEPXCA (10)**

POSIX communication area has not been defined.

**QPXEAPID (11)**

Active PID in POSIX communication area is not a PID allocated to the requesting virtual configuration.

**QPXEAUTH (5)**

Requestor is not authorized to obtain requested information.

**QPXENFND (6)**

Specified user name not found in user database. Returned only when QPXNAMIN is on.

**QPXEOLEN (7)**

Value in QPXGIDSZ is not zero but is too small to contain the SGID-list. The actual length required is returned in QPXGIDCT, in units of 4 bytes.

**QPXEOADR (8)**

The ALET or address range of the SGID-list area is invalid, or the designated area is protected against storing.

**QPXEDBAS (9)**

The user database contents are invalid or inaccessible. Returned only when QPXNAMIN is on.

See Program Exceptions and Machine Checks for possible guest interruptions.

**Note:**

1. The list of the supplementary group IDs is only returned to the storage area pointed to by QPXGIDAD if the number in the QPXGIDSZ field is greater than or equal to the total number of supplementary group IDs for the specified user name or process.

## Function QPXFCNF - Query POSIX Configuration Information

This function returns POSIX system configuration parameters and environmental information.

Format of the HCPQPBK for Query POSIX Configuration Information:

|     |          |          |          |       |       |
|-----|----------|----------|----------|-------|-------|
| Dec |          |          |          |       |       |
| 0   | QPXDIAGC | QPXFCODE | QPXDWLEN | FLAGS | RSVD1 |
| 8   | QPXNGMAX |          | QPXRSD2  |       |       |
| 16  | QPXUNAME |          |          |       |       |

Input:

## DIAGNOSE X'2A0'

### QPXDIAGC

Contains the hexadecimal DIAGNOSE code, QPXDIAGV (value X'02A0').

### QPXFCD

Contains the function code, QPXFCNF (value 4).

### QPXDWLEN

Contains the length of this parameter list in doublewords. This value must be at least 3.

### QPXFLGS

All flag bits must be binary zeros.

### QPXRSVD1

Reserved for IBM use; must contain binary zeros.

All fields of the parameter list not listed by name are reserved and should contain binary zeros. If they do not, the results of DIAGNOSE code X'02A0' are unpredictable.

Output:

When the return code is QPXOK, the following information is returned:

### Ry + 1

Set to the meaningful length of the QPXBK in bytes (the offset just beyond the last output filled in).

### QPXNGMAX

Set to the POSIX {NGROUPS\_MAX} value supported in the current environment. This is the maximum number of entries in the supplementary group ID list for a user name or process.

### QPXRSVD2

Reserved for IBM use; contents are unpredictable.

### QPXUNAME

Set to the user (login) name of the requesting virtual configuration.

Return Codes for Query POSIX Configuration Information:

### QPXOK (0)

Output fields have been set.

### QPXECDE (1)

Incorrect value in QPXDIAGC.

### QPXEFUNC (2)

Invalid function code in QPXFCNF.

### QPXELEN (3)

Length in QPXDWLEN is below the minimum allowed.

### QPXEFLAG (4)

Invalid option flags in QPXFLGS or QPXRSVD1 field is nonzero.

See Program Exceptions and Machine Checks for possible guest interruptions.

## Usage Note

Certain functions and options of DIAGNOSE code X'2A0' report POSIX database contents rather than attributes of the active process. For these that report database contents, the active PID may still be used by an ESM for authority checking. Therefore, it is unpredictable whether or not the requirements to define a POSIX communication area and to supply a valid active PID are enforced for these functions.

## Responses

**Program Exceptions and Machine Checks:** One of the following Program Exceptions or Machine Checks may be reflected to the issuing virtual machine indicating guest or host error conditions. In all cases, no meaningful return code is given, and the guest instruction (Diagnose) is nullified, suppressed, or terminated according to the architecture.

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                                              |
| Specification exception                                               | Any of the following: <ul style="list-style-type: none"> <li>• Rx is the same register as Ry or Ry+1.</li> <li>• Ry is register 15.</li> <li>• The address of the parameter list (QPXBK) specified in Rx is not on a doubleword boundary.</li> </ul>                                                                                      |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | Attempt to fetch from or store into the QPXBK failed. Regardless of the value of QPXDWLEN, an access exception may be recognized for a minimum of one doubleword at the QPXBK address. Conversely, an access exception may not be recognized for the portion of the operand beyond the length supported by CP for the function requested. |
| Storage-error machine check                                           | A real storage or paging error was encountered.                                                                                                                                                                                                                                                                                           |
| Processing-damage machine check                                       | A CP internal logic error occurred. (A CP abend usually accompanies this result.)                                                                                                                                                                                                                                                         |

## DIAGNOSE Code X'2A4' – POSIX Process ID (PID) Services

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE code X'2A4' supports several function codes that designate various POSIX process ID services. They assist in the creation, deletion, identification and execution of POSIX processes in the virtual configuration.

Entry Values:

### Rx

contains a function code specifying which function DIAGNOSE code X'2A4' is to perform. Rx can not be register 15 and can not be the same as Ry or Ry+1. Additional inputs for each function are described below.

The following POSIX process ID services can be invoked using this DIAGNOSE code:

- Function 0 - Identify the POSIX communication area
- Function 1 - Allocate a PID
- Function 2 - Deallocate a PID

### Ry + 1

may contain additional information based upon the specific function being performed.

Exit Values:

### Ry

on return, contains a return code. Ry can not be register 15 and can not be the same as Rx or Rx+1. The return codes and additional outputs for each function are described below.

### Rx + 1

may contain additional information based upon the specific function being performed.

## Function 0 - Identify the POSIX communication area

This function identifies the invoking virtual machine's POSIX communication area to CP.

Input:

**Rx+1**

specifies the length and location of the virtual machine's POSIX communication area. The POSIX communication area must reside entirely in the prefix area, above location 511 (decimal), and it must be at least 4 bytes in length. Bytes 0 and 1 of Rx+1 contain the length, in bytes, of the POSIX communication area. Bytes 2 and 3 contain the displacement into the prefix area of the first byte of the POSIX communication area. Key-controlled protection and low-address protection do not apply to accesses to this area.

The virtual subsystem reset operation causes the length and location of the POSIX communication area to become undefined to CP. This operation is performed during the system-reset-clear or system-reset-normal function performed by commands such as IPL, SYSTEM CLEAR, SYSTEM RESET and DETACH CPU.

The POSIX communication area has the following format:

Offset

**0-3**

is used by the virtual machine to identify to CP the "active" POSIX process executing on a virtual CPU. This process is identified by its PID. A value of X'00000000' indicates to CP that there is no currently active POSIX process executing on the virtual CPU.

Return Codes for Identify the POSIX communication area:

**0**

The POSIX communication area has been successfully identified to CP

**4**

Rx+1 contains an invalid length and/or address

See Program Exceptions for possible guest interruptions.

**Notes:**

1. This area may be referenced during the execution of other DIAGNOSES such as X'280', X'29C' and X'2A0'.
2. In a virtual machine with multiple virtual CPUs, the program controlling the virtual machine need only invoke this function once, because it identifies the displacement into each virtual CPU's prefix area. These programs normally use prefixing to identify a separate prefix area for each virtual CPU. This results in a separate POSIX communication area for each virtual CPU.

## Function 1 - Allocate a PID

This function allocates a PID for use by a new POSIX process and initializes the new process' POSIX IDs. The POSIX IDs are the real UID, effective UID, saved set-UID, real GID, effective GID, saved set-GID and the supplementary GIDs.

Input:

**Rx+1**

contains the PID of the newly created process' parent process, or X'00000000'. If Rx+1 contains a valid, non-zero PID, the new process' POSIX IDs are initialized to those of the identified process. If Rx+1 contains X'00000000', the new process' POSIX IDs are initialized to the POSIX database values that were in effect when the invoker logged on; the most recent supplementary GID list from the ESM will be in effect for the new process.

Output:

**Ry+1**

upon successful completion, contains the newly allocated PID.

Return Codes for Allocate a PID:

**0**

A PID has been successfully allocated, and the new process' POSIX IDs have been initialized as described above. The new PID is returned to the invoker in Ry+1.

**4**

Rx+1 contains an invalid PID. The PID may be invalid for any of the following reasons:

- It is outside the valid range
- It is not currently allocated
- It is not allocated to the invoking virtual configuration

**8**

The system has no available PIDs to allocate

**12**

Allocating a new PID would exceed the invoking virtual configuration's PID limit

See Program Exceptions for possible guest interruptions.

**Notes:**

1. When the process associated with the PID is deleted, the virtual configuration should issue the Deallocate a PID function so CP will deallocate the PID and make it available for later use by the system.
2. The virtual subsystem reset operation causes all PIDs currently allocated to the virtual configuration to be deallocated. This operation is performed during the system-reset-clear or system-reset-normal function performed by commands such as IPL, SYSTEM CLEAR, SYSTEM RESET and DETACH CPU.

**Function 2 - Deallocate a PID**

This function deallocates a PID and makes it available for later use by the system.

Input:

**Rx+1**

contains the PID to be deallocated. This PID must be currently allocated to the invoking virtual configuration. It must have been allocated by a successful invocation of the Allocate a PID function.

Return Codes for Deallocate a PID:

**0**

The specified PID has been deallocated.

**4**

Rx+1 contains an invalid PID. The PID may be invalid for any of the following reasons:

- It is outside the valid range
- It is not currently allocated
- It is not allocated to the invoking virtual configuration

See Program Exceptions for possible guest interruptions.

**Responses**

**Program Exceptions:** One of the following Program Exceptions may be reflected to the issuing virtual machine indicating guest or host error conditions. In all cases, no meaningful return code is given, and the guest instruction (Diagnose) is nullified, suppressed, or terminated according to the architecture.

| Problem Encountered            | Cause                                        |
|--------------------------------|----------------------------------------------|
| Privileged-operation exception | The virtual machine is in the problem state. |

| Problem Encountered     | Cause                                                                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception | Any of the following: <ul style="list-style-type: none"> <li>• An invalid function code is specified.</li> <li>• Rx is register 15.</li> <li>• Ry is register 15.</li> <li>• Rx is the same register as Ry or Ry+1.</li> <li>• Ry is the same register as Rx+1.</li> </ul> |

## DIAGNOSE Code X'2AC' – HCD Dynamic I/O

**Privilege Class:** B

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'2AC' to enable the HCD service virtual machine to query I/O configuration information stored in CP (ICIBK) and to execute dynamic changes to CP's I/O configuration.

Function Codes:

**X'00'**

Query I/O Configuration Information

**X'01'**

Perform Dynamic I/O Changes

Entry Values (Function 00 and 01):

**Rx**

is a general register that contains the desired function code

**Ry**

is a general register that contains the guest real address of a buffer to store the I/O configuration information (function 0) or the guest real address of the configuration control block (CCB) that describes the dynamic I/O change requests (function 1).

**Note:** All addresses passed on DIAGNOSE code X'2AC' are guest absolute addresses in the host-primary address space.

Exit Values (Function 01 Only):

**Rx**

contains a return code indicating the result of the request. Refer to [“Responses” on page 1092](#) for a description of the possible values.

**Ry**

when Rx is non-zero, Ry may contain a value that helps further describe the error. Refer to [“Responses” on page 1092](#) for a description of the possible values.

The entire ARSPL may be replaced in guest storage upon completion of a DIAGNOSE code X'254' function.

## Responses

**Condition Codes and Return Codes:** Upon completion of DIAGNOSE code X'2AC', control is returned to the issuer with a condition code and, when applicable, a return code set to indicate the status of the requested function.

Table 238. Condition Codes for Query I/O Configuration Information (Function 0)

| Condition Code | Return Code in Rx | Description                                                                                 |
|----------------|-------------------|---------------------------------------------------------------------------------------------|
| 0              | N/A               | I/O configuration information was successfully stored in the guest's buffer                 |
| 3              | N/A               | I/O configuration information is unavailable; HCD is not controlling CP's I/O configuration |

Table 239. Condition Codes and Return Codes for Perform Dynamic I/O Changes (Function 1)

| Condition Code | Return Code in Rx | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | N/A               | All change requests were successfully executed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 1              | 4 (X'04')         | The specified IOCDS could not be switched to make it the active IOCDS. However, all other change requests (if any), were successfully executed. The guest Ry is set to a hardware response code indicating why the IOCDS file could not be made active. For more information about the hardware response code see <a href="#">z/VM: I/O Configuration</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 1              | 8 (X'08')         | <p>None of the change requests were processed because pre-processing checks with one or more of the requests failed. No backout is required. The guest Ry is set to the number of requests that failed pre-processing. Each request (CCB entry) contains a return code indicating its pre-processing status.</p> <ul style="list-style-type: none"> <li>• RC0 - Request passed pre-processing</li> <li>• RC2 - CHPID type is unknown</li> <li>• RC4 - CHPID specified is a managed CHPID</li> <li>• RC8 - CHPID specified by or associated with the change was online</li> <li>• RC12 - CHPID is physically available</li> <li>• RC20 - FORCE was not specified</li> <li>• RC28 - Device is not subchannel disabled</li> <li>• RC32 - Device is a PAV base with a PAV alias still associated with it</li> <li>• RC36 - RDEV is not offline</li> <li>• RC40 - RDEV is offline but attached (boxed)</li> <li>• RC44 - RDEV class mismatch</li> <li>• RC48 - RDEV is an HCPRIO RDEV</li> <li>• RC56 - RDEV has an active I/O operation associated with it</li> <li>• RC60 - Unsupported request</li> <li>• RC76 - PCI Function is not offline</li> </ul> |
| 1              | 12 (X'0C')        | None of the change requests were processed because it was determined that there was not enough Hardware System Area (HSA) storage to carry out the requested hardware changes. No backout is required. The guest's Ry is set to zero if this is the only error. If pre-processing checks with one or more of the individual requests failed also, then the guest's Ry is set to the number of requests that failed pre-processing. Each request (CCB entry) contains a return code (listed above) indicating its pre-processing status.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

*Table 239. Condition Codes and Return Codes for Perform Dynamic I/O Changes (Function 1) (continued)*

| <b>Condition Code</b> | <b>Return Code in Rx</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                     | 16 (X'10')               | All of the change requests passed pre-processing checks but none of them were actually processed due to the fact that CP could not cause the processor to enter configuration mode to perform dynamic hardware changes. No backout is required. The guest's Ry contains the hardware response code indicating why CP could not enter configuration mode. For more information about the hardware response code see <a href="#">z/VM: I/O Configuration</a> .                                                                                                                                                                                                                                                                                                            |
| 1                     | 20 (X'14')               | An error was encountered during the processing of a dynamic change request. Backout is required! The guest's Ry contains the CCB entry index number of the request that failed. The request (CCB entry) that failed contains a non-zero return code (and possibly a hardware response code — for more information about the hardware response code see <a href="#">z/VM: I/O Configuration</a> ). All previous requests were processed successfully (RC0) while all subsequent requests were not executed. <ul style="list-style-type: none"> <li>• RC64 - Hardware command failed (possibly accompanied by a hardware response code).</li> <li>• RC68 - Backout is required; backout is requested from this point</li> <li>• RC72 - Software command failed</li> </ul> |
| 1                     | 24 (X'18')               | Recovery information could not be retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 1                     | 92 (X'5C')               | The data area size specified in the CCB header or CCBX header was zero or negative.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 1                     | 96 (X'60')               | The dynamic I/O change request was too large for CP to process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 2                     | N/A                      | A dynamic I/O change request is currently being processed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 3                     | N/A                      | I/O configuration information is unavailable; HCD is not controlling the I/O configuration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Program Exceptions:** DIAGNOSE code X'2AC' may result in one of the following program exceptions:

| <b>Problem Encountered</b> | <b>Cause</b>                                                                         |

## DIAGNOSE Code X'2C0' – HMC Data Source Load

**Privilege Class:** A

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'2C0' to load binary image files from z/Architecture Hardware Management Console's data sources. Using DIAGNOSE code X'2C0' ensures that CP will construct an appropriate Service Call instruction.

Results of the I/O operation are contained in the R15 register and the storage buffer pointed to by Ry before the instruction's execution will be overlaid with the data retrieved from the SCLP device.

Issuing DIAGNOSE code X'2C0' with Ry equal to zero will cause the system to return the size of the CP Buffer in R15. The size of the CP Buffer is fixed and may not be changed.

With Ry nonzero, the DIAGNOSE operates by first allocating a permanent CP internal buffer and clearing it to X'FF's. Next, the file is loaded from one of two sources, depending on the operating environment of the system: If z/VM is operating as a first level system within an LPAR, then a Service Call (Type 7) instruction is executed and the *filename* file is loaded into CP's buffer from the Hardware Console's DVD disk drive or FTP source from which the LPAR was IPLed. If z/VM is operating as a guest under z/VM, then the file "*filename* IMAGE \*" is loaded from a CPACCESS'ed minidisk.

The operation of the DIAGNOSE fills the CP buffer with X'FF' bytes and then reads the requested file into the start of the buffer. If, for example, the buffer is 4MB in length and the file that is loaded is 800K long, then the buffer from 0K to 800K contains the file and from 800K to 4096K contains X'FF's. The entire 4MB buffer is then copied into the virtual machine's buffer area specified in Ry.

**Note:** If the requested file exceeds the length of the CP buffer, then host real storage will be overlaid and the system's integrity will be compromised. In the event of an overlay the z/VM operating system will probably abend with an LDF001 hard abend.

Entry Values:

### Rx, Rx+1

Contains the eight-byte EBCDIC name of the file to be loaded. When running under the z/VM operating system, the file "*filename* IMAGE \*" is loaded from a CPACCESS'ed minidisk.

### Ry

Two different operations may be performed depending upon the value in Ry.

A value of 0 indicates that the size of the CP defined buffer is to be returned. This is the amount of data that the X'2C0' DIAGNOSE will return, regardless of the file's size, which is 4MB.

A nonzero value is the address of the buffer in the guest virtual machine where the data is to be placed. This buffer must be the size that is reported by issuing an Ry=0 call and the buffer must be page-aligned.

Example:

## DIAGNOSE X'2C4'

```
SR      Ry,Ry
DIAG    0,Ry,X'2C0'
ST      R15,BUFSIZE

CMSSTOR OBTAIN,BYTES=(R15),BNDRY=PAGE
ST      R1,BUFFERAD

LM      Rx,Rx+1,=CL8'filename'
L        Ry,BUFFERAD
DIAG    Rx,Ry,X'2C0'
LTR     R15,R15
BNZ     ERROR
...

```

### Return Values:

A return code is provided in R15.

The Condition Code is unspecified.

When called with Ry=0, then the returned value in R15 is the size of the required virtual buffer.

When Ry specifies the virtual buffer address, the results of the data operation are returned in R15.

| Return Code | Meaning                                                                                |
|-------------|----------------------------------------------------------------------------------------|
| 0 (X'00')   | The buffer has been loaded with the specified file.                                    |
| 1 (X'01')   | The virtual buffer pointed to by Ry is not page aligned.                               |
| 2 (X'02')   | The SCLP interface is currently in use. Retry at a later time.                         |
| 4 (X'04')   | The SCLP returned a "Not Normal" indication.                                           |
| 5 (X'05')   | The SCLP returned a "Not Complete" indication.                                         |
| 6 (X'06')   | Invalid virtual address supplied in Ry.                                                |
| 7 (X'07')   | Invalid i-ASIT for address in Ry.                                                      |
| 8 (X'08')   | Paging subsystem error.                                                                |
| 1000–1999   | SCLP start request failed. Value is HCPPCRRQ return code + 1000.                       |
| 2000–2999   | SCLP completion error. Value is xxx + 2000. (NOTE: 2003 is SCLP File Load Error.)      |
| 3000–3999   | Virtual page address translation error. Value is HCPTRANS RC + 3000.                   |
| 4000–4999   | z/VM HCPCLVLH failed. Value is HCPCLVLH return + 4000. (NOTE: 4059 is File Not Found.) |

## DIAGNOSE Code X'2C4' – FTP Services

**Privilege Class:** B (See notes below)

**Addressing Mode:** 24-bit, 31-bit or 64-bit

DIAGNOSE X'2C4' provides FTP services for files residing on a removable medium in an HMC device.

### Notes:

1. A class Any user may issue DIAGNOSE X'2C4' if the user's directory includes the OPTION LXAPP statement, and if the user specifies a location indicator (any of bits 32-39 turned on).
2. If the user's directory does *not* include the OPTION LXAPP statement, then that user must be class B.

Entry Values:

### Rx

The general register containing the guest absolute address of the FTP services parameter list (FPL). The FPL must be on a doubleword boundary.

**Ry**

The general register containing the FTP function code and the location indicator. The function code is in bits 56-63. The possible function codes are:

**X'00'**

NOOP

**X'01'**

GET

**X'02'**

PUT

**X'03'**

APPEND

**X'04'**

DIR

**X'05'**

NLST

**X'06'**

DELETE

The location indicator is in bits 32-39 and all values are reserved for IBM use.

Exit Values:

**Ry**

On return, contains a return code indicating the result of the request. See [“Responses” on page 1098](#) for a description of the possible return codes.

**FPL**

The parameter list consists of an input area, an output area, and a file identifier. The area must be aligned on a doubleword boundary. The FPL format is as follows:

Figure 111. DIAGNOSE X'2C4' FPL Parameter List Format

**Buffer Address**

Is a doubleword containing the guest real address of the buffer to be used for the FTP function. The buffer must be aligned on a 4K page boundary.

**Buffer Length**

Is a doubleword containing the length of the buffer to be used for the FTP function.

## DIAGNOSE X'2C4'

### File Offset

Is a doubleword containing the offset in the file to be used for the FTP function.

### Interruption Parameter

Is a fullword field containing user data to be stored at guest real storage location 128-131 in the host-primary address space upon presentation of the FTP services external interruption, at the completion of the FTP services request.

### Bytes Transferred

Is a doubleword that returns the number of bytes transferred by the FTP function, at the completion of the FTP services request.

### File Size

Is a doubleword that returns the size in bytes of the file being processed by the FTP function, at the completion of the FTP services request.

### Failing Address

Is a doubleword that returns the address in the buffer associated with a failure of the FTP function, at the completion of the FTP services request.

### File Identifier

Is a 192-byte field containing the file identifier on which the FTP function is to operate, followed by a X'00' to mark the end of the identifier.

## Responses

Upon completion, DIAGNOSE X'2C4' sets one of the following return codes in Ry:

Table 240. DIAGNOSE Code X'2C4' Return Codes in Ry

| Return Code in Register Ry | Meaning                 |
|----------------------------|-------------------------|
| 0 (X'00')                  | FTP function initiated. |
| 4 (X'04')                  | FTP interface in use.   |
| 8 (X'08')                  | Interface error.        |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE X'2C4' is given incorrect data:

| Problem Encountered            | Cause                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Privileged-operation exception | The issuer of DIAGNOSE X'2C4' does not have the appropriate privilege class or directory authorization.                                                                                                                                                                                                                                                                 |
| Specification exception        | Any of the following: <ul style="list-style-type: none"><li>• The address contained in Rx is not on a doubleword boundary.</li><li>• The value contained in Ry is not in range.</li><li>• The buffer is not on a page boundary.</li><li>• The buffer length is not in range.</li><li>• The buffer is not addressable.</li><li>• The buffer is not read/write.</li></ul> |

**FTP Services External Interruption:** An FTP services external interruption is presented when a DIAGNOSE X'2C4' request has completed. The interruption is a floating condition and is presented to the first virtual CPU in the virtual configuration that is enabled for the interruption subclass. The interruption condition is cleared once the interruption has been presented, as well as by a virtual subsystem reset (for example, a SYSTEM RESET or IPL command).

The subclass mask to enable for the interruption is bit 22 of control register 0.

The FTP services condition is indicated by an external-interruption code of X'2603' stored at guest real location 134-135 and a sub-interruption code of X'08' stored at guest real location 132. The interruption parameter associated with the original DIAGNOSE X'2C4' request is stored at guest real locations 128-131. In addition, one of the following status codes will be stored at guest real location 133:

**X'00'**

Request completed successfully.

**X'04'**

Program check condition detected when storing results in original request buffer.

**X'08'**

Paging I/O error encountered when storing results in original request buffer.

**X'0C'**

Request was cancelled due to time out condition sensed by z/VM. The function can now be retried by the guest.

**X'10 + error code'**

Request completed with error.

**Note:** All locations updated as a result of the external interruption are in the host-primary address space.

The Bytes Transferred, File Size, and Failing Address fields in the original FPL are filled in when an FTP services external interruption is made pending. In the case of a X'0C' status code, these fields are not returned to the guest.

**DIAGNOSE X'2C4'**

INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some jurisdictions do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM websites are provided for convenience only and do not in any manner serve as an endorsement of those websites. The materials at those websites are not part of the materials for this IBM product and use of those websites is at your own risk.

IBM may use or distribute any of the information you provide in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

*IBM Director of Licensing*  
*IBM Corporation*  
*North Castle Drive, MD-NC119*  
*Armonk, NY 10504-1785*  
*US*

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

The performance data and client examples cited are presented for illustrative purposes only. Actual performance results may vary depending on specific configurations and operating conditions.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

Statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information may contain examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to actual people or business enterprises is entirely coincidental.

#### **COPYRIGHT LICENSE:**

This information may contain sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

## **Programming Interface Information**

---

This information primarily documents intended Programming Interfaces that allow the customer to write programs to obtain services of z/VM.

This information also documents information that is NOT intended to be used as Programming Interfaces of z/VM. This information is identified where it occurs by an introductory statement to a chapter or section.

## **Trademarks**

---

IBM, the IBM logo, and [ibm.com](https://www.ibm.com/legal/copytrade)® are trademarks or registered trademarks of International Business Machines Corp., in the United States and/or other countries. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on [IBM Copyright and trademark information](https://www.ibm.com/legal/copytrade) (<https://www.ibm.com/legal/copytrade>).

The registered trademark Linux is used pursuant to a sublicense from the Linux Foundation, the exclusive licensee of Linus Torvalds, owner of the mark on a worldwide basis.

## **Terms and Conditions for Product Documentation**

---

Permissions for the use of these publications are granted subject to the following terms and conditions.

### **Applicability**

These terms and conditions are in addition to any terms of use for the IBM website.

## Personal Use

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

## Commercial Use

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

## Rights

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the above instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

## IBM Online Privacy Statement

---

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user, or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth below.

This Software Offering does not use cookies or other technologies to collect personally identifiable information.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see:

- The section entitled **IBM Websites** at [IBM Privacy Statement](https://www.ibm.com/privacy) (<https://www.ibm.com/privacy>)
- [Cookies and Similar Technologies](https://www.ibm.com/privacy#Cookies_and_Similar_Technologies) ([https://www.ibm.com/privacy#Cookies\\_and\\_Similar\\_Technologies](https://www.ibm.com/privacy#Cookies_and_Similar_Technologies))

# Bibliography

---

This topic lists the publications in the z/VM library. For abstracts of the z/VM publications, see [z/VM: General Information](#).

## Where to Get z/VM Information

---

The current z/VM product documentation is available in [IBM Documentation - z/VM \(https://www.ibm.com/docs/en/zvm\)](https://www.ibm.com/docs/en/zvm).

## z/VM Base Library

---

### Overview

- [z/VM: License Information](#), GI13-4377
- [z/VM: General Information](#), GC24-6286

### Installation, Migration, and Service

- [z/VM: Installation Guide](#), GC24-6292
- [z/VM: Migration Guide](#), GC24-6294
- [z/VM: Service Guide](#), GC24-6325
- [z/VM: VMSES/E Introduction and Reference](#), GC24-6336

### Planning and Administration

- [z/VM: CMS File Pool Planning, Administration, and Operation](#), SC24-6261
- [z/VM: CMS Planning and Administration](#), SC24-6264
- [z/VM: Connectivity](#), SC24-6267
- [z/VM: CP Planning and Administration](#), SC24-6271
- [z/VM: Getting Started with Linux on IBM Z](#), SC24-6287
- [z/VM: Group Control System](#), SC24-6289
- [z/VM: I/O Configuration](#), SC24-6291
- [z/VM: Running Guest Operating Systems](#), SC24-6321
- [z/VM: Saved Segments Planning and Administration](#), SC24-6322
- [z/VM: Secure Configuration Guide](#), SC24-6323

### Customization and Tuning

- [z/VM: CP Exit Customization](#), SC24-6269
- [z/VM: Performance](#), SC24-6301

### Operation and Use

- [z/VM: CMS Commands and Utilities Reference](#), SC24-6260
- [z/VM: CMS Primer](#), SC24-6265
- [z/VM: CMS User's Guide](#), SC24-6266
- [z/VM: CP Commands and Utilities Reference](#), SC24-6268

- [z/VM: System Operation](#), SC24-6326
- [z/VM: Virtual Machine Operation](#), SC24-6334
- [z/VM: XEDIT Commands and Macros Reference](#), SC24-6337
- [z/VM: XEDIT User's Guide](#), SC24-6338

## Application Programming

- [z/VM: CMS Application Development Guide](#), SC24-6256
- [z/VM: CMS Application Development Guide for Assembler](#), SC24-6257
- [z/VM: CMS Application Multitasking](#), SC24-6258
- [z/VM: CMS Callable Services Reference](#), SC24-6259
- [z/VM: CMS Macros and Functions Reference](#), SC24-6262
- [z/VM: CMS Pipelines User's Guide and Reference](#), SC24-6252
- [z/VM: CP Programming Services](#), SC24-6272
- [z/VM: CPI Communications User's Guide](#), SC24-6273
- [z/VM: ESA/XC Principles of Operation](#), SC24-6285
- [z/VM: Language Environment User's Guide](#), SC24-6293
- [z/VM: OpenExtensions Advanced Application Programming Tools](#), SC24-6295
- [z/VM: OpenExtensions Callable Services Reference](#), SC24-6296
- [z/VM: OpenExtensions Commands Reference](#), SC24-6297
- [z/VM: OpenExtensions POSIX Conformance Document](#), GC24-6298
- [z/VM: OpenExtensions User's Guide](#), SC24-6299
- [z/VM: Program Management Binder for CMS](#), SC24-6304
- [z/VM: Reusable Server Kernel Programmer's Guide and Reference](#), SC24-6313
- [z/VM: REXX/VM Reference](#), SC24-6314
- [z/VM: REXX/VM User's Guide](#), SC24-6315
- [z/VM: Systems Management Application Programming](#), SC24-6327
- [z/VM: z/Architecture Extended Configuration \(z/XC\) Principles of Operation](#), SC27-4940

## Diagnosis

- [z/VM: CMS and REXX/VM Messages and Codes](#), GC24-6255
- [z/VM: CP Messages and Codes](#), GC24-6270
- [z/VM: Diagnosis Guide](#), GC24-6280
- [z/VM: Dump Viewing Facility](#), GC24-6284
- [z/VM: Other Components Messages and Codes](#), GC24-6300
- [z/VM: VM Dump Tool](#), GC24-6335

## z/VM Facilities and Features

---

### Data Facility Storage Management Subsystem for z/VM

- [z/VM: DFSMS/VM Customization](#), SC24-6274
- [z/VM: DFSMS/VM Diagnosis Guide](#), GC24-6275
- [z/VM: DFSMS/VM Messages and Codes](#), GC24-6276
- [z/VM: DFSMS/VM Planning Guide](#), SC24-6277

- *z/VM: DFSMS/VM Removable Media Services*, SC24-6278
- *z/VM: DFSMS/VM Storage Administration*, SC24-6279

## Directory Maintenance Facility for z/VM

- *z/VM: Directory Maintenance Facility Commands Reference*, SC24-6281
- *z/VM: Directory Maintenance Facility Messages*, GC24-6282
- *z/VM: Directory Maintenance Facility Tailoring and Administration Guide*, SC24-6283

## Open Systems Adapter

- Open Systems Adapter/Support Facility on the Hardware Management Console ([https://www.ibm.com/docs/en/SSLTBW\\_2.3.0/pdf/SC14-7580-02.pdf](https://www.ibm.com/docs/en/SSLTBW_2.3.0/pdf/SC14-7580-02.pdf)), SC14-7580
- Open Systems Adapter-Express ICC 3215 Support (<https://www.ibm.com/docs/en/zos/2.3.0?topic=osa-icc-3215-support>), SA23-2247
- Open Systems Adapter Integrated Console Controller User's Guide ([https://www.ibm.com/docs/en/SSLTBW\\_2.3.0/pdf/SC27-9003-02.pdf](https://www.ibm.com/docs/en/SSLTBW_2.3.0/pdf/SC27-9003-02.pdf)), SC27-9003
- Open Systems Adapter-Express Customer's Guide and Reference ([https://www.ibm.com/docs/en/SSLTBW\\_2.3.0/pdf/iaa2z1f0.pdf](https://www.ibm.com/docs/en/SSLTBW_2.3.0/pdf/iaa2z1f0.pdf)), SA22-7935

## Performance Toolkit for z/VM

- *z/VM: Performance Toolkit Guide*, SC24-6302
- *z/VM: Performance Toolkit Reference*, SC24-6303

The following publications contain sections that provide information about z/VM Performance Data Pump, which is licensed with Performance Toolkit for z/VM.

- *z/VM: Performance*, SC24-6301. See *z/VM Performance Data Pump*.
- *z/VM: Other Components Messages and Codes*, GC24-6300. See *Data Pump Messages*.

## RACF Security Server for z/VM

- *z/VM: RACF Security Server Auditor's Guide*, SC24-6305
- *z/VM: RACF Security Server Command Language Reference*, SC24-6306
- *z/VM: RACF Security Server Diagnosis Guide*, GC24-6307
- *z/VM: RACF Security Server General User's Guide*, SC24-6308
- *z/VM: RACF Security Server Macros and Interfaces*, SC24-6309
- *z/VM: RACF Security Server Messages and Codes*, GC24-6310
- *z/VM: RACF Security Server Security Administrator's Guide*, SC24-6311
- *z/VM: RACF Security Server System Programmer's Guide*, SC24-6312
- *z/VM: Security Server RACROUTE Macro Reference*, SC24-6324

## Remote Spooling Communications Subsystem Networking for z/VM

- *z/VM: RSCS Networking Diagnosis*, GC24-6316
- *z/VM: RSCS Networking Exit Customization*, SC24-6317
- *z/VM: RSCS Networking Messages and Codes*, GC24-6318
- *z/VM: RSCS Networking Operation and Use*, SC24-6319
- *z/VM: RSCS Networking Planning and Configuration*, SC24-6320

## TCP/IP for z/VM

- [z/VM: TCP/IP Diagnosis Guide](#), GC24-6328
- [z/VM: TCP/IP LDAP Administration Guide](#), SC24-6329
- [z/VM: TCP/IP Messages and Codes](#), GC24-6330
- [z/VM: TCP/IP Planning and Customization](#), SC24-6331
- [z/VM: TCP/IP Programmer's Reference](#), SC24-6332
- [z/VM: TCP/IP User's Guide](#), SC24-6333

## Prerequisite Products

### function [590](#)

ACNT command [699](#), [715](#)

activate CP directory, DIAGNOSE code X'3C' [45](#)

add

- your own accounting records and source code [716](#)

ADD function of ALSERV macro [831](#)

adding an ALE to an access list [802](#)

address

- absolute [5](#)

- guest [5](#)

- processing of [5](#)

- real [5](#)

- spaces, selection of [7](#)

address lists [306](#), [453](#), [479](#), [493](#), [512](#)

address space identification token (ASIT) [801](#)

address space services, ADRSPACE macro [811](#)

address space services, DIAGNOSE code X'23C' [1037](#)

address spaces

- access-list entry (ALE)

- X'240' [1042](#)

- creating [814](#)

- definition [797](#)

- destroying [818](#)

- dropping addressability [803](#)

- identification [812](#)

- identification token (ASIT) [812](#)

- isolating a shared [804](#)

- management functions

- X'23C' [1037](#)

- mapping

- X'244' [1044](#)

- mapping minidisks to [804](#)

- name [812](#)

- permitting another user to access [801](#)

- primary [799](#)

- querying information [826](#)

- restoring to private state [820](#)

- selection of [7](#)

- states [812](#), [820](#)

- support [799](#)

addressability to an address space, establish [802](#)

addressability, parameter [394](#)

addresses

- absolute [297](#)

- guest [297](#)

- processing of [297](#)

- real [297](#)

addressing exception

- APPCVM CONNECT [428](#)

- APPCVM QRYSTATE [450](#)

- APPCVM RECEIVE [460](#)

- APPCVM SENDCNF [469](#)

- APPCVM SENDCNFD [474](#)

- APPCVM SENDDATA [486](#)

- APPCVM SENDERR [498](#)

- APPCVM SENDREQ [503](#)

- APPCVM SETMODFY [507](#)

- APPCVM SEVER [517](#)

- DIAGNOSE code X'254' [1055](#)

- DIAGNOSE code X'D0' [161](#)

- general definition [8](#)

- IUCV ACCEPT [322](#), [528](#)

- IUCV CONNECT [329](#), [532](#)

- IUCV DECLARE BUFFER [332](#), [536](#)

- IUCV DESCRIBE [336](#), [539](#)

- IUCV INTERRUPT POLL [339](#), [542](#)

## IUCV macro functions

### ACCEPT

from the DASD block I/O system service [720](#)  
from the error logging system service [727](#)  
from the Symptom system service [771](#)  
parameter list format [321](#), [526](#)  
return codes [322](#), [527](#)  
using [319](#), [524](#)

### CONNECT

parameter list format [327](#), [531](#)  
return codes [328](#), [531](#)  
to DASD block I/O system service [719](#)  
to error logging system service [727](#)  
to signal system service [745](#)  
to symptom system service [771](#)  
using [324](#), [529](#)

### DECLARE BUFFER

parameter list format [332](#), [535](#)  
return codes [332](#), [536](#)  
using [331](#), [533](#)

### DESCRIBE

parameter list format [334](#), [539](#)  
return codes [335](#)  
using [334](#), [538](#)

for use in APPC/VM [521](#)

### INTERRUPT POLL

IPOLL [542](#)  
parameter list format [338](#), [541](#)  
return codes [338](#)  
using [337](#), [540](#)

### PURGE

parameter list format [341](#)  
return codes [343](#)  
using [340](#)

QUERY [344](#), [543](#)

### QUIESCE

parameter list format [346](#)  
return codes [346](#)  
using [345](#)

### RECEIVE

parameter list format [349](#)  
return codes [351](#)  
using [348](#)

### REJECT

parameter list format [353](#)  
return codes [353](#)  
using [352](#)

related to APPC/VM [391](#)

### REPLY

parameter list format [356](#)  
return codes [358](#)  
using [355](#)

### RESUME

parameter list format [362](#)  
return codes [363](#)  
using [362](#)

RETRIEVE BUFFER [365](#), [548](#)

### SEND

parameter list format [368](#)  
return codes [369](#)  
to the DASD block I/O system service [721](#)

## IUCV macro functions (*continued*)

### SEND (*continued*)

to the signal system service [747](#)  
using [366](#)

### SET CONTROL MASK

parameter list format [372](#)  
return codes [373](#)  
using [372](#)

### SET MASK

parameter list format [375](#), [554](#)  
return codes [375](#)  
using [374](#), [553](#)

settings for optional parameters [395](#)

### SEVER

from the DASD block I/O system service [720](#)  
from the error logging system service [727](#)  
from the signal system service [748](#)  
from the symptom system service [771](#)  
parameter list format [377](#), [557](#)  
return codes [377](#), [559](#)  
using [376](#), [556](#)

shared functions that can be used in CMS [521](#)

shared functions that should be avoided in [521](#)

terminology [306](#)

### TEST COMPLETION

parameter list format [380](#)  
return codes [382](#), [564](#)  
using [379](#), [562](#)

TEST MESSAGE [383](#), [566](#)

using HELP for [523](#)

## IUCV return codes

ACCEPT [322](#), [527](#)

CONNECT [328](#), [531](#)

DECLARE BUFFER (DCLBFR) [332](#), [536](#)

## RECEIVE

### IUCV function

- condition codes [350](#)
- format [348](#)
- parameter descriptions [348](#)

## RECEIVE (continued)

### IUCV function (continued)

- parameter list format [349](#)
- program exceptions [351](#)
- return codes [351](#)
- using [348](#)

### VMCF function [1015](#), [1017](#)

receive accounting records [698](#)

### RECEIVE function of APPCVM

- addressing for [453](#)
- completion [462](#)
- condition codes [454](#)
- description [451](#)
- format [451](#)
- from communication partner [463](#)
- input parameter list format [453](#)
- mapped with APPC [580](#)
- output parameter list format [456](#)
- overview [393](#)
- parameter descriptions [451](#)
- program exceptions [460](#)
- return codes [454](#)
- state changes [461](#)
- state checks [461](#)

receive signals from the signal system service [747](#)

Receive state [388](#), [393](#), [403](#), [404](#)

### RECEIVE\_AND\_WAIT, APPC verb

- abend conditions [582](#)
- mapped with APPC/VM [580](#)
- parameters [580](#)
- state changes [582](#)

receiving data using APPC/VM [393](#)

reentrant program example, data spaces [808](#)

### REFPAGE macro

DECLARE function [879](#)

INFORMB function [880](#)

INFORML function [886](#)

list of functions [877](#)

notifying CP of future reference patterns [805](#)

## REJECT

### IUCV function

- condition codes [353](#)
- format [352](#)
- parameter descriptions [352](#)
- parameter list format [353](#)
- program exceptions [354](#)
- return codes [353](#)
- using [352](#)

### VMCF function [1013](#), [1017](#)

relating APPC with APPC/VM [571](#)

release pages, DIAGNOSE code X'10' [24](#)

## REMOVE

ALSERV function [835](#)

MAPMDISK function [857](#)

remove the block I/O environment [211](#)

repeat the active file a specified number of times [28](#)

## REPLY

### IUCV function
