|                                         |    |
|-----------------------------------------|----|
| DIAGNOSE Code X'0C' – Pseudo Timer..... | 23 |
|-----------------------------------------|----|

|                                                                                  |    |
|----------------------------------------------------------------------------------|----|
| Usage Notes.....                                                                 | 23 |
| Responses.....                                                                   | 23 |
| DIAGNOSE Code X'10' – Release Pages.....                                         | 24 |
| Usage Notes.....                                                                 | 24 |
| Responses.....                                                                   | 25 |
| DIAGNOSE Code X'14' – Input Spool File Manipulation.....                         | 25 |
| Subcode X'0000'—Read the Next Spool File Buffer (Data Record).....               | 26 |
| Subcode X'0004'—Read the Next Print Spool File Block.....                        | 27 |
| Subcode X'0008'—Read the Next Punch Spool File Block.....                        | 28 |
| Subcode X'000C'—Order a File to the Front of a Queue.....                        | 28 |
| Subcode X'0010'—Repeat the Active File a Specified Number of Times.....          | 28 |
| Subcode X'0014'—Restart an Active File at the Beginning.....                     | 29 |
| Subcode X'0018'—Backspace One Record.....                                        | 29 |
| Subcode X'001C'—Read the Next Monitor Spool File Block.....                      | 29 |
| Subcode X'0020'—Read the Next Monitor Spool Record.....                          | 30 |
| Subcode X'0024'—Read the Last Spool File Buffer.....                             | 30 |
| Subcode X'0028'—Position a Spool File to the Designated Record.....              | 30 |
| Subcode X'002C'—Select a File for Processing and Read the Next Spool Buffer..... | 31 |
| Subcode X'0FFE'—Select the Next File Not Previously Selected.....                | 31 |
| Subcode X'0FFF'—Retrieve Next File Descriptor.....                               | 34 |
| Usage Notes.....                                                                 | 34 |
| Responses.....                                                                   | 35 |
| DIAGNOSE Code X'18' – Standard DASD I/O.....                                     | 36 |
| Usage Notes .....                                                                | 37 |
| Responses.....                                                                   | 37 |
| Example.....                                                                     | 38 |
| DIAGNOSE Code X'20' – 370 Synchronous I/O for DIAGNOSE Support.....              | 38 |
| Usage Notes.....                                                                 | 39 |
| Responses.....                                                                   | 39 |
| DIAGNOSE Code X'24' – Device Type and Features.....                              | 40 |
| Usage Notes.....                                                                 | 40 |
| Responses.....                                                                   | 42 |
| DIAGNOSE Code X'28' – Dynamic Channel Program Modification.....                  | 42 |
| Usage Notes.....                                                                 | 43 |
| Responses.....                                                                   | 43 |
| DIAGNOSE Code X'34' – Read System Dump Spool File.....                           | 44 |
| Usage Notes.....                                                                 | 44 |
| Responses.....                                                                   | 45 |
| DIAGNOSE Code X'3C' – Activate z/VM CP Directory.....                            | 45 |
| Usage Notes.....                                                                 | 45 |
| Responses.....                                                                   | 46 |
| DIAGNOSE Code X'44' – Voluntary Time Slice End.....                              | 46 |
| Usage Notes.....                                                                 | 47 |
| Responses.....                                                                   | 47 |
| DIAGNOSE Code X'48' – Second Level SVC 76.....                                   | 47 |
| DIAGNOSE Code X'4C' – Generate Accounting Records.....                           | 47 |
| Usage Notes.....                                                                 | 48 |
| Responses.....                                                                   | 50 |
| DIAGNOSE Code X'54' – Control the Function of the PA2 Key.....                   | 50 |
| Usage Note.....                                                                  | 51 |
| Responses.....                                                                   | 51 |
| DIAGNOSE Code X'58' – 3270 Virtual Console Interface.....                        | 51 |
| Usage Notes.....                                                                 | 52 |
| Responses.....                                                                   | 60 |
| DIAGNOSE Code X'5C' – Error Message Editing.....                                 | 60 |
| Usage Notes.....                                                                 | 61 |
| Responses.....                                                                   | 61 |
| DIAGNOSE Code X'60' – Determine Virtual Machine Storage Size.....                | 62 |

|                                                                      |     |
|----------------------------------------------------------------------|-----|
| Responses.....                                                       | 62  |
| DIAGNOSE Code X'64' – Named Saved Segment Manipulation.....          | 62  |
| Subcode X'00' – LOADSHR.....                                         | 63  |
| Subcode X'04' – LOADNSHR.....                                        | 64  |
| Subcode X'08' – PURGESEG.....                                        | 65  |

| DIAGNOSE Code X'40' – Clean-Up After Virtual IPL by Device.....                | 1031        |
| Usage Note.....                                                                | 1031        |
| Responses.....                                                                 | 1031        |
| DIAGNOSE Code X'E0' – System Trace File Interface.....                         | 1031        |
| Subcode X'00000008' – Open (read-only).....                                    | 1033        |
| Subcode X'0000000C' – Read.....                                                | 1033        |
| Subcode X'00000010' – Close (read-only).....                                   | 1034        |
| Usage Notes.....                                                               | 1035        |
| Trace Block Containing CP Trace Table Entries.....                             | 1035        |
| DIAGNOSE Code X'214' – Pending Page Release.....                               | 1035        |
| Responses.....                                                                 | 1037        |
| DIAGNOSE Code X'23C' – Address Space Services.....                             | 1037        |
| Create-Space Function.....                                                     | 1038        |
| Destroy-Space Function.....                                                    | 1039        |
| Query-Space Function.....                                                      | 1039        |
| Permit-Access Function.....                                                    | 1040        |
| Isolate-Space Function.....                                                    | 1041        |
| DIAGNOSE Code X'240' – Access List Services.....                               | 1042        |
| Add-ALE Function.....                                                          | 1042        |
| Remove-ALE Function.....                                                       | 1043        |
| Responses.....                                                                 | 1044        |
| DIAGNOSE Code X'244' – Mapping Services.....                                   | 1044        |
| Identify-pool Function.....                                                    | 1044        |
| Define-mapping Function.....                                                   | 1045        |
| Remove-mapping function.....                                                   | 1046        |
| Save-list Function.....                                                        | 1047        |

|                                                                                               |      |
|-----------------------------------------------------------------------------------------------|------|
| Responses.....                                                                                | 1048 |
| DIAGNOSE Code X'254' – Access Real Subsystem.....                                             | 1048 |
| Hardware Specifications.....                                                                  | 1048 |
| Open CP Connection.....                                                                       | 1049 |
| Close CP Connection.....                                                                      | 1051 |
| Perform I/O.....                                                                              | 1052 |
| Responses.....                                                                                | 1054 |
| Access Real Subsystem External Interruption.....                                              | 1056 |
| DIAGNOSE Code X'25C' – Directory Query.....                                                   | 1056 |
| Usage Notes.....                                                                              | 1059 |
| Responses.....                                                                                | 1060 |
| DIAGNOSE Code X'264' – CP Communication.....                                                  | 1060 |
| Subcode X'00000000'—Establish CP communication area.....                                      | 1061 |
| Subcode X'00000004'—Remove CP communication area.....                                         | 1062 |
| DIAGNOSE Code X'278' – Extract XLINK Control Blocks.....                                      | 1062 |
| Responses.....                                                                                | 1065 |
| DIAGNOSE Code X'280' – Set POSIX IDs - security values.....                                   | 1065 |
| Function EXCSETID - Request changes in POSIX security values for an exec() function call..... | 1066 |
| Function EXCSSID - Request changes in saved set-IDs for an exec() function call.....          | 1067 |
| Responses.....                                                                                | 1068 |
| DIAGNOSE Code X'29C' – Set-POSIX-IDs Services.....                                            | 1071 |
| Function SPXFUSER - Set User IDs (UIDs) for the Active Process.....                           | 1072 |
| Function SPXFGRP - Set Group IDs (GIDs) for the Active Process.....                           | 1074 |
| Function SPXFNGRP – Change to a New Group.....                                                | 1075 |
| Function SPXFSGID – Change the supplementary group ID list.....                               | 1077 |
| Responses.....                                                                                | 1078 |
| DIAGNOSE Code X'2A0' – Query POSIX IDs.....                                                   | 1078 |
| Function QPXFPROC - Query Process Attributes.....                                             | 1079 |
| Function QPXFUSER - Query the User Database.....                                              | 1080 |
| Function QPXFGRP - Query the Group Database.....                                              | 1083 |
| Function QPXFSGID - Query the Supplementary Group IDs.....                                    | 1085 |
| Function QPXFCONF - Query POSIX Configuration Information.....                                | 1087 |
| Usage Note.....                                                                               | 1088 |
| Responses.....                                                                                | 1088 |
| DIAGNOSE Code X'2A4' – POSIX Process ID (PID) Services.....                                   | 1089 |
| Function 0 - Identify the POSIX communication area.....                                       | 1089 |
| Function 1 - Allocate a PID.....                                                              | 1090 |
| Function 2 - Deallocate a PID.....                                                            | 1091 |
| Responses.....                                                                                | 1091 |
| DIAGNOSE Code X'2AC' – HCD Dynamic I/O.....                                                   | 1092 |
| Responses.....                                                                                | 1092 |
| DIAGNOSE Code X'2C0' – HMC Data Source Load.....                                              | 1095 |
| DIAGNOSE Code X'2C4' – FTP Services.....                                                      | 1096 |
| FPL.....                                                                                      | 1097 |
| Responses.....                                                                                | 1098 |

| 22. Summary of the Effects of Byte X'19' Bits 6 and 7 on Read/Write Processing..... | 207  |
| 23. Status codes for block I/O entries.....                                         | 209  |

|                                                                       |     |
|-----------------------------------------------------------------------|-----|
| 24. DIAGNOSE X'250' condition codes.....                              | 212 |
| 25. Condition codes and return codes for the Initialize function..... | 212 |
| 26. Condition codes and return codes for the Read/Write function..... | 212 |
| 27. Condition codes and return codes for the Remove function.....     | 213 |
| 28. Program exceptions.....                                           | 214 |
| 29. Version definitions.....                                          | 226 |
| 30. Subcode X'00000004' Return Codes.....                             | 227 |
| 31. Return Virtual LAN System Information (DSECT CSISRESP) .....      | 228 |
| 32. Return IVL Membership Information (DSECT CSISISTR) .....          | 229 |
| 33. Subcode X'00000008' Return Codes.....                             | 230 |
| 34. Subcode X'0000000C' Return Codes.....                             | 231 |
| 35. Return Controller Information (DSECT CSICRESP).....               | 231 |
| 36. Controller Information (DSECT CSICCSTR).....                      | 232 |
| 37. Vswitch Information (DSECT CSICVSTR).....                         | 233 |
| 38. Subcode X'00000010' Return Codes.....                             | 234 |
| 39. Subcode X'00000014' Return Codes.....                             | 234 |
| 40. Return Guest LAN Information (DSECT CSIGRESP).....                | 235 |
| 41. Guest LAN Information (DSECT CSIGGSTR).....                       | 235 |
| 42. Connected Adapter Information (DSECT CSIGASTR).....               | 237 |
| 43. Authorized User Information (DSECT CSIGUSTR).....                 | 237 |
| 44. Subcode X'00000018' Return Codes.....                             | 237 |
| 45. Subcode X'0000001C' Return Codes.....                             | 238 |
| 46. Return Virtual Switch Information (DSECT CSIVRESP).....           | 240 |
| 47. Virtual Switch Information (DSECT CSIVVSTR).....                  | 240 |
| 48. RDEV Information (DSECT CSIVRSTR) .....                           | 245 |

|                                                                          |     |
|--------------------------------------------------------------------------|-----|
| 49. Segment Information (DSECT CSIVSSTR).....                            | 249 |
| 50. Take-Over MAC Address Information (DSECT CSIVTSTR).....              | 251 |
| 51. Connected Adapter Information (DSECT CSIVASTR).....                  | 251 |
| 52. Authorized User Information (DSECT CSIVUSTR).....                    | 251 |
| 53. Authorized Port Information (DSECT CSIVPSTR).....                    | 252 |
| 54. Authorized User VLAN Information (DSECT CSIVLSTR).....               | 252 |
| 55. Global Virtual Switch Member Information (DSECT CSIVMSTR).....       | 252 |
| 56. Subcode X'00000020' Return Codes.....                                | 253 |
| 57. Return Virtual Port or Virtual NIC Information (DSECT CSIPRESP)..... | 254 |
| 58. Port or NIC Information (DSECT CSIPNSTR).....                        | 255 |
| 59. Device Information (DSECT CSIPDSTR) .....                            | 257 |
| 60. Data Device Details (DSECT CSIPTSTR).....                            | 258 |
| 61. Active Segment Information (DSECT CSIPSSTR).....                     | 258 |
| 62. MAC Address Information (DSECT CSIPMSTR).....                        | 259 |
| 63. Subcode X'00000024' Return Codes.....                                | 260 |
| 64. MAC Services Return MAC Address (DSECT CSIMRESP).....                | 262 |
| 65. Subcode X'00000030' Return Codes.....                                | 262 |
| 66. Sequence of Functions.....                                           | 302 |
| 67. CP System Services and Their User IDs.....                           | 318 |
| 68. Applicable Codes Based on the Condition Code.....                    | 396 |
| 69. Possible APPC/VM Sever Codes.....                                    | 399 |
| 70. Sever Codes Generated by VM.....                                     | 400 |
| 71. APPC/VM States.....                                                  | 404 |
| 72. APPC/VM States for Coordinated Resource Recovery.....                | 405 |
| 73. Error Conditions.....                                                | 408 |

|                                                                                             |     |
|---------------------------------------------------------------------------------------------|-----|
| 74. Summary of Locally Known LU Names.....                                                  | 420 |
| 75. APPC/VM-Defined SENDERR Codes.....                                                      | 494 |
| 76. APPC Conversation States and Corresponding APPC/VM Implementation.....                  | 572 |
| 77. Base Set of APPC Verbs and APPC/VM Functions.....                                       | 573 |
| 78. APPC Operator Control Verbs Mapped to AVS Commands.....                                 | 574 |
| 79. Supported HCPRPD Return Codes.....                                                      | 600 |
| 80. Format of information in the HCPA0LBK control block.....                                | 615 |
| 81. Generic command audit format of ACIPARMS.....                                           | 637 |
| 82. Supported Return Codes.....                                                             | 638 |
| 83. Generic DIAGNOSE Call Format of the ACIPARMS Parameter List.....                        | 638 |
| 84. Supported Return Codes.....                                                             | 638 |
| 85. ACILVIDL and Buffer Data Examples for VLAN AWARE Virtual Switches.....                  | 639 |
| 86. ACILVIDL and Buffer Data Examples for Guest LANs and VLAN UNAWARE virtual switches..... | 639 |
| 87. (X)AUTOLOG Command Format of the ACIPARMS Parameter List.....                           | 640 |
| 88. (X)AUTOLOG ESM output fields in ACIPARMS.....                                           | 641 |
| 89. Supported HCPRPWEF Return Codes for the AUTOLOG and XAUTOLOG.....                       | 641 |
| 90. CHANGE Command Audit Format of the ACIPARMS Parameter List.....                         | 642 |
| 91. Supported HCPRPIRA Return Codes.....                                                    | 642 |
| 92. CHANGE Command Format of the ACIPARMS Parameter List.....                               | 643 |
| 93. Supported HCPRPIRA Return Codes.....                                                    | 643 |
| 94. CLOSE TO Command Format of the ACIPARMS Parameter List.....                             | 644 |
| 95. Supported HCPRPIRA Return Codes for the CLOSE TO Command.....                           | 644 |
| 96. COUPLE Command Format of the ACIPARMS Parameter List.....                               | 644 |
| 97. Supported HCPRPIRA Return Codes for the COUPLE Command.....                             | 645 |
| 98. COUPLEN Command Format of the ACIPARMS Parameter List.....                              | 645 |

|                                                                                       |     |
|---------------------------------------------------------------------------------------|-----|
| 99. Supported HCPRPIRA Return Codes for the COUPLEN Command.....                      | 646 |
| 100. FOR Command MAC/AUDIT Format of the ACIPARMS Parameter List.....                 | 646 |
| 101. Supported Return Codes for the FOR Command.....                                  | 647 |
| 102. GIVE return.....                                                                 | 647 |
| 103. LINK Command Format of the ACIPARMS Parameter List.....                          | 648 |
| 104. Supported HCPRPIRA Return Codes for the LINK Command.....                        | 648 |
| 105. LOGOFF Command Format of the ACIPARMS Parameter List.....                        | 649 |
| 106. AT Command Guest LOGOFF Format of the ACIPARMS Parameter List.....               | 650 |
| 107. LOGON Command Format of the ACIPARMS Parameter List.....                         | 650 |
| 108. LOGON ESM output fields in ACIPARMS.....                                         | 652 |
| 109. Supported HCPRPWEF Return Codes for the LOGON Command.....                       | 653 |
| 110. AT Command Guest LOGON Format of the ACIPARMS Parameter List.....                | 653 |
| 111. MESSAGE Command MAC/AUDIT Format of the ACIPARMS Parameter List.....             | 654 |
| 112. Supported Return Codes for the MESSAGE Command.....                              | 654 |
| 113. Supported HCPRPIRA Return Codes for the PURGE Command.....                       | 655 |
| 114. QUERY TAG FILE Command Format of the ACIPARMS Parameter List.....                | 655 |
| 115. Supported Return Codes.....                                                      | 656 |
| 116. QUERY RDR/PRT/PUN Command Format of the ACIPARMS Parameter List.....             | 656 |
| 117. Supported HCPRPIRA Return Codes.....                                             | 656 |
| 118. SEND Command Audit Call Format of the ACIPARMS Parameter List.....               | 657 |
| 119. SEND Command Security Label MAC Check Format of the ACIPARMS Parameter List..... | 657 |
| 120. Supported Return Codes.....                                                      | 658 |
| 121. SPOOL Command Format of the ACIPARMS Parameter List.....                         | 658 |
| 122. Supported HCPRPIRA Return Codes for the SPOOL TO Command.....                    | 658 |
| 123. ACIPARMS format.....                                                             | 659 |

|                                                                                      |     |
|--------------------------------------------------------------------------------------|-----|
| 124. Supported Return Codes.....                                                     | 659 |
| 125. START real printer with SECLABEL option authorization call.....                 | 659 |
| 126. Supported Return Codes for the START Real Printer with SECLABEL.....            | 660 |
| 127. STORE HOST Command Format of the ACIPARMS Parameter List.....                   | 660 |
| 128. Supported Return Codes.....                                                     | 661 |
| 129. TAG Command Format of the ACIPARMS Parameter List.....                          | 661 |
| 130. Supported Return Codes for the TAG Command.....                                 | 662 |
| 131. TRANSFER Command Format of the ACIPARMS Parameter List.....                     | 662 |
| 132. Supported Return Codes for the TRANSFER Command.....                            | 662 |
| 133. TRANSFER Command Format of the ACIPARMS Parameter List.....                     | 663 |
| 134. Supported HCPRPIRA Return Codes.....                                            | 663 |
| 135. TRSAVE TO Command Format of the ACIPARMS Parameter List.....                    | 664 |
| 136. Supported HCPRPIRA Return Codes for the TRSAVE TO Command.....                  | 664 |
| 137. TRSOURCE Command Format of the ACIPARMS Parameter List.....                     | 664 |
| 138. Supported HCPRPIRA Return Codes for the TRSOURCE Command.....                   | 665 |
| 139. TRSOURCE ENABLE Command Format of the ACIPARMS Parameter List.....              | 665 |
| 140. Supported Return Codes.....                                                     | 666 |
| 141. VMRELOCATE Command Format of the ACIPARMS Parameter List.....                   | 666 |
| 142. VMDUMP TO Command and DIAGNOSE X'94' Format of the ACIPARMS Parameter List..... | 667 |
| 143. Supported Return Codes.....                                                     | 667 |
| 144. DIAGNOSE Code X'14' Format of the ACIPARMS Parameter List.....                  | 668 |
| 145. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'14'.....                    | 668 |
| 146. DIAGNOSE Code X'64' Format of the ACIPARMS Parameter List.....                  | 668 |
| 147. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'64'.....                    | 669 |
| 148. DIAGNOSE Code X'68' Format of the ACIPARMS Parameter List.....                  | 669 |

|                                                                              |     |
|------------------------------------------------------------------------------|-----|
| 149. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'68' .....           | 670 |
| 150. DIAGNOSE Code X'88' Format of the ACIPARMS Parameter List.....          | 670 |
| 151. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'88' .....           | 670 |
| 152. DIAGNOSE Code X'B8' Format of the ACIPARMS Parameter List.....          | 671 |
| 153. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'B8' .....           | 671 |
| 154. DIAGNOSE Code X'BC' Format of the ACIPARMS Parameter List.....          | 671 |
| 155. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'BC' .....           | 672 |
| 156. DIAGNOSE Code X'D4' Format of the ACIPARMS Parameter List.....          | 672 |
| 157. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'D4' .....           | 673 |
| 158. DIAGNOSE Code X'E4' Command Format of the ACIPARMS Parameter List.....  | 673 |
| 159. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'E4' .....           | 674 |
| 160. DIAGNOSE Code X'290' Command Format of the ACIPARMS Parameter List..... | 674 |
| 161. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'290' .....          | 675 |
| 162. DIAGNOSE Code X'23C' Format of the ACIPARMS Parameter List.....         | 675 |
| 163. Supported HCPRPIRA Return Codes for DIAGNOSE Code X'23C' .....          | 675 |
| 164. APPC CONNECT Format of the ACIPARMS Parameter List.....                 | 676 |
| 165. Supported HCPRPIRA Return Codes for APPC CONNECT.....                   | 676 |
| 166. APPC setting of VMDALTID format of ACIPARMS.....                        | 677 |
| 167. Supported Return Codes.....                                             | 677 |
| 168. APPC SEVER Format of the ACIPARMS Parameter List.....                   | 678 |
| 169. APPC connect with password validation.....                              | 678 |
| 170. Supported Return Codes.....                                             | 679 |
| 171. Directory Command Format of the ACIPARMS Parameter List.....            | 679 |

| 235. DIAGNOSE X'280' condition codes.....                                               | 1068 |
| 236. Condition codes and return codes for changing effective and saved set-IDs.....     | 1068 |
| 237. Condition codes and return codes for changing saved set-IDs only.....              | 1070 |
| 238. Condition Codes for Query I/O Configuration Information (Function 0).....          | 1093 |
| 239. Condition Codes and Return Codes for Perform Dynamic I/O Changes (Function 1)..... | 1093 |
| 240. DIAGNOSE Code X'2C4' Return Codes in Ry.....                                       | 1098 |

# About This Document

This document contains reference information pertaining to specific services and facilities of CP, such as the DIAGNOSE instruction, IUCV, APPC/VM, and VM data spaces.

## Intended Audience

This information is intended for systems programmers and applications programmers who will be writing programs for IBM® z/VM®.

To get the most out of this information, you should have a general idea of what z/VM does and what a virtual machine is. You should also have a working knowledge of Basic Assembler Language programming.

## Syntax, Message, and Response Conventions

The following topics provide information on the conventions used in syntax diagrams and in examples of messages and responses.

### How to Read Syntax Diagrams

Special diagrams (often called *railroad tracks*) are used to show the syntax of external interfaces.

To read a syntax diagram, follow the path of the line. Read from left to right and top to bottom.

- The  symbol indicates the beginning of the syntax diagram.
- The  symbol, at the end of a line, indicates that the syntax diagram is continued on the next line.
- The  symbol, at the beginning of a line, indicates that the syntax diagram is continued from the previous line.
- The  symbol indicates the end of the syntax diagram.

Within the syntax diagram, items on the line are required, items below the line are optional, and items above the line are defaults. See the examples in [Table 1 on page xxxv](#).

| Table 1. Examples of Syntax Diagram Conventions                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Syntax Diagram Convention                                                                                                                                                                                                                                                                                                                                                       | Example                                                                                                                                                                           |
| <b>Keywords and Constants</b><br>A keyword or constant appears in uppercase letters. In this example, you must specify the item KEYWORD as shown.<br><br>In most cases, you can specify a keyword or constant in uppercase letters, lowercase letters, or any combination. However, some applications may have additional conventions for using all-uppercase or all-lowercase. |  KEYWORD  |
| <b>Abbreviations</b><br>Uppercase letters denote the shortest acceptable abbreviation of an item, and lowercase letters denote the part that can be omitted. If an item appears entirely in uppercase letters, it cannot be abbreviated.<br><br>In this example, you can specify KEYWO, KEYWOR, or KEYWORD.                                                                     |  KEYWOrd  |

Table 1. Examples of Syntax Diagram Conventions (continued)

| Syntax Diagram Convention                                                                                                                                                                                                                                                                                                                                                                                                                       | Example                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Symbols</b><br>You must specify these symbols exactly as they appear in the syntax diagram.                                                                                                                                                                                                                                                                                                                                                  | * Asterisk<br>: Colon<br>, Comma<br>= Equal Sign<br>- Hyphen<br>() Parentheses<br>. Period                                                                                                                                                                                                                                         |
| <b>Variables</b><br>A variable appears in highlighted lowercase, usually italics.<br>In this example, <i>var_name</i> represents a variable that you must specify following KEYWORD.                                                                                                                                                                                                                                                            | ► KEYWORD — <i>var_name</i> ◄                                                                                                                                                                                                                                                                                                      |
| <b>Repetitions</b><br>An arrow returning to the left means that the item can be repeated.<br>A character within the arrow means that you must separate each repetition of the item with that character.<br>A number (1) by the arrow references a syntax note at the bottom of the diagram. The syntax note tells you how many times the item can be repeated.<br>Syntax notes may also be used to explain other special aspects of the syntax. | <br><br><br>Notes:<br><sup>1</sup> Specify <i>repeat</i> up to 5 times. |
| <b>Required Item or Choice</b><br>When an item is on the line, it is required. In this example, you must specify A.<br>When two or more items are in a stack and one of them is on the line, you must specify one item. In this example, you must choose A, B, or C.                                                                                                                                                                            | ► A ◄<br>                                                                                                                                                                                                                                      |
| <b>Optional Item or Choice</b><br>When an item is below the line, it is optional. In this example, you can choose A or nothing at all.<br>When two or more items are in a stack below the line, all of them are optional. In this example, you can choose A, B, C, or nothing at all.                                                                                                                                                           | <br>                                                                                                                                                       |

| Table 1. Examples of Syntax Diagram Conventions (continued)                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Syntax Diagram Convention                                                                                                                                                                                                                                                                                                    | Example                                                                                                                                                                                        |
| <p><b>Defaults</b></p> <p>When an item is above the line, it is the default. The system will use the default unless you override it. You can override the default by specifying an option from the stack below the line.</p> <p>In this example, A is the default. You can override A by choosing B or C.</p>                |                                                                                                              |
| <p><b>Repeatable Choice</b></p> <p>A stack of items followed by an arrow returning to the left means that you can select more than one item or, in some cases, repeat a single item.</p> <p>In this example, you can choose any combination of A, B, or C.</p>                                                               |                                                                                                              |
| <p><b>Syntax Fragment</b></p> <p>Some diagrams, because of their length, must fragment the syntax. The fragment name appears between vertical bars in the diagram. The expanded fragment appears in the diagram after a heading with the same fragment name.</p> <p>In this example, the fragment is named "A Fragment."</p> |  <p><b>A Fragment</b></p>  |

## Examples of Messages and Responses

Although most examples of messages and responses are shown exactly as they would appear, some content might depend on the specific situation. The following notation is used to show variable, optional, or alternative content:

**xxx**

Highlighted text (usually italics) indicates a variable that represents the data that will be displayed.

**[]**

Brackets enclose optional text that might be displayed.

**{ }**

Braces enclose alternative versions of text, one of which will be displayed.

**|**

The vertical bar separates items within brackets or braces.

**...**

The ellipsis indicates that the preceding item might be repeated. A vertical ellipsis indicates that the preceding line, or a variation of that line, might be repeated.

## Where to Find More Information

For more information about z/VM functions, see the other documents listed in the [“Bibliography”](#) on page 1105.

## **Links to Other Documents and Websites**

The PDF version of this document contains links to other documents and websites. A link from this document to another document works only when both documents are in the same directory or database, and a link to a website works only if you have access to the Internet. A document link is to a specific edition. If a new edition of a linked document has been published since the publication of this document, the linked document might not be the latest edition.

## How to provide feedback to IBM

---

We welcome any feedback that you have, including comments on the clarity, accuracy, or completeness of the information. See [How to send feedback to IBM](#) for additional information.

# Summary of Changes for z/VM: CP Programming Services

---

This information includes terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations for the current edition are indicated by a vertical line (|) to the left of the change.

## SC24-6272-73, z/VM 7.3 (September 2025)

---

This edition includes changes to support product changes that are provided or announced after the general availability of z/VM 7.3.

### [7.3 VM66878] Enhanced QDIO virtual switch vNIC simulation

With the PTF for APAR VM66878 (CP), z/VM 7.3 provides guests with the ability to define simulated enhanced QDIO (EQDIO) network interface cards (vNICs) on the virtual switch. With this support, a guest has the option to establish and activate a network connection in either traditional QDIO or EQDIO mode. QDIO mode requires three devices to activate a network connection but EQDIO mode requires only a single device.

The following topic is updated:

- “Subcode X'00000024'—Return Virtual Port, Virtual NIC or HiperSockets Logical Port Information” on [page 253](#)

## SC24-6272-73, z/VM 7.3 (July 2025)

---

This edition includes changes to support product changes that are provided or announced after the general availability of z/VM 7.3.

The following topic is updated:

- “[7.3 VM66823] z/VM support for the IBM z17 family” on [page xli](#)

## SC24-6272-73, z/VM 7.3 (June 2025)

---

This edition includes changes to support product changes that are provided or announced after the general availability of z/VM 7.3.

### [7.3 VM66823] z/VM support for the IBM z17 family

| With the PTFs for APARs VM66823 and VM66853 (7.3 CP) and VM66857 (7.3 RACF), z/VM 7.3 provides support for the IBM z17® family. For more information, see [z/VM support for the IBM z17 family](#) in the *z/VM: Migration Guide*.

The following topics are updated:

- “DIAGNOSE Code X'26C' – Access Certain System Information” on [page 225](#)
- “Subcode X'00000010'—Return Controller Information” on [page 231](#)
- “Subcode X'00000020'—Return Virtual Switch Information” on [page 238](#)

## SC24-6272-73, z/VM 7.3 (July 2024)

---

This edition includes changes to support product changes provided or announced after the general availability of z/VM 7.3.

## **[VM66742] VSwitch recovery logic is updated to eliminate endless recovery attempts**

With the PTF for APAR VM66742, the VSwitch recovery logic is updated. When a device reset and re-initialization of a VSwitch Uplink Port does not clean up an error condition after multiple attempts, the VSwitch recovery logic now stops its device recovery attempts and issues message HCP3233E.

For DIAGNOSE Code X'26C' – Access Certain System Information, the [“Subcode X'00000020'—Return Virtual Switch Information”](#) on page 238 topic is updated:

- In Table 48 on page 245, offset X'15' error code X'12' is changed from "Reserved for future use" to "VSWITCH CONNECT Required".

## **Miscellaneous updates for July 2024**

The z/VM format of the response to the Store System Information (STSI) instruction for SYSIB 3.2.2 is documented. See [Chapter 30, “Store System Information \(STSI\) Instruction,”](#) on page 973.

## **SC24-6272-73, z/VM 7.3 (April 2024)**

---

This edition includes terminology, maintenance, and editorial changes.

### **Miscellaneous updates for April 2024**

The *userid* and *password* parameters of [“DIAGNOSE Code X'84' – Directory Update-in-Place”](#) on page 91 must be specified by using uppercase.

## **SC24-6272-73, z/VM 7.3 (December 2023)**

---

This edition includes terminology, maintenance, and editorial changes.

## **SC24-6272-73, z/VM 7.3 (May 2023)**

---

This edition includes changes to support product changes provided or announced after the general availability of z/VM 7.3.

### **[VM66679] VMEVENT Enhancements**

With the PTF for APAR VM66679, z/VM 7.3 provides the following new and changed VMEVENT data for use in operations automation, resource monitoring, and auditing:

- New disconnect and reconnect events. Reconnect events include logon-by and terminal information as part of the event message.
- Additional logon-by and terminal information is added to the existing logon event.
- Class 0 type 3 and class 1 type 3 provide a full-precision (32-bit) timeout interval for the logoff timeout service.
- An enhancement to the reporting of "runnable". The runnable event is now reported only when "runnable" is a result of a state change. Superfluous reports of "runnable" when there is no need to report an event are eliminated.

The following topic is updated:

- [“Receiving \\*VMEVENT Events”](#) on page 773

## **SC24-6272-73, z/VM 7.3 (September 2022)**

---

This edition supports the general availability of z/VM 7.3. Note that the publication number suffix (-73) indicates the z/VM release to which this edition applies.

## **Eight-member SSI support**

This support increases the maximum size of a single system image (SSI) cluster from four members to eight, enabling clients to grow their SSI clusters to allow for increased workloads and providing more flexibility to use live guest relocation (LGR) for nondisruptive upgrades and workload balancing.

The following data area is updated:

- [“SFBLOK - VM/SP 370 Spool File Control Block” on page 988](#)

---

# Part 1. CP DIAGNOSE Instructions

The capability of adding customer-written CP routines to the system allows you to define new DIAGNOSE codes or replace existing DIAGNOSE codes by redefining them, and to enable or disable either new or existing DIAGNOSE codes. See [z/VM: CP Exit Customization](#) for additional information.

This part contains the following chapters:

- Chapter 1, “[The DIAGNOSE Instruction in a Virtual Machine](#),” on page 3, which tells you how to use the DIAGNOSE instruction and the different types of DIAGNOSE instructions.
- Chapter 2, “[The IBM-Supplied DIAGNOSE Codes](#),” on page 13, which provides a detailed description of each IBM-Supplied DIAGNOSE code.

# Chapter 1. The DIAGNOSE Instruction in a Virtual Machine

In a real processor, the DIAGNOSE instruction performs processor-dependent diagnostic functions. In a virtual machine, you use the DIAGNOSE interface to request that CP perform services for your virtual machine. When your virtual machine attempts to execute a DIAGNOSE instruction, control is returned to CP. CP uses information provided in the *code* portion of the instruction to determine what service it should perform. Once this service is provided, control returns to the virtual machine.

Thus, because a DIAGNOSE instruction issued in a virtual machine results only in returning control to CP and not in performing real-processor DIAGNOSE functions, think of DIAGNOSE codes as a method of communicating virtual machine requirements to CP.

## Instruction Format

The machine language format of a DIAGNOSE instruction is:

### 83

is X'83', the machine language operation code for the DIAGNOSE instruction.

**Note:** There is no assembler mnemonic for DIAGNOSE.

### RxRy

typically designate the general registers that contain the operand values or operand storage addresses to be passed through the DIAGNOSE interface.

The use of the Rx and Ry fields varies by DIAGNOSE code and subcode. In some cases, Rx and/or Ry may designate a pair of consecutive registers, referred to as registers Rx and Rx+1 and/or Ry and Ry+1.

### B

is the base register. IBM recommends that you specify Register 0 as the base register (see note [“1” on page 3](#) following).

### DDD

is either all or part of the actual DIAGNOSE code value, in hexadecimal (see note [“1” on page 3](#) following). This value is also called the *displacement*. IBM does not use codes X'100' through X'1FC'.

### Notes:

1. With the DIAGNOSE instruction, the effective address (contents of the base register plus the displacement) is **not** used to address the data. Ordinarily, the contents of the base register plus the displacement equal the DIAGNOSE code. However, if you specify the base register to be register 0, its contents are not added to the displacement; the displacement alone determines the DIAGNOSE code. IBM recommends that you always specify the base register as register 0; therefore, you should always set bits 16 through 19 to 0. The DIAGNOSE code, or displacement, must always be a multiple of four.
2. If Rx, Ry or, if applicable, Rx+1 or Ry+1 contains an address, it must be a second-level address (that is, an address in the storage that appears real to the issuing virtual machine), unless otherwise specified.
3. The description of each DIAGNOSE instruction includes an **Addressing Mode** specification which indicates whether it supports 24-bit, 31-bit or 64-bit addressing modes.

4. Because DIAGNOSE instructions execute differently in a virtual machine than in a real machine, your program should determine that it is operating in a virtual machine before issuing a DIAGNOSE instruction, and prevent execution of a DIAGNOSE instruction when in a real machine. If the first byte (version code) stored by the Store CPU ID instruction is X'FF', then the program is running in a virtual machine.
5. A virtual machine issuing an I/O DIAGNOSE instruction should run with interrupts disabled. This prevents the loss of information pertaining to the DIAGNOSE operation such as status conditions and sense data.
6. Use of the DIAGNOSE instruction within a transaction will cause the transaction to abort with either a restricted-instruction transaction-abort code or a transaction-constraint exception. (See [z/Architecture Principles of Operation \(https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf\)](https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf) for details on transactional execution.)

**Example of the DIAGNOSE Instruction:** The example in Figure 1 on page 4 demonstrates how to code a DIAGNOSE code in a small Assembler program. This example happens to use DIAGNOSE code X'00', which stores the z/VM extended identification code at a specified location in guest storage.

```
DIAG00    CSECT
*This demonstrates the use of DIAGNOSE code X'00', which
*stores the z/VM Identification Code at a specified address.
        BALR 12,0
        USING *,12
        LA 2,LOC                STORAGE ADDRESS IN R2 (Rx)
        LA 3,L'LOC              # BYTES TO BE STORED IN R3 (Ry)
        DC X'83',X'23',XL2'0000' PIECE TOGETHER THE DIAG. CODE
        BR 14
        DS 0D                  FORCE DOUBLEWORD BOUNDARY
LOC      DS XL64                STORAGE LOCATION
        END
```

Figure 1. Example of a DIAGNOSE Code in an Assembler Program

The DC (Declare Constant) line in this program is the actual DIAGNOSE code.

**X'83'**

is the machine language operation code for the DIAGNOSE instruction.

**X'23'**

is the specification of the RxRy general register pair. Here, Rx is 2 and Ry is 3.

**XL2'0000'**

is the base register and the displacement. The base register (0) is the first half byte. The remaining bits are the displacement, which (for the DIAGNOSE instruction) is the 3-digit hexadecimal DIAGNOSE code (000).

## Macro Format

Using the DIAG macro automatically generates the correct machine format of the DIAGNOSE instruction. The macro format for the DIAG macro is:

**DIAG**

Requests that CP perform the DIAGNOSE instruction.

**Rx**

is the general register that contains the Rx operand value or operand storage address required for the particular DIAGNOSE function.

**Ry**

is the general register that contains the Ry operand value or operand storage address required for the particular DIAGNOSE function.

**code**

is the actual DIAGNOSE value. This code can be specified as anything that is acceptable for a Y-type address constant. The constant must resolve to a supported DIAGNOSE code.

**Example of the DIAG Macro:**

```
DIAG    2,3,X'0000'
```

The above example generates the X'83' instruction for DIAGNOSE code X'00'.

## Privilege Classes

---

Some DIAGNOSE codes, like some CP commands, are reserved for authorized users only. Each DIAGNOSE code description in this section tells you who may issue that particular code. For more information on the letter values used in this entry, see [z/VM: CP Commands and Utilities Reference](#).

## Address Translation Modes and Restrictions

---

When used without a qualifier, the term XC encompasses both ESA/XC and z/XC architectures. The qualified terms *ESA/XC* and *z/XC* are used only when it is important to distinguish one architecture from the other.

A program can change mode from ESA/XC mode to z/XC mode and from z/XC mode to ESA/XC mode.

Some DIAGNOSE codes can be issued only by XC virtual machines, and others can be issued by any type of virtual machine. Some DIAGNOSE codes cannot be issued by an XC virtual machine in access register mode, while some can be issued but only refer to the host-primary address space. Some DIAGNOSE codes can be issued only when 370 Accommodation is active. Some DIAGNOSE codes can use logical addresses, which refer to any guest address space, including the real, primary, secondary, or home space or any address space designated by an ALET in an access register. These capabilities and restrictions are noted in the description of the DIAGNOSE code.

Except for Diagnoses that accept logical addresses, XC virtual machines in primary space mode and non-XC virtual machines ignore the access registers; all addresses refer to the host-primary address space. XC virtual machines in access register mode ignore the contents of access register 0 when an address is passed in general register 0; the access register is assumed to contain an ALET X'00000000', which indicates the host-primary address space. All exceptions are noted in the description of the DIAGNOSE code.

A DIAGNOSE code issued by ESA, XA, and Z virtual machines may refer to a logical address. Such addresses are references to the address space identified by the translation and address-space control bits in the guest Program Status Word (PSW). This means that the guest can refer to an address that is in its real, primary, secondary, or home space, as well as one that is access-register designated. In access-register mode, the access register corresponding to the general register that contains a logical address is used to obtain the ALET for the address space, although if access register 0 is designated it is assumed to contain an ALET of X'00000000'.

The description of each DIAGNOSE instruction includes an **Addressing Mode** specification which indicates whether it supports 24-bit, 31-bit or 64-bit addressing modes.

## How Addresses Are Processed

---

z/VM processes addresses according to the type of virtual machine in which a guest is running and the addressing mode which is set.

| Type of Guest                                      | Address Length                                                     | Address Space Containing Address                                                          |
|----------------------------------------------------|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| ESA and XA                                         | 24- or 31-bit, depending on the addressing mode <sup>1</sup>       | host-primary <sup>2</sup>                                                                 |
| ESA, XA, and ESA/XC                                | 24- or 31-bit, depending on the addressing mode <sup>1</sup>       | guest-real, guest-primary, guest-secondary, guest-home, or ALET-specified <sup>4, 5</sup> |
| ESA/XC, primary-space mode                         | 24- or 31-bit, depending on the addressing mode <sup>1</sup>       | host-primary                                                                              |
| ESA/XC, access-register mode                       | 24- or 31-bit, depending on the addressing mode <sup>1</sup>       | host-primary or ALET-specified, depending on the DIAGNOSE function                        |
| z/XC, primary-space mode                           | 24-, 31-, or 64-bit, depending on the addressing mode <sup>1</sup> | host-primary                                                                              |
| z/XC, access-register mode                         | 24-, 31-, or 64-bit, depending on the addressing mode <sup>1</sup> | host-primary or ALET-specified, depending on the DIAGNOSE function                        |
| ESA, XA, and Z in z/Architecture <sup>®</sup> mode | 24-, 31-, or 64-bit, depending on the addressing mode <sup>1</sup> | host-primary <sup>2, 3</sup>                                                              |
| ESA, XA, and Z in z/Architecture mode              | 24-, 31-, or 64-bit, depending on the addressing mode <sup>1</sup> | guest-real, guest-primary, guest-secondary, guest-home, or ALET-specified <sup>5</sup>    |

**Notes:**

1. Exception: I/O DIAGNOSE codes are always processed in 31-bit mode.
2. With the exception of address spaces accessed through DIAGNOSE code X'248', these types of virtual machines have access to a single host (CP) created absolute address space, in which all guest real and absolute addresses reside. This is the absolute address space created by CP at log on time to represent the virtual machine's main storage.
3. z/Architecture has 8-byte register values. Address values passed for DIAGNOSE instructions in 64-bit addressing mode use all 8 bytes of the register.
4. An XC virtual machine can operate only in primary-space mode or in access-register mode and thus may use logical addresses that are either guest-real or ALET-specified.
5. The DIAGNOSE must be defined as accepting a logical address, in which case the address space is selected based on the translation and address-space control bits in the guest PSW at the time the DIAGNOSE instruction is issued.

Unless otherwise specified, Most addresses passed in DIAGNOSE functions and CP programming interface macros are guest real addresses. Those functions that perform I/O operations or cross-virtual-machine communications generally take guest absolute addresses. In cases where the addressed area is referenced asynchronously (that is, during a process that continues after the DIAGNOSE instruction itself completes), addresses are also guest absolute. Consult the description of the individual DIAGNOSE function to determine whether its operand addresses are real or absolute.

Guest real addresses in the host-primary space are subject to prefixing, whereas guest absolute addresses are not. Addresses in spaces other than the host-primary space are never subject to prefixing. (In particular, references using an ALET other than X'00000000' are not subject to prefixing.) For more information on real and absolute addresses and prefixing, see the [Enterprise Systems Architecture/390 Principles of Operation \(publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf\)](https://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf), [z/VM: ESA/XC Principles of Operation, z/Architecture Principles of Operation \(https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf\)](https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf), or [z/VM: z/Architecture Extended Configuration \(z/XC\) Principles of Operation](https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf), based on the architecture mode of the virtual machine.

Unless otherwise specified, all storage references by the DIAGNOSE and IUCV instructions and by CP programming interface macros are multiple-access references, as defined in the Enterprise Systems Architecture/390 Principles of Operation ([publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf](http://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf)), *z/VM: ESA/XC Principles of Operation*, *z/Architecture Principles of Operation* (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>), or *z/VM: z/Architecture Extended Configuration (z/XC) Principles of Operation*, based on the architecture mode of the virtual machine.

## How Address Spaces Are Selected

When a virtual machine logs on, a *host address space* is created to serve as the virtual machine's storage. This storage appears as absolute storage (as defined in the Enterprise Systems Architecture/390 Principles of Operation ([publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf](http://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf)), *z/VM: ESA/XC Principles of Operation*, *z/Architecture Principles of Operation* (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>), or *z/VM: z/Architecture Extended Configuration (z/XC) Principles of Operation*, based on the architecture mode of the virtual machine) to the program running in the virtual machine. This address space is called the virtual machine's *host-primary* address space. Using VM data spaces, a virtual machine can also gain access to other host address spaces, which may be other virtual machines' host-primary spaces or data spaces created by this or other virtual machines.

XA, ESA, and Z virtual machines can reference these additional address spaces through DIAGNOSE code X'248' only. XC virtual machines can switch between two translation modes, called primary-space mode and access-register mode. Like a non-XC virtual machine, an XC machine in primary-space mode addresses only the host-primary space. An XC virtual machine in access-register mode can reference data in all accessible address spaces directly using nearly the full instruction set, including most of the DIAGNOSE functions described here.

XA, ESA, and Z machines can create their own address spaces and can switch among five translation modes called real-space mode, primary-space mode, secondary-space mode, home-space mode, and access-register mode. DIAGNOSE codes that accept logical addresses for parameters use the address space designated by the translation and address-space control bits in the guest PSW to determine which address space the logical address references.

For each storage address referenced, the descriptions of the individual DIAGNOSE codes specify whether the address is a host-primary address regardless of translation mode, a guest-logical address whose address space designation is determined by the guest PSW, or an AR-specified or ALET-specified address. An AR-specified address is one for which the address space is identified by an Access-List-Entry Token (ALET) in an access register. An ALET-specified address is one for which the address space is identified by an ALET in a parameter list. In either case, the ALET is translated by means of host access-register translation (host ART) to identify the target address space.

For more information on access registers, ALETs, and host ART, see Enterprise Systems Architecture/390 Principles of Operation ([publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf](http://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf)) and *z/VM: ESA/XC Principles of Operation*. For information on creating and gaining access to host address spaces see Chapter 25, "CP Macros," on page 807.

## How Error Conditions Are Reported

While trying to perform a DIAGNOSE function, CP may encounter errors. Most DIAGNOSE functions report these errors through program interruptions, as other instructions do. Some functions report errors through condition codes and return codes instead. The condition codes and return codes are unique to each function and are defined with the individual functions. The program interruptions are explained below.

The DIAGNOSE instruction in a virtual machine can give the following program interruptions:

| Program Interruption           | Cause                                                                                                                      |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Operation exception            | For some DIAGNOSE functions, these exceptions indicate that the virtual machine is not authorized to perform the function. |
| Privileged-operation exception |                                                                                                                            |

| <b>Program Interruption</b>                            | <b>Cause</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                                | <p>Any of the following:</p> <ul style="list-style-type: none"> <li>• The DIAGNOSE function code is not supported.</li> <li>• An unknown subfunction was requested.</li> <li>• For some DIAGNOSE functions, the virtual machine is not authorized to perform the function.</li> <li>• The DIAGNOSE function is not supported in the architecture mode of the virtual machine.</li> <li>• A virtual machine issued a DIAGNOSE function that does not support 64-bit addressing mode.</li> <li>• An incorrect register number was specified.</li> <li>• A field in a parameter list is invalid, or a reserved field is non-zero.</li> <li>• An operand or parameter list is not aligned on the required storage boundary.</li> <li>• An operand's address and length are such that the operand would cross a 4K-byte boundary, for a DIAGNOSE function that does not support operands crossing such a boundary.</li> </ul> |
| Operand exception                                      | For I/O functions patterned after 370-XA and ESA/390 I/O instructions, an invalid subchannel ID was specified or an operand contained an invalid field value or a non-zero reserved field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Access exceptions (see “Access Exceptions” on page 8.) | An error occurred while attempting to reference an operand in storage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Note that certain conditions, such as an invalid parameter-list field or an attempt to perform an unauthorized function, are reported differently for different DIAGNOSE functions. Consult the description of the individual function for specific information.

## Access Exceptions

As explained in [Enterprise Systems Architecture/390 Principles of Operation \(publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf\)](https://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf), [z/VM: ESA/XC Principles of Operation, z/Architecture Principles of Operation \(https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf\)](https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf), and [z/VM: z/Architecture Extended Configuration \(z/XC\) Principles of Operation](https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf), the term *access exceptions* refers to a class of program interruptions that can arise while trying to refer to an operand in storage. These are:

### Addressing exception

The storage address designates a location not available in the target address space. For an address space which is this or another virtual machine's host-primary space, this happens when the address is above the defined storage size and does not designate a location in a saved segment loaded into the address space. For an address space created through VM Data Spaces services, this happens when the address is above the address-space size specified when the space was created.

### Protection exception

The attempted storage reference (fetch or store) is forbidden by one of several protection mechanisms. These mechanisms are described below.

### ALET-specification exception

For an XC virtual machine in access-register mode, the ALET designating the address space in which the operand resides is not a correctly-formed ALET.

### Addressing-capability exception

For an XC virtual machine in access-register mode, the ALET designating the address space in which the operand resides is correctly-formed but designates a host access-list entry that is in the revoked state.

**ALEN-translation exception**

For an XC virtual machine in access-register mode, the ALET designating the address space in which the operand resides is correctly-formed but does not designate a host access-list entry that is in either the valid or the revoked state.

For more information on ALETs and on host access-list entries and their states, see *z/VM: ESA/XC Principles of Operation* or *z/VM: z/Architecture Extended Configuration (z/XC) Principles of Operation*.

**Condition Codes and Return Codes**

After CP executes a DIAGNOSE code, certain responses may be sent back to you indicating whether the execution was successful. Three types of responses that you may receive are:

- **Condition codes** (sometimes referred to as **completion codes**), which appear in the PSW (program status word).
- **Return codes**, which appear in a register. The exact register where they appear is specified in the responses section of the documentation for each DIAGNOSE code, along with both decimal and hexadecimal values for each return code.
- **Program Exceptions.**

The responses section of each DIAGNOSE code shows the significance of all applicable condition codes and return codes.

**Storage Protection Mechanisms**

Several means are provided to control access to storage by DIAGNOSE and other instructions. Some of these apply to *fetch* references, that is, attempts to use the contents of storage as input to a function. Others apply to *store* references, that is, attempts to place function results into storage. A third class of reference, *update*, involves both fetching and storing. Both fetch- and store-protection mechanisms apply to update references. Violation of these mechanisms generally results in a program interruption for protection exception, or in a return code specific to the invoked DIAGNOSE function.

Some protection mechanisms apply to *synchronous* references only, that is, to references that occur during the execution of the DIAGNOSE instruction itself. *Asynchronous* references, such as those for an I/O operation initiated by a DIAGNOSE function that does not wait for completion, are not subject to such mechanisms. In addition, some mechanisms are not enforced for I/O and cross-virtual-machine communication functions at all, whether they are synchronous or not. In all cases, an access must pass every enforced protection mechanism to succeed. If any test fails, access is denied.

Unless otherwise specified, the DIAGNOSE instruction enforces all applicable protection mechanisms.

The specific protection mechanisms are:

**Key-controlled protection**

Under key-controlled protection, a four-bit access key (usually from the PSW, but for some operations, specified as an operand) is compared with the access-control bits of the storage key of each 4K-byte block in guest absolute storage. If the keys match, or if the access key is zero, then the access is permitted; if not, then store accesses are forbidden, and an additional fetch-protection bit for the storage block determines whether fetch accesses are forbidden as well. Not all DIAGNOSE functions enforce key-controlled protection.

In XA, ESA, XC, and Z virtual machines, certain additional mechanisms can modify key-controlled protection for storage references synchronous with the instruction (DIAGNOSE). They are:

**Fetch-protection override**

Fetch-protection override (FPO) inhibits key-controlled fetch protection for effective addresses 0-2047 in the host-primary address space; these addresses generally map to reserved locations in the prefix area. That is, FPO causes fetches from these addresses to be permitted even if the keys do not match and the block at 0-4095 is marked fetch-protected. FPO is enabled by control register 0, bit 6; if this bit is off, then FPO is not invoked, and addresses 0-2047 are handled exactly like addresses 2048-4095. Not all DIAGNOSE functions honor FPO. Also, because FPO

suppresses key-controlled protection, it is not relevant in cases where key-controlled protection is not enforced.

### Storage-protection override

Storage-protection override (SPO) is an optional feature on ESA/390 processors. SPO appears installed on the virtual machine if and only if it is installed on the real machine. SPO suppresses key-controlled protection, for both fetches and stores, for storage blocks whose access-control bits have the value 9, regardless of the value of the access key. SPO is enabled by control register 0, bit 7; if this bit is off, then SPO is not invoked, and key 9 is treated no differently from other keys. Because SPO suppresses key-controlled protection, it is not relevant in cases where key-controlled protection is not enforced.

Fetch-protection override and storage-protection override are not applicable to asynchronous references, nor to references to channel control words (CCWs), indirect data address words (IDAWs), or the data designated by CCWs and IDAWs.

### Low-address protection

Low-address protection (LAP) prevents stores into effective addresses 0-511 in the host-primary address space; these addresses generally map to reserved locations in the prefix area. LAP is enabled by control register 0, bit 3; if this bit is off, then LAP is not invoked, and addresses 0-511 receive no special protection. LAP applies only to synchronous store references. LAP does not apply to data buffers referenced by CCWs and IDAWs. Not all DIAGNOSE functions enforce LAP.

### Host page protection

Host page protection prohibits storing into those 4K-byte blocks that contain read-only pages of a saved segment. Host page protection also prohibits changing the storage keys for those pages. Host page protection applies to both synchronous and asynchronous store references and is enforced by all DIAGNOSE functions.

### Host access-list-controlled protection

Host access-list-controlled protection prohibits storing into address spaces referenced through host access-list entries that convey read-only access. This mechanism never applies to references to the host-primary space made implicitly or through ALET X'00000000', because these references do not involve an access-list entry. Host access-list-controlled protection *does* apply to references through a non-zero ALET which happens to designate the host-primary space. Host access-list-controlled protection is applicable only in access-register mode in an XC virtual machine, because that is the only mode in which the program can store into spaces other than the host-primary space. Host access-list-controlled protection applies to both synchronous and asynchronous store references and is enforced by all DIAGNOSE functions.

Table 2 on page 10 summarizes these storage protection mechanisms and the cases in which they apply to DIAGNOSE functions.

Table 2. Summary of Storage Protection Mechanisms

| Protection Mechanism                   | Applies to          |                     |              |              |
|----------------------------------------|---------------------|---------------------|--------------|--------------|
|                                        | Synch Fetch         | Synch Store         | Asynch Fetch | Asynch Store |
| Key-controlled protection              | Varies              | Varies              | Varies       | Varies       |
| Fetch-protection override              | Varies <sup>1</sup> | No                  | No           | No           |
| Storage-protection override            | Varies <sup>2</sup> | Varies <sup>2</sup> | No           | No           |
| Low-address protection                 | No                  | Varies              | No           | No           |
| Host page protection                   | No                  | Yes                 | No           | Yes          |
| Host access-list-controlled protection | No                  | Yes                 | No           | Yes          |

Table 2. Summary of Storage Protection Mechanisms (continued)

| Protection Mechanism                                                                                                                                                                                                                                                                                                                                                                                                                                      | Applies to  |             |              |              |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|-------------|--------------|--------------|

| All DIAGNOSE functions enforce the mechanism on this type of access.                                                                                                                                                                                                                                                                                                                                                                                      |             |             |              |              |
| <b>Varies</b>                                                                                                                                                                                                                                                                                                                                                                                                                                             |             |             |              |              |
| Some DIAGNOSE functions enforce the mechanism on this type of access. Unless otherwise specified in the DIAGNOSE function description, the mechanism <i>is</i> enforced.                                                                                                                                                                                                                                                                                  |             |             |              |              |
| <b>No</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |             |             |              |              |
| The mechanism does not apply to this type of access.                                                                                                                                                                                                                                                                                                                                                                                                      |             |             |              |              |
| <b>1</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |             |              |              |
| Fetch-protection override is a modification to key-controlled protection; therefore, it can apply only when key-controlled protection applies. However, some DIAGNOSE functions which enforce key-controlled protection still do not honor fetch-protection override. Unless otherwise specified in the DIAGNOSE function description, fetch-protection override <i>does</i> apply to synchronous fetches whenever key-controlled protection is enforced. |             |             |              |              |
| <b>2</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |             |              |              |
| Storage-protection override is a modification to key-controlled protection for synchronous storage references; it applies when and only when key-controlled protection is enforced.                                                                                                                                                                                                                                                                       |             |             |              |              |

## DIAGNOSE Codes That Are Not Programming Interfaces

The DIAGNOSE codes described in [Chapter 2, “The IBM-Supplied DIAGNOSE Codes,”](#) on page 13 are supported Programming Interfaces of z/VM.

The DIAGNOSE codes described in [Appendix F, “Reserved DIAGNOSE Codes,”](#) on page 1031 are reserved for IBM use and are NOT Programming Interfaces.

## Chapter 2. The IBM-Supplied DIAGNOSE Codes

This chapter contains information on the individual DIAGNOSE codes available to z/VM users. Wherever possible, this information includes the following:

- Privilege class of the DIAGNOSE code
- Entry and exit register values
- Condition codes and return codes
- Programming exceptions
- Usage notes.

These DIAGNOSE codes are provided by IBM and by default are enabled. You can disable, modify, and enable them with system configuration statements or commands. See *z/VM: CP Commands and Utilities Reference* for specific command information and *z/VM: CP Exit Customization* for "how-to" information.

### DIAGNOSE Code X'00' – Store Extended-Identification Code

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'00' to examine the z/VM extended-identification code.

**Entry Values:**

**Rx**

Contains the guest real storage address where you want to store the z/VM extended-identification code. This address must be aligned on a doubleword boundary.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space into which you want to store the z/VM extended-identification code. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the z/VM extended-identification code is in the host-primary address space.

**Ry**

Contains the number of bytes that you want to store. This value is an unsigned binary number.

**Exit Values:**

**Ry**

Contains its original value less the number of bytes that were stored.

### Usage Notes

1. For a discussion of how z/VM processes addresses, see [“How Addresses Are Processed”](#) on page 5.
2. Execution of the DIAGNOSE code X'00' instruction makes a copy of the information shown in Table 3 on page 13 available to your virtual machine at the location specified by Rx (and in Ax if your virtual machine is an XC virtual machine in access-register mode).

Please note that the service level reported assumes that all service has been applied for this level. If the service updates have been applied selectively, then the service level reported may be incorrect.

Table 3. DIAGNOSE code X'00' — Bit Map Fields

| Field                             | Characteristics | Description                                                                    |
|-----------------------------------|-----------------|--------------------------------------------------------------------------------|
| Reserved (formerly "System name") | 8 bytes, EBCDIC | Contains the constant 'VM/ESA' (for compatibility with the prior product name) |

*Table 3. DIAGNOSE code X'00' — Bit Map Fields (continued)*

| <b>Field</b>             | <b>Characteristics</b> | <b>Description</b>                                                                                                                                                                                        |
|--------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Environment              | 2 bytes, binary        | Identifies the z/VM execution environment. See “2.a” on page 14 for more information.                                                                                                                     |
| Version Information      | 1 byte, hexadecimal    | The version number of the product identified in the System Name field. It is an unsigned binary number. See usage note “5” on page 16.                                                                    |
| Version code             | 1 byte, hexadecimal    | Bits 0-7 of the host system's CPUID. This field will always be 00 when the z/VM host system is running in a logical partition. This field will always be FF when the z/VM host system is running on z/VM. |
| reserved                 | 2 bytes, hexadecimal   | z/VM stores zeros in this field.                                                                                                                                                                          |
| Processor address        | 2 bytes, hexadecimal   | The address of the processor on which z/VM is currently running                                                                                                                                           |
| User ID                  | 8 bytes, EBCDIC        | The user ID of the virtual machine issuing the DIAGNOSE                                                                                                                                                   |
| Licensed program bit map | 8 bytes, hexadecimal   | The level of CP that is installed. See “2.b” on page 14 for the bit settings.                                                                                                                             |
| Time zone differential   | 4 bytes, hexadecimal   | Represents the time zone differential in seconds from Coordinated Universal Time (UTC) (see note “2.c” on page 16 below).                                                                                 |
| Release Information      | 4 bytes, hexadecimal   | The first byte is the release number, the second byte is the release modification level, and the third and fourth bytes are the service level. All three subfields are unsigned binary numbers.           |

**Notes:**

a. The z/VM execution environment bits contain:

- When bit 0 = 1, CP is running in a logical partition (LPAR mode). Bit 0 will always have a value of 1 because the machines supported by z/VM V6.1 and later provide only LPAR mode.
- When bit 1 = 1, CP is running in 64-bit mode. Bit 1 will always have a value of 1 because the DIAGNOSE code X'00' instruction can be issued only when CP runs in 64-bit mode.
- Bits 2 to 15 are reserved and are currently zeros.

b. The bit map contains:

**X'0000000000000000'**  
for VM/XA SF 1

**X'4000000000000000'**  
for VM/XA SF 2

**X'6000000000000000'**  
for VM/XA SP™ 1

**X'7000000000000000'**  
for VM/XA SP 2

**X'7800000000000000'**  
for VM/XA SP 2 with APSS

**X'7C00000000000000'**  
for VM/XA SP 2.1

**X'7E00000000000000'**  
for VM/XA SP 2.1 spool file origin enhancements

**X'7F00000000000000'**  
for VM/ESA Version 1 Release 1.0 ESA Feature

**X'7F80000000000000'**  
for VM/ESA Version 1 Release 1.1

**X'7FC0000000000000'**  
for VM/ESA Version 1 Release 2.0

**X'7FE0000000000000'**  
for VM/ESA Version 1 Release 2.1

**X'7FF0000000000000'**  
for VM/ESA Version 1 Release 2.2

**X'7FF8000000000000'**  
for VM/ESA Version 2 Release 1.0

**X'7FFE000000000000'**  
for VM/ESA Version 2 Release 2.0

**X'7FFF000000000000'**  
for VM/ESA Version 2 Release 3.0

**X'7FFF800000000000'**  
for VM/ESA Version 2 Release 4.0

**X'7FFFC00000000000'**  
for z/VM Version 3 Release 1.0

**X'7FFFE00000000000'**  
for z/VM Version 4 Release 1.0

**X'7FFFF00000000000'**  
for z/VM Version 4 Release 2.0

**X'7FFFF80000000000'**  
for z/VM Version 4 Release 3.0

**X'7FFFFC0000000000'**  
for z/VM Version 4 Release 4.0

**X'7FFFFE0000000000'**  
for z/VM Version 5 Release 1.0

**X'7FFFFFF000000000'**  
for z/VM Version 5 Release 2.0

**X'7FFFFFF800000000'**  
for z/VM Version 5 Release 3.0

**X'7FFFFFFC00000000'**  
for z/VM Version 5 Release 4.0

**X'7FFFFFFE00000000'**  
for z/VM Version 6 Release 1.0

**X'7FFFFFFF00000000'**  
for z/VM Version 6 Release 2.0

**X'7FFFFFFF80000000'**  
for z/VM Version 6 Release 3.0

**X'7FFFFFFFC0000000'**  
for z/VM Version 6 Release 4.0

**X'7FFFFFFFE0000000'**  
for z/VM Version 7 Release 1.0

**X'7FFFFFFF00000000'**

for z/VM Version 7 Release 2.0

**X'7FFFFFFF80000000'**

for z/VM Version 7 Release 3.0

Bit 13 (X'0004000000000000') indicates whether Year 2000 support is present in CP.

To determine what VM environment you are in and what CP resources are available to you, use the high-order bit from this bit map. Specifically, if the high-order bit is on, the environment is VM/SP, VM/SP HPO, or VM/ESA® (370 Feature). If the high-order bit is off, the environment is VM/XA SP, VM/ESA (ESA Feature), or z/VM. Do not try to get this information from the first five bytes returned by DIAGNOSE code X'00'.

- c. The time zone differential is a signed hexadecimal fullword value in seconds. Negative values represent differentials west of Coordinated Universal Time (UTC), and positive values represent differentials east of Coordinated Universal Time.
3. If z/VM is executing in a virtual machine, up to 40 bytes of extended identification data is appended to the first 40 bytes described above. Up to five nested levels of z/VM virtual machines are supported by this DIAGNOSE instruction. Thus, a maximum of 200 bytes of data can be returned to the virtual machine that initially issued the DIAGNOSE instruction.
4. The CP level does not indicate the release of CMS. To determine the release of CMS, use the "Query Functional Level of CP and CMS" routine (DMSQEFL), which is described in [z/VM: CMS Callable Services Reference](#). DMSQEFL also returns the release of CP.
5. In VM/ESA Version 2 Release 1.0, the Version Information byte was created from the third byte of the Environment field. Because VM releases prior to VM/ESA Version 2 Release 1.0 are not being updated by APAR, the Version Information for all of these releases is X'00'. For VM/ESA Version 2 Release 1.0 and later, the Version Information will reflect the true version number. For example, the Version Information for VM/ESA Version 2 Release 1.0 is X'02'.
6. When part of an SSI cluster, the diagnose x'00' output depends on the relocation domain to which the issuing user is assigned. This output shows the virtual CP level that is being presented to the issuer of the diagnose. Virtual CP levels may differ among users on the same system when they belong to different relocation domains. See the explanation of relocation domains in [z/VM: CP Planning and Administration](#) for more details. Also see the documentation of the CP SET VMRELOCATE and CP QUERY VMRELOCATE commands and the VMRELOCATE directory statement for details about how a user is assigned to a relocation domain.

## Responses

**Program Exceptions:** These program exceptions can occur if the DIAGNOSE code X'00' is given incorrect input data:

| Problem Encountered                                                   | Cause                                                        |
|-----------------------------------------------------------------------|--------------------------------------------------------------|
| Specification exception                                               | The address contained in Rx is not on a doubleword boundary. |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                 |
| Access exception (See <a href="#">"Access Exceptions"</a> on page 8.) | An error occurred trying to store the extended ID code.      |

## DIAGNOSE Code X'04' – Examine Host Storage

**Privilege Class:** C, E

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'04' to examine host storage for diagnostic, monitoring, and tuning purposes only.

**Entry Values:**

**Rx**

Contains the guest real address of a list of host addresses that you want to examine.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the list of host addresses that you want to examine. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the list of host addresses is in the host-primary address space.

**Ry**

Contains:

- The number of entries in the list
- An indicator of the address format (31-bit or 64-bit).
- An indicator of the length of data to be returned for each entry.
- An indicator of the address type (host logical or host real)

**Ry+1**

Contains the guest real address of the result field. The result field contains the values retrieved from the specified host locations.

When Ry is register 15, Ry+1 is register 0.

**Ay+1**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space of the result field. If Ry+1 designates general register 0, if Ay+1 contains X'00000000', or if the virtual machine is not in XC mode, the result field is in the host-primary address space.

## Usage Notes

1. The guest real addresses that you specify in Rx and Ry+1 must be in the same page of guest real storage. In XC virtual machines in access register mode, the ALET in Ax (or zero if Ax designates access register 0) must match the ALET in Ay+1 (or zero if Ay+1 designates access register 0).
2. Because this DIAGNOSE code is intended mainly for system performance monitoring, it is recommended that the page addressed by Rx and Ry+1 also be resident in host storage at the time the DIAGNOSE instruction is executed. This can be accomplished by having the instruction itself on the same page or by locking the page in host storage; otherwise, DIAGNOSE code X'04' processing causes a page to be paged-in and therefore may affect the performance monitoring data.
3. For a discussion of how z/VM processes addresses, see [“How Addresses Are Processed”](#) on page 5.
4. For each address in the list of host addresses, z/VM provides the data obtained from that address. z/VM stores this data into the result field identified by Ry+1, and possibly by Ay+1 if the virtual machine is an XC virtual machine running in access-register mode.

Entries in the list of addresses pointed to by Rx correspond (1-to-1) to the entries in the result field pointed to by Ry+1. Execution of this DIAGNOSE can be thought of as a loop that fetches the first element from the list of addresses (pointed to by Rx) and stores the data from that location into the first element of the result field (pointed to by Ry+1). Then the second address is fetched and the second data item is stored. This continues until the number of addresses in the count field have been fetched and the corresponding data stored or until an exception is encountered.

Figure 2. DIAGNOSE X'04' Register Entries

It is possible for the results array to overlap the address array. If destructive overlap occurs, incorrect data may be returned. An addressing exception may be presented when destructive overlap causes an address to change before it is fetched.

An overlap can occur only if the Ry+1 address is greater than the Rx address and yet within the bounds of the addresses to be examined.

5. In a multiprocessor environment, each processor has a prefix register that it uses to relocate addresses between 0 and 4095 (8191 if the host is in z/Architecture mode) to another frame in storage. The prefix register enables each processor to use a different frame to avoid conflict with other processors for such activity as interrupt code recording. Thus, the above range refers to different areas of storage, depending upon which processor generates the address. All references to host real storage are handled as if they were made on the master processor.
6. Fetching and storing of data is consistent with the Enterprise Systems Architecture/390 Principles of Operation ([publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf](http://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf)) and z/Architecture Principles of Operation (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>) for both operands of the MOVE (MVC) instruction.
7. Because real storage is volatile, the contents of host storage can change at any time after it is copied into the result field.
8. The number of entries in the list that you specify in Ry must be greater than zero and cannot exceed:
  - 1024 if bit 0 of Ry is 0
  - 512 if bit 0 of Ry is 1
 Otherwise, a specification exception is returned.

9. If bit 0 of Ry is 0 (indicating 31-bit addresses), bit 1 of Ry must be 0 (indicating a length of 4 bytes). If bit 0 of Ry is 1 (indicating 64-bit addresses), bit 1 of Ry must be 1 (indicating a length of 8 bytes).
10. If the loaded data is greater than 4 KB in length, the frames backing the host logical storage pages are not necessarily contiguous in host real storage.

## Responses

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'04' is given incorrect input data:

| Problem Encountered                                   | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## DIAGNOSE Code X'08' – Virtual Console Function

**Privilege Class:** Any

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

Use DIAGNOSE code X'08' to have your virtual console issue CP commands. Your virtual machine must specify the command and operands, and indicate whether CP is to return the command response to your

display or to a buffer. In addition to returning the command response, CP sets a completion code and may set a condition code.

**Entry Values:****Rx**

Must point to the character string in guest real storage (storage that appears real to the issuing virtual machine) containing the CP commands and parameters. If the character string contains multiple commands, each command and its associated parameters must be separated from adjacent commands by the value X'15'.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the CP commands and parameters. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the CP commands and parameters are in the host-primary address space.

**Rx+1**

If the X'40' flag is set in the flag byte of Ry then Rx+1 points to the buffer in guest real storage where CP is to return the command response. This address must be real to your virtual machine. The buffer can cross page boundaries.

**Ax+1**

Used only by XC virtual machines in access-register mode. If the X'40' flag is set in the flag byte of Ry then Ax+1 contains the ALET for the address space of the buffer for the command response.

**Ry**

In z/Architecture mode the high order word of register Ry is ignored. The 4 bytes of the low order register word contains the following:

- The high-order byte containing flag bits
- Three bytes that specify the length of the CP commands and parameters; the length is given in bytes and the maximum allowable length is 240 characters.

You can set the flag bits as follows:

**X'80'**

When this flag is ON, passwords on the LINK, AUTOLOG, and XAUTOLOG commands are permitted only when the SET PASSWORD *command* INCLUDE option is in effect. If the SEPARATE option is in effect for the associated SET PASSWORD command, the command specified in this DIAGNOSE will be rejected with return code 118 (command format not valid) in Ry+1.

When this flag is OFF, the SET PASSWORD command is ignored and the password can be included on the specified command.

**X'40'**

CP is to return the command response in the buffer pointed to by register Rx+1 (and possibly Ax+1 if the virtual machine is an XC virtual machine running in access-register mode).

**X'20'**

CP is to return a request to the virtual machine that a password is needed for the LINK, AUTOLOG, or XAUTOLOG commands. This allows the virtual machine to prompt the user for the password.

If the last three bytes in Ry equal the value X'000000', the DIAGNOSE command causes a console function read to be issued to your terminal. The response buffer is ignored.

If the command response is to be returned in a buffer, Rx and Ry cannot be consecutive registers, and neither can be register 15. In addition, the Ry+1 register must be set up as follows:

**Ry+1**

In z/Architecture mode the high order word of register Ry+1 is ignored. The 4 bytes of the low order register word contains the length of the buffer. The length specified must be greater than 0. Ry+1 only applies if the X'40' flag is specified in the flag byte in the leftmost byte of Ry.

**Exit Values:**

**Ry**

If an error is encountered while processing the command issued using DIAGNOSE code X'08', CP issues an error message and sets a return code in Ry. The return code is the hexadecimal representation of the numeric portion of the error message. For example, if error message 045E is returned, CP sets a return code of X'002D', which is the hexadecimal representation of the message number, 45.

If the virtual machine assumes responsibility for prompting and a password is not in the command buffer on a LINK, AUTOLOG, or XAUTOLOG command issued through DIAGNOSE code X'08', and the information in the command buffer is valid, one of five unique return codes (in hexadecimal representation) is passed back to the virtual machine by register Ry. These return codes indicate which password prompt the virtual machine should issue. For the AUTOLOG and XAUTOLOG commands, the short logon prompt and the extended logon prompt return codes are 8013 (X'1F4F'), 8016 (X'1F50'), and 8017 (X'1F51'), respectively. The LINK, AUTOLOG, or XAUTOLOG request should then be reissued with another DIAGNOSE code X'08' with the password in the command buffer.

## Usage Notes

1. If the CP command response is to be returned to the user's buffer, and is an error message, the buffer contains the error code and text if the user's EMSG setting is ON, OFF or IUCV. If the user's EMSG setting is TEXT, only the error message text is placed in the buffer. If the EMSG setting is CODE, only the error code is placed in the buffer. In all cases, the Ry+1 register contains the length of all data placed in the buffer. If the buffer is too small to contain the entire response, as many full lines as will fit are placed in the buffer.

If the CP command is not returned in the user's buffer, it is displayed according to the EMSG setting.

An exception to this is if an invalid command is encountered during DIAGNOSE code X'08' processing, the CP error message *HCPCMD001E UNKNOWN CP COMMAND* is not displayed or returned in the user's buffer. The Ry register contains a return code of 1.

2. If CP is executing multiple commands and encounters an invalid command, processing stops, and CP ignores the remaining commands.
3. If you use DIAGNOSE code X'08' to issue the XAUTOLOG command (without the SYNC option), the response is not returned in a buffer. This is because this is an asynchronous command, and it has not necessarily completed by the time the DIAGNOSE instruction finishes execution.
4. You can use the SET D8ONECMD command to control whether CP will accept multiple commands imbedded in a single command and separated with X'15' characters. You can also use the QUERY D8ONECMD command to find out the D8ONECMD settings (number of commands) for your own virtual machine or another user's virtual machine. For more information, see [z/VM: CP Commands and Utilities Reference](#).

## Responses

**Condition Codes:** If the command response is to be returned in a buffer, CP sets a condition code and returns information as follows:

| Condition Code | Status                                                                           | Ry Contains                                                                                                                         | Ry+1 Contains                                                                     |
|----------------|----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| 0              | The DIAGNOSE request was successful (although the CP command may not have been). | The return code from the CP command. The return code 6890 indicates that the executing virtual machine's D8ONECMD setting was FAIL. | The length of the response or error message, if it was to be returned in a buffer |

## DIAGNOSE Code X'08'

| Condition Code | Status                                                                                                    | Ry Contains                                                                                                                         | Ry+1 Contains                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| 1              | The DIAGNOSE request was not successful. The response does not fit in the user-specified response buffer. | The return code from the CP command. The return code 6890 indicates that the executing virtual machine's D8ONECMD setting was FAIL. | A value that specifies how many bytes of the response or error message would not fit into the buffer <sup>1</sup> |

**Note:** <sup>1</sup>If the response buffer overflow is greater than X'7FFFFFFF', then Ry+1 contains the value X'7FFFFFFF'.

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'08' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                                               | Any of the following: <ul style="list-style-type: none"><li>• The command buffer is greater than 240 bytes long.</li><li>• A response buffer is specified, and Rx or Ry is specified as R15.</li><li>• A response buffer is specified, and Rx and Ry are specified as consecutive registers.</li><li>• The length of the response buffer is zero.</li><li>• The response buffer exceeds the architected storage limit (16MB for 24-bit ESA; 2048MB for 31-bit ESA).</li></ul> |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to: <ul style="list-style-type: none"><li>• Fetch the command string</li><li>• Store the command response.</li></ul>                                                                                                                                                                                                                                                                                                                                 |

## Examples

The following are two examples showing how to specify DIAGNOSE code X'08'. Note that this is not part of the interface definition. Depending on your conventions and programming language, your code may look quite different.

The first example shows how a program issues the SET IMSG OFF command. In this example, the response is returned to the user's terminal:

|       |                         |
|-------|-------------------------|
| LA    | 6, CMMD                 |
| LA    | 10, CMMDL               |
| DC    | X'83', X'6A', XL2'0008' |
| .     | .                       |
| .     | .                       |
| CMMD  | DC C' SET IMSG OFF'     |
| CMMDL | EQU *-CMMD              |
| .     | .                       |
| .     | .                       |

The second example shows how to specify a string of commands when multiple commands are to be issued:

|    |                         |
|----|-------------------------|
| LA | 6, CMMD                 |
| LA | 10, CMMDL               |
| DC | X'83', X'6A', XL2'0008' |
| .  | .                       |
| .  | .                       |

|       |     |                   |
|-------|-----|-------------------|
| CMMD  | DC  | C 'SET EMSG OFF'  |
|       | DC  | X'15'             |
|       | DC  | C 'PURGE PRT ALL' |
| CMMDL | EQU | *-CMMD            |

## DIAGNOSE Code X'0C' – Pseudo Timer

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'0C' to cause CP to store four doublewords of time information at the address specified in the Rx register.

**Entry Values:**

**Rx**

Contains the address of a 32-byte area where the time information is to be stored. The address must be in second-level storage (that is, in the storage that appears real to your virtual machine) and must be on a doubleword boundary.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the 32-byte area where the time information is to be stored. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the time information area is in the host-primary address space.

**Exit Values:** The output area contains the following information:

|    |           |
|----|-----------|
| 0  | MM/DD/YY  |
| 8  | HH:MM:SS  |
| 10 | VIRTCPU   |
| 18 | TOTALPROC |

The first eight bytes of the output area contain the date, month/day-of-month/year, in EBCDIC. The next eight bytes contain the time of day, hours:minutes:seconds, in EBCDIC. The next eight bytes (16 through 23), VIRTCPU, contain the virtual time consumed by the virtual CPU that issued the DIAGNOSE instruction. The last eight bytes (24 through 31), TOTALPROC, contain the total of the virtual time (VIRTCPU) and the simulation time spent on behalf of the virtual CPU that issued the DIAGNOSE instruction. Thus, TOTALPROC is always greater than or equal to VIRTCPU. The difference between them represents the time that CP has spent specifically on behalf of the virtual CPU.

These values are also part of the response for the CP command, INDICATE USER. The last 16 bytes contain the virtual and total processor time used by the virtual machine that issued the DIAGNOSE instruction. VIRTCPU and TOTALPROC are doubleword, unsigned integers; the time is expressed in microseconds, not as TOD clock units.

## Usage Notes

For a discussion of how z/VM processes addresses, refer to [“How Addresses Are Processed”](#) on page 5.

## Responses

**Program Exceptions:** These program exceptions can occur if the DIAGNOSE X'0C' is given incorrect input data:

| Problem Encountered                                                   | Cause                                                             |
|-----------------------------------------------------------------------|-------------------------------------------------------------------|
| Specification exception                                               | The address contained in Rx is not on a doubleword boundary.      |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                      |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to store into the time-information area. |

## DIAGNOSE Code X'10' – Release Pages

**Privilege Class:** Any

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

Use DIAGNOSE code X'10' to release pages of second-level storage.

**Entry Values:**

**Rx**

Contains the guest real address of the first page of storage to be released. This address must be on a page boundary, otherwise a specification exception occurs.

**Ax**

For XC virtual machines in the access-register mode, Ax contains the ALET designating the address space in which storage is to be released. Even when Rx is general register 0, the **actual contents** of Ax are used in XC access-register mode.

**Ry**

Contains the guest real address of the last page to be released. This address must be on a page boundary, and must be greater than or equal to the address specified in the Rx register; otherwise, a specification exception occurs.

The results of the DIAGNOSE X'10' operation on a particular page depend on whether the page is a mapped or unmapped page, and for unmapped pages, whether the page is contained in a saved segment or not. A page is considered mapped when the DEFINE function of the MAPMDISK macro has been used to associate the page with a DASD block on a minidisk; otherwise, it is an unmapped page. If the page is:

- An unmapped page that is not contained in a saved segment, then the page is unlocked (if it was locked through the LOCK command), the current contents of the page are discarded and the page is considered to contain binary zeros.
- An unmapped page that is contained in a saved segment, then no operation is performed. The page remains unchanged.
- Is a mapped page, then the page is unlocked (if it was locked through the LOCK command), the current contents of the page are discarded, and upon next reference the contents of the page are refreshed from the associated DASD block.

The range of storage between the addresses specified in the Rx and Ry registers must be contained entirely within the defined storage for the address space. That is, this DIAGNOSE code cannot be used to release discontinuous storage. If an attempt is made to release discontinuous storage, an addressing exception is recognized.

For an XC virtual machine in the access-register mode, a specification exception is recognized if an attempt is made to release storage in a host-primary address space through a nonzero ALET.

## Usage Notes

1. The addresses contained in Rx and Ry must be on a page boundary. A page boundary is a storage address whose low-order three digits, expressed in hexadecimal, are zero.
2. Do not use DIAGNOSE code X'10' to release discontinuous storage.
3. If a virtual machine attempts to release a shared page within its defined virtual storage, the page is not released. No further action is taken.

4. It is unpredictable whether a modified mapped page has been saved on its associated mapped DASD block unless the modified page has been specifically saved through the SAVE function of the MAPMDISK macro.

To ensure that the modified mapped page has been saved on DASD do not release the page through DIAGNOSE code X'10' until the save-completion external interrupt signals completion of the MAPMDISK SAVE function.

5. If DIAGNOSE code X'10' is issued to release pages locked by the CP LOCK command, those pages are unlocked.
6. The largest address allowed for a guest in 24-bit or 31-bit addressing mode is the smaller of the address of the end of the first address space extent and either 2047M for a S/390® Architecture guest or 2048M for a z/Architecture guest. For a z/Architecture guest in 64-bit addressing mode, the limit is the address of the end of the first address space extent.

## Responses

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'10' is given incorrect data:

| Problem Encountered                                                     | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                                                 | Any of the following: <ul style="list-style-type: none"> <li>The address of the last page (specified in Ry) is less than the address of the first page (specified in Rx).</li> <li>The virtual machine attempts to release page 0 of its host-primary address space.</li> <li>The address contained in Rx or Ry is not on a page boundary (see Usage Note “1” on page 24).</li> <li>For an XC virtual machine in the access-register mode, an attempt was made to release storage in this or another virtual machine's host-primary address space through a nonzero ALET.</li> </ul> |
| Privileged-operation exception                                          | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Access exception (See “ <a href="#">Access Exceptions</a> ” on page 8.) | An error occurred trying to store into the designated storage area. (Host access-list-controlled protection is the only protection mechanism which generates a protection exception. Key-controlled protection and low-address protection are not enforced. But note that low-address protection is preempted by the specification exception if the page at guest real address 0 is included in the range. Likewise, a host-page-protection exception condition results in either a specification exception (for discontinuous storage) or no operation (for contiguous storage).)   |
| Addressing exception                                                    | The designated storage area includes discontinuous storage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Protection exception                                                    | The designated storage area includes read-only storage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## DIAGNOSE Code X'14' – Input Spool File Manipulation

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'14' to access and to control input spool files in your reader. You can access descriptions of files in your reader, change the copy count of a file, read files, backspace to the previous record, or select the next or a specific file to process.

**Entry Values:****Rx**

The first data register (contents determined by subcode).

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the buffer, if Rx points to a buffer. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the buffer is in the host-primary address space.

**Ry**

The second data register (contents determined by subcode).

**Ry+1**

Contains the actual subcode that was issued (Ry and Ry+1 must be an even-odd pair).

The possible subcodes, which are described in the following sections, are:

**Subcode****Function****X'0000'**

Read the Next Spool File Buffer (Data Record)

**X'0004'**

Read the Next Print Spool File Block

**X'0008'**

Read the Next Punch Spool File Block

**X'000C'**

Order a File to the Front of a Queue

**X'0010'**

Repeat the Active File a Specified Number of Times

**X'0014'**

Restart an Active File at the Beginning

**X'0018'**

Backspace One Record

**X'001C'**

Read the Next Monitor Spool File Block

**X'0020'**

Read the Next Monitor Spool Record

**X'0024'**

Read the Last Spool File Buffer

**X'0028'**

Position Spool File to Designated Record

**X'002C'**

Select a File for Processing and Read the Next Spool Buffer

**X'0FFE'**

Select the Next File Not Previously Selected and Select Read to EOF Files

**X'0FFF'**

Retrieve Next File Descriptor

**Subcode X'0000'—Read the Next Spool File Buffer (Data Record)****Rx**

the buffer address (full page)

**Ry**

the virtual spool reader address

**Ry+1**

X'00000000' (the subcode)

This subcode returns a page of spool data to the user's buffer. The buffer must be a full page (4K) in length and must not cross a page boundary. If the buffer crosses a page boundary, a specification exception occurs. Subcode X'0000' can be issued consecutively as many times as necessary to read an entire file on the user's virtual reader queue. Different results occur depending on how the virtual reader has been spooled.

If there is no file currently active on the virtual reader device specified, the first data page (in SPLINK format; refer to [“SPLINK - VM/SP 370 Spool File Data Block”](#) on page 992) of the first eligible file in the user's virtual reader queue is returned in the user's buffer. A file is eligible if it is not in *hold* status and if its class matches that of the virtual reader. The file is opened on the virtual reader when an eligible file is found.

If there is no file already active on the virtual reader and there are no eligible files, then condition code 2 is returned.

When there is an active file already on the specified virtual reader, condition code 3 with return code X'0C' in Ry+1 is returned if it is not active due to a previous DIAGNOSE code X'14' operation. If it is active due to a previous DIAGNOSE code X'14' operation, the next page of data is returned.

When an SPLINK (data page) from a file created on a punch is returned, all write CCWs in the page are converted and returned as X'41' opcodes.

When EOF (end of file) is reached and *continuous* read is not set, condition code 1 is returned. No data is passed back in the user's buffer and the file remains open.

If *continuous* read is set, processing continues with the first page of data from the next logical file. The search for the next logical file begins either at the top of the user's reader queue or at the file just processed, depending on the reader's *rescan* or *norescan* setting. If the reader is spooled *rescan*, the search begins with the first file in the virtual reader queue. If the reader is spooled *hold/norescan*, the search will begin with the next logical file (after the one just processed) in the virtual reader queue. For all other combinations of *norescan* (with *continuous*) the search will start with the first file in the virtual reader queue.

When a new file is selected because the reader is spooled *continuous*, the previously read file is closed and the newly read file is opened. This may be a read of the first page of the same file if that file was set for multiple copies. When the reader is spooled for *continuous* read, condition code 1 (EOF) is returned when no more eligible files are found. When this condition is reached, no data is returned in the user's buffer and the last file read remains open.

Condition code 3 is set if the virtual reader specified does not exist or is not a reader. The appropriate return code is placed in Ry+1 to indicate which of these is the case. See [“Responses”](#) on page 35 to determine the meaning of these return codes.

## Subcode X'0004'—Read the Next Print Spool File Block

**Rx**

the buffer address (13 doublewords)

**Ry**

the virtual spool reader address

**Ry+1**

X'00000004' (the subcode)

This subcode returns the next eligible file on the virtual reader queue that was created on a printer or console. A file is eligible if it is not in *hold* status and if its class matches that of the virtual reader. The spool file descriptor block (SFBLOK; refer to Appendix A, [“Data Areas Used by DIAGNOSE Codes,”](#) on page 985) for the file is returned in the user's virtual buffer. The file is not opened. The buffer must not cross a page boundary. If the buffer crosses a page boundary, a specification exception occurs.

## DIAGNOSE Code X'14'

The default size of the spool file block returned is 13 doublewords. However, a different size buffer may be specified by using extended mode. See usage note [“1” on page 34](#) for a description of extended mode.

If the specified reader device is not already in use by DIAGNOSE code X'14' the first eligible printer or console file is returned. If DIAGNOSE code X'14' is using the specified device and if this is a repeat call for a printer spool file block, the chain search continues from the point following the last block given to the virtual machine. In this case, condition code 1 is set when there are no more print files. If this is the first call for a spool file block, or if there have been intervening calls for file reading, the spool input chain is searched from the beginning. If no files are found, condition code 2 is set.

Condition code 3 is set if the virtual reader specified does not exist or is not a reader. The appropriate return code is placed in Ry+1 to indicate which of these is the case. See [“Responses” on page 35](#) to determine the meaning of these return codes.

## Subcode X'0008'—Read the Next Punch Spool File Block

### Rx

the buffer address (13 doublewords)

### Ry

the virtual spool reader address

### Ry+1

X'00000008' (the subcode)

Processing for subcode X'0008' is the same as for subcode X'0004', except that only files created on a punch are processed.

## Subcode X'000C'—Order a File to the Front of a Queue

### Rx

the file ID

### Ry

the virtual spool reader address

### Ry+1

X'0000000C' (the subcode)

This subcode moves a file to the front of the user's reader queue so that it can be the next one processed.

The spool input queue is searched for the file specified. If it is found and it is not in *hold* status, the file is moved to the front of the queue and condition code 0 is set. The file is ordered to the top of the queue but it is not opened and no spool data is returned.

If the specified file is not found, if the specified file is in *hold* status or if the specified file's class does not match the class of the virtual reader, condition code 2 is set.

Condition code 3 is set if the virtual reader specified does not exist or is not a reader. The appropriate return code is placed in Ry+1 to indicate which of these is the case. See [“Responses” on page 35](#) to determine the meaning of these return codes.

A specification exception occurs if the spool file ID specified is 0 or is greater than 9999.

## Subcode X'0010'—Repeat the Active File a Specified Number of Times

### Rx

the new copy count for the active file

### Ry

the virtual spool reader address

### Ry+1

X'00000010' (the subcode)

The count of the active file is set to the specified value, the maximum being 255. If the count is greater than 255, it is set to 255. If the count is negative, a specification error occurs. If there is no active file, condition code 2 is set.

Condition code 3 is set if the virtual reader specified does not exist or is not a reader. The appropriate return code is placed in Ry+1 to indicate which of these is the case. See [“Responses” on page 35](#) to determine the meaning of these return codes.

## Subcode X'0014'—Restart an Active File at the Beginning

**Rx**

unused

**Ry**

the virtual spool reader address

**Ry+1**

X'00000014' (the subcode)

If the device has an active file, the record pointers are set to the beginning of the file. Therefore, the next read receives the first file record. If no file is active, condition code 2 is set.

Condition code 3 is set if the virtual reader specified does not exist or is not a reader. The appropriate return code is placed in Ry+1 to indicate which of these is the case. See [“Responses” on page 35](#) to determine the meaning of these return codes.

## Subcode X'0018'—Backspace One Record

**Rx**

the buffer address (full page)

**Ry**

the virtual spool reader address

**Ry+1**

X'00000018' (the subcode)

If the device has an active file, the record pointer is set to the previous record unless it is already positioned at the first record. For example, if a normal subcode X'0000' operation was just used to read the third data page of the file, a subsequent subcode X'0018' operation returns the second data page of the file. The record is returned to the user as in a normal X'0000' read subfunction. The buffer must be a full page (4K) in length and must not cross a page boundary. If the buffer crosses a page boundary, a specification exception occurs. The record pointer is set so that the next X'0000' read operation returns the third data page again.

If the record pointer is already positioned at the first record, subcode X'0018' returns condition code 1 and the first page of the file is returned in the buffer. If no file is active, condition code 2 is set.

Condition code 3 is set if the virtual reader specified does not exist or is not a reader. The appropriate return code is placed in Ry+1 to indicate which of these is the case. See [“Responses” on page 35](#) to determine the meaning of these return codes.

When an SPLINK (data page) from a file created on a punch is returned, all write CCWs in the page are converted and returned as X'41' opcodes.

## Subcode X'001C'—Read the Next Monitor Spool File Block

**Rx**

the buffer address (13 double words)

**Ry**

the virtual spool reader address

**Ry+1**

X'0000001C' (the subcode)

Condition code 2 is always returned, because monitor spool files are not supported in z/VM.

## **Subcode X'0020'—Read the Next Monitor Spool Record**

**Rx**

the buffer address (full page)

**Ry**

the virtual spool reader address

**Ry+1**

X'00000020' (the subcode)

Condition code 2 is always returned, because monitor spool files are not supported in z/VM.

## **Subcode X'0024'—Read the Last Spool File Buffer**

**Rx**

the start address of a full-page virtual buffer

**Ry**

the virtual spool reader address

**Ry+1**

X'00000024' (the subcode)

The last spool buffer (active file) is read. The specified device is checked for an already active file and, if there is one, the last full-page buffer is made available to the virtual machine in SPLINK format. If there is no active file, the condition code of the virtual machine is set to 2.

The buffer must be a full page (4K) in length and must not cross a page boundary. If the buffer crosses a page boundary, a specification exception occurs.

Condition code 3 is set if the virtual reader specified does not exist or is not a reader. The appropriate return code is placed in Ry+1 to indicate which of these is the case. See [“Responses” on page 35](#) to determine the meaning of these return codes.

When an SPLINK (data page) from a file created on a punch is returned, all write CCWs in the page are converted and returned as X'41' opcodes.

## **Subcode X'0028'—Position a Spool File to the Designated Record**

**Rx**

the relative number of the record

**Ry**

the virtual spool reader address

**Ry+1**

X'00000028' (the subcode)

The number in (Rx) becomes the number of the new current record. The first data page in the file would be record number 1. No spool data is returned with this subfunction. Only the current record pointer is changed so that reading resumes at the specified record the next time a read operation is issued.

Condition code 2 is returned if no file is active or if the device is not ready.

If the value in Rx would set the current record beyond the end of the file, the condition code is set to 3 and code X'14' is returned in Ry+1.

Condition code 3 is set if the virtual reader specified does not exist or is not a reader. The appropriate return code is placed in Ry+1 to indicate which of these is the case. See [“Responses” on page 35](#) to determine the meaning of these return codes.

## Subcode X'002C'—Select a File for Processing and Read the Next Spool Buffer

### Rx

the start address of full-page virtual buffer

### Ry

the virtual spool reader address

### Ry+1

*nnnnyyyy* where *nnnn* is the file identifier of the requested file and *yyyy* is the function subcode.

The spool input chain is searched for the file specified, following the same procedure as subcode X'000C'. If the file is found, it is moved to the head of the chain, the processing continues, and the file is read as if subcode X'0000' had been issued.

If the specified file is not found, if the specified file is in *hold* status or if the specified file's class does not match the class of the virtual reader, condition code 2 is set.

The buffer must be a full page (4K) in length and must not cross a page boundary. If the buffer crosses a page boundary, a specification exception occurs.

Condition code 3 is set if the virtual reader specified does not exist or is not a reader. The appropriate return code is placed in Ry+1 to indicate which of these is the case. See [“Responses” on page 35](#) to determine the meaning of these return codes.

When an SPLINK (data page) from a file created on a punch is returned, all write CCWs in the page are converted and returned as X'41' opcodes.

## Subcode X'0FFE'—Select the Next File Not Previously Selected

There are two basic functions of DIAGNOSE code X'14' subcode X'0FFE':

- Select the Next File Not Previously Seen
- Select the Read to EOF Files.

Each of these has an initialize capability and a select capability. The input registers are different for each of these functions. The first byte of Ry determines which of these two functions is being requested. If the first byte of Ry is X'00' then the "Select the Next File Not Previously Seen" function is being requested. If the first byte of Ry is *not* X'00' then the "Select the Read to EOF Files" function is being requested.

(The following two items describe the "Select Next File Not Previously Selected" function.)

### Select Next File Not Previously Seen - INIT

#### Rx

the virtual address of an output buffer; the default size is 252 bytes when invoked without extended mode. See usage note [“2” on page 34](#) for more information. The buffer may cross a page boundary.

#### Ry

X'00000001'

#### Ry+1

a flag, optional size of the spool file block in doublewords, and the subcode X'0FFE'. The format of Ry+1 is *aabb0FFE* where

#### *aa*

is defined as follows:

bit 0, when 1, identifies extended mode (see usage note [“2” on page 34](#) for more information).

bit 1 is reserved and must be 0

bits 2-7 are either 0 or specify the size, in doublewords, of the buffer space to hold the spool file block.

***bb***

is not used and should be 00

**OFFE**

is the DIAGNOSE code X'14' subcode.

All of this user's input spool files that are marked as having previously been seen are reset to the not-yet-seen state, and the descriptor of the first spool file is returned to the user's buffer. Also, CP sets a bit identifying that this spool file has been seen. If no file is selected, a condition code of 1 is reflected to the virtual machine. The virtual buffer specified by Rx may cross a page boundary.

## Select Next File Not Previously Seen - Select

**Rx**

the virtual address of an output buffer; the default size is 252 bytes when invoked without extended mode. See usage note [“2” on page 34](#) for more information. The buffer may cross a page boundary.

**Ry**

X'00000000'

**Ry+1**

a flag, optional size of the spool file block in doublewords, and the subcode X'OFFE'. The format of Ry+1 is *aabbOFFE* where

***aa***

is defined as follows:

bit 0, when 1, identifies extended mode (see usage note [“2” on page 34](#) for more information).

bit 1 is reserved and must be 0

bits 2-7 are either 0 or specify the size, in doublewords, of the buffer space to hold the spool file block.

***bb***

is not used and should be 00

**OFFE**

is the DIAGNOSE code X'14' subcode.

The next reader spool file that has not previously been seen is selected and its descriptor is returned to the user's buffer. Also, CP sets a bit identifying that this spool file has now been seen.

(The next two items describe the "Read to EOF" function.)

## Read to EOF - INIT

**Rx**

not used

**Ry**

The format of Ry is *nnzzyyyy* where

***nn***

is not 00

***zz***

is 00

***yyyy***

is virtual spool reader address.

**Ry+1**

a flag, optional size of the spool file block in doublewords, and the subcode X'OFFE'. The format of Ry+1 is *aabbOFFE* where

***aa***

is defined as follows:

bit 0, when 1, identifies extended mode (see usage note [“2” on page 34](#) for more information).

bit 1 is reserved and must be 0

bits 2-7 are either 0 or specify the size, in doublewords, of the buffer space to hold the spool file block.

**bb**

is not used and should be 00

**OFFE**

is the DIAGNOSE code X'14' subcode.

This function initializes (or re-initializes) the virtual spool reader specified in *yyyy* for reading files to EOF (end of file). Any file previously marked as having been read to EOF on that device is reset, such that it appears to not have been previously read to EOF. A condition code and return code of 0 are reflected to the virtual machine. The INIT function also tells CP to begin to keep track of which spool files are read to EOF on the device. (The SELECT function, described following, resets this.)

## Read to EOF - Select

**Rx**

the virtual address of an output buffer; the default size is 252 bytes when invoked without extended mode. See usage note [“2” on page 34](#) for more information. The buffer may cross a page boundary.

**Ry**

The format of Ry is *nnzzyyyy* where

**nn**

is a not 00

**zz**

is 01

**yyyy**

is virtual spool reader address.

**Ry+1**

a flag, optional size of the spool file block in doublewords, and the subcode X'OFFE'. The format of Ry+1 is *aabbOFFE* where

**aa**

is defined as follows:

- bit 0, when 1, identifies extended mode (see usage note [“2” on page 34](#) for more information).
- bit 1 is reserved and must be 0
- bits 2-7 are either 0 or specify the size, in doublewords, of the buffer space to hold the spool file block.

**bb**

is not used and should be 00

**OFFE**

is the DIAGNOSE code X'14' subcode.

A SELECT function is performed. This function tells CP to stop marking files read to EOF on the virtual spool reader specified in *yyyy*, and then returns the descriptor of the first file found to have been read to EOF on the device. The selected file is no longer considered to have been read to EOF. Invoking this function repeatedly (without an intervening INIT function) will return all files which have been read to EOF.

### Notes:

1. The Read-to-EOF indicator might be turned off by spooling commands in an SSI environment. If a file had been read to EOF on a system other than the originating system and a spooling command is used

to change that file's characteristics, the indicator may be turned off. If this happens, the file is eligible to be read again and is not returned in response to the Read-to-EOF SELECT function.

2. The Read-to-EOF indicator is turned off by a system reset (for example, the CP SYSTEM RESET or IPL command does this). Selective reset of the reader (for example, the CP RESET command) does not turn off the Read-to-EOF indicator.
3. The Read-to-EOF indicator is not turned on for files receiving the EOF indication from their I/O operation unless all records in the file were actually read. This can happen on files which, for example, contain one or more X'5A' records. When these files are read, the X'5A' records are skipped and the Read-to-EOF indicator is not set when the EOF is reached.

For those functions which return a spool file block either the default buffer size can be used or extended mode can be specified. For these functions, the value of Ry+1 is decoded as follows:

If bit 0 of Ry+1 is 0, then the default buffer size is to be used.

If bit 0 of Ry+1 is 1 (that is, extended mode), then bit 1 must be 0 and bits 2 through 7 specify the size, in doublewords, of the spool file block to return.

See usage note [“2” on page 34](#) for the exact format of the data returned.

## Subcode X'0FFF'—Retrieve Next File Descriptor

### Rx

the output buffer address; the default size is 252 bytes when invoked without extended mode. See usage note [“2” on page 34](#) for more information.

### Ry

the spool file ID number

### Ry+1

X'0000FFF' (the subcode)

Ry contains a spool file ID or zero and specifies the point at which to begin the search. Zero identifies the beginning of the chain. The next file belonging to the user, regardless of class, file type, or current usage is selected. The spool file block and the first record (generally, the TAG) are placed in the caller's buffer. The buffer may cross a page boundary. If there are no files on the reader queue or if there is no subsequent file, condition code 1 is returned. If a starting file ID is specified and there is no match for this user, condition code 2 is returned.

For subcode X'0FFF' either the default buffer size can be used or extended mode can be specified. Whether the default or extended mode is to be used is determined as follows:

If bit 0 of Ry+1 is 0, then the default buffer size is to be used.

If bit 0 of Ry+1 is 1 (that is, extended mode), then bit 1 must be 0 and bits 2 through 7 specify the size, in doublewords, of the spool file block to return.

See usage note [“2” on page 34](#) for the exact format of the data returned.

## Usage Notes

1. You can use extended mode for subcodes X'0004' and X'0008'. In extended DIAGNOSE mode, you can specify the size of a spool file block in the high-order byte of Ry+1. If bit 0 is 1, bit 1 must be 0, and bits 2 through 7 define the size of the block in doublewords to be returned. If a block size of 0 is specified in extended mode, a specification exception occurs.
2. Subcodes X'0FFE' and X'0FFF' can be issued in either extended mode or not in extended mode.

When invoked without the extended mode indicator, the spool file block (SFBLOK) and the first record (generally, the TAG) are placed in the caller's buffer. The spool file block is 13 doublewords long and the first data record follows. The total length of this data is 252 bytes.

When invoked in extended mode, an additional 40 bytes of 3800 printer information (such as CHARS, FCB, COPY and FLASH) is returned between the spool file block and first data record. The length specified in Ry+1 is the length of the spool file block returned. The total length of data returned in

the user's buffer is the sum of the spool file block length specified, the 40 bytes of 3800 information (SPCHAR to SPPGLEN in SPLINK), and the 148 bytes of the TAG record. A length of 0 can be specified for the spool file block. In this case, only the 3800 printer information and the TAG data are returned.

3. For a description of the spool file block information returned, refer to SFBLOK and SPLINK in [Appendix A, "Data Areas Used by DIAGNOSE Codes,"](#) on page 985. DSECTs are provided in the HCPGPI macro library as SFBLOK COPY and SPLINK COPY.
4. If an external security manager is installed on your system, subcodes X'0000', X'0004', X'0008', X'002C', X'0FFE', and X'0FFF' may be affected. When these subcodes are issued, the system may skip spool files that you are not authorized to work with. For additional information, contact your security administrator.

## Responses

**Condition Codes:** The following condition codes are applicable for all subcodes except the X'0FFE' SELECT function.

| Condition Code | Return Code in Ry+1 | Meaning                                                                           |
|----------------|---------------------|-----------------------------------------------------------------------------------|
| 0              | None                | Successful completion                                                             |
| 1              | None                | End-of-file reached                                                               |
| 2              | None                | File not found                                                                    |
| 3              | 04 (X'04')          | Device address invalid                                                            |
| 3              | 08 (X'08')          | Device type invalid                                                               |
| 3              | 12 (X'0C')          | Device busy, reader not ready, or device real                                     |
| 3              | 16 (X'10')          | Fatal paging I/O error                                                            |
| 3              | 20 (X'14')          | Invalid file; for subcode X'028': requested record number exceeds the file's size |

The following condition codes are applicable for subcode X'0FFE' SELECT function.

| Condition Code | Return Code in Ry+1 | Meaning                                |
|----------------|---------------------|----------------------------------------|
| 0              | None                | Successful completion                  |
| 1              | None                | No file found meeting SELECT criteria. |

**Program Exception:** These program exceptions can occur if DIAGNOSE code X'14' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                                               | Any of the following: <ul style="list-style-type: none"> <li>• Ry is not an even register.</li> <li>• Ry+1 does not contain a valid subcode.</li> <li>• A buffer crosses a page boundary (except for subfunctions X'0FFE' and X'0FFF'; an exception does <i>not</i> occur for these two subfunctions if a buffer crosses a page boundary).</li> <li>• The new copy count is negative.</li> <li>• The file ID specified is greater than 9999.</li> <li>• The file ID specified is 0.</li> <li>• The subfunction called "Select Next File Not Previously Seen" of subcode X'FFE' was issued and Ry is equal to something other than 0 or 1.</li> <li>• Ry+1 indicates extended mode with a buffer length of zero for subcodes X'0004' or X'0008'.</li> </ul> |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to store into the buffer area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## DIAGNOSE Code X'18' – Standard DASD I/O

**Privilege Class:** Any (370 Accommodation must be active)

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'18' to perform input/output operations to a direct access device of the type fully supported by z/VM.

**Note:** z/VM includes DIAGNOSE code X'18' primarily for VM/SP, VM/SP HPO, and VM/ESA (370 Feature) compatibility. For new applications and new devices, use DIAGNOSE code X'A4'. When DIAGNOSE code X'A4' is used, CP constructs the appropriate channel program for the device being used. DIAGNOSE code X'A4' can be used in all types of virtual machines.

### Entry Values:

#### Rx

Contains the guest real address of the direct-access device.

#### Ry

Contains a channel address word (CAW).

The leftmost bits, 0 through 3, of the CAW contain the protection key used in accessing second-level storage for the I/O operation.

Bit 4 (suspend control) must be zero.

Bits 5 through 7 (unassigned) must be zero.

Bits 8 through 31 contain the channel program address.

Bits 29 through 31 must be zero, designating a doubleword-aligned channel program.

### Register 15

You must load register 15 with the number of READs or WRITEs in the CCW chain.

## Usage Notes

1. No I/O interrupts are returned by CP to the virtual machine; the DIAGNOSE instruction is completed only when all the READ or WRITE commands associated with the DIAGNOSE are completed.
2. Do not use DIAGNOSE code X'18' to read or write record-overflow-formatted data.
3. CP provides error recovery for this DIAGNOSE instruction. The instruction does not complete until the I/O operation has completed, including any error recovery processing.
4. The guest's Rx and Ry registers can be any two registers, neither of which is register 15.
5. The CCW chain specified by the guest must specify I/O on only one cylinder, and must be of the standard format.
6. For the 3350, 3375, 3380, 3390, and 9345 devices, the SET SECTOR CCW should precede each SEARCH CCW.
7. The CCW chain ends with a read or write without command chaining.
8. The CCW chain must not have any indirect data address (IDA), data chain (CD), or program controlled interrupt (PCI) flags.
9. Data crossing 4KB boundaries is handled using indirect data lists.
10. The CCWs must be format 0.
11. The first CCW must be a SEEK CCW.
12. This DIAGNOSE code does not support fixed-block DASD devices. If a program issues a DIAGNOSE code X'18' to a fixed-block DASD device, CP sets cc=1 and places a return code of 2 in register 15.
13. This DIAGNOSE code may be used only when the 370 Accommodation facility is active. Activate the 370 Accommodation facility with the SET 370ACCOM ON command.
14. This DIAGNOSE code does not support HyperPAV alias devices.
15. This DIAGNOSE code does not include Extended Address Volume (EAV) support for minidisks that reside at or above 65520 cylinders. If a program issues a DIAGNOSE code X'18' to such a minidisk, CP sets a condition code of 1 (cc=1) and places a return code of 2 in register 15.

## Responses

**Condition Codes:** On return from DIAGNOSE code X'18', CP sets the condition code as follows. In addition, a return code is placed in register 15.

| Condition Code | Return Code in Register 15 | Meaning                                                                                                                                                                                                                                              |
|----------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | 0 (X'00')                  | I/O completed successfully.                                                                                                                                                                                                                          |
| 1              | 1 (X'01')                  | The device is not attached.                                                                                                                                                                                                                          |
| 1              | 2 (X'02')                  | DIAGNOSE code X'18' does not support this device type, or does not include Extended Address Volume (EAV) support for minidisks.                                                                                                                      |
| 1              | 3 (X'03')                  | An attempt was made to write on read-only disk.                                                                                                                                                                                                      |
| 1              | 4 (X'04')                  | The cylinder or head number on a seek or seek head CCW is not in the range of the user's disk.                                                                                                                                                       |
| 1              | 5 (X'05')                  | A virtual device is busy or has an interrupt pending.                                                                                                                                                                                                |
| 2              | 5 (X'05')                  | The user's CAW is invalid for one of the following reasons: <ul style="list-style-type: none"> <li>• Bit 4 (suspend control) is 1.</li> <li>• Bits 5–7 are not B'0000'.</li> <li>• The channel program address is not doubleword-aligned.</li> </ul> |

| Condition Code | Return Code in Register 15 | Meaning                                                                                                                                                                                                                                                                                 |
|----------------|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2              | 6 (X'06')                  | The CCW or the SEEK/SEARCH arguments are not within the range of the user's storage.                                                                                                                                                                                                    |
| 2              | 7 (X'07')                  | The user's CCW is invalid for one of the following reasons: <ul style="list-style-type: none"> <li>Invalid bits are set in the flag byte of the CCW.</li> <li>The CCWs are not in the order expected by CP.</li> <li>The byte count in CCW is not valid for the CCW command.</li> </ul> |
| 2              | 8 (X'08')                  | The READ/WRITE byte count is 0.                                                                                                                                                                                                                                                         |
| 2              | 9 (X'09')                  | The READ/WRITE byte count is greater than 4096.                                                                                                                                                                                                                                         |
| 2              | 10 (X'0A')                 | The READ/WRITE buffer is not within the user's storage or the buffer is protected.                                                                                                                                                                                                      |
| 2              | 11 (X'0B')                 | The value in register 15, at entry, was not a positive number in the range of 1 to 15, or was less than the number of READs and WRITEs in the channel program.                                                                                                                          |
| 2              | 12 (X'0C')                 | The cylinder number on the SEEK HEAD was not the same number as on the first SEEK.                                                                                                                                                                                                      |
| 3              | 13 (X'0D')                 | Unrecoverable I/O error.<br><br>The CSW (8 bytes) was returned to the user.<br><br>If the CSW indicates a unit check, sense bytes are available if the user issues a SENSE command.                                                                                                     |

## Example

When you are using DIAGNOSE code X'18', your CCW string may look like the following example of a CCW string to read or write two 800-byte records:

```

SEEK,A,CC,6
SET SECTOR (omitted if device does not have RPS feature)
SRCH ID EQ,A+2,CC,5
TIC,*-8,0,0
RD or WRT,DATA1,CC+SILI,bytecount (bytecount to be between 1 and 4096,
                                   inclusive)
SEEK HEAD,B,CC,6 (omitted if HEAD number unchanged)
SET SECTOR (omitted if device does not
            have RPS feature)
SRCH ID EQ,B+2,CC,5
TIC,*-8,0,0
RD or WRT,DATA2,SILI,bytecount (bytecount to be between 1 and 4096,
                               inclusive)

A      SEEK and SRCH arguments for first read/write
B      SEEK and SRCH arguments for second read/write
DATA1  data area for first read/write
DATA2  data area for second read/write

```

**Note:** Indirect addressing is not permitted.

## DIAGNOSE Code X'20' – 370 Synchronous I/O for DIAGNOSE Support

**Privilege Class:** Any (370 Accommodation must be active)

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'20' to perform input/output (I/O) operations to tapes or direct access storage devices (DASDs), and dedicated unit record devices supported by z/VM. For a list of supported devices, see *z/VM: General Information*.

**Note:** z/VM includes DIAGNOSE code X'20' primarily for VM/SP, VM/SP HPO, and VM/ESA (370 Feature) compatibility. For new applications and new devices, use DIAGNOSE code X'A8'. DIAGNOSE code X'A8' can be used in all types of virtual machines.

#### Entry Values:

##### Rx

Contains the virtual device number.

##### Ry

Contains the channel address word (CAW). The leftmost bits, 0 through 3, of the CAW contain the protection key to use in accessing guest storage for the I/O operation.

Bit 4 (suspend control) must be zero.

Bits 5 through 7 (unassigned) must be zero.

Bits 8 through 31 contain the channel program address. Bits 29 through 31 must be zero, designating a doubleword-aligned channel program.

## Usage Notes

1. Do not use DIAGNOSE code X'20' to read or write record-overflow-formatted data on DASD devices.
2. The channel program that you specify must not contain self-modifying CCWs.
3. CP provides error recovery for this DIAGNOSE instruction. The instruction does not complete until the I/O operation has completed, including any error recovery processing.
4. This DIAGNOSE code may be used only when the 370 Accommodation facility is active. Activate the 370 Accommodation facility with the SET 370ACCOM ON command.
5. Diagnose I/O operations issued to virtual Parallel Access Volume bases and aliases are randomly scheduled on any available, appropriate real base or alias device. Certain CCWs, such as Reserve and Release, require base or alias real device affinity. This is handled by CP as needed.
6. This DIAGNOSE code is limited to a minidisk size of 65520 cylinders. If a program issues DIAGNOSE code X'20' to a minidisk larger than 65520 cylinders, CP sets a condition code of 3 (cc=3) and places a return code of 13 in register 15.

## Responses

**Condition Codes:** On return from DIAGNOSE code X'20' processing, CP sets the condition codes and the return codes as follows. In addition, a return code may be placed in register 15.

| Condition Code | Return Code in Register 15 | Meaning                                                                          |
|----------------|----------------------------|----------------------------------------------------------------------------------|
| 0              | Unchanged                  | I/O was completed with no errors; CSW is stored.                                 |
| 1              | 1 (X'01')                  | The device is either not attached, or is not accessible to the virtual machine.  |
| 1              | 5 (X'05')                  | The virtual device is busy or has an interrupt pending.                          |
| 2              | 2 (X'02')                  | A unit exception is reflected in the unit status field; the CSW is stored.       |
| 2              | 3 (X'03')                  | An incorrect length is reflected in the channel status field; the CSW is stored. |

| Condition Code | Return Code in Register 15 | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3              | 13 (X'0D')                 | <p>An unsupported device was specified, a permanent I/O error occurred, or a program issued this DIAGNOSE code to a minidisk larger than 65520 cylinders.</p> <p>If the user specifies an unsupported device, both the CSW and the user's Ry register is set to zero.</p> <p>If a permanent I/O error occurred, the CSW is stored and the user's Ry register contains the sense information in the following format:</p> <p>Byte 0 contains sense byte 2<br/> Byte 1 contains sense byte 3<br/> Byte 2 contains sense byte 0<br/> Byte 3 contains sense byte 1</p> |

## DIAGNOSE Code X'24' – Device Type and Features

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'24' to request identifying information and status information about a particular virtual device.

**Note:** DIAGNOSE code X'24' will no longer be upgraded for new device support. Applications using DIAGNOSE code X'24' should use DIAGNOSE code X'210' to take advantage of new device support. z/VM will continue to include DIAGNOSE code X'24' as a means of locating the address of the virtual console.

### Entry Values:

#### Rx

Must contain one of the following:

- The virtual device number of the device for which information is requested
- The value negative 1 (–1). Specify this when the device is a virtual console whose device number is unknown to your virtual machine.

#### Ry

Not used.

### Exit Values:

#### Rx

Contains information about a virtual console. Rx contains this data only if you specified –1 as an entry value and if CP located the console device.

#### Ry

Contains information about the specified virtual device.

#### Ry+1

Contains information about the real device that is associated with the specified virtual device. However, if Ry has been specified as register 15, CP returns only virtual device information; no information is returned in register Ry+1.

## Usage Notes

1. A CMS application may determine which set of ASCII and APL tables is currently in use with DIAGNOSE code X'24'. The real device terminal code field returned in Rx is set to one of the following values:

**Value**  
**Meaning**

**X'10'**

ASCII mode (TERMINAL APL OFF)

**X'14'**

ASCII/APL, SI state (TERMINAL APL ON, using standard ASCII)

**X'18'**

ASCII/APL, SO state (TERMINAL APL ON, using ASCII/APL)

- For a DIAGNOSE code X'24' to a SNA device connected through VCNA, the real device model number information is correct; however, the real device type may not be reliable.
- This DIAGNOSE code returns device information in the same format as you would receive with CP. It returns the real device type class and real device type fields as **CLASSPEC** (X'02') and **TYPUNSUP** (X'01') for all 3390 or newer DASD. For all new device information, you should use DIAGNOSE code X'210'. For more information, see [Appendix A, "Data Areas Used by DIAGNOSE Codes,"](#) on page 985.

The following tables summarize the type of information that is returned to the Rx, Ry, and Ry+1 registers after the instruction has executed.

Not all of the bits that are significant in VM/SP, VM/SP HPO, and VM/ESA (370 Feature) remain significant in z/VM.

- If the virtual device is a virtual disk in storage, it is not mapped to a real device. However, condition code 0 is returned for successful completion, and register Ry+1 contains information about the simulated real device.
- When issued for a virtual console and the user is logged on to the system console, CP will return real device information indicating that the real device is an undefined line mode terminal.

## Rx Information

| Byte 0                                                | Byte 1 | Byte 2                | Byte 3 |
|-------------------------------------------------------|--------|-----------------------|--------|
| real device terminal code for a local virtual console |        | virtual device number |        |

See [Appendix A, "Data Areas Used by DIAGNOSE Codes,"](#) on page 985 for the meaning of the values returned in the real device terminal code field.

## Ry Information

| Byte 0                    | Byte 1              | Byte 2                | Byte 3               |
|---------------------------|---------------------|-----------------------|----------------------|
| virtual device type class | virtual device type | virtual device status | virtual device flags |

See [Appendix A, "Data Areas Used by DIAGNOSE Codes,"](#) on page 985 for the meanings of values returned in these fields.

## Ry+1 Information

| Byte 0                 | Byte 1           | Byte 2                   | Byte 3                                                                                     |
|------------------------|------------------|--------------------------|--------------------------------------------------------------------------------------------|
| real device type class | real device type | real device model number | real device feature code<br>—or—<br>current device line length for a local virtual console |

See Appendix A, “Data Areas Used by DIAGNOSE Codes,” on page 985 for the meaning of the values returned in these fields.

## Responses

**Condition Codes:** The following chart lists the condition codes CP can return for DIAGNOSE code X'24', the meaning of each condition code, and the registers where data is returned.

| Condition Code | Status                                                             | Rx Contains <sup>1</sup>    | Ry Contains <sup>2</sup>   | Ry+1 Contains           |
|----------------|--------------------------------------------------------------------|-----------------------------|----------------------------|-------------------------|
| 0              | Successful completion                                              | Virtual console information | Virtual device information | Real device information |
| 1              | Undefined                                                          |                             |                            |                         |
| 2              | Virtual device exists but is not associated with a real device     | Virtual console information | Virtual device information |                         |
| 3              | Invalid device number, <b>or</b> the virtual device does not exist |                             |                            |                         |

**Note:**

<sup>1</sup>The Rx register contains information only when DIAGNOSE code X'24' specifies a virtual console whose address is unknown.

<sup>2</sup>If Ry is register 15, CP returns only virtual device information; no information is returned in register Ry+1.

## DIAGNOSE Code X'28' – Dynamic Channel Program Modification

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'28' to modify selected instructions in a channel program after I/O is initiated and before the operation is completed. The channel command words (CCWs) that you can modify are:

- From a Transfer in Channel (TIC) to a No Operation (NOP)
- From a TIC CCW to point to a new list of CCWs
- From a (No Operation) NOP to a TIC CCW
- The fields of a NOP CCW.

In an XC virtual machine, DIAGNOSE code X'28' can be run in access register mode. It addresses only the virtual machine's host-primary address space.

**Entry Values:**

**Rx**

Contains the guest absolute address of the transfer in channel (TIC) or No Operation (NOP) channel command word that was modified by your virtual machine. This channel command word is always in the host-primary address space.

**Ry**

Contains the subchannel number in bits 16 through 31. This device must be a TERMINAL or GRAPHICS class device, a 3704, or a 37x5.

When executed with the 370 Accommodation facility active (the SET 370ACCOM ON command has been issued), the Ry value is interpreted according to the following heuristic: If the Ry value, when

viewed as a System/370 device address, selects a device which exists, and at least one of the following is true, then the Ry value is interpreted as a device address; otherwise, the Ry value is interpreted as a subchannel number.

- There is an active channel program on the device with that device address, and the channel program was started by a System/370 I/O instruction (e.g., SIO or SIOF).
- The Ry value, when viewed as a 370-XA subchannel number, does not select a subchannel with a device assigned to it.
- The Ry value, when viewed as a 370-XA subchannel number, selects a subchannel with a device assigned to it, but there is no active channel program on that device.

**Note:** Rx and Ry cannot be the same register.

## Usage Notes

1. If the AUTOPOLL function has been set on, the operating system running in your virtual machine must use DIAGNOSE code X'28' to notify z/VM whenever a virtual autopolling channel program has been modified. For more information, see the SET AUTOPOLL command in the [z/VM: CP Commands and Utilities Reference](#).
2. SUSPEND/RESUME is not supported using DIAGNOSE code X'28'. A request to modify a TIC/NOP CCW in a:
  - Suspended channel program results in a condition code of 2 and a return code of 9.
  - Currently executing channel program with a CCW containing a suspend bit equal to 1, or on, is honored; the suspend bit is reset in the modified channel program.
3. The address specified in the Rx register, the new address in the modified TIC CCW, and the new CCW list to which the modified TIC CCW points must all be addresses that appear second-level; CP knows these addresses are virtual, but the virtual machine treats them as absolute.
4. When a virtual machine modifies a TIC CCW, it is modifying a virtual channel program. CP has already translated that channel program, and the real channel program may or may not have been completed for the guest virtual machine. DIAGNOSE code X'28' must be issued to inform CP of the change in the virtual channel program so that CP can make the corresponding change in the real CCW before it is executed, if possible. If the real CCW has already been executed, the change has no effect unless it is reexecuted during the running of the channel program.
5. When a NOP or TIC CCW is modified to point to a new list of CCWs, CP translates the new CCWs.

## Responses

**Condition Codes:** On return from DIAGNOSE code X'28' processing, CP sets the condition code listed as follows: In addition, a return code is placed in register 15:

| Condition Code | Return Code in Register 15 | Meaning                                                                                |
|----------------|----------------------------|----------------------------------------------------------------------------------------|
| 0              | 0 (X'00')                  | The real channel program is successfully modified.                                     |
| 1              | 1 (X'01')                  | The same register is specified for Rx and Ry.                                          |
| 1              | 2 (X'02')                  | The device specified by the Ry register is not found.                                  |
| 1              | 3 (X'03')                  | The address specified by the Rx register is not within the user's storage space.       |
| 1              | 4 (X'04')                  | The address specified by the Rx register is not doubleword-aligned.                    |
| 1              | 5 (X'05')                  | A CCW string corresponding to the device (Ry) and address (Rx) specified is not found. |

| Condition Code | Return Code in Register 15 | Meaning                                                                                                                                                                                  |
|----------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1              | 6 (X'06')                  | The CCW at the address specified by the Rx register is neither a TIC nor a NOP; the CCW in the channel program is neither a TIC nor a NOP.                                               |
| 1              | 7 (X'07')                  | The new address in the modified TIC CCW is not within the user's storage space.                                                                                                          |
| 1              | 8 (X'08')                  | The new address in the modified TIC CCW is not doubleword-aligned.                                                                                                                       |
| 1              | 10 (X'0A')                 | The device specified in Ry is not an eligible type.                                                                                                                                      |
| 1              | 14 (X'0E')                 | The target CCW is in the middle of a data chained region.                                                                                                                                |
| 1              | 16 (X'10')                 | A NOP or TIC CCW has been modified to a TIC; the new CCW data address of the TIC target CCW is not translated, and data chaining ID active.                                              |
| 2              | 9 (X'09')                  | The channel program could not be modified; channel end and/or device end occurred already.                                                                                               |
| 2              | 12 (X'0C')                 | The channel program could not be modified; a paging error has occurred when an attempt was being made to derive the real storage address for the CCW pointed to by the modified TIC CCW. |

## DIAGNOSE Code X'34' – Read System Dump Spool File

**Privilege Class:** C, E

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'34' to read the system dump spool file.

### Entry Values:

#### Rx

Contains the guest real address of a page-size buffer that receives the spool file data. If the buffer crosses a page boundary, a specification program exception is returned to your virtual machine.

#### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the buffer that receives the spool file data. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the buffer is in the host-primary address space.

#### Ry

Contains the virtual address of the spool input card reader. Ry must not be register 15.

**Exit Values:** On return, Ry+1 may contain a return code. See the Responses section for a description of these codes.

## Usage Notes

1. The format of a z/VM dump may change from release to release.
2. The format of the dump data is not part of the programming interface.
3. You may not be authorized to issue this DIAGNOSE code if an external security manager is installed on your system. For additional information, contact your security administrator.

## Responses

**Condition Codes:** On return from the DIAGNOSE code X'34' processing, CP sets one of the condition codes listed below. In addition, a return code is placed in Ry+1, as follows:

| Condition Code | Return Code in Ry+1 | Meaning                              |
|----------------|---------------------|--------------------------------------|
| 0              | None                | Data transfer completed successfully |
| 1              | None                | End-of-file reached                  |
| 2              | None                | File not found                       |
| 3              | 4 (X'04')           | Device address invalid               |
| 3              | 8 (X'08')           | Device type invalid                  |
| 3              | 12 (X'0C')          | Device busy                          |
| 3              | 16 (X'10')          | Fatal paging I/O error               |
| 3              | 20 (X'14')          | Invalid file                         |

**Program Exceptions:** These program exceptions can occur if the DIAGNOSE X'34' is given incorrect input data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                 |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                                               | Any of the following: <ul style="list-style-type: none"> <li>• The address contained in Rx is not on a page boundary.</li> <li>• Ry is register 15.</li> <li>• Privilege class violations.</li> </ul> |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                                                                                          |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to store into the result buffer.                                                                                                                                             |

## DIAGNOSE Code X'3C' – Activate z/VM CP Directory

**Privilege Class:** A, B, C

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'3C' to activate or reactivate a valid directory found in the CP-owned volume list. This is usually done at CP initialization time, or as a result of the DIRECTXA command rebuild of the current z/VM CP directory.

**Entry Values:**

**Rx**

Contains the first four bytes of the volume identification of the volume assumed to contain a valid directory.

**Ry**

Contains the last two bytes of the volume identification (in bytes 0 and 1), and the number of the virtual device to which the volume is attached (in bytes 2 and 3).

## Usage Notes

DIAGNOSE code X'3C' activates the z/VM directory residing on the specified volume if one of the following is true:

1. The named volume is the one on which the current CP directory was found at CP initialization time
2. No directory is currently active, and the named volume is currently CP-owned.

## Responses

**Condition Codes:** On return from DIAGNOSE code X'3C', CP sets one of the following condition codes:

| Condition Code | Meaning                                                                                                                                                                         |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | z/VM has successfully activated the CP directory.                                                                                                                               |
| 1              | The directory that was activated is not a current CP directory.                                                                                                                 |
| 2              | The DASD address specified in the volume label was invalid. The volume label and allocation map should be restored to the values that existed prior to the update.              |
| 3              | A fatal I/O error occurred when z/VM attempted to read the CP directory. The volume label and allocation map should be restored to the values that existed prior to the update. |

**Program Exceptions:** These program exceptions can occur if the DIAGNOSE X'3C' is given incorrect input data:

| Problem Encountered            | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception        | <p>If Rx is unchanged:</p> <p>The update is not for the current online directory volume and the issuer of the DIAGNOSE X'3C' does not have the appropriate privilege class.</p> <p>If Rx=0:</p> <p>The update is for the current online directory volume and one or more of the following is true:</p> <ul style="list-style-type: none"> <li>• The issuer of the DIAGNOSE X'3C' does not have the appropriate privilege class.</li> <li>• The new directory is not SSI-enabled, which is not valid in the current system configuration.</li> <li>• The new directory is SSI-enabled, which is not valid in the current system configuration.</li> </ul> <p>Rx should be tested, and if it is zero, the volume label and allocation map should be restored by the function that issued the DIAGNOSE X'3C' to the values that existed prior to the update.</p> |
| Privileged-operation exception | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## DIAGNOSE Code X'44' – Voluntary Time Slice End

**Privilege Class:** Any

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

Use DIAGNOSE code X'44' to notify the scheduler that a spin lock loop exists in your virtual machine. DIAGNOSE code X'44' informs the scheduler that the remainder of the CPU time slice allocated to a virtual CPU is no longer useful. z/OS® and z/VM operating systems use DIAGNOSE code X'44' as the standard method for notifying the scheduler that a spin lock loop exists.

**Entry Values:** Specify the Rx and Ry fields as zero.

## Usage Notes

1. The virtual CPU that issues DIAGNOSE code X'44' is given a dispatching priority lower than other virtual CPUs in the same guest multiprocessing configuration. The other virtual CPUs generally run before the issuing virtual CPU. If there is no other virtual CPU for this virtual machine, then DIAGNOSE code X'44' has no effect.
2. DIAGNOSE code X'44' is useful when the operating system on one guest CPU is waiting to obtain a spin lock, and another guest CPU must be run in order to release the spin lock. The DIAGNOSE causes the CPU holding the spin lock to be run before the issuing CPU runs again.
3. The effects of DIAGNOSE code X'44' are temporary. Within a few seconds, the virtual CPU is scheduled as if the DIAGNOSE were never issued.

## Responses

None.

## DIAGNOSE Code X'48' – Second Level SVC 76

---

**Addressing Mode:** 24-bit or 31-bit

Execution of DIAGNOSE code X'48' provides a null function in z/VM. z/VM supports DIAGNOSE code X'48' only to provide compatibility with VM/SP, VM/SP HPO, and VM/ESA (370 Feature).

In VM/SP, VM/SP HPO, and VM/ESA (370 Feature), the function of DIAGNOSE code X'48' is to distinguish between two or more levels of virtual device numbers in EREP records. In z/VM, CP itself provides this function; you do not have to invoke it using the DIAGNOSE instruction.

If your virtual machine is an XC virtual machine, then DIAGNOSE code X'48' is not valid. A specification exception is recognized if DIAGNOSE code X'48' is attempted from an XC virtual machine.

## DIAGNOSE Code X'4C' – Generate Accounting Records

---

**Privilege Class:** Any, with the directory ACCT option.

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

Use DIAGNOSE code X'4C' to generate accounting records with existing accounting information and to change user accounting information for the next accounting record in the current session. Your virtual machine can issue this DIAGNOSE only if the account (ACCT) option has been specified for you in the system directory.

**Entry Values:**

**Rx**

Contains the guest real address of one of the following:

- A 24-byte parameter list that identifies the accounting information for the next *charge-to* user. The contents of the parameter list depend on the hexadecimal function subcode placed in Ry. In the list below, the hexadecimal numbers are offsets. The format of the parameter list is:

X'00'—the next *charge-to* user ID

X'08'—the next *charge-to* account number

X'10'—the next distribution code

If the address represents a parameter list, the list must be doubleword-aligned.

If the address of the parameter list is zero, no parameter list is used. Instead, the next *charge-to* user ID, account number, and distribution code are taken from the directory entry of the user issuing the DIAGNOSE instruction.

- A variable length data area, up to 70 bytes, that you want to store in an accounting record.

CP interprets the address, based on a hexadecimal function code that is supplied in Ry.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the data area addressed by Rx. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the data area is in the host-primary address space.

**Ry**

Ry contains a hexadecimal function subcode. In z/Architecture mode the high order word of register Ry is ignored. The subcode is put in the low order byte.

**Subcode****Rx points to:****X'0000'**

A parameter list containing only a user ID

**X'0004'**

A parameter list containing a user ID and account number

**X'0008'**

A parameter list containing a user ID and distribution code

**X'000C'**

A parameter list containing a user ID, account number, and distribution code

**X'0010'**

A data area containing up to 70 bytes of user information to be transferred to the accounting record, starting in column 9

**Note:** If Ry contains X'0010', Ry cannot be register 15.

**Ry+1**

If Ry contains X'0010', then Ry+1 must contain the length of the data area that Rx is pointing to. In z/Architecture mode the high order word of register Ry+1 is ignored. The 4 bytes of the low order register word contains the length of the buffer. The length specified in Ry+1 must be greater than zero and less than or equal to 70.

If Ry does not contain X'0010', Ry+1 is ignored.

**Usage Notes**

1. For a discussion of how z/VM processes addresses, refer to [“How Addresses Are Processed” on page 5](#).
2. If Ry contains any valid function subcode other than X'0010':

- Accounting records are generated for the virtual machine's resources, dedicated devices, temporary disk space, virtual disk in storage, and network data transmission records using the accounting information currently set.

The accounting information currently set are the values set with the previous DIAGNOSE X'4C'. If no DIAGNOSE code X'4C' has been issued yet, the user ID, account number, and distribution code are set by logon to the values specified in the user directory.

Columns 79 and 80 of the accounting records generated after DIAGNOSE code X'4C' has been issued have an accounting record identification code of:

- C'C1'—the virtual machine resource records
- C'C2'—the virtual machine dedicated device records
- C'C3'—the virtual machine temporary disk space records
- C'CB'—the virtual machine virtual disk in storage records
- C'CC'—the virtual machine network data transmission records

For more information about accounting records, see [z/VM: CP Planning and Administration](#).

- The parameter list (a 24-byte area whose guest real address is in Rx) is validated:
  - If the address is invalid, an addressing exception is generated.

- If the address is not aligned on a doubleword boundary, a specification exception is generated.
- If the address in Rx is zero, that is, no parameter list exists, the accounting information is reset to equal that of the issuing user ID as set in its directory entry (that is, your user ID, your account number, and your distribution code).

Control is returned to your virtual machine with a condition code of zero.

- If the address in Rx is valid, that is, it points to a parameter list:
  - And if the new user ID specified is invalid, that is, it cannot be found in the system directory:
 

The accounting information is reset to equal that of the issuing user ID as set in its directory entry (that is, your user ID, your account number, and your distribution code).

Control is returned to your virtual machine with a condition code of two.
  - And if the new user ID specified is valid, the accounting information is updated from the parameter list pointed to, based on the hexadecimal function subcode set in Ry; and control is returned to your virtual machine with a condition code of zero:

#### **Subcode**

##### **Accounting Information Changed**

#### **X'0000'**

The next *charge-to* user ID updated from parameter list.

The next *charge-to* account number updated from the new user ID system directory entry

The next distribution code updated from the new user ID system directory entry

#### **X'0004'**

The next *charge-to* user ID updated from the parameter list

The next *charge-to* account number updated from the parameter list

The next distribution code updated from the new user ID system directory entry

#### **X'0008'**

The next *charge-to* user ID updated from the parameter list

The next *charge-to* account number updated from the new user ID system directory entry

The next distribution code updated from the parameter list

#### **X'000C'**

The next *charge-to* user ID updated from the parameter list

The next *charge-to* account code updated from the parameter list

The next distribution code updated from parameter list

#### **X'0010'**

Not a valid parameter list function subcode (see usage note [“3”](#) on page 49)

3. If Rx contains the guest real address of a variable length data area, and Ry contains a function subcode of X'0010':

- If the address specified in Rx is negative or greater than your virtual machine's storage size, an addressing exception is generated.
- If the value in Ry+1 is zero, negative, or greater than 70, a specification exception is generated.
- If both the address and the length are valid, an account buffer is built as follows:
  - The issuing user ID as set at logon (that is, your user ID), is placed in columns 1 through 8.
  - An accounting record identification code of C0 is placed in columns 79 and 80.
  - The data, pointed to by the address in Rx, is moved into the accounting record starting at column 9, for a length equal to the value in Ry+1.
  - Unused columns are initialized to blanks.
  - The accounting buffer is sent to the accounting virtual machine.

- Control is returned to your virtual machine with a condition code of zero.
- 4. For subcodes other than X'0010', the counter containing the number of LINK commands attempted with an invalid password is reset.

## Responses

**Condition Codes:** On return from the DIAGNOSE code X'4C', CP sets one of the following condition codes:

| Condition Code | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | Both the user ID and hexadecimal function subcode are valid. Accounting records are generated using the currently set accounting information, and the accounting information for the next accounting records for this session is updated from the parameter list, if one was specified.                                                                                                                                                                             |
| 1              | The user is not authorized to use the account option.                                                                                                                                                                                                                                                                                                                                                                                                               |
| 2              | Either of the following: <ul style="list-style-type: none"> <li>Your own user ID is no longer in the CP directory. Accounting records have been written, but the accounting information (user ID, account number, distribution code) has not been reset.</li> <li>The user ID contained in the parameter list is not found in the system directory. Accounting records have been written, and the accounting information has been reset to your user ID.</li> </ul> |
| 3              | The hexadecimal function subcode in Ry is invalid.                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'4C' is given incorrect input data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception <sup>1</sup>                                  | Any of the following: <ul style="list-style-type: none"> <li>Subcodes X'0000', X'0004', X'0008', X'000C': the parameter list does not start on a doubleword boundary.</li> <li>Subcode X'0010': Ry is register 15.</li> <li>Subcode X'0010': the value in Ry+1 is less than 1 or greater than 70.</li> </ul> |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                 |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to store into the parameter list or the data area.                                                                                                                                                                                                                                  |

**Note:** <sup>1</sup> Ordinarily, specification and some access exceptions are suppressing or nullifying, that is, the instruction is effectively not executed. However, when these exceptions occur for subcodes X'0000', X'0004', X'0008', or X'000C', of DIAGNOSE code X'4C', accounting records are written for the preceding interval and accounting information is reset to your own user ID, accounting number, and distribution code.

## DIAGNOSE Code X'54' – Control the Function of the PA2 Key

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'54' to control the function of the PA2 function key. You can use the PA2 key to simulate an external interrupt to a virtual machine or to clear the output area of a display screen.

**Entry Values:****Rx**

Contains a value that controls the function of the PA2 key. If Rx contains a nonzero value, the PA2 key simulates an external interrupt to the virtual machine. If Rx contains a zero, the PA2 key clears the output area of the display screen.

**Ry**

Not used.

**Usage Note**

The external interrupt is simulated only when the display screen is in the VM READ, HOLD, or MORE status and the CP TERMINAL APL ON command has been issued.

**Responses**

None.

**DIAGNOSE Code X'58' – 3270 Virtual Console Interface**

---

**Privilege Class:** Any

**Addressing Mode:** 31-bit

Use DIAGNOSE code X'58' to enable your virtual machine to communicate with IBM 3270 display stations.

DIAGNOSE code X'58' operates in all virtual machines; however, only format 0 CCWs are allowed. All storage addresses referred to by DIAGNOSE code X'58' are guest absolute addresses and all designated areas are in host-primary space. Addresses of CCWs and the addresses contained in the CCW, including the pointer to indirect address words (IDAWs) as well as directly referenced data buffers, are 24-bit addresses. DIAGNOSE code X'58' may be used in one of two modes:

- Line mode—the user can write data to the screen, which is in the control of CP and is formatted into specific areas: input, output, and status. The user can write data to either of the following places:
  - The input or output area, beginning at a specified line. Up to a full-screen of data can be written.
  - The output area starting at the next available line. More than a full-screen of data can be written.
- Full screen mode—the user has full control over the format of the screen, and is responsible for error checking and recovery. The user may read from, as well as write to, the display.

In either mode, the virtual machine can provide data stream orders along with data that is sent to the display station. An attribute character provides control information for the display (an example of control information is a request to intensify data when it is displayed).

**Entry Values:****Rx**

Contains the channel address word (CAW). The leftmost bits, 0 through 3, of the CAW contain the protection key to use in accessing guest absolute storage for the I/O operation.

Bit 4 (Suspend Control) must be zero.

Bits 5 through 7 (Unassigned) must be zero.

Bits 8 through 31 contain the channel program address.

Bits 29 through 31 must be zero, designating a doubleword aligned channel program.

**Ry**

Contains the device number of the display station where the operation is to be performed. This value must be right-justified.

For 370-only applications running in an XA, ESA, or XC virtual machine with 370 Accommodation enabled (see the SET 370ACCOM command in the *z/VM: CP Commands and Utilities Reference*), DIAGNOSE code X'58' follows the architecture for the Start I/O (SIO) instruction processing. For more information on the SIO instruction and the status returned, see the *Enterprise Systems Architecture/390 Principles of Operation* or *z/Architecture Principles of Operation* (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>). The guest virtual machine's condition codes (CCs) are changed on the following conditions:

| <b>Code</b> | <b>Description</b>                 |
|-------------|------------------------------------|
| <b>0</b>    | The SIO function has been accepted |
| <b>1</b>    | The CSW has been stored            |
| <b>2</b>    | The channel or subchannel is busy  |
| <b>3</b>    | Not operational.                   |

For ESA applications running in an XA, ESA, XC, or Z virtual machine (including one in access register mode), DIAGNOSE code X'58' follows the interface architecture for the Start Subchannel (SSCH) instruction processing. For more information on the SSCH instruction and the status returned, see the *Enterprise Systems Architecture/390 Principles of Operation* ([publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf](https://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf)), *z/VM: ESA/XC Principles of Operation*, *z/Architecture Principles of Operation* (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>), or *z/VM: z/Architecture Extended Configuration (z/XC) Principles of Operation*, based on the architecture mode of the virtual machine. The guest virtual machine's condition codes are changed on the following conditions:

| <b>Code</b> | <b>Description</b>               |
|-------------|----------------------------------|
| <b>0</b>    | The start function is initiated  |
| <b>1</b>    | The subchannel is status-pending |
| <b>2</b>    | The subchannel is busy           |
| <b>3</b>    | Not operational.                 |

## Usage Notes

1. In an XC virtual machine, DIAGNOSE code X'58' can run in access register mode, but it addresses only the virtual machine's host-primary address space.
2. When a virtual machine issues DIAGNOSE code X'58', it must provide one or more channel command words (CCWs). These CCWs specify the operation to be performed, provide control information for the display station, and specify the address of data to be displayed during a write operation or the address of a buffer where data is to be stored during a read operation. As is usual for I/O operation, storage accesses to CCWs, IDAWs, and data areas are not subject to low-address protection, fetch-protection override, or storage-protection override. Key-controlled protection applies, using the key in Rx bits 0-3. See also the usage note ("8" on page 56) for valid channel programs.
3. When invoking CCW code X'49', both APL and TEXT must be off. Having either APL or TEXT on causes command rejects.
4. Issuing CCW code X'49' from a device other than a 3270 causes command rejects.
5. DIAGNOSE code X'58' is for a virtual 3215 console and causes command rejects if executed with CONMODE 3270.

6. When DIAGNOSE code X'58' is being executed in line mode:

- To display up to a full screen of data starting at a specified line, code a CCW using the following assembler language instructions:

```
DS 0D
DC X'19',AL3(dataddr),AL1(flags),AL1(ctl),AL2(count)
```

### **X'19'**

is the subcode.

### **dataddr**

is the virtual storage address of the first byte of data to be displayed.

### **flags**

are standard CCW flags. The suppress-incorrect-length indicator, bit 34, must be set to a value of 1. Set other bits as needed. To use 31-bit addresses, the use of indirect data address words is required.

### **ctl**

is a control byte defined as follows:

- If the high-order bit (bit 0) is on, CP erases the display station screen before new data is displayed.
- Bits 2 through 7 identify the line on the display screen where the display is to start. A value of 0 (B'xx00 0000') corresponds to the first or top line, a value of 1 (B'xx00 0001') corresponds to the second line, and so forth.
- If the control byte contains the value X'FF', CP erases the display station's output area. No new data is displayed.
- If the control byte contains the value X'FE', CP:
  - Erases the entire screen
  - Rewrites the field attribute bytes for the CP screen format
  - Resets the cursor to the beginning of the input area.

### **count**

specifies the number of bytes of data to be displayed. The maximum value allowed is 3991 bytes. The maximum amount of data that can be displayed at one time depends upon the screen size of the 3270 display station, the line on the screen where the data is to start, and the character set used.

For APL and TEXT character sets, each character that is translated into a compound character counts as two bytes. Therefore, the maximum count of data is 1995. For APL and TEXT data streams that contain some untranslated compound character data, the maximum count lies somewhere between 1995 and 3991. If an APL or TEXT data stream is sent that, after translation, exceeds 3991 bytes, the data is truncated.

For the default or EBCDIC character set:

- A model 2 can display in an area that extends from:
  - Lines 1 through 22 (a maximum of 1760 bytes)
  - Line 23 up to and including the left 59 character positions of line 24 (a maximum of 139 bytes).
- A model 3 can display in an area that extends from:
  - Lines 1 through 30 (a maximum of 2400 bytes)
  - Line 31 up to and including the left 59 character positions of line 32 (a maximum of 139 bytes).
- A model 4 can display in an area that extends from:
  - Lines 1 through 41 (a maximum of 3280 bytes)

- Line 42 up to and including the left 59 character positions of line 43 (a maximum of 139 bytes).
- A model 5 can display in an area that extends from:
  - Lines 1 through 25 (a maximum of 3300 bytes)
  - Line 26 up to and including the left 111 character positions of line 27 (a maximum of 243 bytes).

The above lengths are dependent on hardware characteristics, not on DIAGNOSE code X'58' interface limitations.

- To display data starting at the next available line on the screen, code a CCW using the following assembler language instructions:

```
DS 0D
DC X'49',AL3(dataddr),AL1(flags),AL1(ctl),AL2(count)
```

**X'49'**

is the subcode.

**dataddr**

is the virtual storage address of the first byte of data to be displayed.

**flags**

are standard CCW flags.

**ctl**

is ignored.

**count**

specifies the number of bytes of data to be displayed. The maximum value allowed is 3991 bytes.

When the virtual machine issues CCW code X'49', CP treats the channel program as a normal 3215 channel program, with the following exceptions:

- The data stream is processed as if TERMINAL LINESIZE OFF has been issued. That is, the data stream is broken up only when a X'15' is encountered in the data stream.
- Each time a X'15' is encountered, CP counts exactly one line.
- CP does not translate any code point from X'40' to X'FE', inclusive. CP also does not translate code points X'0E' and X'0F'.

DIAGNOSE code X'8C' should be issued before DIAGNOSE code X'58' and code X'49' to determine the width of the screen. This information should then be used to determine the number of character positions that can be taken up between occurrences of X'15'. The width of the screen minus 2 should be the maximum for that number. If this restriction is not observed, CP cannot manage the screen correctly.

To provide attribute characters for the data, place the attribute character in the data stream immediately following a 3270 start-field order. The start-field order, a 1-byte value, notifies the 3270 display station that the next byte in the data stream is an attribute character. For a description of how the 3270 display station uses attribute characters, and to determine the values to specify for attribute characters and the start-field order, see the *IBM 3270 Information Display System: 3274 Control Unit Description and Programmer's Guide*, GA23-0061. This is a requirement of the hardware, not of the DIAGNOSE code X'58' interface.

**Note:** Through the attribute character, it is possible to define a display field as selector-pen detectable. However, when the selector pen selects the field, CP does not return data from the field to the virtual machine. This is a requirement of the hardware, not of the DIAGNOSE code X'58' interface.

When DIAGNOSE X'58' is specified, any start-field order in the data stream has its associated attribute byte set with the modified data tag off and the protection bit on, regardless of previous settings.

After processing DIAGNOSE code X'58', CP sets a condition code. If the operation is successful (no I/O errors occurred), CP sets a condition code of zero. If an I/O error occurs, CP sets a nonzero condition code.

For 370-only applications running in an XA, ESA, or XC virtual machine with 370 Accommodation enabled, the returned condition codes and CSW status are the standard condition codes and status as defined in System/370 Principles of Operation. The application program is responsible for all I/O status and error checking, just as if START I/O (SIO) were being used instead of DIAGNOSE. This is done by using the TEST I/O (TIO) instruction and examining the returned condition code and the virtual CSW.

For ESA applications running in XA, ESA, XC, or Z virtual machines, the application program is responsible for all I/O status and error checking, just as if a Start Subchannel (SSCH) were being used instead of DIAGNOSE code X'58'. This is done by using the Test Subchannel (TSCH) instruction and by examining the subsequent IRB. For more information on the IRB and the status returned, see System/370 Principles of Operation, *z/VM: ESA/XC Principles of Operation*, *z/Architecture Principles of Operation* (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>), or *z/VM: z/Architecture Extended Configuration (z/XC) Principles of Operation*, based on the architecture mode of the virtual machine.

#### 7. When DIAGNOSE code X'58' is being executed in full-screen mode:

DIAGNOSE X'58' provides a means by which a virtual machine may share, with CP, control of a 3270 display station. Two CCW operations, X'29' and X'2A', in addition to performing the requested I/O, also notify CP that the display station is operating under the control of the virtual machine.

CCW code X'29' performs a Write, Erase/Write, Erase/Write Alternate, or Write Structured Field operation, depending on the value of the control field. The virtual machine must provide appropriate control information beginning with the Write Control Character (WCC) and including 3270 orders following the WCC. Data may be written anywhere on the screen. The virtual machine must provide the address where the write is to begin; it uses a Set Buffer Address (SBA) command to do this. Writing can also start at the current cursor address. CCW code X'29' performs a Write Structured Field operation when the value of the control field is X'20'. The Write Structured Field command sends control information to a 3274 controller.

CCW code X'2A' performs a Read Buffer or a Read Modified operation, depending on the value of the control field.

To specify the full-screen mode CCW, use the following assembler language instructions:

```
DC 0D
DC X'(ccwcode)' ,AL3(dataddr),AL1(flags),AL1(control),AL2(count)
```

#### **ccwcode**

is a 2-digit CCW code (X'29' or X'2A')

#### **dataddr**

for a write operation, specifies the first byte of the data stream (WCC) to be written. For a read operation, specifies the address of the read buffer.

#### **flags**

is the standard CCW flag field

#### **control**

for a write operation (CCW code X'29') the following control field values cause various operations to be performed:

##### **Value**

##### **Operation Performed**

##### **X'80'**

Erase/Write

##### **X'C0'**

Erase/Write Alternate

**X'40'**

Erase/Write Alternate

**X'20'**

Write Structured Field

**All other values**

Write

For a read operation (CCW code of X'2A'), the following control field values cause various operations to be performed:

**Value****Operation Performed****X'80'**

Read Modified

**All other values**

Read Buffer

By adding X'10' to the CONTROL field values for Erase/Write or Erase/Write Alternate, making them X'90' or X'D0' respectively, the break key interrupt is reflected to the virtual machine. This replaces the normal break key function of returning the virtual machine to CP mode, and allows a virtual machine to have full control of the keyboard.

Normal break key function is restored when either full screen mode is reset or a DIAGNOSE code X'58' CCW code X'29' Erase/Write (control code X'80') or Erase/Write Alternate (control code X'C0' or X'40') is issued.

**count**

for a write operation, specifies the number of bytes to be displayed in addition to the number of bytes of control information. For a read operation, it specifies the number of display characters to be read in addition to the number of bytes of control information.

If you are using a local terminal (whose controller is connected to the host computer through a direct channel) the maximum count is 65,535; otherwise, the maximum count is 65,503. The maximum number of displayable positions (a hardware dependency, not a DIAGNOSE code X'58' requirement) for the supported devices is:

**Max. Displayable****Supported Devices****1920 bytes**

3277, 3278, and 3279 Model 2

**2560 bytes**

3278 and 3279 Model 3

**3440 bytes**

3278 Model 4

**3564 bytes**

3278 Model 5

**8. For valid channel programs:**

The channel programs presented by DIAGNOSE code X'58' may contain one or more CCWs. The CCW operation codes supported are the DIAGNOSE code X'58' operation codes X'19', X'49', X'29', and X'2A', and the two general operation codes, X'08' (TIC) and X'03' (NOP). The channel program must be either line mode or full-screen mode; the two modes cannot be mixed in one channel program. The X'19' operation code that clears the screen may be used to start either a line mode or full-screen mode write operation, or it may comprise a whole channel program in itself.

The following rules apply:

- a. The channel program **must** begin with a valid DIAGNOSE code X'58' operation code: X'19', X'49', X'29', or X'2A'.

- b. A X'19' or X'49' write can be command-chained to another X'19', a X'49', a X'08' (TIC), or a X'03' (NOP operation code).
  - c. A X'19' with a CTL value of X'FF' or X'FE' can be chained to any other X'19', X'49', or X'29' operation code, or to an intervening X'08' (TIC) or X'03' (NOP) operation code. In the case of a X'29' operation code, the X'19' **must** be the first CCW in the channel program.
  - d. A X'29' or X'2A' operation code can be chained to another X'29', a X'2A', a X'08' (TIC), or a X'03' (NOP) operation code.
9. For full-screen interactions (for both DIAGNOSE code X'58' and 3270 SIO/SSCH):

The virtual machine console operates in one of two modes: CP or full-screen. CP mode is the default and is indicated by the screen status field in the lower right-hand corner of the screen. When in CP mode, CP controls the screen format, and the data that appears on the screen is provided by CP and the programs running in the virtual machine.

A guest virtual machine can use either DIAGNOSE code X'58' or the 3270 SIO/SSCH instruction to initiate full-screen mode, but not both. Full screen console support enables a guest virtual machine and CP to share a locally-attached display station controlled by CP. The virtual machine can use the display station in full-screen mode; CP can use the same display station as a device in line mode.

When in full-screen mode, the screen format data checking and error checking are under complete control of the program running in the virtual machine.

Line mode is terminated and full screen mode is initiated when the application program issues an Erase/Write, Erase/Write Alternate, or Write Structured Field instruction. Full screen mode may be terminated by a line mode type I/O to the screen anytime the keyboard is in a locked state.

The Terminal BRKKEY command allows the user to specify a PF key, the Clear key, or the PA2 key, as well as the PA1 key, as the break key in full-screen mode; it also allows BRKKEY NONE to be specified. The default break key is PA1. When you press the user-defined break key while in full-screen mode, z/VM puts your virtual machine in CP mode and displays *CP READ* in your status area. When PA1 is not defined as the BRKKEY, PA1 attentions are sent to the virtual machine. Some application programs that could be running in the virtual machine may interpret the PA1 attention as a user request to enter the CP environment. For a further explanation of the use of the PA1 key, see usage note “10” on page 58 (*DIAGNOSE code X'58' full-screen I/O*).

In full-screen mode, all CP messages are queued. The entire queue of CP messages is processed after each of the following operations:

- a. A full-screen read operation (any read operation locks the keyboard)
- b. A full-screen write operation (that locks the keyboard)
- c. The expiration of a 60-second timer for CP priority messages.

If a priority CP message (such as a warning message from the system operator) is to be displayed while in full-screen mode, z/VM posts an attention interruption to the application program, and a 60-second timer is set. The attention interrupt informs the application program that a read operation should be initiated. In general, if the application program does not issue a read request before the 60 seconds have expired, CP erases the screen and displays all queued messages. However, if the application program has issued a full-screen support Write Structured Field instruction, CP does not take over the screen.

Other non-full-screen messages are displayed immediately by z/VM when in full-screen mode.

Interactions between CP and the application program in the virtual machine using full-screen support are in the *IBM 3270 Information Display System: 3274 Control Unit Description and Programmer's Guide*, GA23-0061. The application programmer must be familiar with the operation of the IBM 3270 display station.

If Terminal Breakin GuestCTL has been specified, CP is allowed to break in when the break key is used. An audible alarm is sounded when CP messages are queued. Priority CP messages and DIAGNOSE code X'08' output can still break in and take over the full screen.

Other non-full-screen messages are displayed immediately by z/VM when in full-screen mode (except for those exceptions noted for the Terminal Breakin command).

A full-screen Erase/Write, Erase/Write Alternate, or Write Structure Field operation establishes full-screen mode.

10. For DIAGNOSE code X'58' full-screen I/O:

Listed below are general programming considerations that must be followed to effectively use the DIAGNOSE code X'58' instruction for full-screen I/O:

- a. A full-screen Erase/Write or Erase/Write Alternate operation establishes full-screen mode.
- b. When a mode switch has occurred and the screen is in CP mode, the application program is notified by an X'8E' in the CSW/IRB unit status byte following a full-screen I/O operation. An Erase/Write, Erase/Write Alternate, or Write Structure Field operation instruction should be issued to reestablish full-screen mode and reformat the screen.

An X'8E' in the CSW/IRB unit status byte following an Erase/Write or Erase/Write Alternate instruction indicates that non-full-screen data (CP mode) is waiting to be read. The application program should issue a non-full-screen Read and then reissue the Erase/Write instruction.

- c. The application program must establish an environment to handle attention interruptions. This could be done using the CMS macros HNDINT and WAITD. CP posts an attention interruption to the application program in one of the following conditions:
  - i) CP receives an attention interruption indicating that the virtual machine console operator has caused an interruption (for example, when the Enter key or a PF key is pressed)
  - ii) A CP priority message is to be displayed.
- d. If the test request key is pressed at a local 3270 when in full-screen mode, X'604040' is returned to the application program in the read buffer.
- e. For break key operation in full-screen mode:
  - i) If a 3270 SIO/SSCH or DIAGNOSE code X'58' with bit X'10' of the control option is not set:  
If the break key is pressed, CP posts an attention interrupt to the virtual machine. If the virtual machine responds with a READ, or the break key is pressed a second time, the virtual machine is put in line mode and a CP READ is displayed on the screen's status area.
  - ii) If DIAGNOSE code X'58' with bit X'10' of the control option is set:  
If the break key is pressed, CP posts an attention interrupt to the virtual machine. If the virtual machine responds with a Read, the break key is passed to the virtual machine. If the virtual machine does not respond with a Read and the break key is pressed a second (or more) time, CP posts another attention interrupt to the virtual machine. In both cases, the passing of the break key interrupt to the virtual machine overrides the BRKKEY setting (if the interrupt came by request of the application program using the X'10' bit in the control byte of the previous Erase/Write or Erase/Write Alternate operation).

11. 3270 SIO/SSCH full-screen mode interactions:

Before a guest virtual machine can issue 3270 SIO/SSCH commands, it must first ensure that the console mode is set to 3270. For more information on setting the console mode, see the Terminal Conmode command in the *z/VM: CP Commands and Utilities Reference*. After the console is designated a 3270 console, whenever CP is ready to give up control of the screen it presents a CLEAR attention interrupt to the virtual machine. It is the responsibility of the application program to issue an Erase/Write to refresh the screen. If a virtual machine issues only a Write that does not cover the entire screen, information that CP displayed remains on the screen.

12. Double-byte character set (DBCS) line-mode console output may be sent to the virtual machine console by CP, or when CP obtains messages and responses from a DBCS NLS message repository, or by the virtual machine.

The virtual machine sends line-mode output to its virtual machine console by using mixed DBCS data streams. Mixed DBCS data streams contain DBCS character strings surrounded by a shift out/shift in (SO/SI) pair. Single-byte character set (SBCS) data may or may not be present in the data stream.

**Example 1—A Data Stream Containing SBCS Data**

The following contains SBCS data identified by a B:

```
BBBBBBBBBBBBBBBBBBBBBB
```

**Example 2—A Data Stream Containing DBCS Data**

The following contains DBCS data identified by a D:

```
SODDDDDDDSI
      ↑      ↑
      shift-out character  shift-in character
```

**Example 3—A Data Stream Containing Mixed DBCS Data**

The following contains SBCS data identified by a B and DBCS data identified by a D:

```

      shift-in character
      ↓                ↓
SODDDDDDSIBBBBBBSODDDDSI
      ↑                ↑
      shift-out character

```

The virtual machine can send DBCS line-mode data by issuing SIO, SIOF, or SSCH to a channel program containing a Write CCW addressing a mixed DBCS data stream, or by issuing DIAGNOSE X'58' opcode X'49'. For the I/O request to succeed, TERMINAL TEXT and TERMINAL APL must be turned off. This can be checked with the QUERY TERM command. If these are not turned off, the request fails with a command reject indication.

When a virtual machine issues I/O to a channel program, CP ensures the console is DBCS capable. If a console is DBCS capable and is not an SNA/CCS terminal, CP formats the data for the screen and properly displays the data. If it is not DBCS capable, the request is rejected with a data check indication.

You do not have to insert new line (NL) characters in the data stream to format the data for the physical line size of the terminal on an SIO, SIOF, or SSCH. CP formats the data, using the smaller of the:

- Physical width of the screen or
- Logical line size.

This is determined by the TERMINAL LINESIZE command, as follows:

- If LINESIZE=0, LINESIZE is turned off and the physical width of the screen is used.
- If LINESIZE=1, 2, or 3, a line size of 4 is used, because this is the smallest line-size value that displays one byte of DBCS data.

CP ensures, for the DBCS data, that each line displayed contains an even number of DBCS bytes surrounded by an SO/SI pair. If the data is not an even number of bytes or if the data is not surrounded by an SI/SO pair, the request is rejected with a data check indication.

**Note:** If the data is spooled to the console log or passed to applications over the \*MSG or \*MSGALL connection, the DBCS data stream is properly formatted and displayed after the data is sent.

For SNA/CCS terminals, NL characters are inserted in the data stream based on the smaller of the logical or the physical line size of the terminal before the data is sent to the terminal; the data is then passed to the appropriate SNA/CCS or real terminal processor to complete writing the data to the terminal.

When DIAGNOSE code X'58' opcode X'49' is used, it is the user's responsibility to format the data by inserting NL characters in the data. This is based on the smaller of the logical line size or the physical width of the screen, which is determined by the TERMINAL LINESIZE command. If LINESIZE=0, LINESIZE is turned off and the physical width of the screen is used; if LINESIZE=1, 2, or 3, a line size of 4 is used, because this is the smallest line-size value that displays one byte of DBCS data. When determining the length of the data, keep in mind the following:

## DIAGNOSE Code X'5C'

- SI, NL, and SO characters must be inserted, so space in the data stream must be considered for these characters.
- When an NL character is inserted within DBCS data, the data cannot be split in the middle of a double-byte character.

## Responses

None.

## DIAGNOSE Code X'5C' – Error Message Editing

---

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'5C' to edit error messages according to your setting of the EMSG function, as determined by the SET EMSG command, or according to the setting of the EMSG function of another virtual machine.

### Entry Values:

#### Rx

Contains the address where the first byte of the message to be edited can be found. If the subcode is X'40', the Rx register cannot be register 15.

#### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the message text. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the message text is in the host-primary address space.

#### Rx+1

Contains the length of the message header if the subcode is X'40'.

#### Ry

Consists of *ssxxllll*

##### *ss*

is the subcode and modifier code

##### *xx*

is not checked

##### *llll*

is the length of the message to be edited.

If the alternate user ID modifier (X'80') is specified, Ry cannot be register 15.

#### Ry+1

Contains the address of an 8-byte field containing the alternate user ID and padded with blanks if necessary. (Only if Modifier code X'80' is specified.)

#### Ay+1

Is used only by XC virtual machines in access-register mode. Ay+1 contains the ALET for the address space containing the user ID.

### Subcode

#### Meaning

##### X'00'

Indicates that a 10-byte message header (code) is assumed; the actual contents of the message are not checked.

##### X'20'

Indicates that the length of the message header must be calculated; DIAGNOSE code X'5C' assumes that the header runs up to, but does not include, the first blank. It also assumes the text begins at the location following the first blank.

**X'40'**

Indicates that the length of the message header is being passed in Rx+1; the actual contents of the message are not checked.

**Modifier Code**  
**Meaning**
**X'80'**

Indicates that the issuer wishes to use the EMSG setting of the user ID specified by Ry+1. Although X'00', X'20', and X'40' are all mutually exclusive, you can combine modifier code X'80' with any one of the above subcodes. For example, a subcode of X'A0' is a combination of X'20' and X'80'. Modifier code X'80' is valid only for class B enabled user IDs.

**Exit Values:** On return from DIAGNOSE code '5C', CP sets a condition code (described in the Responses section) and, based on the EMSG setting, returns Rx and Ry.

**EMSG Setting:** CP tests the EMSG setting and returns Rx and Ry to the caller modified as follows:

| EMSG Setting | Rx                                          | Ry                                                                                        |
|--------------|---------------------------------------------|-------------------------------------------------------------------------------------------|
| ON<br>IUCV   | No change                                   | The subcode/modifier code byte is zeroed out. The rest of the register remains unchanged. |
| CODE         | No change                                   | The length of the header, as determined by the subcode.                                   |
| TEXT         | The pointer to the text part of the message | The length of the text alone                                                              |
| OFF          | No change                                   | 0                                                                                         |

## Usage Notes

1. DIAGNOSE code X'5C' does not write the message; it merely rearranges the starting pointer and length.
2. Modifier code X'80' is only valid for class B enabled user IDs.

## Responses

**Condition Codes:** When the alternate user ID modifier (X'80') is specified, one of the following condition codes is returned:

| Condition Code | Meaning                                |
|----------------|----------------------------------------|
| 0              | Successful completion                  |
| 2              | The specified user ID is not logged on |

When the alternate user ID modifier is not specified, the condition code remains unchanged.

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'5C' is given incorrect input data:

| Problem Encountered     | Cause                                                                                                                                                                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception | Any of the following: <ul style="list-style-type: none"> <li>• The subcode in Ry bits 1-7 is invalid.</li> <li>• For subcode X'40': Rx is register 15.</li> <li>• For modifier code X'80': the user ID is not aligned on a doubleword boundary, or Ry is register 15.</li> </ul> |

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to: <ul style="list-style-type: none"> <li>Fetch the message text (subcode X'20' only)</li> <li>Fetch the user ID (modifier code X'80')</li> </ul>                                                                                                            |

## DIAGNOSE Code X'60' – Determine Virtual Machine Storage Size

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'60' to determine your virtual machine's defined storage size, that is, to determine the size of your virtual machine's host-primary address space, excluding any discontinuous saved segment or saved system storage loaded above the defined size.

**Note:** For a virtual machine in 64-bit addressing mode, subcode X'0000000C' of Diagnose X'260' may be used to obtain the virtual machine storage size. Subcode X'00000000' of Diagnose X'260' may be used as an alternative to Diagnose X'60' for a virtual machine in 24-bit or 31-bit addressing mode.

**Entry Values:** You must specify a register number for Rx.

**Exit Values:** On return, the register specified as Rx contains the virtual machine storage size, in bytes.

### Responses

None.

## DIAGNOSE Code X'64' – Named Saved Segment Manipulation

**Privilege Class:** Any

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

Use DIAGNOSE code X'64' to manipulate named saved segments from a user's virtual machine. The DIAGNOSE code X'64' interface is used in application programs as a linkage mechanism to previously-created saved segments. These segments have been defined by the DEFSEG command, initialized by a product or application with the necessary code and data, and saved by the SAVESEG command.

A discontinuous saved segment (DCSS) is a saved segment that occupies one or more architected segments. It can be embedded above the virtual machine's defined storage size and begins and ends on a megabyte boundary.

Saved segments may have been defined as segment spaces or as members of a segment space. All references to named saved segments through any DIAGNOSE code X'64' function is by the name of the saved segment. This means that all names are unique, whether they have been defined as segment spaces or member saved segments. The results of a function are based on whether the object of the processing was a segment space name or a member saved segment name.

**Entry Values:**

**Rx**

Subcodes X'00', X'04', X'08', X'0C', X'10', X'20', X'24', X'2C': Contains the address of an 8-byte buffer containing the name of a saved segment. The saved segment name must be 8 characters or less in

length, on a doubleword boundary, left-justified, and padded with blanks to 8 characters. Access to the segment name is subject to key-controlled protection.

Subcodes X'18', X'38': Contains the address of a parameter area. Parameters include the name of the saved segment, a code for the kind of information to be returned about the segment, and specifications for an output area to receive information. The output area must be in the same address space as the parameter area. Access to the parameter area is subject to key-controlled protection.

**Note:** When running in 64-bit mode, the address in Rx is interpreted as a 31-bit address. In 24- and 31-bit modes, the address is interpreted according to the addressing mode of the guest.

#### **Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the buffer to which Rx points. In the case of subcode X'18', the output area is also in this address space. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the buffer is in the host-primary address space.

#### **Ry**

Contains a function subcode.

In the following pages, the possible functions are listed in the order of their subcodes. After each subcode number is a description of what the function does.

## **Subcode X'00' — LOADSHR**

This function loads a saved segment in shared mode. After this function executes, the storage occupied by the named saved segment is addressable by the virtual machine, even if the loaded saved segment is outside the addressing range of the virtual machine. However, any storage beyond that defined for the virtual machine and below that defined for the saved segment is not addressable. The following describes the processing characteristics as they relate to the different forms of saved segments:

#### **DCSS**

Purges any saved segment that is within the range definition of the DCSS being loaded. If the saved segment being loaded was defined without the SPACE operand, then this segment is made accessible to the user virtual machine.

Rx contains the actual beginning address of the DCSS.

- The beginning address of the DCSS is the first byte of the lowest page value that was specified on the DEFSEG command.

Ry contains a rounded ending address of the DCSS.

- The ending address of a DCSS is rounded up to the last byte of the highest page value that was specified on the DEFSEG command.

#### **Segment space**

This function purges any saved segment within the range definition of the segment space being loaded. If the segment space being loaded has members, each member of the segment space is made accessible to the user virtual machine. Rx contains the actual beginning address of the segment space.

- The beginning address of a segment space is the first byte of the lowest page value that was specified for a member having the lowest page value on the DEFSEG command.

Ry contains a rounded ending address of the segment space.

- The ending address of a segment space is rounded up to the last byte of the highest page value that was specified for a member having the highest page value on the DEFSEG command.

#### **Member saved segment**

This function purges any saved segment that is within the range definition of the segment space that contains the loaded member. However, any previously loaded members that are also part of the same segment space as the member being loaded are unaffected. The loaded member saved segment is made accessible to the user virtual machine.

Rx contains the actual beginning address of the member saved segment.

- The beginning address of the member saved segment is the first byte of the lowest page value that was specified on the DEFSEG command.

Ry contains the actual ending address of this member saved segment.

- The ending address of the member saved segment is rounded up to the last byte of the highest page value that was specified on the DEFSEG command.

If the member saved segment was outside the addressable range of the virtual machine to which it was loaded/attached, the virtual machine may now reference any portion of storage occupied by the segment space that contains the member.

**Notes:**

1. A member saved segment loaded through LOADSHR after a previous member saved segment of the same segment space was loaded through LOADNSHR also produces a nonshared copy of the segment.
2. If a DCSS is already loaded and a request to load it again occurs, then this results in a refreshed copy of any exclusive writeable storage for that DCSS in the virtual machine being attached. If a member saved segment is already loaded and a request to load it again occurs, then this results in a refresh of any exclusive writeable storage for that member saved segment in that virtual machine, but storage for other member saved segments in the same segment space is not refreshed. If a segment space was already explicitly loaded by name, and an explicit request is made to load it by name again, then there is no effect and the segment space storage is not refreshed.

## **Subcode X'04' — LOADNSHR**

Loads a saved segment in exclusive-write mode after purging any existing named saved segment or saved segment.

If the DCSS or segment space was defined with the LOADNSHR operand, any user will be allowed to load an exclusive-write mode copy. If a member saved segment is requested and any member of the space in which it will be loaded was so defined, the same is true.

When a user requests a nonshared copy of a saved segment and that segment fits below the user's maximum definable address space size, the user will be allowed to load the segment. (The maximum definable address space size is determined from the user's directory entry.)

If the saved segment was not defined with the LOADNSHR operand, and its address range(s) goes above the user's maximum definable address space size, a NAMESAVE entry is required in the user's directory entry. If the segment being loaded is a member saved segment, then the NAMESAVE entry is the segment space name.

The effect of loading a segment space or a member of a segment space is similar to what is described under the LOADSHR function. The difference is that the segment space storage is loaded in exclusive-write mode, regardless of the mode in which it was originally defined.

**Notes:**

1. If a member saved segment is loaded through LOADNSHR after a previous member saved segment of the same segment space but with a different name was loaded through LOADSHR, then the load request will terminate in an error. This is because the segment space containing both members has already been loaded in shared mode.
2. The user receives the saved segment in exclusive-write mode, regardless of the mode in which it was originally defined.
3. If a DCSS is already loaded non-shared and a request to load it non-shared again occurs, then this results in a refreshed copy of the entire segment being attached. If a member saved segment is already loaded non-shared and a request to load it non-shared again occurs, then this results in a refreshed copy of the member saved segment being attached, but other member saved segments in the same segment space are not refreshed. If a segment space was already explicitly loaded by name non-shared, and an attempt is made to explicitly load it by name non-shared again, then there is no effect and the segment space storage is not refreshed.

## Subcode X'08' — PURGESEG

Releases a saved segment from guest real storage.

If PURGESEG is invoked for a saved segment not previously loaded, the request is terminated with a condition code of 1. The following describes the processing characteristics as they relate to the different forms of saved segments:

### DCSS

If the DCSS being purged was defined without the SPACE operand, then the result would be the same as described for segment space.

When a PURGESEG is executed for a segment in nonshared mode residing in the users virtual machine address space, the storage is cleared to binary zeros and the keys are reset to zero.

### Segment space

If the segment space being purged was originally loaded by spacename, then each member of the segment space that is loaded or attached to the user virtual machine is purged (see note). This releases the associated storage that was acquired when the corresponding load function was executed.

**Note:** If a user had previously loaded a segment space by spacename and also loaded a member of the same segment space by a DCSS name, and then issued a PURGESEG for the spacename, the result of the purge function does not detach the member saved segment that was loaded through the DCSS name.

If the storage occupied by the saved segment was beyond the defined virtual machine storage size, that storage is no longer addressable by the virtual machine.

### Member saved segment

The loaded or attached member saved segment is purged from the user virtual machine. This releases the associated control block storage that was acquired when the corresponding load function was executed. If the purged member saved segment was the last member of the segment space that was loaded for this virtual machine, the storage associated with the segment space is released.

If the storage occupied by the member saved segment was beyond the defined virtual machine storage size, that storage would still be addressable by the virtual machine if another member of the same segment space was still loaded to the virtual machine.

## Subcode X'0C' — FINDSEG

Returns the start and end page addresses of the named saved segment.

In z/VM, the existence of the saved segment is found by searching for an active segment, and then for a skeleton segment. An active segment search is defined as follows:

1. If the saved segment is attached to the virtual machine, the address information is returned from the description in storage.
2. If the saved segment is a member of a segment space, and if another member of this same segment space is attached to the virtual machine, then the address information is returned from the description in storage. This is true even if the member or space is pending purge.
3. If an active segment (a segment for which a class A or R SDF file is created) is found, the address information is returned from the description in the SDF.

**Note:** A saved segment that is in pending purge status (where its SDF file class is P) is bypassed in the search process.

If a skeleton segment search is entered when no active segment exists:

- Search for a skeleton segment definition (a segment having only a class S SDF file created); if found, then the address information is returned from the description in the SDF.

The following describes the processing characteristics as they relate to the different forms of saved segments.

**DCSS**

The Rx register contains the beginning address.

- The beginning address of the DCSS segment is the first byte of the lowest page value that was specified on the DEFSEG command.

The Ry register contains the ending address.

- The ending address of the DCSS is rounded up to the last byte of the highest page value that was specified on the DEFSEG command.

**Segment space**

If the request is for a segment space that has members, the beginning and ending addresses are the lowest and highest page addresses of any of the members.

The Rx register contains the beginning address.

- The beginning address of a segment space is the first byte of the lowest page value that was specified for a member having the lowest page value on the DEFSEG command.

The Ry register contains the ending address.

- The ending address of a segment space is rounded up to the last byte of the highest page value that was specified for a member having the highest page value on the DEFSEG command.

**Member saved segment**

If the request is for a member of a segment space, the actual beginning and ending addresses are returned for the specified member saved segment as determined from the actual page ranges specified through the DEFSEG command.

The Rx register contains the beginning address, that is, the first byte of the lowest page value that was specified on the DEFSEG command.

The Ry register contains the ending address, that is, the address that is rounded up to the last byte of the highest page value that was specified on the DEFSEG command.

**Subcode X'10' — LOADNOLY**

Loads a saved segment in shared mode only if no overlay condition exists.

The effect of loading a segment space or a member of a segment space is the same as described under the LOADSHR function. In this case, the load would be completed only if an overlay condition did not exist.

**Subcode X'18' — SEGEXT**

Returns information relative to saved segments through user-supplied areas.

Rx is set up to point to a user-supplied buffer (that is, contains a guest real address). The parameter portion of the buffer describes the input to the function and on return from the function the parameter area contains status information. The buffer has a minimum length of three doublewords. The parameter portion of the buffer must reside on a doubleword boundary and cannot cross a page boundary (Rx content + the buffer length cannot cross a page boundary). This reserves a parameter area that may be up to one 4KB-page in length.

The SXIOAREA and SXIOARLN fields of the parameter area define an output area address and length. This area must also reside on a doubleword boundary and cannot cross a page boundary (SXIOAREA content + SXIOARLN content cannot cross a page boundary). This reserves an output area up to one 4KB-page in length. The output area must be in the same address space as the parameter area.

The input buffer format is provided to map the parameter area, and the input buffer area is provided to map the output area for the functions supported.

The format of the parameter and output areas is shown in [Figure 3 on page 67](#).

Ry is set up to contain the X'18' function code.

Input Buffer Format - Parameter Area  
HCPSXIBK COPY (found in the HCPGPI macro library)

|    |          |                      |          |                      |
|----|----------|----------------------|----------|----------------------|

| = | Output based on the OPCODE function | = |
|---|-------------------------------------|---|

Figure 3. The Format of the User-Supplied Areas for the SEGEXT Function

The definition of the parameter area is as follows:

**SXIOPCOD**

is a 1-byte field containing the code for the operation to be performed. Possible values are:

**X'01'**

FINDSPACE

**X'02'**

FINDSKEL

**X'0C'**

FINDSEGA

**X'0D'**

FINDNSSA

Descriptions of these operations follow. Opcodes not defined by this function are reserved for IBM use.

**///...**

is a 3-byte field reserved for IBM use.

**SXIRCODE**

is a 1-byte field containing a return code from the function.

The following return codes and meanings are valid for FINDSPACE, opcode X'01':

**X'00'**

The SXIRNAME and SPACENAM fields are equal, the request was for DCSS.

**X'04'**

The SXIRNAME and SPACENAM fields are not equal, the request was for a member saved segment.

**X'08'**

The SXIRNAME and SPACENAM fields are equal, the request was for a segment space.

The following return codes and meanings are valid for FINDSKEL, opcode X'02' and FINDSEGA, opcode X'0C':

**X'00'**

The name of the segment in SXIRNAME was found to be a DCSS structure.

**X'04'**

The name of the segment in SXIRNAME was found to be a member saved segment structure.

**X'08'**

The name of the segment in SXIRNAME was found to be a segment space structure.

The following return code and meaning are valid for FINDNSSA, opcode X'0D':

**X'00'**

There is an IPLed NSS.

////...

is a 3-byte field reserved for IBM use.

**SXIRNAME**

is an 8-byte field containing the requested segment name. This name is left-justified and padded with blanks if necessary.

For the FINDNSSA operation, SXIRNAME is ignored.

**SXIOAREA**

is a fullword field containing the address of the output area. This area must begin on a doubleword boundary. The output area resides in the same host address space as the input parameter list.

**SXIOARLN**

is a halfword field containing the length of the output area in bytes. The output area must not cross a page boundary.

////...

is a halfword field reserved for IBM use.

The definition of the output area is based on the OPCODE field function.

**SEGEXT Function Operation Codes**

The possible operation codes under the SEGEXT function are listed on the following pages in order of their codes. Following each operation name is a description of how the operation works.

**Opcode X'01' — FINDSPACE**

This operation returns the beginning and ending addresses of a segment space if either a member saved segment name or a segment space name is supplied. In addition, the name of the segment space is returned. If a DCSS name is supplied, then the beginning and ending addresses returned for a segment space are the same as what was defined for a DCSS.

FINDSPACE searches for an active segment, then for a skeleton. The search is defined as follows:

1. If the saved segment is attached to the virtual machine, the address information is returned from the description in storage.
2. If the saved segment is a member of a segment space, and if another member of this same segment space is attached to the virtual machine, the address information is returned from the description in storage.
3. An active segment is sought (a segment for which a class A or R SDF file is created); if it is found, the address information is returned from the description in the SDF.

**Note:** A saved segment that is in pending purge status (where its SDF file class is P) is bypassed in the search process.

4. Search for a skeleton segment definition (a segment having a class S SDF file created); if it is found, the address information is returned from the description in the SDF.

The format of the buffer for the FINDSPACE operation is as shown in [Figure 4 on page 69](#).

|   |          |         |
|---|----------|---------|
| 0 | SXOLSBA  | SXOLSEA |
| 8 | SXOLSNAM |         |

Figure 4. The Format of the User-Supplied Areas for the FINDSPACE Operation

#### **SXOLSBA**

A fullword containing the beginning guest absolute address of the segment space that contains the requested saved segment. The address of the megabyte boundary containing the lowest page definition of the segment space is returned.

#### **SXOLSEA**

A fullword containing the ending guest absolute address of the segment space that contains the requested saved segment. The last address of the megabyte in which the page with the highest definition resides, is returned.

#### **SXOLSNAM**

A doubleword field containing the name of the segment space that contains the requested saved segment. If this name and SXIRNAME are the same, the requested named segment is the segment space or a DCSS. If this name is different from SXIRNAME, the requested named segment is a member of this segment space. The name is returned left-justified, padded with blanks.

If the member saved segment belongs to multiple segment spaces, the segment space name would pertain to the segment space that would have been loaded if a DIAGNOSE code X'64' LOAD was issued.

### **Opcode X'02' – FINDSKEL**

The FINDSKEL operation searches for a skeleton segment search definitions (a segment having a class S SDF file created). If it is found, the address information is returned from the description in the SDF. Any search for any active definitions is bypassed.

For information on the buffer used for the FINDSKEL operation and other information common with FINDSEGA, see the second half of the description of FINDSEGA that follows.

### **Opcode X'0C' – FINDSEGA**

This operation returns the page range values and page range attributes that were specified on a DEFSEG command. When operation code X'02' is specified, the page definition information is related to the skeleton file, a nonactive segment definition whose spool file class is S. The specification of operation code X'0C' returns the page definition information related to an active segment definition.

When FINDSEGA is issued from your virtual machine, only an active segment search is performed (a segment for which a class A or class R SDF file is created). The order of search is as follows:

1. If the saved segment is attached to your virtual machine, the address information is returned from the description in storage.
2. If the saved segment is a member of a segment space, and if another member of this same segment space or the space itself is attached to your virtual machine, the address information is returned from the description in storage.
3. If the saved segment is attached to another virtual machine or is contained inside a segment space and is not in a pending purge state, the address information is returned from the description in storage. If the saved segment was in a pending purge state, the saved segment is bypassed in the search operation. This behavior is the same even if the saved segment is a DCSS structure.
4. The SDF files are searched next. Search for an active segment; if it is found, the address information is returned from the description in the SDF.

**Note:** A saved segment in pending purge state (where its SDF file class is P) is bypassed in the search process.

The FINDSKEL and FINDSEGA operation codes may be used by install programs to initialize the areas within the returned page range addresses with the appropriate code or data. Because z/VM may have an active segment definition as well as a skeleton definition at the same time, the product can now explicitly select the desired definition of the segment.

The page range definition information applies only to a DCSS, a member saved segment, or an NSS. If the FINDSKEL or FINDSEGA is issued for a name that is a segment space, no page range table data is returned.

To determine the segment structure in terms of a DCSS, member saved segment, or a segment space, the return code may be checked.

The format of the buffer for the FINDSKEL, FINDSEGA, or FINDNSSA operation is as shown in Figure 5 on page 70. The output area shown in this figure is used when SXIRNAME is a DCSS, or a member saved segment, or when the FINDNSSA function is performed. See Figure 6 on page 72 for a picture of the output area when SXIRNAME is a segment space.

Output area with maximum output

HCP SXOBK COPY (found in the HCPGPI macro library)

|       |         |         |          |          |
|-------|---------|---------|----------|----------|
| 00    | SXOSKBA |         | SXOSKEA  |          |
| 08    | SXORGCT |         | SXORGCTA |          |
| 10    | SXORGST | SXOPRAT | SXORGEND | //////// |
| ===== |         |         |          |          |
| 408   | SXORGST | SXOPRAT | SXORGEND | //////// |

Figure 5. The Format of the User-Supplied Areas for the FINDSKEL, FINDSEGA, or FINDNSSA operations

#### **SXOSKBA**

A fullword that contains the beginning guest absolute address of the global range of the skeleton or active segment as defined by the DEFSEG command or of the IPLed NSS as defined by the DEFSYS command. The address returned is the lowest page value defined for the member, DCSS, or NSS.

#### **SXOSKEA**

A fullword that contains the ending guest absolute address of the global range of the skeleton or active segment as defined by the DEFSEG command or of the IPLed NSS as defined by the DEFSYS command. The address returned is the last byte of the page for the highest page value defined for the member, DCSS, or NSS.

#### **SXORGCT**

A fullword field containing the count of valid page range entry pairs (Page Range Start and Page Range End) in the output area.

#### **Note:**

1. If the output area length specified by the SXIOAREA field is not large enough to accommodate all the entries, SXORGCT is **not** adjusted to reflect the number of entries contained in the limited size buffer. Refer to the SXORGCTA field.

#### **SXORGCTA**

A fullword field containing the count of valid page range entry pairs (SXORGST and SXORGEND) that were actually placed in the output area page range table. This may be used when the output buffer provided was not large enough to contain all the page range entries that were available.

The start of a 1024-byte page range information table that contains doubleword entries that are broken down into a start (SXORGST) and ending (SXORGEND) address range definition. The attribute of the page

range definition (SXOPRAT) is contained in the fourth byte of the entry. The page range entries are ordered from lowest value to highest value. A maximum of 128 page range entries may be placed in this table.

If the request is issued against a segment space, the page range table is **not** modified. A segment space has no page range definitions associated with itself, only with its members.

#### **SXORGST**

A 3-byte field containing the high-order three bytes of the start page range entry definition. To produce a valid start page address, this value must be placed in the high-order three bytes of a register, and the low order byte of the register must be set to zero. The result is a guest absolute address.

#### **SXOPRAT**

A 1-byte field containing the page range attribute flag. Bit 7 (X'01' – SXOEXCL) of this field indicates an exclusive copy; each user gets a separate copy of this page range. Bit 6 (X'02' – SXOPROT) of this field indicates page ranges that are page protected; users may access these pages in read-only mode. Bit 5 (X'04' – SXONDAT) of this field indicates page ranges, the data in which is not saved in the system data file (SDF). Combinations of these bits produce the following codes:

##### **X'00'**

SW — shared read/write access.

##### **X'01'**

EW — exclusive read/write access.

##### **X'02'**

SR — shared read-only access.

##### **X'03'**

ER — exclusive read-only access.

##### **X'04'**

SN — shared read/write access, no data saved.

##### **X'05'**

EN — exclusive read/write access, no data saved.

##### **X'06'**

SC — shared read-only, no data saved, CP writeable pages.

#### **SXORGEND**

A 3-byte field containing the high-order three bytes of the end page range entry definition. To produce a valid end page address, this value must be placed in the high-order three bytes of a register, and the low-order three hexadecimal digits must be set to X'F'. The result is a guest absolute address.

#### **////...**

A 1-byte field reserved for IBM use.

**Note:** The output area length specified by SXIOAREA dictates the amount of information provided in the output buffer area.

The output area buffer for the FINDSKEL or FINDSEGA operation for SXIRNAME that is a segment space will contain two doublewords of member information for each member entry in the following format:

Output area with maximum output  
HCPSXOBK COPY (found in the HCPGPI macro library)

|     |          |          |
|-----|----------|----------|
| 0   | SXOSKBA  | SXOSKEA  |
| 8   | SXORGCT  | SXORGCTA |
| 10  | SXOMSSNM |          |
| 18  | SXOMEMST | SXOMEMEN |
| =   |          |          |
| 400 | SXOMSSNM |          |
| 408 | SXOMEMST | SXOMEMEN |

Figure 6. The Format of the User-Supplied Output Area – Member List

#### **SXOSKBA**

A fullword that contains the beginning guest absolute address of the global range of the skeleton or active segment as defined by the DEFSEG command. The address returned is the first byte of the lowest page value that was specified for a member having the lowest page value on the DEFSEG command.

#### **SXOSKEA**

A fullword that contains the ending guest absolute address of the global range of the skeleton or active segment as defined by the DEFSEG command. The address returned is rounded up to the last byte of the highest page value that was specified for a member having the highest page value on the DEFSEG command.

#### **SXORGCT**

A fullword field containing the count of defined member saved segment for this segment space.

**Note:** If the output area length specified by SXIOAREA field is not large enough to accommodate all the entries, SXORGCT is **not** adjusted to reflect the number of entries contained in the limited size buffer. Refer to SXORGCTA.

#### **SXORGCTA**

A fullword field containing the count of member saved segment entries that are actually placed in the output area member list table. This may be used when the output buffer provided was not large enough to contain all the member saved segment entries that were available.

**Note:** SXORGCTA reflects only full (two doubleword) entries that were placed in the output area.

The start of a 1024-byte member list information table containing two doubleword entries of the member saved segment names that were defined for the segment space and the starting and ending page range defined for the member.

#### **SXOMSSNM**

The name of a member saved segment that was defined for the segment space identified by the SXIRNAME (requested segment name) field.

#### **SXOMEMST**

The lowest page value defined for the member saved segment when defined by the DEFSEG command. The first 3 bytes contain this page value; the fourth byte contains the status information for the member saved segment.

**X'01'**

MPENP — indicates the member saved segment is in the pending purge state.

**X'02'**

MSAVD — indicates the member saved segment has been saved. If this bit is not on, then it indicates this member is not saved.

**SXOMEMEN**

The highest page value defined for the member saved segment when defined by the DEFSEG command. The first 3 bytes contain this page value. The fourth byte is reserved for IBM use.

**Opcode X'0D' — FINDNSSA**

The FINDNSSA operation returns the page range values and page range attributes that were specified on a DEFSYS command for the issuer’s currently-IPled NSS.

The input buffer content is the same as defined for the FINDSEGA operation. See [Figure 3 on page 67](#) and the accompanying explanation.

The output area content is as defined for the FINDSKEL and FINDSEGA functions for a DCSS or a member saved segment. For more information, see [Figure 5 on page 70](#) and the accompanying explanation.

**Subcode X'20' — LOADSHR (64-Bit)**

Subcode X'20' performs the same function as “[Subcode X'00' — LOADSHR](#)” on page 63, except that output addresses are 64-bit instead of 31-bit.

**Subcode X'24' — LOADNSHR (64-Bit)**

Subcode X'24' performs the same function as “[Subcode X'04' — LOADNSHR](#)” on page 64, except that output addresses are 64-bit instead of 31-bit.

**Subcode X'2C' — FINDSEG (64-Bit)**

Subcode X'2C' performs the same function as “[Subcode X'0C' — FINDSEG](#)” on page 65, except that output addresses are 64-bit instead of 31-bit.

**Subcode X'38' — SEGEXT (64-Bit)**

Subcode X'38' performs the same function as “[Subcode X'18' — SEGEXT](#)” on page 66, except that output addresses are 64-bit instead of 31-bit and the output areas for the operation codes have different formats.

The format of the output areas for opcode X'01' (FINDSPACE) is as shown in [Figure 7 on page 73](#).

Output Area

HCP SXOBK COPY (found in the HCPGPI macro library)

Usage Notes

1. When the host-primary address space of your virtual machine is considered a shareable address space, you can successfully use only the FINDSEG, FINDSPACE, FINDSKEL FINDSEGA, or FINDNSSA operations of DIAGNOSE code X'64'. A request for any of the other operations of this DIAGNOSE code will result in return code X'0CB'.
- The host-primary address space of your virtual machine becomes shareable if your virtual machine uses the PERMIT function of the ADRSPACE macro to grant another virtual machine access to the address space. The host-primary address space remains in the shareable state until your virtual machine subsequently invokes the ISOLATE function of the ADRSPACE macro, or until a subsystem reset operation is performed on your virtual machine (for example through the SYSTEM RESET

command). For more information on ADRSPACE, see [“ADRSPACE — Address Space Services”](#) on page 811.

2. A segment space has a range that may span one or more architected 1 megabyte segments. The beginning address of a segment space is rounded down to the nearest megabyte boundary of the member having the lowest page value. The ending address of a segment space is rounded up to the last address of the last page within the megabyte occupied by the member having the highest page value.
3. Each member saved segment has a range that may span one or more pages. The beginning address of a member saved segment is determined by its lowest page value. The ending address is determined by the last address of the highest page value.
4. If a load with an overlay arrangement occurs, the old segment space is indeed purged, and the new segment space is loaded with the duplicate members.
5. When a member of a segment space is loaded, all members of the segment space are made accessible to the virtual machine.

**Note:** However, to access other member saved segments predictably, the DIAGNOSE code X'64' programming interface or the CMS SEGMENT programming interface must be used.

6. When a LOADxxx is issued, the following search order occurs to resolve the load request:
  - a. The user's loaded saved segments are searched for the specified name.
  - b. Other user's saved segments are searched for the specified name.
  - c. The closed class A SDF files are searched for the specified name.
    - If the specified name is a member of one or more segment spaces:
      - The first segment space for which the user is authorized is made accessible to the user's virtual machine, and the specified member is loaded.
    - If the specified name is a DCSS and the user is authorized for the DCSS, it is loaded.
    - If the specified name is a segment space:
      - If the user is authorized for the segment space, it is made accessible to the user's virtual machine and the entire segment space is loaded.
7. A FINDxxx request for a saved segment of a specified name that is both not currently loaded to the user's virtual machine and in pending purge status, results in a not-found condition.
8. A PURGESEG purges only a saved segment previously loaded by a corresponding LOADxxx function with the same name.
  - If other members of the same segment space are still loaded, then the virtual machine still has access to the member that was purged.

**Note:** An attempt to access a member saved segment after it has been purged cause unpredictable results.
9. If a PURGESEG was issued for the last member of a segment space loaded into a user's virtual machine, the segment space is removed from the user's virtual machine address space. The virtual machine has no accessibility to any area of the segment space.
10. Addresses returned through FINDSPACE are always rounded to megabyte boundaries.
11. The beginning address returned through a LOADxxx, FINDSEG, FINDSEGA, and FINDSKEL is on a page boundary. The ending address is rounded to the page boundary containing the highest page definition.
12. It is the guest's responsibility to serialize writes to writable shared storage.
13. When a DCSS is loaded nonshared, any writable shared storage appears as it was when the DCSS was saved. Changes made to shared pages by other users who have the DCSS loaded shared, are not copied.

14. You may not be authorized to issue subcodes X'00', X'04', X'10', X'20', and X'24' of this DIAGNOSE code if an external security manager is installed on your system. For additional information, contact your security administrator.
15. Subcodes X'00', X'04', X'0C', X'10', and X'18' cannot be used on a DCSS that includes addresses above 2047 MB, because these subcodes support only 31-bit output addresses. If one of these subcodes is used on a DCSS above 2047 MB, the DIAGNOSE code exits with return code X'02C', indicating that the saved segment does not exist.
16. The initial load of a large DCSS can appreciably delay processing of subsequent DIAGNOSE code X'64' requests and the following commands: DEFSEG, SAVESEG, DEFSYS, SAVESYS, INDICATE NSS, IPL of an NSS, PURGE NSS, and QUERY NSS.
17. LOADSHR, LOADNSHR, LOADNOLY, and PURGESEG will fail if executed when VMRELOCATE is in progress.

## Responses

**Condition Codes for a Normal Exit:** Upon a normal exit condition, you receive a condition code of either 0 or 1. Refer to [Table 4 on page 77](#) for the exact results. In the headings for the last two columns of this table, user buffer refers to data in the user's output buffer for SEGEXT functions.

*Table 4. Normal Exit Results with the SEGEXT Function*

| Condition Code | Meaning                                                                                                                                                                                                                                                                                  | Contents of Rx or User Buffer                                           | Contents of Ry or User Buffer                                                                                                                       |

| 0              | (LOAD) The saved segment loaded outside the user's defined virtual storage area.                                                                                                                                                                        | The actual starting address at which the saved segment was loaded.      | The actual ending address of the saved segment.                                                                                                     |
| 0              | (PURGE) The saved segment is purged.                                                                                                                                                                                                                    | No change                                                               | No change                                                                                                                                           |
| 0              | (FINDNSSA) Output area contains NSS configuration information.                                                                                                                                                                                          | No change                                                               | No change                                                                                                                                           |
| 1              | (FIND) The saved segment exists but is not loaded.                                                                                                                                                                                                      | The actual starting address at which the saved segment would be loaded. | The actual ending address of the saved segment in Ry.                                                                                               |
| 1              | (FINDSKEL and/or FINDSEGA) The skeleton or active segment exists but is not loaded.                                                                                                                                                                     | No change                                                               | The actual ending address of the skeleton or active segment at which the saved segment would be loaded.                                             |
| 1              | (FINDSPACE) The saved segment exists but is not loaded. If it is issued with a segment space name, neither the segment space nor its members are loaded.                                                                                                | No change                                                               | The ending address is rounded up to the segment (megabyte) boundary containing the highest page value specified for a member on the DEFSEG command. |
| 1              | (LOAD) The saved segment loaded within the user's defined virtual storage area.<br><br>The member saved segment was outside of the virtual machine's storage, but the segment space containing the member is inside the virtual machine's storage area. | The actual starting address at which the saved segment was loaded.      | The actual ending address of the storage released before the saved segment was loaded, or the ending address of the virtual machine.                |
| 1              | (PURGE) The saved segment does not exist.                                                                                                                                                                                                               | No change                                                               | No change                                                                                                                                           |

**Condition Codes for an Exit with Error:** Upon an exit error condition, you receive a condition code of 2. In addition, Ry contains a return code (in hexadecimal) indicating the exact error. Refer to [Table 5 on page 78](#) for return code messages.

**Note:** In this table, return codes are given in both hexadecimal and decimal forms, as the decimal number corresponds to a CP message number unless otherwise noted.

Table 5. Results of Exit with Error from DIAGNOSE code X'64'

| Condition Code | Return Code in Ry | Meaning              |
|----------------|-------------------|----------------------|
| 2 (FINDNSSA)   | 44 (X'02C')       | An NSS is not IPLed. |

Table 5. Results of Exit with Error from DIAGNOSE code X'64' (continued)

| Condition Code | Return Code in Ry | Meaning                                                                                                                                                                                                                                                                                                                                                                      |
|----------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2 (FINDSEGA)   | 44 (X'02C')       | The saved segment does not exist or is part of a segment space that is incomplete.                                                                                                                                                                                                                                                                                           |
| 2              | 53 (X'035')       | The user is not in the CP directory.                                                                                                                                                                                                                                                                                                                                         |
| 2              | 174 (X'0AE')      | Paging I/O error                                                                                                                                                                                                                                                                                                                                                             |
| 2              | 203 (X'0CB')      | An operation other than FINDSEG, FINDSPACE, FINDSKEL or FINDSEGA was requested when the host-primary address space was in the shareable state. This return code does not correspond to a CP message number.                                                                                                                                                                  |
| 2              | 449 (X'1C1')      | The user is not authorized.                                                                                                                                                                                                                                                                                                                                                  |
| 2              | 475 (X'1DB')      | A fatal I/O error occurred reading the CP directory.                                                                                                                                                                                                                                                                                                                         |
| 2              | 1015 (X'3F7')     | Insufficient storage is available to satisfy your request.                                                                                                                                                                                                                                                                                                                   |
| 2              | 1351 (X'547')     | The saved segment would overlay the existing segment. Rx contains the address of the first segment that would be overlaid.                                                                                                                                                                                                                                                   |
| 2              | 1352 (X'548')     | An unacceptable condition occurred.                                                                                                                                                                                                                                                                                                                                          |
| 2              | 1357 (X'54D')     | Reserved. Not used by z/VM.                                                                                                                                                                                                                                                                                                                                                  |
| 2              | 1358 (X'54E')     | An attempt was made to load a CP-owned DCSS in nonshared mode.                                                                                                                                                                                                                                                                                                               |
| 2              | 1367 (X'557')     | The user attempted to load a member saved segment in a mode (NONSHARE) different than the mode (SHR) established for the segment space to which it belongs.                                                                                                                                                                                                                  |
| 2              | 6874 (X'1ADA')    | This result is returned if the DEFine STORage CONFIGuration command is used to define the storage configuration for the virtual machine's base address space and more than one configuration extent is specified. Saved systems and segments cannot be loaded into storage that is greater than or equal to the starting address of the second storage configuration extent. |

**Note:** A return code from a load function is always associated with the item that would have produced a successful load. In an example where three choices are possible:

- M1 is a member of segment spaces S1, S2, S3
- S1 is a restricted segment space
- S2 is a segment space with pending purge status
- S3 is a segment space that will have a paging problem

A load of M1 is attempted by a user not authorized for S1. The return code associated with the loading of M1 using segment space S3 would have been returned. If no other options (no S2 or S3) were available, the unauthorized return code would have been given. If S1 and S2 were options, and S2 is in pending purge, then the return associated with the S2 status would have been given.

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'64' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                                               | Any of the following: <ul style="list-style-type: none"> <li>• Ry is not a valid subcode.</li> <li>• Rx is not aligned on a doubleword boundary or the buffer crosses a page boundary.</li> <li>• The output area is not aligned on a doubleword boundary or it crosses a page boundary.</li> </ul>                                           |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                                                  |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to: <ul style="list-style-type: none"> <li>• Fetch the DCSS name (for functions other than X'0018' and X'0038')</li> <li>• Store into the SEGEXT output area (for functions X'0018' and X'0038' only)</li> <li>• Fetch and store into the SEGEXT parameter list (for functions X'0018' and X'0038' only).</li> </ul> |

## DIAGNOSE Code X'70' – Time-of-Day Clock Accounting Interface

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'70' to request timing information from CP. Each time the virtual machine is run, CP provides the accumulated CPU time the virtual machine has used (VTIME) and a time-of-day (TOD) time stamp to be used in subsequent accounting calculations. Programs that are running in the virtual machine may use the timing information to calculate the amount of processor time used by each job.

XC virtual machines in access register mode cannot execute DIAGNOSE code X'70'.

**Note:** For more information, see *Enterprise Systems Architecture/390 Principles of Operation* ([publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf](http://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf)), *z/VM: ESA/XC Principles of Operation*, *z/Architecture Principles of Operation* (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>), or *z/VM: z/Architecture Extended Configuration (z/XC) Principles of Operation*.

### Entry Values:

#### Rx

is the guest real address of a 16-byte storage area in the host-primary address space to be used as a communication area (CA). The storage area must be aligned on a doubleword boundary, must not cross a 4K-byte boundary, and must be in the virtual machine's real storage, preferably in page zero. Page zero is preferred because page zero is in storage for the user, and the communication-area page must be locked. Thus when page zero is used, CP does not have to lock an additional page.

Key-controlled protection and low-address protection do not apply to accesses to the communication area.

If Rx contains the value X'FFFFFFFF', the Time-of-Day clock accounting interface for the issuing virtual CPU is reset. If the interface was not enabled, no action is taken.

#### Ry

Not used.

After a virtual machine issues a DIAGNOSE code X'70' to enable the TOD clock accounting interface, CP updates the communication area each time the virtual machine is run. The first 8 bytes of the communication area contain the total CPU time accumulated to date by the virtual CPU while running in interpretive-execution mode (CA.VTIME) up to the guest TOD clock time (CA.TOD) in the next 8-byte field. The difference between any current value of the guest TOD clock and the value of the guest TOD clock

stored in the communication area (CA.TOD) represents the current value of the delta VTIME accumulated by the guest in addition to the VTIME stored in the communication area (CA.VTIME). Programs running in the virtual machine should not change the communication area.

DIAGNOSE code X'70' may not be issued in access-register mode in an XC virtual machine.

## Usage Notes

1. In a virtual machine with multiple virtual CPUs, the guest - typically a system control program (SCP) - must use a separate communication area for each of its CPUs. If the guest runs in an attached-processor (AP) or a multiprocessor (MP) configuration, the SCP has to issue DIAGNOSE code X'70' from each virtual CPU, identifying a different communication area.
2. When the wait-state interpretation capability is specified for the guest by CP, the guest remains dispatched, even when it enters the PSW enabled-wait state. In this case, the time spent dispatched in wait state is included in the virtual CPU time reported for the guest in the accounting communication area (CA.VTIME).
3. To avoid receiving widely differing results, care should be taken when using the information returned by DIAGNOSE code X'70' to analyze program performance of small portions of code. Processor performance characteristics, such as the cache storage size, influence the information returned. For example, the number of references to data which is not currently in cache may affect the amount of virtual time reported by DIAGNOSE code X'70'. Cache storage size and other processor performance characteristics may vary between processor models. Refer to the processor characteristics documentation for your hardware.
4. CP uses the real processor's CPU Timer value to maintain the communication area VTIME value. Although the CA values are accurate, when calculating consumed CPU time between CP updates to the Communication Area, it is important to remember that ESA/390 architecture does not require that the CPU Timer value be decremented each time the CPU's TOD clock advances. The CPU Timer may not count the time during which the CPU is not executing instructions. Thus, the difference between a current value of the guest TOD clock and CA.TOD may not be entirely reflected in CA.VTIME the next time the CA values are updated. This could result in calculated VTIME values that are slightly larger than actual consumed processor time at that moment. With extremely frequent sampling, the VTIME that is computed with the following algorithm may appear to regress slightly.

Programmers who need to calculate an exact value should consider using the guest CPU Timer instead of DIAGNOSE code X'70'. For details on CPU Timer and CPU TOD Clock operation, see [Enterprise Systems Architecture/390 Principles of Operation \(publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf\)](http://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf) and [z/Architecture Principles of Operation \(https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf\)](https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf).

**Tutorial Notes:** The following notes are tutorial information, not requirements of the DIAGNOSE code X'70' interface:

1. To use the information that CP has stored in the communication area for accounting purposes, perform the following steps:
  - a. Preserve the TOD value in the communication area (CA.TOD) by storing a copy of it in your storage or registers.
  - b. Get the current TOD by issuing the STORE CLOCK (STCK) instruction.
  - c. Subtract the TOD in the communication area from the current TOD obtained in step “1.b” on page 81. This difference is the amount of processor time the virtual machine has used since it was last run (delta.VTIME).
  - d. Add the accumulated processor time that is stored in the communication area (CA.VTIME) to the result obtained in step “1.c” on page 81. The result is the total amount of processor time the virtual machine has used up to the present time.
  - e. Ensure that the TOD value stored in the communication area (CA.TOD) has not changed since step “1.a” on page 81 was performed, that is, the TOD in the communication area (CA.TOD) must be equal to the copy obtained in step “1.a” on page 81. If it has changed, repeat the procedure from step “1.a” on page 81.

## Responses

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'70' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Special-operation exception                                           | DIAGNOSE code X'70' cannot run in an XC virtual machine that is in access register mode.                                                                                                                                                                                                                                 |
| Specification exception                                               | Any of the following: <ul style="list-style-type: none"> <li>The communication area is not aligned on a doubleword boundary.</li> <li>The communication area crosses a page boundary.</li> <li>The TOD clock accounting interface is already active for the virtual CPU using a different communication area.</li> </ul> |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                             |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to store into the communication area; key-controlled protection and low-address protection do not apply.                                                                                                                                                                                        |

## DIAGNOSE Code X'74' – Saving and Loading an Image Library File

**Privilege Class:** A, B, C, or E

**Addressing Mode:** 24-bit or 31-bit

**Entry Values:**

**Rx**

Contains the first 4 characters of the image library file name. Rx cannot be register 15.

**Rx+1**

Contains the last 4 characters of the image library file name, where the name is left-justified and padded with blanks.

**Ry**

Contains the guest real address of the start of the data area. The area must start on a page boundary. Accesses to the data area are not subject to key-controlled protection or low-address protection.

Ry cannot be register 15.

**Ay**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the image library file. If Ry designates general register 0, if Ay contains X'00000000', or if the virtual machine is not in XC mode, the image library file is in the host-primary address space.

**Ry+1**

Bits 0-7 contain a subcode for either loading or saving of the image library file. Bits 8-31 contain the length of the image library data in bytes. CP rounds the length up to a multiple of 4K bytes, and saves or loads the resulting number of bytes. Partial pages are not saved or loaded.

The following subcodes are bits 0 through 7 of the Ry+1 register.

| Subcode | Function | Description                                                                           |
|---------|----------|---------------------------------------------------------------------------------------|
| X'00'   | LOAD     | Loads an image library into guest real storage from an image library file.            |
| X'04'   | SAVE     | Saves an image library from the guest's real storage area into an image library file. |

## Usage Notes

1. If the number of bytes to save (in Ry+1) is specified as zero, the image library is not created. If an image library with the same name already existed, it will be unchanged.
2. Using VMRELOCATE for a virtual machine that might be using this function is not recommended and may have undesired results. If a virtual machine reads an Imagelib and is then relocated to another system, any subsequent save of that Imagelib will be written out to a different system, not the one from which it was read.

## Responses

**Condition Codes for a Normal Exit:** Upon a normal exit condition, you receive a condition code of 0 or 1, indicating that the image library file was saved or loaded successfully. You also receive a return code in Ry. Refer to the following chart for the meaning:

| Function and Condition Code | Return Code in Ry | Meaning                                           |
|-----------------------------|-------------------|---------------------------------------------------|
| LOAD, CC=0                  | 0 (X'00')         | An image library file was loaded successfully.    |
| SAVE, CC=0                  | 0 (X'00')         | The new image was saved successfully.             |
| SAVE, CC=1                  | 0 (X'00')         | An image file of the same name has been replaced. |

**Condition Codes for an Exit with Error:** Upon finding an error condition, you receive a condition code of 3, indicating that the image library file was not saved or loaded successfully. You will also receive a return code in Ry. Refer to the following chart for the meaning:

| Function and Condition Code | Return Code in Ry | Meaning                                                                                                          |
|-----------------------------|-------------------|------------------------------------------------------------------------------------------------------------------|
| LOAD, CC=3                  | 4 (X'04')         | Image library file not found                                                                                     |
| LOAD, CC=3                  | 20 (X'14')        | The image length specification is greater than the actual size of the image. The residual byte count is in Ry+1. |
| LOAD, CC=3                  | 24 (X'18')        | Paging or spooling error                                                                                         |
| LOAD, CC=3                  | 28 (X'1C')        | The image length specification is less than the actual size of the image. The residual byte count is in Ry+1.    |
| LOAD, CC=3                  | 36 (X'24')        | Abnormal termination occurred; an NSI001 softabend generated.                                                    |
| LOAD, CC=3                  | 40 (X'28')        | Invalid file name specified                                                                                      |
| SAVE, CC=3                  | 8 (X'08')         | Image library file currently active                                                                              |
| SAVE, CC=3                  | 24 (X'18')        | Paging or spooling error                                                                                         |
| SAVE, CC=3                  | 32 (X'20')        | Spool space full                                                                                                 |
| SAVE, CC=3                  | 36 (X'24')        | An abnormal termination occurred; an NSI001 softabend generated                                                  |
| SAVE, CC=3                  | 40 (X'28')        | Invalid file name specified                                                                                      |
| SAVE, CC=3                  | 44 (X'2C')        | No spool file IDs available                                                                                      |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'74' is given incorrect data:

| <b>Problem Encountered</b>                                            | <b>Cause</b>                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                                               | Any of the following: <ul style="list-style-type: none"> <li>• R15 is specified as Rx or Ry.</li> <li>• The address in Ry is not on a page boundary.</li> <li>• The register specified for Rx is the same as Ry.</li> <li>• The Rx and Ry registers are not at least two registers apart.</li> </ul> |
| Privileged-operation exception                                        | Any of the following: <ul style="list-style-type: none"> <li>• The guest does not have the correct privilege class (A, B, C, or E).</li> <li>• The virtual machine is in the problem state.</li> </ul>                                                                                               |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to: <ul style="list-style-type: none"> <li>• Fetch the data area (SAVE function); Key-controlled protection does not apply.</li> <li>• Store into the data area (LOAD function); Key-controlled protection and low-address protection do not apply.</li> </ul>              |

## DIAGNOSE Code X'7C' – Logical Device Support Facility

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'7C' to create, and communicate with, logical 3270 terminals. DIAGNOSE code X'7C' provides the following functions:

- The INITIATE function opens a logical communication path between the calling virtual machine that issues the DIAGNOSE code (the DIAGNOSE code X'7C' guest) and CP. It causes a logical device to be created and the VM logo to be directed to it.
- The ACCEPT function collects output data that CP has directed to a logical device. It is invoked after the DIAGNOSE code X'7C' guest is notified through an external interrupt that output data is to be processed.
- The STATUS function notifies CP of the completion and ending status of an ACCEPT function for logical printers.
- The PRESENT function passes input data to CP. The location of the data is described by an address or a complemented address. If a complemented address is used, it is the address of a list that describes a data stream occupying multiple data buffers.
- The TERMINATE function notifies CP to delete a specific logical device. If the logical device is the console of a virtual machine, the virtual machine is placed in FORCE DISCONNECT state. If the logical device is dialed to a virtual machine, the dialed connection is reset. If the logical printer is attached to a virtual machine, it is detached from that virtual machine. If an input or output operation is being processed, it is terminated with a unit check and intervention required.

### Entry Values:

#### Rx

Is any user-specified register except R15 that contains the logical device address used to coordinate CP and virtual machine operations.

If a specific address is requested for the INITIATE function, the low-order two bytes of Rx specify the device address. Addresses in the range X'0000' to X'nnnn-1' are valid, where nnnn is the hexadecimal representation of the maximum number of logical devices as specified on the SET MAXLDEV command. The system default for nnnn-1 is 4095, and thus the default range of valid addresses is X'0000' to X'0FFF'.

**Rx+1**

For the INITIATE function, Rx+1 contains the following information about the pseudo device to be created:

- The first byte indicates optional features:
  - Bit 0 — 3270 extended features are to be supported (not valid for 3277s or 328Xs).
  - Bit 1 — the ACCEPT function must be followed by STATUS function (must be on for logical printers).
  - Bit 2 — the specific device address is requested.
  - Bit 3 — an IP address is supplied in Ry+1.
  - Bit 4 — Ry+1 points to a 16-byte field containing an IPv6 address. If bit 3 is on, bit 4 is ignored.

**Rule:** The 16-byte field must not cross a page boundary.

- The second byte contains the model number: X'y0' through X'y5' (the first four bits (y) of the model number are ignored).
- The third byte contains the device class and must be X'40' (graphic).
- The fourth byte indicates the device type:
  - X'01' - 3278 or 3279 (3270 family displays except the 3277)
  - X'02' - 328X (3270 family printers)
  - X'04' - 3277 display

The following constitute valid model, class and type input. (The first four bits, (y), of the model number are ignored. Also, X'y0' is accepted, but treated as model X'y2'.)

|        |        |
|--------|--------|
| 3277   | y04004 |
| 3277   | y24004 |
| 3278/9 | y24001 |
| 3278/9 | y34001 |
| 3278/9 | y44001 |
| 3278/9 | y54001 |
| 328X   | y04002 |
| 328X   | y14002 |
| 328X   | y24002 |
| 328X   | y34002 |
| 328X   | y44002 |

For the ACCEPT function, Rx+1 is a register that contains the address of a data buffer. Zero may not be used as the data-buffer address.

For the PRESENT function in buffer format, Rx+1 is a register that contains the address of the data buffer.

For the PRESENT function in a list format, Rx+1 is a complemented address of a list of buffer entries. For more information on this format see “PRESENT: DIAGNOSE code X'7C' subcode X'00000003'” on [page 90](#). If this form of PRESENT ends with condition code 0, return code 3, an external interrupt is reflected when processing of the data is complete.

For a PRESENT from a printer, if Rx+1 is zero, an asynchronous device end interrupt is reflected. For a PRESENT from a non-printer device, Rx+1 may not be zero.

For the STATUS function, Rx+1 contains the sense data in the low order byte of the register.

**Ry**

Is any user-specified register except R15 that contains one of the following subcodes:

**Subcode****Function**

**X'00000001'**

INITIATE

## DIAGNOSE Code X'7C'

**X'00000002'**

ACCEPT

**X'00000003'**

PRESENT

**X'00000004'**

TERMINATE

**X'00000005'**

TERMINATE (All)

**X'00000006'**

STATUS

### Ry+1

For the INITIATE function, Ry+1 is a register that may contain the IP address associated with the logical device. This information is recorded and is used in appropriate command responses, operator messages, accounting records, and access control interface parameter lists.

For the ACCEPT and PRESENT functions, Ry+1 is a register that contains the length of the data buffer. For the BUFFER form of the PRESENT function, the buffer length cannot exceed 4096 bytes. For ACCEPT and for the BUFFER form of PRESENT, the length must be greater than zero. For the LIST form of the PRESENT function, this register is not used to contain the length; bits 1-31 of Ry+1 are ignored in this case. The contents of Ry+1 are also ignored when PRESENT is issued with zero in Rx+1 to generate an asynchronous device end from a printer.

### PRESENT

When bit 0 is set to 1, the data is from a Read-Buffer request; when bit 0 is set to 0, the data is from a Read-Modified request.

### ACCEPT

When bit 0 is set to 1, move partial data if the buffer is too short (Partial ACCEPT); when bit 0 is set to 0, move all data; if all data cannot be moved, the issuer receives a condition code of 1, and Ry+1=3; the size of the buffer needed is returned in Ry.

DIAGNOSE code X'7C' may not be issued in access-register mode in an XC virtual machine. All addresses passed on DIAGNOSE code X'7C' are guest absolute addresses in the host-primary address space. Key-controlled protection and low-address protection do not apply to storage references by DIAGNOSE code X'7C'.

**Exit Values:** On a successful return from an INITIATE function, Rx contains the logical device address assigned to the newly created logical device. This logical device address is returned by the INITIATE function, and must be specified by the user for an ACCEPT, PRESENT, TERMINATE, or STATUS function.

On return from an ACCEPT function, Ry contains the length of the data transferred. The maximum buffer length for an ACCEPT is X'7FFFFFFF'.

On completion of any of the DIAGNOSE functions, Ry+1 contains the return code.

## Usage Notes

1. Even if the input is an address, z/VM uses all 32 bits of the Rx and Ry input registers.
2. DIAGNOSE code X'7C' ACCEPT sets a return code of 0 whether the CCW is command chained. It also issues an external interrupt subcode, X'02', for each new command chained CCW.

## Responses

**Condition Codes and Return Codes:** One of the following condition codes is returned from the DIAGNOSE code X'7C' call. The codes are:

- 0 — Function completed with no errors
- 1 — Error condition
- 2 — Busy condition

## 3 — Device addressing error

In addition to the condition codes, a return code that indicates the specific cause of the problem is returned in Ry+1 as follows:

| Condition Code | Return Code in Ry+1 | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | 0 (X'00')           | Normal completion                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 0              | 1 (X'01')           | (ACCEPT) Another ACCEPT is required for another Write data stream.                                                                                                                                                                                                                                                                                                                                                                                             |
| 0              | 2 (X'02')           | (ACCEPT) Another ACCEPT is required for the next segment of the current data stream.                                                                                                                                                                                                                                                                                                                                                                           |
| 0              | 3 (X'03')           | (PRESENT) An external interrupt is presented when processing of the data is finished. Note that the issuer may receive an external interrupt other than the one that indicates that the PRESENT is completed. **Program Exceptions:** These program exceptions can occur if the DIAGNOSE X'7C' is given incorrect input data:

| Problem Encountered            | Cause                                                                                                                                |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception        | Either of <ul style="list-style-type: none"> <li>An incorrect privilege class</li> <li>Rx or Ry specified as register 15.</li> </ul> |
| Privileged-operation exception | The virtual machine is in the problem state.                                                                                         |
| Special-operation exception    | DIAGNOSE code X'7C' cannot run in an XC virtual machine that is in access register mode.                                             |

## Logical Device External Interrupt Code X'2402'

The logical device support uses a special external interrupt code to notify the DIAGNOSE code X'7C' guest of a change in status for a specific logical device. The external interrupt code is X'2402'. This interrupt causes a fullword of data to be stored at location X'80' in the DIAGNOSE code X'7C' guest's virtual machine. The interrupt is masked on and off by bit 22 of control register zero.

The format of the stored fullword is:

**Address**  
**Contents**

**80-81**

Logical device number

**82**

Flag byte

**83**

External interrupt reason code

The **flag byte** contains the following status flags:

**Bit****Meaning****0**

Data from the last PRESENT was discarded by the system (the subsequent I/O was a Write instead of a Read).

**1**

A data transfer error occurred on the previous PRESENT (LIST form of the PRESENT).

The logical device external interrupt reason codes stored in location X'83' are:

**Code****Meaning****01**

CP is terminating the logical device.

**02**

A Write has been issued to the device (an ACCEPT must be done).

**03**

A previous PRESENT is now finished. (User received CC=0 and RC=3, or CC=2 and RC=2 after a PRESENT)

**04**

A Read Buffer command has been issued to the device.

**05**

A Read Modified command has been issued to the device.

## Logical Device Support Facility Functions

The following logical device functions manage communications and the transfer of data between CP and the DIAGNOSE code X'7C' guest.

### INITIATE: DIAGNOSE code X'7C' subcode X'00000001'

The INITIATE function opens a logical communications path between the DIAGNOSE code X'7C' guest and the z/VM Control Program. It causes a logical device to be created, initialized with device, model, and type information, enabled, and the z/VM logo to be directed to it. During the enabling process, if the device supports extended features, a WSFQ (Write Structured Field Query) is issued to the device to determine its characteristics, and the Reply information used to update the device characteristics of the logical device, and also saved to be used to respond to future DIAGNOSE code X'8C' requests issued by the logical device user's virtual machine.

Rx+1 must contain the model number in byte 2, and the device class and type in bytes 3 and 4.

Rx is used only if a specific logical device is requested: bit 2 of Rx+1 is on. If so, Rx contains the logical device number.

If a specific address is not requested, then CP assigns the next available address to the new logical device. When more than one logical device will be created with specific device addresses requested, it is recommended that these devices be created in the range of X'0F80' to X'0FFF'. This is because logical devices will not be created from this range unless there is a specific request from this range or there are no other logical device addresses available. Reserving this range for specific logical device requests minimizes the possibility of finding a device address already in use.

Ry+1 is used only if an IP address is supplied: bit 3 of Rx+1 is on. If so, Ry+1 contains the IP address to be associated with the logical device.

On completion of the INITIATE, the newly assigned logical device address is placed in Rx. This value is used on subsequent DIAGNOSE operations to indicate the logical device being used. This address is also provided with any external interrupts for the device so that the DIAGNOSE code X'7C' guest can associate the interrupt with a specific logical device.

**ACCEPT: DIAGNOSE code X'7C' subcode X'00000002'**

The ACCEPT function collects data that CP has directed to a logical device. It is invoked after the DIAGNOSE code X'7C' guest is notified through external interrupt that output data is to be processed. Upon invocation, Rx+1 must contain the data buffer address and Ry+1 the buffer length. If the data buffer supplied was too short to contain the data, the function returns the required buffer size in Ry and no data is moved. This action can be overridden by setting an indicator in the length register (bit zero in Ry+1 set to 1) when the function is invoked. In this case, the data **is** moved to the short buffer and a condition code of 0 and a return code of 2 is sent. The system moves the next portion of the data on the next ACCEPT. Upon successful completion of function processing, the data length is returned in Ry, and the data buffer contains the CCW OP code in its first byte (only the first time if several operations are required to collect all the data from that CCW) and data in the remaining buffer space.

**STATUS: DIAGNOSE code X'7C' subcode X'00000006'**

The STATUS function allows status to be returned to CP after an ACCEPT function is performed. It must be used with a logical 328x printer to indicate when the printer has completed the printout and the ending status of the printer.

**PRESENT: DIAGNOSE code X'7C' subcode X'00000003'**

The PRESENT function passes input data to CP. The location of the data is described by an address or a complemented<sup>1</sup> address in Rx+1. If the register contains an address, it is the address of a data buffer 4096 bytes or less in length. In this case, Ry+1 contains the length of that data buffer. If Rx+1 contains a complemented address, it is the address of a list that describes a data stream occupying multiple data buffers and/or greater than 4096 bytes in length. In this case, Ry+1 is not used to describe the data length. However, in either case, a high-order bit of 1 in Ry+1 indicates whether the data is the result of a Read Buffer or Read Modified CCW.

If a list describes the data, the list must be in the format:

|      |              |              |
|------|--------------|--------------|
| flag | Length SEG1  | Address SEG1 |
| flag | Length SEG2  | Address SEG2 |
| =    |              |              |
| flag | Length SEGn* | Address SEGn |

The list must start on a fullword boundary. Each entry consists of a flag byte, a 3-byte unsigned length field and a 4-byte buffer address field that describe the length and location of sequential segments of a

<sup>1</sup> Refers to the two's complement of the address.

data stream. Bit X'80' set to 1 in the flag byte marks the last entry; other bits are reserved and should be zeros.

A single entry list may be used to describe a single data buffer greater than 4096 bytes in length. Neither the list nor the data may be modified before transfer of the data has completed.

A PRESENT may be either solicited or unsolicited. If solicited, then a Read Buffer or Read Modified was directed by CP to the logical device and the DIAGNOSE code X'7C' guest is notified through an external interrupt of that fact. When the guest responds with a DIAGNOSE code X'7C' PRESENT, the input data is received immediately and the DIAGNOSE completes with a condition code of 0 (zero), and a return code of 0 (zero).

If unsolicited, processing differs depending on whether the PRESENT is buffer format or list format. If buffer format, then the input data is moved to a CP buffer awaiting a Read from CP, and the DIAGNOSE completes with a condition code of 0 (zero) and a return code of zero (0). When eventually a Read is processed by CP, the data saved in the CP buffer satisfies the Read. If list format, the data is left in its input list format, and the DIAGNOSE completes with a condition code of zero (0) and a return code of 3. Later, when a Read is processed by CP, and the input data received (that is, moved from the DIAGNOSE code X'7C' input buffers), the DIAGNOSE X'7C' guest is notified through an external interrupt that the previous PRESENT is now finished.

### **TERMINATE: DIAGNOSE code X'7C' subcode X'00000004'**

The TERMINATE function causes CP to delete a specific logical device. If the logical device is the console of a virtual machine, the virtual machine is placed in Force Disconnect state. If the logical device is dialed, the connection is reset; if attached, it is detached from that virtual machine. If an input or output operation is being processed, it is terminated with a unit check and intervention required. The logical device is deleted, and its logical device address is made available again.

### **TERMINATE (All): DIAGNOSE code X'7C' subcode X'00000005'**

The TERMINATE (all) function notifies CP to terminate all logical devices created by the DIAGNOSE code X'7C' guest.

## **DIAGNOSE Code X'84' – Directory Update-in-Place**

---

**Privilege Class:** B

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE code X'84' enables a class B user to replace certain data in any user, identity, or subconfiguration stanza of the CP object directory. The user must specify the stanza and can replace the following data:

- The logon password
- The default virtual machine storage size
- The maximum virtual machine storage size
- Privilege classes
- Logical editing symbols
- The initial program load (IPL) system
- IPL parameter data
- The account number
- The distribution code
- User options
- The minidisk access mode
- The minidisk read, write, or multiple password
- The minidisk device type, allocation definition, and volume serial

- Options of the SCREEN directory control statement
- XAUTOLOG user IDs
- The type of virtual machine (XA, ESA, XC, Z)
- The maximum number of virtual processors
- The maximum number of spool files
- Virtual processor ID and VECTOR and CRYPTO option values
- User's default date format setting.

See the individual operation descriptions in [Table 6 on page 94](#) to understand when the results of each operation take effect.

DIAGNOSE code X'84' can neither add new entries to, nor delete existing entries from, the object directory. It can only replace existing object directory data. This DIAGNOSE instruction has no effect on definition control statements in the CP source directory.

In SSI-enabled directories, the changes to identity and subconfiguration object directory entries are applied as if the changes are made to the statements in the corresponding stanza in the source directory. Because settings specified in a subconfiguration stanza can override settings in the associated identity stanza, changes made using DIAGNOSE X'84' to an identity object directory entry might not appear to have any affect if overridden by settings specified in the subconfiguration stanza.

Object directories for SSI-ready directories do not contain separate entries for identity and subconfiguration stanzas specified in the source directory. Rather, when the object directory is built, the identity stanza and the single associated subconfiguration stanza are merged into a single entry that appears as if it was created from a single user stanza. Therefore, changes to the object directory for identity and subconfiguration stanzas are made specifying the user ID from the IDENTITY statement.

For more information, see the [Creating and Updating a User Directory](#) section in *z/VM: CP Planning and Administration*.

### **Entry Values:**

#### **Rx**

must contain the guest real address of a variable-length parameter list.

#### **Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the parameter list. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the parameter list is in the host-primary address space.

#### **Ry**

must specify the length of the parameter list as a number of bytes.

The parameter list must contain at least a fixed-length area 24 bytes long, followed by an optional variable length area of up to 223 bytes and a 4-byte fence (X'FF') or two sequential blanks. Data in the fixed-length area identifies the directory stanza to be updated, the password of the user ID associated with the stanza, and the data field to be replaced in the directory stanza. All entries in the parameter list must contain unpacked, EBCDIC data.

|    |                                          |
|----|------------------------------------------|
| 0  | USER userid/IDENTITY userid/SUBCONFIG id |
| 8  | password                                 |
| 10 | operation                                |
| 18 | optional<br>variable<br>length<br>area   |

The parameter list is organized as follows:

#### **Fixed-length area**

##### **USER *userid*/IDENTITY *userid*/SUBCONFIG *id***

is the 1- to 8-character USER or IDENTITY user ID, or the SUBCONFIG ID whose stanza is updated. If the value is less than 8 characters, then it must be left aligned and padded on the right with blanks to 8 characters. The value must be specified in uppercase.

##### ***password***

is the current CP password of the USER, IDENTITY, or SUBCONFIG whose stanza is updated. If the value is less than 8 characters, then it must be left aligned and padded on the right with blanks to 8 characters. The value must be specified in uppercase. For a subconfiguration stanza, specify the password of the associated IDENTITY.

If this field is blank, the update-in-place function is processed in *test mode* and the directory is not updated. Test mode lets you check the syntax of the directory operations without modifying the CP user directory or any operational controls.

##### ***operation***

is a 1- to 8-character value that identifies the data in the stanza that is to be replaced. If the value is less than 8 characters, then it must be left aligned and padded on the right with blanks to 8 characters. Valid values and the data that each identifies for replacement are defined in the description of the variable-length area that follows.

#### **Variable-length area**

[Table 6 on page 94](#) shows, for each value of the operation field, the data that must be in the variable-length area of the parameter list, and the format and characteristics of the data. [Table 6 on page 94](#) also shows specific information concerning all DIAGNOSE code X'84' operations.

| Table 6. DIAGNOSE Code X'84' Operations |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Operation                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ACCOUNT                                 | <p>Replaces all of the user's accounting numbers, up to eight, to be effective at the next user logon.</p> <p>The ACCOUNT operation can change a user or identity stanza, but cannot change a subconfiguration stanza.</p> <p><i>aaaaaaaa1[aaaaaaaa2[aaaaaaaa3...[aaaaaaaa8]]]</i></p> <p><b>aaaaaaaa1...aaaaaaaa8</b><br/>is a list of up to eight accounts. Each account is 1-8 digits, left-aligned and padded with blanks. The list is terminated by a blank account number or X'FFFFFFF'.</p> <p>The first account in the list is the primary or logon account number.</p> <p><b>Usage Note:</b> All existing values are replaced in the directory stanza; therefore, specify values that are to be retained as well as values that are to be changed. Trailing blanks are not truncated, but passed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| CPU                                     | <p>Replaces attributes of a user's virtual processor, to be effective at the next user logon.</p> <p>The CPU operation can change a user or identity stanza, but cannot change a subconfiguration stanza.</p> <p><i>pp [VECTOR NOVECTOR] [CPUID bbbbbb][CRYPTO NOCRYPTO]</i></p> <p><b>pp</b><br/>is a 2-digit hexadecimal virtual processor address between X'00' and X'3F' followed by a blank and one of the following:</p> <p><b>VECTOR NOVECTOR</b><br/>designates the specified processor as having or not having VECTOR capability.</p> <p><b>CPUID bbbbbb</b><br/>assigns the value following as the processor's CPUID where <i>bbbbbb</i> is a valid hexadecimal number.</p> <p><b>CRYPTO NOCRYPTO</b><br/>designates the specified processor as having or not having CRYPTO capability.</p> <p><b>Usage Notes:</b></p> <ol style="list-style-type: none"> <li>1. This operation can be used only to alter virtual processors defined by a CPU directory statement.</li> <li>2. If you use DIAGNOSE code X'84' to add a VECTOR designation to a CPU, it will have no effect if the user has specified NOVF on the OPTION directory control statement in the directory stanza.</li> <li>3. You can add a CRYPTO designation to a virtual CPU only if the user has a CRYPTO directory statement in the directory stanza.</li> </ol> |
| DATEFMT                                 | <p>Replaces the user's default date format setting, to be effective at the next user logon.</p> <p><i>[SHOrtdate FULldate ISOd ate SYSdefault]</i></p> <p><b>SHOrtdate FULldate ISOd ate SYSdefault</b><br/>sets the virtual machine's default date format to the specified setting.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Table 6. DIAGNOSE Code X'84' Operations (continued)

| Operation | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DISTRIB   | <p>Replaces the user's distribution identification value, to be effective at the next user logon.</p> <p>The DISTRIB operation can change a user or identity stanza, but cannot change a subconfiguration stanza.</p> <p><i>ddddddddd</i></p> <p><b>ddddddddd</b><br/>is the distribution identification word, which is a 1- to 8-character value, left-aligned and padded with blanks.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| EDITCHAR  | <p>Replaces the user's logical editing symbols for terminal and command analysis, to be effective at the next user logon.</p> <p>The EDITCHAR operation can change a user or identity stanza, but cannot change a subconfiguration stanza.</p> <p><i>symbols</i></p> <p><b>symbols</b><br/>is an 8-byte value containing logical editing symbols.</p> <p>The first four bytes, counting from the left, are line edit symbols. The first or high-order byte is the line-end symbol (#), the second byte is the line-delete symbol (¢), the third byte is the character-delete symbol (@), and the fourth byte is the escape-character symbol ("). All existing symbols in the directory are replaced. Therefore, specify existing symbols that are to be retained as well as symbols that are to be changed. Unspecified symbols must contain blanks. The last four bytes of the 8-byte value are reserved for future IBM use.</p> <p><b>Usage Note:</b> You cannot use any of the letters A through Z, the numbers 0 through 9, or the bytes X'0E' (shift out) or X'0F' (shift in) as a logical line edit symbol.</p> |
| IACCOUNT  | <p>Forces the creation of an accounting record for the current account number and replaces the primary account number in the directory stanza in the object directory, the new account number being effective immediately.</p> <p>The IACCOUNT operation can change a user or identity stanza, but cannot change a subconfiguration stanza.</p> <p><i>aaaaaaaa</i></p> <p><b>aaaaaaaa</b><br/>is a 1- to 8-character account number, left-aligned and padded with blanks. The number is assumed to be a valid value in the customer accounting scheme.</p> <p><b>Usage Note:</b> If the new account number specified is not one of the alternate account numbers presently in the directory stanza of the object directory, then the primary account number is simply replaced and is not preserved as a valid alternate account number.</p>                                                                                                                                                                                                                                                                          |

| Table 6. DIAGNOSE Code X'84' Operations (continued) |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Operation                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| IPL                                                 | <p>Replaces the user's automatic IPL statement, to be effective at the next user logon.</p> <p><i>name/aaaa</i> [PARM [<i>dddddd...dddddd</i>]]</p> <p><b><i>name/aaaa</i></b><br/>is a 1- to 8-character system name or virtual device number, left-aligned and padded with blanks.</p> <p><b>PARM</b><br/>is a keyword indicating that data is to follow.</p> <p><b><i>dddddd...dddddd</i></b><br/>is up to 48 characters of variable data.</p> <p><b>Usage Note:</b> All existing values are replaced in the directory stanza; therefore, specify values that are to be retained as well as values that are to be changed. Trailing blanks are not truncated, but passed.</p>                                                                                            |
| LOGPASS                                             | <p>Replaces the password of the specified user ID, to be effective at the next user logon.</p> <p><i>password</i></p> <p>The LOGPASS operation can change a user or identity stanza, but cannot change a subconfiguration stanza.</p> <p><b><i>password</i></b><br/>is a new 1- to 8-byte logon password, left-aligned and padded with blanks. The password must start in column 1 of the variable length area.</p>                                                                                                                                                                                                                                                                                                                                                         |
| MACHINE                                             | <p>Replaces the user's virtual machine data, to be effective at the next user logon.</p> <p>The MACHINE operation can change a user or identity stanza, but cannot change a subconfiguration stanza.</p> <p>[XA ESA XC Z] [MAXCPU <i>nn</i>]</p> <p><b>XA ESA XC Z</b><br/>sets the default virtual machine type designation.</p> <p><b>MAXCPU <i>nn</i></b><br/>sets the maximum number of virtual processors that the virtual machine can have. The variable <i>nn</i> is a number between 1 and 64.</p> <p><b>Usage Notes:</b></p> <ol style="list-style-type: none"> <li>1. Use either or both of the above option values in any order, separated by a single blank.</li> <li>2. The list is terminated by two consecutive blanks or the string X'FFFFFFFF'.</li> </ol> |
| MAXSTOR                                             | <p>Replaces the user's maximum virtual machine storage size. The new maximum storage size is enforced at the time of the next DEFINE STORAGE or user logon. Changing the maximum storage size does not cause any change to the currently defined storage size of the target user even if the new maximum is smaller than the user's currently defined storage size.</p> <p><i>nnnnnnnnnu</i></p> <p><b><i>nnnnnnnnnu</i></b><br/>is the maximum virtual machine storage size, a 1- to 8-byte left-justified decimal value followed by a 1-character storage unit suffix. See the STORAGE operation for the list of storage unit suffixes, maximum input values, and usage notes.</p>                                                                                        |

Table 6. DIAGNOSE Code X'84' Operations (continued)

| Operation | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MDISK     | <p>Replaces the default access mode and password definitions for the specified MDISK address, which must exist in the directory stanza. The change is effective immediately.</p> <p>The MDISK has two formats of parameter lists based on the length of the device address and the access mode of the device definition. Format 1 is the preferred format. Format 2 is for VM/SP, VM/SP HPO, and VM/ESA (370 Feature) compatibility.</p> <p>Format 1: {VDEV <i>aaaa mmmm [readpass [writepas [multipas]]]}</i></p> <p>Format 2: {<i>aaammm[readpass][writepas][multipas]}</i></p> <p><b>VDEV</b><br/>indicates that this is a format 1 parameter list.</p> <p><b>aaaa/aaa</b><br/>is a hexadecimal minidisk address. The format 1 address must be 1-4 digits. The format 2 address must be 1-3 digits.</p> <p><b>mmmm/mmm</b><br/>The default access mode of the device definition. The format 1 value must be 1-4 characters. The format 2 value must be 1-3 characters.</p> <p>Valid access modes are R, RR, W, RW, M, MR, MW. These access modes can be concatenated with optional suffix letters. For format 1, the allowed suffix letters are V, S, and E. They can be used in the following combinations: V, S, E, VS, or VE. When concatenated with a mode, some of the possible combinations would be RV, RRS, WE, MVE, or MRVS. For format 2, the only suffix letter allowed is V. The mode is replaced completely so you must specify it exactly as you want it to appear.</p> <p><b>readpass writepas multipas</b><br/>The passwords are 1- to 8-character values that enable the user to LINK to a desired DASD in the appropriate mode. All of the passwords are replaced, so you must supply all of the values to be retained as well as those that are changed. The values for access mode and for passwords must be valid. For more information, see <a href="#">MDISK Statement in z/VM: CP Planning and Administration</a>.</p> <p><b>Usage Notes:</b></p> <ul style="list-style-type: none"> <li>• Format 1 — A positional set of alphanumeric character strings. Each value is separated from the previous by a single blank. The line is terminated by two or more blanks or a fence of X'FFFFFFFF'. The format is identified by the value <i>VDEV</i> starting in column 25, followed by a blank. The rest of the elements are in the following list. They are positional and separated by a single blank: <ul style="list-style-type: none"> <li>– A hexadecimal 1- to 4-digit minidisk address. If less than four digits, the address must be padded to the left with zeros.</li> <li>– A 1- to 4-character access mode</li> <li>– A 1- to 8-character read password</li> <li>– A 1- to 8-character write password</li> <li>– A 1- to 8-character multiple password</li> </ul> </li> <li>• Format 2 — A 30-byte field, column-dependent format. All values must be left-aligned and padded with blanks. The field contains the following contents: <ul style="list-style-type: none"> <li>– Bytes 1 through 3, counting from the left, specify a hexadecimal 1- to 3-digit minidisk address.</li> <li>– Bytes 4 through 6 specify the access mode.</li> <li>– Bytes 7 through 14 specify the read password.</li> <li>– Bytes 15 through 22 specify the write password.</li> <li>– Bytes 23 through 30 specify the multiple password.</li> </ul> </li> </ul> |

The options field must be followed by the value X'FFFFFFFF' or by at least two blanks.</li> <li>3. A description of each option and a list of valid values is available in <i>z/VM: CP Planning and Administration</i>. See <a href="#">OPTION Directory Statement</a>.</li> </ol> |
| PRIORITY                                            | <p>Is accepted and ignored for compatibility with VM/SP HPO Release 5 and later.</p> <p><i>pp</i></p> <p>The PRIORITY operation can change a user or identity stanza, but cannot change a subconfiguration stanza.</p> <p><b><i>pp</i></b><br/>HPO dispatching priority is ignored.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PRIVILEGE                                           | <p>Replaces the user's current privilege class definition with a new set of classes.</p> <p>The PRIVILEGE operation can change a user or identity stanza, but cannot change a subconfiguration stanza.</p> <p><i>c[cccccccccccccccccccccccccccccccc]</i></p> <p><b><i>cccccccccccccccccccccccccccccccc</i></b><br/>is the privilege class parameter, a 32-byte value, where each byte represents a privilege class. Valid values for each byte are A-Z, and 1-6. The data must be left-justified and padded with blanks. This field can be all blanks, in which case the specified virtual machine has the default classes (defined on the PRIV_CLASSES statement in the system configuration file) each time the user logs on. The new privilege classes are effective the next time the user logs on.</p> <p><b>Usage Note:</b> All existing classes in the directory stanza are replaced. Therefore, specify values that are to be retained as well as values that are to be changed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Table 6. DIAGNOSE Code X'84' Operations (continued)

| Operation | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RMDISK    | <p>Alters the minidisk extents and the volume serial number for a minidisk that currently exists in the user directory.</p> <p>The RMDISK update-in-place takes effect immediately for all subsequent <i>new</i> LINKs to the specified minidisk and for ALL <i>new</i> minidisks established by virtue of subsequent LOGONs.</p> <p>LINKs to the specified minidisk that were established prior to the RMDISK operation continue to use the <i>old</i> extents that were in effect at the time of that LINK. In this case, a DETACH followed by a re-LINK is performed (or LOGOFF followed by LOGON, which is in effect the same thing), is necessary to access the new extents.</p> <p><i>aaaa dddddddd rrrrrrrrrr cccccccccc volser</i></p> <p><b>aaaa</b><br/>is a 1- to 4-hexadecimal digit minidisk address. If less than four digits, the value must be padded to the left with zeros up to 4 digits. The hexadecimal address must be a currently existing minidisk for the specified user ID.</p> <p><b>dddddddd</b><br/>is the device type of the real DASD. Select the appropriate value from the following list:</p> <p>3350, 3370, 3375, 3380, 3390, 9332, 9335, 9336, 9345 or FB-512. The 9345 must be formatted as an ECKD™ device.</p> <p><b>rrrrrrrrrr</b><br/>is the cylinder (CKD/ECKD) or block (FBA) relocation factor that identifies the beginning of the new allocation. It is the caller's responsibility to specify a cylinder or block location factor that is valid for the device type that is specified. This field must be a 1- to 10-character decimal value.</p> <p><b>ccccccccc</b><br/>is a decimal count of the number of cylinders (CKD/ECKD) or blocks (FBA) to be allocated or END which is defined as the remaining cylinders or blocks of the volume. It is the caller's responsibility to specify a cylinder or block count value that is valid for the device type that has been specified. This field must be a 1-10 character decimal value or END. A table of maximum minidisk sizes is documented in <i>z/VM: CP Planning and Administration</i>. See <a href="#">MDISK Statement</a> in <i>z/VM: CP Planning and Administration</i>.</p> <p><b>volser</b><br/>is a 1- to 6-character new volume serial identification. Any 1- to 6-character EBCDIC value, other than blank(s), is accepted.</p> <p><b>Usage Notes:</b></p> <ol style="list-style-type: none"> <li>1. The variable-length area must contain all of the positional fields, each field separated from its predecessor by at least one blank. Trailing data, if any, that follows the last positional field (and its blank delimiter) is ignored.</li> <li>2. All other fields associated with the minidisk (default link mode, passwords, minidisk and DASD options) remain unchanged.</li> <li>3. When coding the device type value, a 3380C is treated as a 3380 if you are coming from a VM/SP, VM/SP HPO, or VM/ESA (370 Feature) system.</li> </ol> |

| Table 6. DIAGNOSE Code X'84' Operations (continued) |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Operation                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| SCREEN                                              | <p>Replaces the user's SCREEN color and highlight control options, to be effective at the next user logon.</p> <p><i>cccccccchhhhhhhhh...cccccccchhhhhhhhh</i></p> <p><b>cccccccchhhhhhhhh</b><br/>are the display screen options, specified in an 80-byte area composed of ten doubleword fields. The ten fields are paired into five sets corresponding to the five display areas of the SCREEN. You must specify these areas in the following order:</p> <ol style="list-style-type: none"> <li>1. CP output</li> <li>2. VM output</li> <li>3. Input redisplay</li> <li>4. Input area</li> <li>5. Status area.</li> </ol> <p>Each of the five doubleword sets has a color field and an extended highlight field. Within each doubleword set you must specify the color first followed by the extended highlight value. You must specify all fields, including those you do not want to change. Each of the options you specify must also be left-justified in its respective 8-byte field. For more information, see the <a href="#">SCREEN Statement</a> topic in <i>z/VM: CP Planning and Administration</i>.</p> |
| SPOOLF                                              | <p>Replaces the user's spool file characteristics. The new maximum number of spool files will be effective the next time the user logs on.</p> <p><b>MAXSPOOL <i>nnnn</i></b><br/><b>MAXSPOOL <i>nnnn</i></b><br/>sets the new maximum spool file number where <i>nnnn</i> is the maximum spool file number for this user. The number is between 1 and 9999.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 6. DIAGNOSE Code X'84' Operations (continued)

| Operation | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STORAGE   | <p>Replaces the user's default virtual machine storage size, to be effective at the next user logon.</p> <p><b>nnnnnnnnu</b><br/> is the virtual machine storage size, a 1- to 8-byte left-justified decimal value followed by a 1-character storage unit suffix. The value specified can be any value less than or equal to the user's current maximum storage value in the directory.</p> <p><b>Storage units / Suffix (u)</b><br/> <b>Maximum input value (nnnnnnnn)</b></p> <p><b>Kilobytes / K</b><br/> 2096128</p> <p><b>Megabytes / M</b><br/> 99999999</p> <p><b>Gigabytes / G</b><br/> 99999999</p> <p><b>Terabytes / T</b><br/> 16777216</p> <p><b>Petabytes / P</b><br/> 16384</p> <p><b>Exabytes / E</b><br/> 16</p> <p><b>Usage Notes:</b></p> <ol style="list-style-type: none"> <li>1. The K suffix is provided for upward compatibility only; a K specification is rounded up to a MB value. The maximum specification is 2096128K (2047 MB).</li> <li>2. The maximum input value of 99999999 for the M or G suffix is not a size limit but the physical limit of the parameter (8 digits plus suffix). If the maximum input value for one of these suffixes does not allow you to define the amount of storage you want, you need to use a larger storage unit.</li> <li>3. The maximum size you can specify is 16E (or 16384P or 16777216T), although the actual maximum size supported may be restricted by the model of the server where the directory is used.</li> <li>4. An XC virtual machine can address up to 2047 MB of storage in its base address space.</li> <li>5. Giving many virtual machines very large storage sizes might affect real storage availability. For each virtual machine, CP creates one or more segment tables in host real storage to represent the virtual machine storage: <ul style="list-style-type: none"> <li>• For a virtual machine less than or equal to 512 MB, one frame is allocated for the segment table.</li> <li>• For a virtual machine larger than 512 MB but less than or equal to 1 GB, two contiguous frames are allocated for the segment table.</li> <li>• For a virtual machine larger than 1 GB but less than or equal to 1.5 GB, three contiguous frames are allocated for the segment table.</li> <li>• For a virtual machine larger than 1.5 GB but less than or equal to 2 GB, four contiguous frames are allocated for the segment table.</li> <li>• For a virtual machine larger than 2 GB, multiple segment tables are created, plus one or more higher level (region) tables are created to identify the segment tables. If needed, multiple levels of region tables are created. Each region table occupies 1-4 contiguous frames.</li> </ul> </li> </ol> |

| Table 6. DIAGNOSE Code X'84' Operations (continued) |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Operation                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| TACCOUNT                                            | <p>Forces the creation of an accounting record for the current account number. Then replaces the <i>active</i> account number with the new one specified in the parameter list. The user's definition in the object directory is left unchanged. The account number is temporary, terminated by a LOGOFF, by another TACCOUNT operation, an IACCOUNT operation, or a SET ACCOUNT command.</p> <p><i>aaaaaaaa</i></p> <p><b><i>aaaaaaaa</i></b></p> <p>is the 1- to 8-character account number, left-aligned and padded with blanks. The number is assumed to be a valid value in the customer accounting scheme.</p>                                                     |
| XAUTOLOG                                            | <p>Replaces the list of class G user IDs authorized to XAUTOLOG this user, to be effective immediately.</p> <p>The XAUTOLOG operation can change a user or identity stanza, but cannot change a subconfiguration stanza.</p> <p>[<i>uuuuuuu1</i> [<i>uuuuuuu2</i> ... [<i>uuuuuuu8</i>]]]</p> <p><b>[<i>uuuuuuu1</i> [<i>uuuuuuu2</i> ... [<i>uuuuuuu8</i>]]]</b></p> <p>lists up to eight user IDs, each a 1- to 8-character value, separated by single blanks. The list is terminated by two consecutive blanks or the string X'FFFFFFF'. All XAUTOLOG user IDs are replaced, so specify user IDs that are to be retained as well as those that are to be changed.</p> |
| XSTORE                                              | <p>Accepted for compatibility only. Expanded storage (XSTORE) is not supported. Specifying this operation has no effect.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Exit Values:**
**Ry**

Contains 0 unless the condition code is 1, in which case the value is the appropriate return code shown in the following list.

## Usage Note

Users defined with the LBYONLY operand in the password field of their USER statement in the CP directory may be restricted from performing functions that require password validation. A user ID defined with the LBYONLY operand cannot be the target of DIAGNOSE X'84' operations unless the virtual machine issuing the diagnose has the D84NOPAS option in its directory stanza and the operation specified is not LOGPASS or MDISK.

## Responses

**Condition Codes:** Upon return from DIAGNOSE code X'84', CP sets one of the following condition codes:

| Condition Code | Meaning                                                                                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | The object directory was updated.                                                                                                                                                 |
| 1              | DIAGNOSE code X'84' has detected an error. The directory is unchanged. The return code defines the error.                                                                         |
| 3              | DIAGNOSE code X'84' has encountered a paging error while trying to access or update an object directory page. The directory remains unchanged. The return code defines the error. |

**Abend Codes:**

| Abend Code | Meaning                                                                 |
|------------|-------------------------------------------------------------------------|
| UDU001     | An error has been detected in one of the directory blocks for the user. |

**Return Codes (in Ry):**

| Return Code | Meaning                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')   | The directory update was successful.                                                                                                                      |
| 26 (X'1A')  | The specified device address was not found.                                                                                                               |
| 28 (X'1C')  | The value in the OPERATION field of the parameter list is invalid. Operations not allowed for subconfiguration stanzas are treated as invalid operations. |
| 30 (X'1E')  | The specified user ID could not be found.                                                                                                                 |
| 31 (X'1F')  | The password specified in the fixed-length area of the parameter list does not match the current password of the user ID being updated.                   |
| 40 (X'28')  | The storage size requested exceeds the maximum defined for this virtual machine.                                                                          |
| 41 (X'29')  | The storage size requested exceeds the maximum allowed for the specified storage unit.                                                                    |
| 42 (X'2A')  | The conversion of the storage size from alphanumeric to binary failed with a syntax error.                                                                |
| 43 (X'2B')  | The value specified for the virtual machine storage size is invalid.                                                                                      |
| 53 (X'35')  | The specified privilege classes contain an invalid character.                                                                                             |
| 70 (X'46')  | An option value specified to the OPTIONS operation is invalid.                                                                                            |
| 72 (X'48')  | The option value contains a syntax error or an invalid character.                                                                                         |
| 80 (X'50')  | The parameter list contains an invalid minidisk address.                                                                                                  |
| 81 (X'51')  | The parameter list specifies an invalid access mode for a minidisk.                                                                                       |
| 91 (X'5B')  | No attributes were found on the SCREEN operation.                                                                                                         |
| 92 (X'5C')  | Invalid attributes were found on the SCREEN operation.                                                                                                    |
| 101 (X'65') | The parameter list is too large, greater than the maximum of 255 bytes.                                                                                   |
| 102 (X'66') | The length of the parameter list is less than 24 bytes.                                                                                                   |
| 110 (X'6E') | No parameter data currently exists in the directory.                                                                                                      |
| 111 (X'6F') | The parameter length is invalid.                                                                                                                          |
| 121 (X'79') | The virtual address is invalid.                                                                                                                           |
| 122 (X'7A') | This user has no minidisk defined at this virtual address.                                                                                                |
| 123 (X'7B') | The specified device type is invalid.                                                                                                                     |
| 124 (X'7C') | The specified starting cylinder or block is invalid.                                                                                                      |
| 125 (X'7D') | The specified number of cylinders or blocks is invalid.                                                                                                   |
| 126 (X'7E') | The specified volume serial number is invalid.                                                                                                            |
| 230 (X'E6') | An invalid option was specified for the SPOOLF operation.                                                                                                 |
| 231 (X'E7') | The MAXSPOOL value was missing.                                                                                                                           |
| 232 (X'E8') | The MAXSPOOL value equals zero.                                                                                                                           |

|               |                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 233 (X'E9')   | The MAXSPOOL value contains an invalid EBCDIC value.                                                                                 |
| 234 (X'EA')   | The MAXSPOOL value was greater than 9999.                                                                                            |
| 240 (X'F0')   | The CPU specified was not found in the directory for this user.                                                                      |
| 241 (X'F1')   | An invalid option was specified for the CPU operation.                                                                               |
| 242 (X'F2')   | The specified CPU address is invalid.                                                                                                |
| 243 (X'F3')   | The CPUID value contains an invalid EBCDIC value.                                                                                    |
| 244 (X'F4')   | The CPUID value was greater than six bytes long.                                                                                     |
| 245 (X'F5')   | The CPUID value was missing.                                                                                                         |
| 246 (X'F6')   | CRYPTO was specified for the CPU operation but the user does not have a CRYPTO directory control statement in their user definition. |
| 250 (X'FA')   | Too many user IDs were specified for the XAUTOLOG operation.                                                                         |
| 251 (X'FB')   | An invalid user ID was specified for the XAUTOLOG operation.                                                                         |
| 260 (X'104')  | The MAXCPU value was missing.                                                                                                        |
| 261 (X'105')  | An invalid option was specified for the MACHINE operation.                                                                           |
| 262 (X'106')  | Conflicting values were specified for the MACHINE operation.                                                                         |
| 263 (X'107')  | The MAXCPU value contains an invalid EBCDIC value. It was not in the range of 1 to 64.                                               |
| 264 (X'108')  | The XC virtual machine type conflicts with the V=R/V=F option for this virtual machine. V=R and V=F are not supported.               |
| 290 (X'122')  | An option is missing for the DATEFMT operation.                                                                                      |
| 291 (X'123')  | An invalid option was specified for the DATEFMT operation.                                                                           |
| 292 (X'124')  | More than one option was specified for the DATEFMT operation.                                                                        |
| 410 (X'19A')  | An error occurred while writing a directory page out to a direct access device. (See following note.)                                |
| 475 (X'1DB')  | An error occurred while reading a directory page. (See following note.)                                                              |
| 550 (X'226')  | An invalid symbol was specified for the EDITCHAR operation.                                                                          |
| 1507 (X'5E3') | The active CP directory is invalid.                                                                                                  |

**Note:** To update the directory, use the service program (DIRECTXA) described in *z/VM: CP Planning and Administration*. For more information on formatting the DIRECTXA utility, see *z/VM: CP Commands and Utilities Reference*.

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'84' is given incorrect input data:

| Problem Encountered                                   | Cause                                                                                                                                                                                 |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Privileged-operation exception                        | Any of the following: <ul style="list-style-type: none"> <li>The virtual machine is in the problem state.</li> <li>The user does not have the appropriate privilege class.</li> </ul> |
| Access exception (See “Access Exceptions” on page 8.) | An error occurred trying to fetch the parameter list.                                                                                                                                 |

## DIAGNOSE Code X'88' – Validate User Authorization/Link Minidisk

**Privilege Class:** G

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE code X'88' is used by a service virtual machine to authenticate a client agent's access to a target virtual machine's minidisks and to gain access to those minidisks on the client's behalf. If an external security manager (ESM) is not controlling the use of this diagnose instruction, the issuing virtual machine must have the DIAG88 option in its User Directory entry. When under ESM control, special authorization is required to use this function. Contact your administrator to obtain any needed permissions. This capability should be granted only to trusted programs.

An application may verify its ability to use DIAGNOSE code X'88' through use of subcode negative 1 (-1). When an application has the ability to use DIAGNOSE code X'88', it is assumed that the issuing virtual machine will first use subcode X'00' or subcode X'08' to validate that a client is permitted to access the resources of a target virtual machine. After performing this validation, the issuing virtual machine may then use subcode X'04' to obtain access to the target machine's minidisks on behalf of the client.

An agent may be granted access to a target machine's minidisks if the agent's logon password is known and either the agent is the target or is authorized in the User Directory to access the target via LOGONBY. In other words, if a client knows how to log on to the target virtual machine, either directly or using LOGONBY, it may be granted access to that machine's minidisk resources.

CMS provides simplified programming access to DIAGNOSE code X'88' through use of the DMSPASS callable service. For more information, see [DMSPASS callable service in z/VM: CMS Callable Services Reference](#).

### Entry Values for Subcode X'00':

**Rx**

X'00000000'

**Ry**

Pointer to the parameter list, D88PARM0. D88PARM0 COPY is provided in the HCPGPI macro library.

**Ay**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the parameter list. If Ry designates general register 0, if Ay contains X'00000000', or if the virtual machine is not in XC mode, the parameter list is in the host-primary address space.

### D88PARM0 DSECT

The parameter list is in this format:

|    |                                   |
|----|-----------------------------------|
| 0  | D88PTARG - Target user identifier |
| 8  | D88PAGNT - Agent user identifier  |
| 10 | D88PPSWD - Password               |
| 18 |                                   |

### D88PTARG

is the user ID of the target virtual machine whose resources are to be accessed.

## **DIAGNOSE code X'88'**

### **D88PAGNT**

is the user ID of the end user requesting access to the target user's resources.

### **D88PPSWD**

is the password of the end user requesting access to the target user's resources.

## **Subcode -1 – Verify Authorization to Use DIAGNOSE Code X'88'**

Subcode -1 provides an application with the ability to invoke DIAGNOSE code X'88', without any additional parameters, to ensure the virtual machine has all needed authorizations to use DIAGNOSE code X'88', including those of the ESM. To use this functionality, invoke the CMS callable service DMSPASS, specifying the domain parameter as -1.

### **Entry Values for Subcode -1:**

#### **Rx**

X'FFFFFFFF'

#### **Ry**

Is not used.

#### **Ay**

Is not used.

## **Subcode X'00' – Validate User Authorization**

Subcode X'00' verifies that the supplied password is valid (for LOGON) for the designated agent. If the first character of the password is a blank, the verification is bypassed. If the target and agent user identifiers are different, this function ensures that the agent is authorized for LOGONBY to the target. Subcode X'00' is provided for compatibility with previous releases of z/VM. Applications should use subcode X'08' instead.

## **Subcode X'04' – Link Minidisk**

Subcode X'04' links to a minidisk owned by the target virtual machine.

### **Entry Values for Subcode X'04':**

#### **Rx**

X'00000004'

#### **Ry**

Pointer to the parameter list, D88PARM0.

#### **Ay**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the parameter list. If Ry designates general register 0, if Ay contains X'00000000', or if the virtual machine is not in XC mode, the parameter list is in the host-primary address space.

### **D88PARM0 DSECT**

The parameter list is in this format:

|    |                                   |
|----|-----------------------------------|
| 0  | D88PTARG - Target user identifier |
| 8  | D88PAGNT - Agent user identifier  |
| 10 | D88PPSWD - Password               |
| 18 | D88PMDSK - Minidisk address       |
| 1A | D88PVADD - Virtual device address |
| 1C | D88PMODE - Link mode              |
| 1E | Reserved                          |

20

**D88PTARG**

is the user ID of the target virtual machine whose minidisk is to be linked.

**D88PAGNT**

is the user ID of the end user requesting the access to the target user's minidisk.

**D88PPSWD**

is the minidisk password.

**D88PMDSK**

is the address of the target virtual machine minidisk to be linked.

**D88PVADD**

is the virtual device address in the requesting virtual machine's configuration at which the link is to be established.

**D88PMODE**

is the mode in which the link is to be established. This may be any of the valid LINK modes (R, RR, W, WR, M, MR, or MW). In addition, the first character may be specified as X, in which case the link is established as follows:

- If a password is supplied, the link is established in the highest mode associated with that password.
- If public access is permitted (ALL is the password defined in the User Directory), the link is established in the highest mode with such access.
- For the minidisk owner, the link is established in the mode associated with the minidisk definition in the User Directory.
- Otherwise, the link is established as read only (RR).

**Exit Values:** Return codes are set for DIAGNOSE code X'88'.

Subcode X'08' – Validate User Authorization

Subcode X'08' verifies that the supplied password is valid (for LOGON) for the designated agent. If the target and agent user identifiers are different, this function ensures that the agent is authorized for LOGONBY to the target.

Subcode X'08' is similar to subcode X'00', with the exception that subcode X'08' handles password phrases and all necessary calls to an ESM. The caller does not have to worry about case, valid characters, or lengths.

Entry Values for Subcode X'08':

**Rx**  
is X'00000008'.

**Ry**  
is a pointer to the parameter list, D88PARM0.

**Ay**  
is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space that contains the parameter list. If Ry designates general register 0, Ay is not examined. The ALET is assumed to be 0, which indicates the host-primary address space.

D88PARM0 DSECT

The parameter list is in this format:

**D88PTARG**  
is the user ID of the target virtual machine whose identity the agent would like to assume after authentication. If this field is not null or blank and is not the same as D88PAGNT, the agent's authorization to use LOGONBY to access the target user ID is verified. If D88PTARG is null or blank, it is assumed to be the same as D88PAGNT.

**D88PAGNT**  
is the user ID of the agent whose password is to be verified.

**D88PPLEN**  
is the length, in bytes, of the password; the maximum value is 200. Applications should be coded to allow up to 200 characters (including blanks), but should also be aware that an ESM might impose further restrictions on the password length. For example, RACF® supports passwords that are up to 100 characters in length.

**D88PPHRA**

is the password of the agent user ID. The password field is ignored if the agent user ID is defined in the CP directory as NOPASS.

**Exit Values:** Return codes are set for DIAGNOSE code X'88'.

## Responses

### Return Codes:

Return codes for subcode -1 are as follows:

| Return Code in Rx | Meaning                                            |
|-------------------|----------------------------------------------------|
| 0 (X'00')         | The issuer is authorized to use this diagnose.     |
| 8 (X'08')         | The issuer is not authorized to use this diagnose. |
| 40 (X'28')        | ESM required, but is not available.                |

Return codes for subcode X'00' are as follows:

| Return Code in Rx | Meaning           |
|-------------------|-------------------|
| 0 (X'00')         | Access granted.   |
| 8 (X'08')         | Access denied.    |
| 24 (X'18')        | Paging I/O error. |

Return codes for subcode X'04' are as follows:

| Return Code in Rx | Meaning                                      |
|-------------------|----------------------------------------------|
| 0 (X'00')         | Minidisk linked read/write.                  |
| 4 (X'04')         | Minidisk linked read-only.                   |
| 8 (X'08')         | Access denied.                               |
| 12 (X'0C')        | Minidisk password required.                  |
| 16 (X'10')        | Minidisk password incorrect.                 |
| 20 (X'14')        | Link failed. Ry = LINK error message number. |
| 24 (X'18')        | Paging I/O error.                            |

Return codes for subcode X'08' are as follows:

| Return Code in Rx | Meaning                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')         | Agent is authenticated and is authorized to act as target.                                                                                          |
| 8 (X'08')         | Agent password not valid. This return code is also used when the agent user ID is defined in the CP directory with a password of NOLOG or AUTOONLY. |
| 24 (X'18')        | Paging I/O error.                                                                                                                                   |
| 28 (X'1C')        | Agent authenticated but is not authorized to act as target.                                                                                         |
| 32 (X'20')        | Agent password has expired.                                                                                                                         |
| 36 (X'24')        | ESM active, but does not support password phrases.                                                                                                  |
| 40 (X'28')        | ESM required, but is not available.                                                                                                                 |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'88' is given incorrect data:

| <b>Problem Encountered</b>                                            | <b>Cause</b>                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Privileged-operation exception                                        | Any of the following: <ul style="list-style-type: none"> <li>• The virtual machine is in the problem state.</li> <li>• The issuer does not have class G privileges.</li> <li>• The issuer does not have the DIAG88 User Directory option.</li> <li>• The ESM is required, but is not available (subcodes X'00' and X'04' only).</li> </ul>                            |
| Specification exception                                               | One of the following: <ul style="list-style-type: none"> <li>• Rx and Ry are the same register</li> <li>• The Rx register does not contain a valid subcode.</li> <li>• The address of the parameter list specified in Rx is not on a doubleword boundary.</li> <li>• A password length is zero or greater than 200.</li> <li>• The agent user ID is blank.</li> </ul> |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch the parameter list.                                                                                                                                                                                                                                                                                                                 |

## **DIAGNOSE Code X'8C' – Access 3270 Display Device Information**

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'8C' to allow a virtual machine to obtain certain 3270 display device information instead of issuing a Write Structured Field Query command. If the characteristics of the display are altered dynamically, the data returned by DIAGNOSE code X'8C' does not reflect the changes. (This is because the information is obtained only at power-on time, or when the device becomes enabled for CP's use.)

### **Entry Values:**

#### **Rx**

Is the guest real address of a user-provided data buffer; the buffer must start on a doubleword boundary. Rx cannot be register 15.

#### **Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the data buffer. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the data buffer is in the host-primary address space.

#### **Ry**

Is the length of the user-provided data buffer. This value must be greater than zero.

#### **Rx+1**

Must contain one of the following:

- The virtual device number of the 3270 display device for which information is requested
- The value negative 1 (-1). Specify -1 when the device is a virtual console whose device address is unknown to your virtual machine.

### **Exit Values:**

**Rx+1**

Contains a return code—see the Responses section for a description.

**Ry**

Contains the residual count if the length specified on entry is greater than the amount of data received.

The data returned in the user-specified data buffer by DIAGNOSE code X'8C' is in the following format:

| Byte 0 | Byte 1               | Bytes 2 and 3                        | Bytes 4 and 5                         | Bytes 6 through nnn                     |
|--------|----------------------|--------------------------------------|---------------------------------------|-----------------------------------------|
| Flags  | Number of partitions | Screen width, in cells (hexadecimal) | Screen height, in cells (hexadecimal) | Write Structured Field Query reply data |

The flags are defined as follows:

- X'80'—Extended color present
- X'40'—Extended highlighting present
- X'20'—Programmable symbol sets (PSS) present
- X'02'—3270 emulation
- X'01'—14-bit addressing allowed.

## Usage Notes

- The data returned in bytes 6 through *nnn* is the data returned from the Write Structured Field (WSF) Query, issued by CP. This data is stripped of the AID value X'88'. (The AID value signals the beginning of the WSF read-partition query reply data. Refer to your device operations manual for a more detailed description).
- If the write structured field is not supported by the display, only six bytes of information are available: the flags and number of partitions, which contain zeros, and screen width and height, which contain their correct values.
- If a paging error occurs when the pageable buffer that contains the query reply data is being paged in, up to six bytes of data are returned in the buffer specified by Rx, and if more than six bytes were requested, the residual count is returned in Ry. If less than six bytes were requested, that number of bytes is returned.
- The amount of data returned by DIAGNOSE code X'8C' can be computed as follows:
  - If Ry(after) equals Ry(before)
  - Then the data length equals Ry(after)
  - Else the data length equals Ry(before) - Ry(after).

## Responses

**Return Codes:** Upon completion of DIAGNOSE code X'8C', one of the following return codes is placed in Rx+1:

| Return Code in Rx+1 | Meaning                                                                                                            |
|---------------------|--------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')           | Successful completion                                                                                              |
| 2 (X'02')           | The specified device does not exist. It is not a display-type device, or the user is running in disconnected mode. |
| 4 (X'04')           | An I/O error has occurred (CP was unable to page in the guest's buffer).                                           |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'8C' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                                               | Any of the following: <ul style="list-style-type: none"> <li>• The length specified in Ry is negative or zero.</li> <li>• The virtual device number specified does not exist.</li> <li>• The buffer address is not on a doubleword boundary.</li> <li>• The Rx specified is register 15.</li> </ul> |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                                                                                                                                                                                        |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to store into the data buffer.                                                                                                                                                                                                                                             |

## DIAGNOSE Code X'90' – Read Symbol Table

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'90' to find the address of a specific symbol contained in the symbol table for diagnosis, monitoring, or tuning activities only.

The loader creates a symbol table at load time that contains all the external symbols in the system. This symbol table does not have a maximum size.

**Entry Values:**

**Rx**

Contains the length of the symbol. Trailing blanks are not counted. The value contained in Rx must be greater than or equal to 6, and less than or equal to 8; otherwise, you will get a specification error.

**Ry**

Contains the host logical storage address of the symbol.

**Ay**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the symbol. If Ry designates general register 0, if Ay contains X'00000000', or if the virtual machine is not in XC mode, the symbol is in the host-primary address space.

## Usage Note

If the CSECT at the symbol is greater than 4 KB in length, the frames backing the host logical storage pages are not necessarily contiguous in host real storage.

## Responses

**Condition Codes:** After executing DIAGNOSE code X'90', you receive a condition code indicating the success or failure of the instruction as follows:

| Condition Code | Status                            | Rx Contains                                                                            | Ry Contains                                                                   |
|----------------|-----------------------------------|----------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| 0              | Resident symbol found             | The length of the symbol if it is a CSECT (zero if the symbol is an entry point only). | The host logical storage address of the symbol in the system execution space. |
| 2              | Symbol not found, or paging error | Unchanged                                                                              | Unchanged                                                                     |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'90' is given incorrect input data:

| Problem Encountered                                                   | Cause                                                                        |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------|
| Specification exception                                               | The length of the symbol (specified in Rx) is less than 6 or greater than 8. |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                 |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch the symbol.                                |

## DIAGNOSE Code X'94' – VMDUMP and Symptom Record Service

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'94' to:

- Request a dump of guest real storage to a system data file, in VMDUMP format, that can be processed by the DUMPLOAD utility for non-CP dumps, and viewed by the VM Dump Tool VMDUMPTL command for CP dumps.
- Request that CP process a symptom record. A copy of the completed symptom record is placed in the dump file (if a dump was requested), and copies of the completed symptom record are available to authorized symptom record recording virtual machines. Symptom records should be used to record suspected errors in IBM software or in IBM hardware.

### Entry Values:

#### Rx

Is the address of the parameter string in guest real storage.

#### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the parameter string. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the parameter string is in the host-primary address space.

#### Ry

Is the length of the parameter string. When a request to process a symptom record accompanies a dump request, Ry should not be register 15.

## Supported Parameters

The parameters supported by DIAGNOSE code X'94' are in the following syntax diagram. If you are unfamiliar with reading syntax diagrams, see [“Syntax, Message, and Response Conventions”](#) on page xxxv. The parameter string must be no longer than 240 bytes, and must not be fetch-protected from the invoking program. It is a character string with the same format as the operands of the VMDUMP command, with the exception of the parameters described, which are unique to DIAGNOSE code X'94'.

**Main Params**

Notes:

<sup>1</sup> On an individual request, the address space qualifiers, ranges, dump address list, format, and optional parameters can be specified in any order. Address ranges and the format apply to the address space last specified on the request.

<sup>2</sup> When DCSS or DSS is specified and no address range operand is specified, the default range is ignored and no part of the address space is dumped. Also, if the address space qualifier specified refers to an address space other than the primary space, the default range is 0-ALL.

<sup>3</sup> This path is followed only when the starting address is zero *by default*. If zero is specified explicitly, the path starting with *hexloc1* is followed.

## Options

## Notes:

<sup>1</sup> The user who is to receive the dump files can be specified, even by default, only once and only on the first request for the dump.

<sup>2</sup> If *\*dumpid* is specified, it *must* be last.

## Parameters Unique to DIAGNOSE code X'94'

### DUMP list-addr

indicates that the dump address ranges are in hexadecimal form within a separate dump address list. *List-addr* is the address of the dump address list in the same address space as the parameter list. It is expressed as a 4-byte hexadecimal address immediately following the DUMP keyword and a single blank. See [“Dump Address List” on page 116](#) for a complete description of the dump address list.

### DUMPDW list-addr

indicates that the dump address ranges are in hexadecimal form within a separate dump address list. *List-addr* is the address of the dump address list in the same address space as the parameter list. It is expressed as an 8-byte hexadecimal address immediately following the DUMPDW keyword and a single blank. See [“Dump Address List” on page 116](#) for a complete description of the dump address list.

### NORETURN

indicates that the invoking virtual machine may not transfer the spool file back to itself from the dump receiver, using the TRANSFER or CHANGE command. This parameter must be used only with the SYSTEM or TO *userid* (in other words, not your own user ID) parameter designating the authorized receiver of the dump file. This facility can be used to restrict access to dumps of shared virtual machine storage to certain authorized users.

### SR symptom-rec-addr

indicates that a symptom record is to be processed by CP. *Symptom-rec-addr* is the address of the symptom record in the same address space as the parameter string. It is expressed as a 4-byte hexadecimal address immediately following the SR keyword and a single blank. This parameter may be used to record suspected software errors in IBM products. Symptom records should not be used to record end-user errors. Errors that are presented through DIAGNOSE code X'94' using the SR keyword are those that need the attention of the personnel who are responsible for first-level problem determination at an installation.

**SRDW *symptom-rec-addr***

indicates that a symptom record is to be processed by CP. *Symptom-rec-addr* is the address of the symptom record in the same address space as the parameter string. It is expressed as an 8-byte hexadecimal address immediately following the SRDW keyword and a single blank. This parameter may be used to record suspected software errors in IBM products. Symptom records should not be used to record end-user errors. Errors that are presented through DIAGNOSE code X'94' using the SRDW keyword are those that need the attention of the personnel who are responsible for first-level problem determination at an installation.

**NODUMP**

indicates that the symptom record is to be made available to the authorized symptom record recording virtual machine, but no virtual machine dump is to be taken. This parameter may only be used with the SR parameter indicating the address of a symptom record to be processed.

The remaining parameters are exactly as specified for the VMDUMP command in [z/VM: CP Commands and Utilities Reference](#).

**Dump Address List**

A virtual machine program that issues DIAGNOSE code X'94' can provide dump address lists containing address ranges to be dumped. These lists are in hexadecimal format and the maximum number of dump address lists is 2,049. When the DUMP or DUMPDW keyword is used, you must store the 4 or 8 byte address of the first list in the DIAGNOSE code X'94' parameter list described above, following the DUMP keyword and separated from it by a blank. When the DUMPDW keyword is used, the address of the first list is an 8-byte address. The first word of each list contains a pointer to the next list.

The dump address list can be in one of four formats based on whether an address space qualifier is specified. [Figure 10 on page 116](#) shows the 31-bit base format (without an address space qualifier), and [Figure 11 on page 116](#) shows the 31-bit extended format (with an address space qualifier). [Figure 12 on page 116](#) shows the 64-bit base format, and [Figure 13 on page 117](#) shows the 64-bit extended format.

Figure 10. 31-bit Base format dump address list (without an address space qualifier)

Figure 11. 31-bit Extended format dump address list (with an address space qualifier)

Figure 12. 64-bit Base format dump address list (without an address space qualifier)

Figure 13. 64-bit Extended format dump address list (with an address space qualifier)

#### NEXT-LIST-ADDRESS

is the fullword or doubleword address of the next dump address list or a fullword containing binary zeros if no further list exists.

#### ADDRESS-RANGE-COUNT

is the fullword count of the number of address ranges included in this dump address list. It must be greater than zero.

#### TYPE

is a one-byte flag indicating:

- whether the address ranges in the list are specified in address/length or address/address form (X'80')
- whether the address space qualifier is specified (X'40')
- whether the addresses are 31-bit or 64-bit (X'20').

Bits 3-7 are reserved and must contain binary zeros.

|                   |                                          |
|-------------------|------------------------------------------|
| 1... .. (X'80')   | 0 = address/length                       |
|                   | 1 = address/address                      |
| .1.. .. (X'40')   | 0 = no address space qualifier specified |
|                   | 1 = address space qualifier specified    |
| ..1. .... (X'20') | 0 = 31-bit addresses                     |
|                   | 1 = 64-bit addresses                     |

#### address/length

Ranges are specified as the starting address and length.

For 31-bit addresses, the length is specified as a 4 byte value. For 64-bit addresses, the length is specified as an 8-byte value.

#### address/address

Ranges are specified as the starting address and ending address.

#### ADDRESS-SPACE-QUALIFIER

is the 4-byte ALET specifying the address space with which each address range in the dump address list is associated.

#### Notes:

1. The values represented by this format of an ALET and the format specified on the DIAGNOSE invocation (for example, for DCSS) can be the same. However, the format is different - in the dump address list, the ALET is a 4-byte value; on the invocation, the ALET is the 8-digit hexadecimal representation of the 4-byte value.
2. Only the primary address space can be specified when in z/Architecture mode.

#### ADDRESS-RANGE-DATA

consists of pairs of fullwords or doublewords containing the starting address of each range followed by either the length or the ending address, depending on the setting of the TYPE flag. The number of range entries is contained in the ADDRESS-RANGE-COUNT field.

These ranges point to data in the address space identified by the address space qualifier. If there is no address space qualifier, the ranges point to data in the primary address space. The ranges are not affected by any address space qualifier specified in the parameter string.

## Usage Notes Regarding Dumping a Virtual Machine

1. The requested dump file contains only storage that the user is authorized by storage key to access. Any block of storage that is fetch protected with a key other than that of the invoking program is not dumped. A virtual machine program that executes in key zero can dump any part of virtual storage. Shared segments which comprise named saved systems and discontinuous saved segments are also dumped, subject to the same protection rule. Only second-level storage (that is, guest real storage) is dumped. Operating systems that execute in translate mode create third-level (guest virtual) storage.  
**Note:** In addition to storage key authorization, the virtual machine must be permitted to access the requested address space.
2. You cannot specify inline address ranges and DUMP or DUMPDW address list ranges that refer to the same space on the same invocation of DIAGNOSE code X'94'.
3. The maximum address that VMDUMP can dump is X'7FFFFFFF' for ESA/390 machines, and X'FFFFFFFF' (512 Gigabytes - 1) for z/Architecture machines.
4. The absence of discontinuous saved segments when DCSS is specified results in an error only if no other area of storage was requested.
5. The dump address list must contain at least one address range.
6. The DUMP, DUMPDW and NORETURN parameters may not be specified on the same invocation of DIAGNOSE code X'94' with CLOSE, CANCEL, CONT, or NOCONT. See the VMDUMP command documentation for a list of other parameters with the same restriction.
7. When multiple DIAGNOSE code X'94' invocations are used in continuous output mode, the NORETURN parameter is only accepted on the first request which opens the file. Once successfully specified, it may be repeated on later requests. However, if it is not specified on the first request, subsequent requests (affecting the same VMDUMP file) that specify NORETURN cause an error.
8. When multiple DIAGNOSE code X'94' invocations are used in continuous output mode, the DUMP parameter may be specified on any request to dump storage.
9. You may not be authorized to issue this DIAGNOSE code if an external security manager is installed on your system. This restriction applies only to the VMDUMP TO command. For additional information, contact your security administrator.
10. Long-running DIAGNOSE code X'94' processing can be halted by the user by entering #CP CPHX. Another user can halt a user during DIAGNOSE code X'94' processing by using the CPHX or FORCE command. A TERM BRKKEY (normally set to PA1 key) will not halt DIAGNOSE code X'94' processing.
11. For more information on the VMDUMP command, see the Usage Notes in [z/VM: CP Commands and Utilities Reference](#).

## Usage Notes Regarding Dump Address Lists

1. The dump address list must contain at least one address range.
2. If the dump address list does not contain address space qualifiers then DIAGNOSE code X'94' processing will consider the address ranges in the dump address list to apply to the primary address space.
3. Because address space qualifiers are within the dump address list any address space qualifiers specified on the same DIAGNOSE code X'94' invocation with a DUMP *list-addr* option will not affect the addresses in the dump address list. For example, if the DIAGNOSE code X'94' parameter string contained

```
'ASIT 12A456B81B345F78 FORMAT CMS DUMP list-addr'
```

the address space qualifier ASIT 12A456B81B345F78 would apply only to the FORMAT CMS option. The addresses in the dump address list would either default to the primary address space or be qualified by the address-space-qualifier(s) within the dump address list.

You cannot specify dump ranges for the same address space in both the parameter list and the dump address list.

## Usage Notes Regarding Symptom Records

1. DIAGNOSE code X'94' processing always creates and records a symptom record when taking a dump. If the guest uses the SR or SRDW keyword, CP updates that symptom record and records it for the guest.
2. A symptom record is processed only if it resides within storage that the user is authorized by storage key to access. If the storage within which the symptom record resides is fetch-protected with a key other than that of the invoking program, the symptom record is not processed; if a dump was requested along with symptom record processing, CP generates a symptom record to be placed in the virtual machine dump. This record contains only CP environment information. A symptom record supplied by a virtual machine that executes in key zero is always processed, regardless of where in guest real storage the symptom record resides.
3. The program that issues the DIAGNOSE code X'94' must initialize the required fields within the symptom record with information describing a problem before it issues DIAGNOSE code X'94'.
4. CP updates the symptom record to contain the following information:
  - CP environment data in section 1
  - The architectural level of the CP symptom record processor (C'10') in section 2
  - Return and reason codes in section 2.1.

If the invoking program is running with a PSW key that is neither the storage key of the symptom record nor zero, the system records the symptom record but does not update the invoker's copy in virtual machine storage with CP environment data.

5. Symptom records which are over 3500 decimal bytes in length are truncated before being placed in a dump or made available to symptom record recording virtual machines.
6. All fields designated by an RS are updated within the caller's symptom record by CP. The conventions for initializing the contents of the RS (required from system service) fields are:
  - a. The customer-assigned system node name (ADSRID) is the value specified on the SYSTEM\_IDENTIFIER statement in the system configuration file for the CPU on which CP is running while processing the DIAGNOSE code X'94' request.
  - b. The ADSRTOD field is in Coordinated Universal Time (UTC). The ADSRGMT field contains the clock zone differential that may be of value to users who want to convert to local. If the STCK instruction completes with a nonzero condition code, the clock value (ADSRTIME) is hex zeros, and the printable time/date fields are blanks.
7. When the SR or SRDW parameter is coded, registers Rx+1 and Ry+1 reflect the results of symptom record processing in the form of hexadecimal return codes and reason codes. If the symptom record storage within the virtual machine can be written to, the ADSRRET and ADSRREA fields in section 2.1 contain these same results. The return code and reason code value reflect the most severe level of error that occurred. The reason code value contains the value for the first error found at the severity level indicated by the return code.
 

If the symptom strings in sections 3 and 4 contain other than alphanumeric or national characters, pound signs, slashes, or blanks, a return code of 4 and a reason code of X'0E08' are generated.
8. The SDB syntax of the symptoms in sections 3 and 4 is not validated.
9. If a DIAGNOSE code X'94' is issued with the SR or SRDW keyword in the parameter list, and section 1 of the symptom record is already initialized, the CP environment sections (RS fields) are not updated within the symptom record. An unmodified copy of the symptom record is sent to each virtual machine connected to the CP Symptom Recording system service (\*SYMPTOM). \*SYMPTOM is documented in [Chapter 22, "Symptom System Service \(\\*SYMPTOM\)," on page 771.](#)
10. The SR, SRDW and NODUMP parameters may not be specified on the same invocation of DIAGNOSE code X'94' with CLOSE, CANCEL, CONT, or NOCONT.
11. When multiple DIAGNOSE code X'94' invocations are used in continuous output mode, the SR or SRDW parameter can be specified on any one invocation to supply the symptom record in the dump. When a program issues a DIAGNOSE code X'94' request only to add a symptom record and does not

want to dump any areas of guest storage, it should include a dummy address range of zero. This is required because, if no address range or DUMP/DUMPDW address list is specified, all of guest storage is dumped. Because page zero is always included in VMDUMP files, a request such as *0 SR addr* does not result in any added output.

## 12. Input symptom record storage

Unused space is not compressed from the symptom record. The symptom record sections are written in the sequence and at the displacements in which they are presented. No unused symptom record storage should be passed by means of the DIAGNOSE code X'94' instruction. For example, there should not be preassigned, unused space at the end of symptom record sections 3, 4, or 5. The length for that section (contained in section 2) should only be the length of the *used* portion of the section when the DIAGNOSE code X'94' is issued; otherwise, the common storage that is allocated to the service routine and the CMS symptom record file contain wasted space.

## 13. Symptom record recording considerations

When a DIAGNOSE code X'94' is issued with a parameter list containing an SR or SRDW keyword, CP sends copies of the symptom record asynchronously to authorized virtual machines that are connected to the CP Symptom Recording system service (\*SYMPTOM). Control is returned to the virtual machine that issued the DIAGNOSE code X'94' instruction after a copy of the symptom record is placed on the recording queue. For more information on \*SYMPTOM, see [Chapter 22, "Symptom System Service \(\\*SYMPTOM\)," on page 771](#).

# Responses

**Condition Codes and Return Codes:** Upon completion of DIAGNOSE code X'94', control is returned to the invoker with a condition code set to indicate the status of both input parameter list processing and dump processing. A return code in Ry indicates the results of processing the input parameter string and the dump request (if present).

If symptom record processing was requested, return and reason codes in registers Ry+1 and Rx+1, respectively, indicate the result of symptom record processing (condition codes are not used to reflect the status of symptom record processing).

The condition codes are listed in [Table 7 on page 120](#).

*Table 7. DIAGNOSE Code X'94' Condition Codes*

| Condition Code | Meaning                                                                                                                                                              |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | The function has completed successfully. All requested ranges have been dumped.                                                                                      |
| 1              | The function completed with error(s). Portions of the requested address ranges have been dumped. Ry contains a return code which indicates the reason for the error. |
| 2              | The function failed. No dump has been created. Ry contains a return code which indicates the reason for the failure.                                                 |

The return codes in Ry are listed in [Table 8 on page 120](#).

*Table 8. DIAGNOSE Code X'94' Return Codes*

| Condition Code | Return Code | Meaning                                                                                                                                                                                                                                                         |
|----------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0,1            | 0 (X'00')   | Successful completion. <ul style="list-style-type: none"> <li>CC = 0 indicates that all requested areas were dumped.</li> <li>CC = 1 indicates that the DCSS operand was specified without any ranges or dump address list, and no DCSSs are loaded.</li> </ul> |
| 2              | 4 (X'04')   | Parameter list exceeds 240 bytes.                                                                                                                                                                                                                               |

Table 8. DIAGNOSE Code X'94' Return Codes (continued)

| Condition Code | Return Code | Meaning                                                                                                                                                                                                                                                                                                                                            |
|----------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1,2            | 8 (X'08')   | System I/O error reading a guest page.<br><ul style="list-style-type: none"> <li>• CC = 1 indicates that at least one requested page could not be dumped.</li> <li>• CC = 2 indicates that the parameter list or dump address list could not be accessed.</li> </ul>                                                                               |
| 1,2            | 12 (X'0C')  | Storage access violates guest fetch protection.<br><ul style="list-style-type: none"> <li>• CC = 1 indicate that at least one requested page could not be dumped.</li> <li>• CC = 2 indicates that the parameter list or dump address list could not be accessed.</li> </ul>                                                                       |
| 2              | 16 (X'10')  | Invalid dump address range. More than 2,049 dump address lists, ending address less than start, or range length of 0 given, or too many ranges in the address list. (A single list must fit within a page of storage.)                                                                                                                             |
| 2              | 20 (X'14')  | Conflicting options.                                                                                                                                                                                                                                                                                                                               |
| 2              | 24 (X'18')  | Userid missing or longer than eight characters.                                                                                                                                                                                                                                                                                                    |
| 2              | 28 (X'1C')  | hexloc missing or invalid hexadecimal value. If dump address list is used, number of ranges specified was zero.                                                                                                                                                                                                                                    |
| 2              | 32 (X'20')  | Required parameter missing or invalid.                                                                                                                                                                                                                                                                                                             |
| 2              | 36 (X'24')  | User ID not in directory.                                                                                                                                                                                                                                                                                                                          |
| 2              | 40 (X'28')  | Spooling error.                                                                                                                                                                                                                                                                                                                                    |
| 2              | 44 (X'2C')  | hexloc exceeds storage size.                                                                                                                                                                                                                                                                                                                       |
| 2              | 48 (X'30')  | Return code unused but reserved for compatibility with VM/SP, VM/SP HPO, and VM/ESA (370 Feature)                                                                                                                                                                                                                                                  |
| 2              | 52 (X'34')  | Invalid address points to storage outside of user area.                                                                                                                                                                                                                                                                                            |
| 2              | 56 (X'38')  | Soft abend occurred during processing.                                                                                                                                                                                                                                                                                                             |
| 1, 2           | 60 (X'3C')  | Unaddressable range given. At least one range given was above guest storage and did not fall within a discontinuous saved segment. The unaddressable ranges are not dumped.<br><ul style="list-style-type: none"> <li>• CC=1 indicates the valid addresses given are dumped.</li> <li>• CC=2 indicates that no valid ranges were given.</li> </ul> |
| 2              | 64 (X'40')  | For an XC virtual machine in access-register mode: ALET in the parameter list is missing or invalid                                                                                                                                                                                                                                                |
| 2              | 68 (X'44')  | For an XC virtual machine in access-register mode: Access register is missing or invalid.                                                                                                                                                                                                                                                          |
| 2              | 72 (X'48')  | For an XC virtual machine in access-register mode: ASIT in the parameter list is missing or invalid.                                                                                                                                                                                                                                               |
| 2              | 76 (X'4C')  | For an XC virtual machine in access-register mode: Address-space identifier in the parameter list is missing or invalid.                                                                                                                                                                                                                           |

*Table 8. DIAGNOSE Code X'94' Return Codes (continued)*

| <b>Condition Code</b> | <b>Return Code</b> | <b>Meaning</b>                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                     | 80 (X'50')         | For an XC virtual machine in access-register mode: An address space has become inaccessible to your virtual machine. One or more pages associated with that address space were not dumped.                                                                                                                                                                                           |
| 2                     | 84 (X'54')         | You have used an operand that is not valid for your virtual machine mode or architecture mode.                                                                                                                                                                                                                                                                                       |
| 1                     | 92 (X'5C')         | CP cannot add the requested information to the current virtual machine dump. Either more than 200 address spaces have been requested, or there have been more DIAGNOSE X'94' invocations requesting data from a single address space than allowed. Only 900 invocations are allowed for ESA/390 and ESA/XC architecture and 500 invocations are allowed for z/Architecture and z/XC. |
| 2                     | 96 (X'60')         | Unable to access the address space due to an ALEN-translation exception condition.                                                                                                                                                                                                                                                                                                   |
| 2                     | 100 (X'64')        | Unable to access the address space due to an ALET-specification exception condition.                                                                                                                                                                                                                                                                                                 |
| 2                     | 104 (X'68')        | Unable to access the address space with the specified address space identifier (addressing-capability exception condition).                                                                                                                                                                                                                                                          |
| 2                     | 108 (X'6C')        | Authorization request failed.                                                                                                                                                                                                                                                                                                                                                        |
| 2                     | 112 (X'70')        | Unable to access the address space with the specified ASIT (addressing-capability exception condition).                                                                                                                                                                                                                                                                              |
| 2                     | 116 (X'74')        | The parameter list or dump address list is in a space that does not exist or that you are not authorized to access.                                                                                                                                                                                                                                                                  |
| 2                     | 120 (X'78')        | The space designated by the ALET parameter or the address space qualifier in the dump address list cannot be accessed due to an addressing-capability exception condition.                                                                                                                                                                                                           |
| 2                     | 124 (X'7C')        | The space designated by the AREG parameter cannot be accessed due to an addressing-capability exception condition.                                                                                                                                                                                                                                                                   |
| 1                     | 132(X'84')         | Processing halted by CPHX or FORCE command.                                                                                                                                                                                                                                                                                                                                          |

Upon completion of DIAGNOSE code X'94', if the SR or SRDW parameter was specified, the return codes shown in [Table 9 on page 122](#) are placed in Ry+1:

*Table 9. DIAGNOSE X'94' Symptom Record Processing Return Codes*

| <b>Return Code</b> | <b>Meaning</b>                                                                                                |
|--------------------|---------------------------------------------------------------------------------------------------------------|
| 0 (X'00')          | Successful completion. The symptom record was recorded and updated (if necessary) in virtual machine storage. |
| 4 (X'04')          | Error(s) detected within the DIAGNOSE code X'94' request. The entire input symptom record was recorded.       |
| 8 (X'08')          | Error(s) detected within the DIAGNOSE code X'94' request. A partial symptom record was recorded.              |

Table 9. DIAGNOSE X'94' Symptom Record Processing Return Codes (continued)

| Return Code | Meaning                                                                                                |
|-------------|--------------------------------------------------------------------------------------------------------|
| 18 (X'12')  | An error was detected within the DIAGNOSE code X'94' request. None of the symptom record was recorded. |
| 22 (X'16')  | An error was detected within the DIAGNOSE code X'94' service. None of the symptom record was recorded. |

The reason code shown in [Table 10 on page 123](#) may be returned in Rx+1 when Ry+1 contains a return code value of X'00':

Table 10. DIAGNOSE X'94' Reason Codes for Return Code X'00'

| Reason Code | Meaning               |
|-------------|-----------------------|
| X'0000'     | Successful completion |

The reason codes shown in [Table 11 on page 123](#) may be returned in Rx+1 when Ry+1 contains a return code value of X'04':

Table 11. DIAGNOSE X'94' Reason Codes for Return Code X'04'

| Reason Code | Meaning                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| X'0164'     | The input symptom record was copied, but the key of the storage containing the symptom record did not allow the symptom record to be updated. |
| X'0E08'     | The input symptom record was processed, but invalid characters were found in section 3 or 4.                                                  |

The reason codes shown in [Table 12 on page 123](#) may be returned in Rx+1 when Ry+1 contains a return code value of X'08':

Table 12. DIAGNOSE X'94' Reason Codes for Return Code X'08'

| Reason Code | Meaning                                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'0158'     | The total length of the input symptom record exceeds 3500 decimal bytes.                                                                                        |
| X'015C'     | Optional portions of the input symptom record were not in accessible storage. The resulting record includes all accessible entries of the input symptom record. |

The reason codes shown in [Table 13 on page 123](#) may be returned in Rx+1 when Ry+1 contains a return code value of X'12':

Table 13. DIAGNOSE X'94' Reason Codes for Return Code X'12'

| Reason Code | Meaning                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| X'0104'     | The first two bytes of the symptom record do not contain the characters SR.                                                                        |
| X'0108'     | The input symptom record does not contain the required entries of section 2.                                                                       |
| X'010C'     | The input symptom record does not contain the required entries of section 2.1.                                                                     |
| X'0114'     | The input symptom record does not contain the required entries of section 3.                                                                       |
| X'012C'     | Required portions of the input symptom record are not in accessible storage.                                                                       |
| X'0E04'     | The input symptom record is a duplicate; a continuous mode dump is being processed, and a symptom record has already been placed in the dump file. |

## DIAGNOSE Code X'98' – Real I/O

**Privilege Class:** Any

**Addressing Mode:** 31-bit

Using DIAGNOSE code X'98', a virtual machine can lock and unlock virtual pages and can execute its own real channel programs.

The subfunctions of DIAGNOSE code X'98' are LOCK, UNLOCK, and SSCH-Real. The requested subfunction is identified by a code in the Rx register. The LOCK subfunction locks a single 4 KB page of virtual machine storage in host real storage. In addition, it returns to the virtual machine the absolute storage address of the frame used to lock the guest page. The UNLOCK subfunction unlocks a single 4 KB page of virtual machine storage that was previously locked by DIAGNOSE code X'98'. In addition, multiple 4 KB pages can be locked or unlocked by invoking the Block Diagnose X'98' Request. This allows multiple occurrences of a Diagnose X'98' subfunction to be executed with only a single invocation of the Diagnose instruction. The SSCH-Real subfunction initiates execution of a real channel program for XA, ESA, XC, and Z virtual machines.

DIAGNOSE code X'98' allows a virtual machine to bypass CCW translation and initiate execution of real channel programs. Execution of this DIAGNOSE bypasses most software and hardware protection mechanisms. For example, the virtual machine is able to read from, or write to, **any** frame in storage that does not have a storage key of 0. If the virtual machine is running a program with an error in it, system (that is, other users) security and integrity may be compromised. The ability to execute DIAGNOSE code X'98' is controlled by the directory OPTION statement, and should be granted only to the most trusted programs after careful consideration of the possible security and integrity exposures.

### LOCK Subfunction

This subfunction locks a selected page of virtual machine absolute storage into host real storage below 2 GB, thus excluding the page from future paging activity. Locking pages can enhance the efficiency of a particular virtual machine by keeping frequently-used pages resident in real storage. When the LOCK subfunction is issued, it operates exactly like the LOCK command, obtaining a real storage page from the normal paging area.

#### Entry Values:

##### Rx

contains X'00000000' the subfunction code

##### Ry

contains the guest absolute address to be translated and locked. Ry cannot be register 15.

##### Ay

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the page to be locked. This address space must be owned by the virtual machine issuing DIAGNOSE code X'98'. If Ry designates general register 0, if Ay contains X'00000000', or if the virtual machine is not in XC mode, the page to be locked is in the host-primary address space.

#### Exit Values:

##### Ry+1

contains one of the following:

- The host absolute address (set by CP with condition code 0)
- A return code (set by CP with condition code 3):

| Return Code | Meaning                           |
|-------------|-----------------------------------|
| 1 (X'01')   | Reserved.                         |
| 2 (X'02')   | This is an invalid guest address. |

| Return Code | Meaning                                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3 (X'03')   | Page cannot be locked.                                                                                                                                                                    |
| 5 (X'05')   | ALET-specification exception condition for an XC virtual machine in access-register mode: Ay contains an ALET that cannot be translated.                                                  |
| 6 (X'06')   | ALEN-translation exception condition for an XC virtual machine in access-register mode: Ay contains an ALET that cannot be translated.                                                    |
| 7 (X'07')   | For an XC virtual machine in access-register mode, the issuer of this DIAGNOSE is not the owner of the address space or the issuer is the owner but the address space has been destroyed. |

## UNLOCK Subfunction

This subfunction unlocks a page of virtual machine storage that was previously locked by DIAGNOSE code X'98'. Real storage pages become available for normal paging operations.

### Entry Values:

#### Rx

contains X'00000004'—the subfunction code

#### Ry

contains the guest absolute address of the page to be unlocked

#### Ay

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the page to be unlocked. This address space must be owned by the virtual machine issuing DIAGNOSE code X'98'. If Ry designates general register 0, if Ay contains X'00000000', or if the virtual machine is not in XC mode, the page to be unlocked is in the host-primary address space.

**Exit Values:** If UNLOCK was successful, the condition code is 0 and Ry+1 is unchanged.

If UNLOCK was not successful, the condition code is 3 and Ry+1 contains one of the following return codes:

| Return Code | Meaning                                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 (X'01')   | Reserved.                                                                                                                                                                                 |
| 2 (X'02')   | This is an invalid guest address                                                                                                                                                          |
| 3 (X'03')   | Page is already unlocked                                                                                                                                                                  |
| 5 (X'05')   | ALET-specification exception condition for an XC virtual machine in access-register mode: Ay contains an ALET that cannot be translated.                                                  |
| 6 (X'06')   | ALEN-translation exception condition for an XC virtual machine in access-register mode: Ay contains an ALET that cannot be translated.                                                    |
| 7 (X'07')   | For an XC virtual machine in access-register mode, the issuer of this DIAGNOSE is not the owner of the address space or the issuer is the owner but the address space has been destroyed. |

## SSCH-Real Subfunction

This subfunction initiates execution of a real channel program that the virtual machine has built in locked pages of storage. The address of the first CCW in the ORB is a host absolute address, as are the data addresses and transfer addresses (in TIC CCWs). For more information on ORB, see the Enterprise Systems Architecture/390 Principles of Operation ([publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf](http://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf)), *z/VM: ESA/XC Principles of Operation*, *z/Architecture Principles of Operation* (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>), or *z/VM: z/Architecture Extended Configuration (z/XC)*

*Principles of Operation*, based on the architecture mode of the virtual machine. This subfunction is valid for an XA, ESA, XC, or Z virtual machine, and it operates as a SSCH instruction. Condition codes 0, 1, and 2 are compatible with normal virtual I/O operation of that instruction. Condition code 3 is extended to provide a return code to indicate error conditions unique to the Real I/O interface. The device identified by the parameter register must be defined and dedicated or a full-pack minidisk. The device cannot be read/only. To protect host storage from overlay by guest Real I/O, the subchannel key in the ORB must be nonzero.

**Entry Values:**
**R1**

contains the subsystem identification (SID) for the virtual device

**Rx**

contains X'0000000C'—the subfunction code

**Ry**

contains the guest logical address of the ORB.

**Ay**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the ORB. If Ry designates general register 0, if Ay contains X'00000000', or if the virtual machine is not in XC mode, the ORB is in the host-primary address space.

**Exit Values:**
**Ry+1**

contains the return code (set by CP with condition code 3), as follows:

| Return Code | Meaning                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 (X'01')   | The device is not operational or is not attached.                                                                                                  |
| 2 (X'02')   | The device is neither dedicated nor a full-pack minidisk, or is read-only, or the device is already active with a system function such as SPXTAPE. |
| 3 (X'03')   | The subchannel key in the ORB is zero.                                                                                                             |

## Block Diagnose X'98' Request

Use the Block Diagnose X'98' subfunction to allow multiple occurrences of a Diagnose X'98' subfunction to be executed with only a single invocation of the Diagnose instruction. Both the LOCK and UNLOCK subfunctions are supported with the Block Diagnose X'98' instruction.

**Entry Values:**
**Rx**

contains X'00000010'— the subfunction code to specify a Block Diagnose X'98' request.

**Ry**

contains the real address of a Diagnose X'98' Multiple Request Block for the function to be performed. The address must be on a word boundary; otherwise a specification exception will occur.

Ry cannot be register 15.

**Exit Values:**
**Ry+1**

A global return code reflected by the Diagnose X'98' processor, which specifies the overall results of the Block Diagnose X'98' request.

The global return code may be checked by the program to quickly determine whether all specified Diagnose X'98' subfunctions within the array have completed successfully. If the global return code is zero, there is no need to examine each individual RC field value in order to determine successful completion.

| Return Code | Meaning                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')   | All requests completed successfully.                                                                                                    |
| 1 (X'01')   | One or more requests specified in the Diagnose X'98' Multiple Request Block RC field must be checked to determine the failing requests. |
| 2 (X'02')   | Reserved.                                                                                                                               |
| 3 (X'03')   | Reserved.                                                                                                                               |
| 4 (X'04')   | Reserved. Not used by z/VM.                                                                                                             |
| 5 (X'05')   | Invalid value specified in the Diagnose X'98' Multiple Request Block DIAG field.                                                        |
| 6 (X'06')   | Invalid value specified in the Diagnose X'98' Multiple Request Block FCN field.                                                         |
| 7 (X'07')   | Invalid value specified in the Diagnose X'98' Multiple Request Block LENGTH field.                                                      |

## Diagnose X'98' Multiple Request Block

The Diagnose X'98' Multiple Request Block is used by the program to specify multiple occurrences of a single Diagnose X'98' subfunction to CP for execution. The Diagnose X'98' Multiple Request Block is a self defining control block, which is divided into two sections. The first section is the Diagnose X'98' Multiple Request Block Fixed Header which is used to define the control block, provide parameters, a response area, and is global to the entire request. This fixed header section is common for all Block Diagnose X'98' requests.

The second section of this request block is variable in size, containing an array of Diagnose X'98' subfunction requests. The number of requests within the array is determined from the LENGTH and FCN fields specified in the fixed area of the request block. The data within an array entry is determined by the FCN code specified, which can be the LOCK subfunction (FCN code X'00'), the UNLOCK subfunction (FCN code X'04'), or the RELEASE AND LOCK subfunction (FCN code X'20').

The following is the layout for the entire Diagnose X'98' Multiple Request Block:

## DIAGNOSE Code X'98'

**Diagnose X'98' Multiple Request Block Fixed Header:** The fixed header section of the Diagnose X'98' Multiple Request Block has a length of 16 bytes for all requests. The following is a list of fields which make up the fixed header:

### DIAG

Is the halfword DIAGNOSE code. It must contain the halfword X'0098'.

### FCN

Specifies the Diagnose X'98' subfunction:

**X'00'**

LOCK

**X'04'**

UNLOCK

**X'20'**

RELEASE AND LOCK

### LENGTH

Is the length in bytes of the entire Diagnose X'98' Multiple Request Block. The valid range for the length field is X'28' to X'1000'.

////////

Indicates fields reserved for future use.

### LOCK Subfunction FCN Code X'00'

The LOCK subfunction locks multiple pages of a virtual machine's absolute storage into host real storage below 2 GB, thus excluding the pages from future paging activities. When the LOCK function is issued, it

is identical to issuing multiple CP LOCK commands, obtaining real storage frames from the normal paging area.

An XC virtual machine can lock pages only within the host-primary address space. The Ay register is ignored.

The following structure is required for each individual LOCK request included in the array area of a FCN=X'00' Diagnose X'98' Multiple Request Block:

|    |                        |      |      |    |
|----|------------------------|------|------|----|
| 0  | GUEST ABSOLUTE ADDRESS |      |      |    |
| 8  | HOST ABSOLUTE ADDRESS  |      |      |    |
| 10 | ////////////////////   | //// | PARM | RC |

**GUEST ABSOLUTE ADDRESS**

Is the 8-byte guest absolute address that the program wants to lock in host storage. The 4 KB page which contains the specified address will be locked in host storage. The value specified does not need to be on a page boundary.

**HOST ABSOLUTE ADDRESS**

Is the 8-byte host absolute address for the program-specified GUEST ABSOLUTE ADDRESS, which is returned by CP upon a successful completion of the lock request. Zeros will be returned if the lock request was not successful.

**PARM**

Is not used by the LOCK subfunction. (PARM is used only by the RELEASE AND LOCK subfunction.)

**RC**

Is a 2-byte return code which specifies the completion status of this individual Diagnose X'98' subfunction request. The following return codes may be returned for the LOCK subfunction:

| Return Code             | Meaning                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| 0 (X'00')               | LOCK request completed successfully. The HOST ABSOLUTE ADDRESS field will contain the translated address. |
| 1 (X'01')               | Reserved.                                                                                                 |
| 2 (X'02')               | Invalid guest address specified in the GUEST ABSOLUTE ADDRESS field.                                      |
| 3 (X'03')               | Page is already locked by Diagnose X'98'.                                                                 |
| 4 (X'04')               | Page is currently resident above 2 GB and cannot be moved to LOCK.                                        |
| 5-7 (X'05'-X'07')       | Reserved for future use.                                                                                  |
| 8 (X'08')               | Paging error occurred while attempting to lock the page.                                                  |
| 9-65535 (X'09'-X'FFFF') | Reserved for future use.                                                                                  |

////////

Indicates fields reserved for future use.

**UNLOCK Subfunction FCN Code X'04'**

The UNLOCK subfunction unlocks multiple pages of virtual machine storage that were previously locked by Diagnose code X'98'. The real storage frames that are unlocked will become available again for normal CP paging.

The following structure is required for each individual UNLOCK request included in the array area of a FCN=X'04' Diagnose X'98' Multiple Request Block:

|    |                        |      |                      |    |
|----|------------------------|------|----------------------|----|
| 0  | GUEST ABSOLUTE ADDRESS |      |                      |    |
| 8  | ////////////////////   |      | //////////////////// |    |
| 10 | ////////////////////   | //// | PARM                 | RC |

**GUEST ABSOLUTE ADDRESS**

Is the 8-byte guest absolute address that the program wants to unlock in CP storage. The 4 KB page which contains the specified address will be unlocked in CP storage. The value specified does not need to be on a page boundary.

**PARM**

Is not used by the UNLOCK subfunction. (PARM is used only by the RELEASE AND LOCK subfunction.)

**RC**

Is a 2-byte return code which specifies the completion status for this individual Diagnose X'98' subfunction request. The following return codes may be returned for the UNLOCK Subfunction:

| Return Code             | Meaning                                                              |
|-------------------------|----------------------------------------------------------------------|
| 0 (X'00')               | UNLOCK request completed successfully.                               |
| 1 (X'01')               | Reserved.                                                            |
| 2 (X'02')               | Invalid guest address specified in the GUEST ABSOLUTE ADDRESS field. |
| 3 (X'03')               | Page is already unlocked.                                            |
| 4-7 (X'04'-X'07')       | Reserved for future use.                                             |
| 8 (X'08')               | Paging error occurred while attempting to unlock the page.           |
| 9-65535 (X'09'-X'FFFF') | Reserved for future use.                                             |

////////

Indicates fields reserved for future use.

**RELEASE AND LOCK Subfunction FCN Code X'20'**

The RELEASE AND LOCK subfunction clears multiple pages of a virtual machine's absolute storage and locks them in real storage, based on the value specified in the PARM field, thus excluding the pages from future paging activities. A PARM value of X'01' indicates that the page can be locked anywhere in real storage, but the preference will be to lock it in storage above 2 GB. A PARM value of X'02' indicates that the page must be locked in real storage below 2 GB. If the page is already resident in storage above 2 GB, it must be moved.

When the RELEASE AND LOCK function is issued, it is identical to issuing multiple CP LOCK commands, obtaining real storage frames from the normal paging area.

An XC virtual machine can lock pages only within the host-primary address space. The Ay register is ignored.

The following structure is required for each individual RELEASE AND LOCK request included in the array area of a FCN=X'20' Diagnose X'98' Multiple Request Block:

|    |                        |      |      |    |
|----|------------------------|------|------|----|
| 0  | GUEST ABSOLUTE ADDRESS |      |      |    |
| 8  | HOST ABSOLUTE ADDRESS  |      |      |    |
| 10 | ////////////////////   | //// | PARM | RC |

**GUEST ABSOLUTE ADDRESS**

Is the 8-byte guest absolute address that the program wants to lock in host storage. The 4 KB page which contains the specified address will be locked in host storage. The value specified does not need to be on a page boundary.

**HOST ABSOLUTE ADDRESS**

Is the 8-byte host absolute address for the program-specified GUEST ABSOLUTE ADDRESS, which is returned by CP upon a successful completion of the lock request. Zeros will be returned if the lock request was not successful.

**PARM**

Specifies where in real storage the page will be locked:

**X'01'**

Lock the page anywhere in storage, with a preference of above 2 GB.

**X'02'**

Lock the page below 2 GB.

**RC**

Is a 2-byte return code which specifies the completion status of this individual Diagnose X'98' Subfunction request. The following return codes may be returned for the RELEASE AND LOCK subfunction:

| Return Code               | Meaning                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')                 | RELEASE AND LOCK request completed successfully. The HOST ABSOLUTE ADDRESS field will contain the translated address. |
| 1 (X'01')                 | Reserved.                                                                                                             |
| 2 (X'02')                 | Invalid guest address specified in the GUEST ABSOLUTE ADDRESS field.                                                  |
| 3 (X'03')                 | Page is already locked by Diagnose X'98'.                                                                             |
| 4 (X'04')                 | Page is currently resident above 2 GB and could not be moved to LOCK.                                                 |
| 5-7 (X'05'-X'07')         | Reserved for future use.                                                                                              |
| 8 (X'08')                 | Paging error occurred while attempting to lock the page.                                                              |
| 9 (X'09')                 | Release of Shared Readable/Exclusive Readable is not allowed.                                                         |
| 10 (X'0A')                | Invalid PARM value specified.                                                                                         |
| 11 (X'0B')                | Storage could not be disassociated from the page.                                                                     |
| 12-65535 (X'0C'-X' FFFF') | Reserved for future use.                                                                                              |

//////

Indicates fields reserved for future use.

**Block Diagnose X'98' Request Condition Codes**

The following are the condition codes which may be set on completion of a Block Diagnose X'98' Request:

| Condition Code | Meaning                                   |
|----------------|-------------------------------------------|
| 0              | All requests completed successfully.      |
| 3              | Non-zero global return code was returned. |

**Usage Notes**

1. If you attempt to lock a prefix page in a virtual multiprocessor configuration, an error code of 2 is returned.

2. If you attempt to lock a page that has been mapped with the DEFINE function of the MAPMDISK macro, an error code of 2 is returned.
3. The LOCK subfunction requires an available real storage frame in the area the system uses for paging.
4. If you LOCK a page in a shared segment and do not issue an UNLOCK, the page will be unlocked when the last user of the shared segment releases the storage at LOGOFF (or uses another command which clears storage).
5. The LOCK command issued for a user ID's virtual pages operates independently of the DIAGNOSE code X'98' page locking facility. Pages locked by the LOCK command cannot be unlocked by DIAGNOSE code X'98', nor can pages locked by DIAGNOSE code X'98' be unlocked by the UNLOCK command.
6. Pages that are locked by DIAGNOSE code X'98' are not unlocked by the operation of the ADRSPACE ISOLATE and ADRSPACE PERMIT macros (see [“ADRSAPCE — Address Space Services”](#) on page 811).
7. SSCH-Real does not support suspend/resume in channel programs. New I/O starts cannot be executed before previous I/O operations are concluded (early redrive is not supported).
8. At completion of an I/O operation started by DIAGNOSE code X'98', the CCW address returned to the virtual machine in the IRB on an XA, ESA, XC, or Z Test Subchannel instruction is a host absolute address.
9. The address-limit-checking facility of the Channel Subsystem is not available to users of the DIAGNOSE code X'98' SSCH-Real. The host absolute addresses used in the channel program are random addresses from the viewpoint of the virtual machine, so limit checking is meaningless. If the address-limit-checking control is set on in the ORB, it is ignored by the control program when scheduling the I/O.
10. If too many pages of real storage are locked, there may not be enough remaining frames to allow the system to operate efficiently. It is important for the system programmer to control the use of this facility.

## Responses

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'98' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                                                                     |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| Operand exception (z/VM SSCH-real subfunction only)                   | Any of the following: <ul style="list-style-type: none"> <li>Invalid subchannel ID</li> <li>Invalid entries in the ORB.</li> </ul>        |
| Operation exception                                                   | The user does not have the correct directory authorization.                                                                               |
| Specification exception                                               | Any of the following: <ul style="list-style-type: none"> <li>Ry=R15, Rx=Ry, or Rx=Ry+1</li> <li>Unknown subfunction requested.</li> </ul> |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                              |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch the ORB (SCCH-real subfunction).                                                                        |

**Program Exceptions:** These program exceptions can occur when issuing a Block X'98' request.

| Problem Encountered | Cause                                                                                                                                                                    |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Operation exception | The virtual machine is not authorized to issue a Diagnose X'98' instruction. The virtual machine must have the OPTION DIAG98 specified in its CP system directory entry. |

| Problem Encountered     | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## DIAGNOSE Code X'9C' – Voluntary Time Slice Yield

**Privilege Class:** Any

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

Use DIAGNOSE code X'9C' to notify the scheduler that a spin lock loop exists in your virtual machine. DIAGNOSE code X'9C' informs the scheduler that the remainder of the CPU time slice allocated to a virtual CPU is no longer useful and that another virtual CPU in your virtual machine should be favored for execution by the scheduler.

**Entry Values:**

**Rx**

In z/Architecture mode, bits 0-31 of register Rx are ignored, bits 48-63 contain the CPU address of the virtual CPU that should be favored by the scheduler for execution, and bits 32-47 are unused and should contain zeros. In ESA/390 mode, bits 16-31 of register Rx contain the CPU address of the virtual CPU that should be favored by the scheduler for execution and bits 0-15 are unused and should contain zeros.

## Usage Notes

1. DIAGNOSE code X'9C' is useful when the operating system on one guest CPU is waiting to obtain a spin lock, and it is known which other guest CPU is holding the lock and needs to be run before the issuing guest CPU can again run productively.
2. The virtual CPU that issues DIAGNOSE code X'9C' will have its dispatching priority modified such that the target virtual CPU specified in Rx will generally run before the issuing virtual CPU is run again. If there is no other virtual CPU for this virtual machine, or the specified virtual CPU does not exist, then DIAGNOSE code X'9C' has no effect.
3. The effects of DIAGNOSE code X'9C' are temporary. After a brief time, the virtual CPU is scheduled as if the DIAGNOSE were never issued.

## Responses

**Program Exceptions:** These program exceptions can occur when issuing DIAGNOSE code X'9C' :

| Problem Encountered            | Cause                                        |
|--------------------------------|----------------------------------------------|
| Privileged-operation exception | The virtual machine is in the problem state. |

## DIAGNOSE Code X'A0' – Obtain ACI Information

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'A0' to:

- Return the Access Control Interface (ACI) groupname for a given user ID (subcode 0)
- Determine whether an External Security Manager (ESM) is installed (subcode 8).
- Return External Security Manager (ESM) product information (subcode 72 (X'48')).

**Note:** Only the basic DIAGNOSE code X'A0' interface is described in this book. An external security manager (ESM) may extend that interface, for its own internal use or as an API.

DIAGNOSE code X'A0' cannot be issued in access-register mode in an XC virtual machine.

### Entry Values:

#### Rx

For subcode 0, Rx contains the guest real address of a 16-byte doubleword aligned buffer. The first 8 bytes of this buffer contains a user ID (left-justified, followed by spaces) passed as input. The second 8 bytes are used by CP to pass the groupname back to the guest. For subcode 8 Rx is not used. For subcode 72 Rx contains the guest real address of a doubleword aligned buffer to receive the ESM Product Information, this buffer should be 277 bytes in length to ensure that it will accommodate the maximum amount of data that might be returned.

#### Ry

Contains a right-adjusted subcode value:

- 0 — to request the return of the groupname associated with the input user ID
- 8 — to request a test to determine if an ESM is installed.
- 72 — to request ESM product information.

**Note:** An ESM may support additional subcode values. If you have an ESM installed, consult the ESM documentation for information on such extensions, their register usage, and applicable restrictions.

### Exit Values:

Normal Exit:

#### Rx

Unchanged

#### Ry

Unchanged

- For subcode 0, the guest condition code is set to 0 on a successful request.
- For subcode 8, the guest condition code is set to 0 if the ACI program has been installed, or to 1 if it has not been installed.
- For subcode 72 returned ESM product information is in the following format:

#### ESM name

8-byte character string

#### ESM version

4-byte character string

#### ESM is active

Flag byte (bit 0 indicates ESM is active)

**Vendor name**

8-byte character string

**ESM product information**

1-byte length of the following variable length character string

Error with Exit:

**Rx**

Unchanged

**Ry**

Unchanged.

- For subcode 0, the user ID that was specified is invalid. The condition code is set to 1.

## Responses

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'A0' is given incorrect data:

Table 14. DIAGNOSE X'A0' Program Checks

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                     |

| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch the user ID or store either the group name or the ESM product information.                                                                                                                              |

## DIAGNOSE Code X'A4' – Synchronous I/O (Standard CMS Blocksize)

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'A4' to perform synchronous input/output operations to a direct access device formatted by CMS and supported by z/VM. Using DIAGNOSE code X'A4' ensures that CP will construct the appropriate channel program for the device being accessed. DIAGNOSE code X'A4' operates in all supported virtual machine architectures. Results of the I/O operation are contained in the synchronous block I/O parameter list (HCPSBIOP) and in the condition code and return code.

**Entry Values:**

**Rx**

contains the real address of the synchronous block I/O parameter list (HCPSBIOP). The address must be on a word boundary; otherwise a specification exception will occur.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the synchronous block I/O parameter list (HCPSBIOP) and list of block entries (see [“Block Entries \(SBILIST\)”](#) on page 140). If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the HCPSBIOP and SBILIST are in the host-primary address space.

Three different I/O operations can be performed through DIAGNOSE code X'A4': READ, WRITE, and FORMAT.

Operations are specified using the request-type field of the HCPSBIOP. The way to request each operation shown, see [“Synchronous Block I/O Parameter List \(HCPSBIOP\)”](#) on page 136.

Synchronous Block I/O Parameter List (HCPSBIOP)

The synchronous block I/O parameter list (HCPSBIOP) is the parameter list that DIAGNOSE code X'A4' uses in controlling the block I/O request. The parameters for read and write I/O operations include:

- Virtual device number
- Storage protection key
- Request type
- Block size
- Address of the block number/data address list
- Number of pairs in the block number/data address list
- Number of blocks processed by CP
- Device and subchannel status
- Residual count
- Sense data count
- Sense data.

These fields of the HCPSBIOP must be filled in:

- Virtual device number
- Storage protection key
- Request type
- Block size
- Address of the block entries list
- Number of pairs in the block entries list.

See the Responses section for the HCPSBIOP fields that are filled in upon completion of the operation.

The HCPSBIOP for the read and write request type is as follows (the HCPSBIOP COPY file is provided in the HCPGPI macro library):

SBIOPI DSECT

| 14 | Sense Data               |                          |      |                          |              |             |  |
| 16 |                          |                          |      |                          |              |             |  |
| 18 |                          |                          |      |                          |              |             |  |
| 20 |                          |                          |      |                          |              |             |  |
| 22 |                          |                          |      |                          |              |             |  |

The fields in this HCPSBIOP are defined as follows:

**Device Number**

Bits 0 through 15 of word 0 contains a virtual device number (1 to 4 digits) of the DASD to which this operation is targeted. The DASD must be fully supported. This field is filled in by the issuer of the DIAGNOSE, and is returned unchanged.

**Storage Protection Key**

Bits 16 through 19 of word 0 contain the subchannel key for all fetching of output data and for the storing of input data associated with the start function. This key is matched with a storage key during these storage references. Bits 20 through 23 must be zeros; otherwise an operand exception occurs. Bit 20 represents suspend control, which is not supported. The storage protection key is filled in by the issuer of the DIAGNOSE and is returned unchanged.

**I/O Request Type**

Bits 30 through 31 of word 0 contain the request type for this I/O operation. If bit 30 of word 0 is 1, then the I/O operation is to read data from DASD to storage. If bit 31 of word 0 is 1, then the I/O operation is to write data from storage to DASD. The user must set exactly one of bits 30 and 31 — the other must be zeros; otherwise, an operand exception occurs. Bits 24 through 29 of word 0 are reserved for future use and must be zeros; otherwise, an operand exception occurs.

In other words, the I/O request-type bits must be:

```
WRITE  = B'0000 0001'
READ   = B'0000 0010'
```

Anything else is invalid.

**Block Size**

Bits 0 through 31 of word 1 contain the size of the storage blocks for this request. The block size must be one of the following:

- 1024
- 2048
- 4096

If you set the block size to other than the above, processing of the DIAGNOSE terminates and a return code of 8 and a condition code of 2 are set. For a read or write request to CKD or ECKD DASD, if the block size does not match the physical block size of the DASD, the DIAGNOSE request ends with an incorrect length indication, and the results of the Read or Write are unpredictable.

**Address of Block Entries**

Bits 0 through 31 of word 2 designate the guest absolute address of the list of DASD block number and data address pairs for this request. This list resides in the host-primary address space and is described in “Block Entries (SBILIST)” on page 140. All 32 bits of this field are used for the address; high-order bits beyond the address size must be zero.

The three rightmost bits of the block entries address must be zeros, specifying that the SBILIST is on a doubleword boundary; otherwise an operand exception occurs.

If the data address specifies a location protected against fetching or specifies a location outside the storage of the virtual machine, the processing of the DIAGNOSE terminates and a return code of 10 and a condition code of 2 are set.

Fetch-protection override and storage-protection override do not apply to references to the SBILIST.

**Count of Block Entries**

Bits 0 through 31 of word 3 contain the count of DASD block number and data address pairs in the SBILIST. For a read or write request, the maximum allowed is 500 and the minimum is 1; otherwise, the processing of the DIAGNOSE terminates and a return code of 11 and a condition code of 2 are set.

This is an unsigned binary number. The field is returned unchanged.

**Blocks Processed by CP**

Bits 0 through 31 of word 4 contains the number of blocks which were successfully processed by the Control Program. Blocks are processed sequentially, in the order the user provided. The data areas associated with unprocessed blocks are unpredictable.

**Device Status**

Bits 0 through 7 of word 5 identify the conditions in the device when the channel program ended. Each of the eight bits represents one condition, as defined in the Enterprise Systems Architecture/390 Principles of Operation and z/Architecture Principles of Operation (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>). This is returned to the issuer.

**Subchannel Status**

Bits 8 through 15 of word 5 identify the conditions in the subchannel when the channel program ended. Each of the eight bits represents one condition, as defined in the Enterprise Systems Architecture/390 Principles of Operation and z/Architecture Principles of Operation (<https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf>). This is returned to the issuer.

**Residual Count**

Bits 16 through 31 of word 5 contain the residual count from the CCW in control when the channel program ended. This is returned to the issuer of the DIAGNOSE.

**Logical Path Mask (LPM)**

Bits 0 through 7 of word 6 contain a mask of paths that the channel subsystem can use to execute the I/O operation requested by the DIAGNOSE. If the issuer of the DIAGNOSE requires that the I/O be issued down a specific path, that path must be represented in this field. If this field contains zeros, the issuer of the DIAGNOSE does not wish the I/O operation to be restricted to a particular path or paths.

**Note:** A positional correspondence exists between the bit positions in the logical path mask and the channel path IDs in the subchannel.

**Reserved**

Bits 8 through 31 of word 6 are reserved for future use and must be zeros; otherwise, an operand exception occurs.

Bits 0 through 15 of word 7 are reserved for future use and must be zeros; otherwise an operand exception occurs.

**Sense Data Count**

Bits 16 through 31 of word 7 contain the amount of sense data present if a unit check is indicated. This is returned to the issuer of the DIAGNOSE. This field is returned unchanged if unit check is not present.

**Reserved**

Bits 0 through 31 of words 8 through 13 are reserved for future use and must be zeros; otherwise an operand exception occurs.

**Sense Data**

Bits 0 through 31 of words 14 through 21 contain the sense data (as limited by the sense data count) if a unit check is indicated. This is returned to the issuer of the DIAGNOSE. This field is returned unchanged if unit check is not present.

The parameters for format I/O operations include:

- Virtual device number
- Request type
- Block size
- Logical block address
- Number of blocks to format
- Address of format data block
- CP blocks to format
- IBM service diagnostic information.

These fields of the HCPSBIOP must be filled in:

- Virtual device number
- Request type
- Block size
- Logical block address.

The HCPSBIOP for the format request type is as follows (the HCPSBIOP COPY file is provided in the HCPGPI macro library):

SBIOP DSECT

| 20 |                              |        |                                  |            |

22

The fields in this HCPSBIOP are defined as follows:

Device Number

Bits 0 through 15 of word 0 contains a virtual device number (1 to 4 digits) of the DASD to which this operation is targeted. The DASD must be fully supported. This field is filled in by the issuer of the DIAGNOSE, and is returned unchanged.

I/O Request Type

Bit 29 of word 0 contains the request type for this I/O operation. When bit 29 is 1, the I/O operation is to format data from DASD to storage. Bits 24 through 28, 30, and 31 of word 0 are reserved for future use and must be zeros; otherwise, an operand exception occurs.

In other words, the I/O request-type bit for format must be:

```
FORMAT = B'0000 0100'
```

Anything else is invalid.

Format is only valid for an emulated device that represents a real SCSI device associated with 2105 or 2107 attributes.

### Block Size

Word 1 contains the size of the storage blocks for this request. The block size must be 512 when the device number is an emulated device that represents a real SCSI device.

If you set the block size to other than 512, processing of the DIAGNOSE terminates and a return code of 8 and a condition code of 2 are set.

### Logical Block Address

Words 2 and 3 contain the logical block address where formatting will begin.

### Number of Blocks to Format

Words 4 and 5 contain the request number of blocks to be formatted. When zero, formatting will continue until the end of the device is reached.

### Address of Format Data Block

Words 6 and 7 contain the address of a 512-byte block which contains the data that will be written multiple times to the disk, starting at the logical block address and continuing for the number of blocks specified. When zero, zeros will be written.

### CP Blocks to Format

Words 8 and 9 contain the number of blocks which CP will attempt to process when zero is specified in the Number of Blocks to Format field.

### IBM Service Diagnostic Information

Words 10, 11, and 12 contain information which can be used by IBM Service when condition code 3 with return code 13 (X'0D') in register 15 is returned.

### Reserved

Words 13 through 21 are reserved for future use and must be zeros; otherwise, an operand exception occurs.

## Block Entries (SBILIST)

The block entries (SBILIST) describing the CMS block number and data address pairs have the following format:

|   |              |              |
|---|--------------|--------------|
| 0 | Block Number | Data address |
|---|--------------|--------------|

The fields in the SBILIST are defined as follows:

### Block Number

Bits 0 through 31 of word 0 contain the CMS block number for this request. This is provided by the issuer of the DIAGNOSE. Block numbers are assigned sequentially to CMS records, starting with zero.

### Data Address

Bits 0 through 31 of word 1 designate the guest absolute address of the data for this request, in the host-primary address space. For a Write request, this is the location in storage from which the data is written to DASD. For a Read request, this is the location in storage to which the data read from DASD is placed.

If the data address specifies a location in a shared segment for a read request or specifies a location outside the storage of the virtual machine, the processing of the DIAGNOSE is terminated and return code 12, condition code 2 is set. The field in HCPSBIOP called *blocks processed by CP* indicates the number of list entries for which data transfer was successful. List entries are processed sequentially, in the order the user provided. The *blocks processed by CP* field is set to zero if the error was detected before any I/O was attempted.

Fetch-protection override, storage-protection override, and low-address protection do not apply to references to the data area.

## Usage Notes

1. No I/O interrupts are returned by CP to the virtual machine; the DIAGNOSE instruction is completed only when the Read or Write commands associated with the DIAGNOSE are completed.
2. One way to figure out the block size of a CMS formatted disk automatically is to read the label record and look at the length field. The length field is in the fourth word of the record. For CKD or ECKD devices, the label record is in cylinder 0, track 0, record 3 (block number 2). For FBA devices, the label record is in the second 512 byte block (block number 1, using a blocksize of 512 bytes).
3. Use DIAGNOSE code X'A4' to perform synchronous I/O in a nonsynchronous environment.
4. Diagnose I/O operations issued to virtual Parallel Access Volume bases and aliases are randomly scheduled on any available, appropriate real base or alias device. Certain CCWs, such as Reserve and Release, require base or alias real device affinity. This is handled by CP as needed.
5. This DIAGNOSE code does not support HyperPAV alias devices.
6. This DIAGNOSE code is limited to a minidisk size of 65520 cylinders, regardless of formatted block size. If a program issues DIAGNOSE code X'A4' to a minidisk larger than 65520 cylinders, CP sets a condition code of 1 (cc=1) and places a return code of 4 in register 15.

## Responses

Upon completion of a Read or Write operation, HCPSBIOP is updated with the number of blocks processed by CP, the device and subchannel status, the residual count, the sense data count and the sense data (if a unit check is indicated).

**Condition Codes and Return Codes:** Upon completion of DIAGNOSE code X'A4', you receive a condition code, along with a return code in register 15:

- If you receive a condition code of 0, the I/O operation was completed successfully. The return code in register 15 is 0 also.
- If you receive a condition code of 1, an error condition was detected which prevented complete execution of the channel program built for the DIAGNOSE I/O request. No I/O was performed unless the return code in Register 15 is 1.

In addition, the return codes shown in [Table 15 on page 141](#) are set in the guest's register 15:

*Table 15. DIAGNOSE Code X'A4' Return Codes.* DIAGNOSE Code X'A4' Return Codes in the Guest's Register 15 with CC=1

| Condition Code | Return Code in Register 15 | Meaning                                                                           |
|----------------|----------------------------|-----------------------------------------------------------------------------------|
| 1              | 1 (X'01')                  | Device not attached (See Note below.)                                             |
| 1              | 2 (X'02')                  | Device is not a supported DASD.                                                   |
| 1              | 3 (X'03')                  | Attempt to write to a read-only disk                                              |
| 1              | 4 (X'04')                  | A program issued a DIAGNOSE code X'A4' to a minidisk larger than 65520 cylinders. |
| 1              | 5 (X'05')                  | Device is busy, or has an interrupt pending                                       |

**Note:** This indicates that either the device has not been logically attached, or the physical path to the device has been lost. If the physical path to the device has been lost, then some portion of the channel program may have been executed. This is because CP may have used multiple real channel programs to perform the I/O operation. The *blocks processed by CP* field in HCPSBIOP must be examined to determine how much, if any, of the I/O request was completed. Device verification is required to determine why the physical path to the device was lost.

- If you receive a condition code of 2, a specification exception was detected (the HCPSBIOP was not set up correctly). No I/O was performed, except when the return code in register 15 is 16. One of the return codes shown in [Table 16 on page 142](#) is set in the guest's register 15:

*Table 16. DIAGNOSE Code X'A4' Return Codes*

| Condition Code | Return Code in Register 15 | Meaning                                                                                                                  |
|----------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------|
| 2              | 7 (X'07')                  | Guest DASD block number is invalid                                                                                       |
| 2              | 8 (X'08')                  | Blocksize equals zero, or is unsupported                                                                                 |
| 2              | 9 (X'09')                  | The number of blocks specified exceeds the size of the mdisk                                                             |
| 2              | 10 (X'0A')                 | The address of the SBILIST is invalid, or the SBILIST is fetch-protected                                                 |
| 2              | 11 (X'0B')                 | The number of buffer list entries was not a positive number within the range of 1 to 500                                 |
| 2              | 12 (X'0C')                 | One of the buffers identified in the buffer list is not within the guest's storage (for example, its address is invalid) |
| 2              | 16 (X'10')                 | Unsolicited status was pending at the real subchannel or device (See note below.)                                        |

**Note:** The channel program may not have completed, and thus the ending status may not pertain to this I/O request. The *blocks processed by CP* field in the HCPSBIOP must be examined to determine how much, if any, of the I/O request was completed. Device verification will be required to determine why unsolicited status was pending at the real subchannel or device.

- If you receive a condition code of 3, an unrecoverable I/O error occurred. If the device status field indicates a unit check, sense data is stored in the sense data field, and the amount of sense data is stored in the sense data count field. One of the return codes shown in [Table 17 on page 142](#) is set in the guest's register 15:

*Table 17. DIAGNOSE Code X'A4' Return Codes in the Guest's Register 15 with CC=3*

| Condition Code | Return Code in Register 15 | Meaning                                                                                                                         |
|----------------|----------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| 3              | 13 (X'0D')                 | A permanent I/O error or a soft abend occurred, or the I/O was terminated at the user's request by entering an exigent command. |
| 3              | 15 (X'0F')                 | Paging error occurred; channel data check status is set, unless the paging error occurred while accessing the SBILIST.          |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'A4' is given incorrect input data:

| Problem Encountered     | Cause                                                             |
|-------------------------|-------------------------------------------------------------------|
| Specification exception | The address HCPSBIOP (specified in Rx) is not on a word boundary. |

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Operand exception                                                     | <p>Any of the following:</p> <ul style="list-style-type: none"> <li>• In word 0 of the HCPSBIOP, bits 20 to 23 are not all set to zero.</li> <li>• In word 0 of the HCPSBIOP, both bits 30 and 31 (I/O request type) are set to 0 or both are set to 1.</li> <li>• In the HCPSBIOP, the address of the block entries list is not on a doubleword boundary.</li> <li>• In the HCPSBIOP, the bits in these reserved fields are not all set to zeros: <ul style="list-style-type: none"> <li>– word 6, bits 8 to 31</li> <li>– word 7, bits 0 to 15</li> <li>– words 8 through 13</li> </ul> </li> </ul> |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch or store the HCPSBIOP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## DIAGNOSE Code X'A8' – Synchronous I/O (for All Devices)

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'A8' to perform synchronous input/output operations to all fully supported devices, except channel-to-channel adapters, consoles, and graphics devices.

DIAGNOSE code X'A8' uses the synchronous general I/O parameter list (HCPSGIOP) to receive and return data.

### Entry Values:

#### Rx

Contains the guest real address of the synchronous general I/O parameter list (HCPSGIOP). The HCPSGIOP must be on a word boundary; otherwise a specification exception occurs.

#### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the synchronous general I/O parameter list. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the parameter list is in the host-primary address space.

To perform general I/O operations using DIAGNOSE code X'A8', the HCPSGIOP needs to have the following fields filled in: virtual device number, storage protection key, request flag, and channel program address.

## Synchronous General I/O Parameter List (HCPSGIOP)

The synchronous general I/O parameter list (HCPSGIOP) is the parameter list that DIAGNOSE code X'A8' uses in controlling the general I/O request. These parameters include:

- Virtual device number
- Storage protection key
- Request flag
- Channel program address
- CCW address at interrupt

- Device and subchannel status
- Residual count
- Sense data count
- Sense data.

The synchronous general I/O parameter list has the following format (the HCPSGIOP COPY file is provided in the HCPGPI macro library):

## HCPSGIOP DSECT

Word (decimal)

|    |                              |         |                  |                  |                           |
|----|------------------------------|---------|------------------|------------------|---------------------------|
| 0  | Device Number                | Key     | Flag             | 0000000000000000 | 0000000000000000          |
| 2  | Channel Program Address      |         |                  | 0000000000000000 | 0000000000000000          |
| 4  | Channel Command Word Address |         |                  | Dev. St.         | Subch. St. Residual Count |
| 6  | LPM                          | Options | 0000000000000000 | 0000000000000000 | Sense Count               |
| 8  | 0000000000000000             |         |                  | 0000000000000000 | 0000000000000000          |
| 10 | 0000000000000000             |         |                  | 0000000000000000 | 0000000000000000          |
| 12 | 0000000000000000             |         |                  | 0000000000000000 | 0000000000000000          |
| 14 | Sense Data                   |         |                  |                  |                           |

Figure 14. DIAGNOSE X'A8' Synchronous General I/O Parameter List (HCPSGIOP) Format

The fields in the HCPSGIOP are defined as follows:

### Device Number

Bits 0 through 15 of word 0 contains a virtual device number (1-4 digits) of the device to which this operation is targeted. The device must be fully supported, but virtual channel-to-channel adapters, virtual console devices, and graphics devices are not allowed. This field is filled in by the issuer of the DIAGNOSE, and is returned unchanged.

### Storage Protection Key

Bits 16 through 19 of word 0 contain the subchannel key for all fetching of CCWs, IDAWs and output data and for the storing of input data associated with the start function. This key is matched with a storage key during these storage references. Bits 20 through 23 must be zeros; otherwise an operand exception occurs. Bit 20 represents suspend control, which is not supported. The storage protection key is filled in by the issuer of the DIAGNOSE and is returned unchanged.

### I/O Request Flag

Bits 24 through 31 of word 0 contain the request flag for this I/O operation.

Bit 24 of word 0 specifies the format of the channel-command words (CCWs) which make up the channel program designated by the channel program address field. If bit 24 is zero, format-0 CCWs are specified. If bit 24 is one, format-1 CCWs are specified. Both format CCWs are allowed in all virtual machines.

Bits 25 through 29 of word 0 are reserved for future use and must be zeros; otherwise an operand exception occurs. This field is filled in by the issuer of the DIAGNOSE and is returned unchanged.

If bit 30 (SGIDAWF2) is on, it indicates that format-2 IDAWs are used in the channel program for all CCWs that have the IDAW flag set to one. Otherwise, format-1 IDAWs are used.

If bit 31 (SGIDAW2K) is on, it indicates that format-2 IDAWs use a storage block size of 2K. Otherwise, format-2 IDAWs use a storage block size of 4K. SGIDAW2K is ignored if SGIDAWF2 is off.

Both bit 30 and bit 31 may be on if and only if bit 24 is also on. Otherwise, an operand exception is recognized.

#### **Reserved**

Bits 0 through 31 of word 1 are reserved for future use and must be zeros; otherwise an operand exception occurs.

#### **Channel Program Address**

Bits 0 through 31 of word 2 designate the location of the first CCW in the host-primary address space. If format-0 CCWs have been specified in bit 24 of word 0, then bits 0 through 7 of word 2 must be zeros. If format-0 CCWs have been specified and bits 0 through 7 do not contain zeros, an operand exception occurs. If format-1 CCWs have been specified, then bit 0 of word 2 must be zero. If bit 0 is not zero, an operand exception occurs. This field is filled in by the issuer of the DIAGNOSE and is returned unchanged.

The three rightmost bits of the channel-program address must be zeros, specifying the CCW on a doubleword boundary; otherwise an operand exception occurs.

If the CCW address specifies a location protected against fetching or specifies a location outside the storage of the virtual machine, the processing of the DIAGNOSE is terminated and return code 13, condition code 3 is set. The subchannel status indicates a program-check condition and the CCWA = CPA + 8.

#### **Reserved**

Bits 0 through 31 of word 3 are reserved for future use and must be zeros; otherwise an operand exception occurs.

#### **Channel Command Word Address at Interrupt**

Bits 0 through 31 of word 4 form an absolute address. The address indicated represents the CCW + 8 of the last executed CCW. This is returned to the issuer of the DIAGNOSE.

#### **Device Status**

Bits 0 through 7 of word 5 identify the conditions in the device when the channel program ended. Each of the eight bits represents one condition, as defined in the [Enterprise Systems Architecture/390 Principles of Operation \(publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf\)](https://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf) and [z/Architecture Principles of Operation \(https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf\)](https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf). This is returned to the issuer of the DIAGNOSE.

#### **Subchannel Status**

Bits 8 through 15 of word 5 identify the conditions in the subchannel when the channel program ended. Each of the eight bits represents one condition, as defined in the [Enterprise Systems Architecture/390 Principles of Operation \(publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf\)](https://publibfp.dhe.ibm.com/epubs/pdf/dz9ar008.pdf) and [z/Architecture Principles of Operation \(https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf\)](https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf). This is returned to the issuer of the DIAGNOSE.

#### **Residual Count**

Bits 16 through 31 of word 5 contain the residual count from the CCW in control when the channel program ended. This is returned to the issuer of the DIAGNOSE.

#### **LPM - Logical Path Mask**

Bits 0 through 7 of word 6 contain a mask of paths that the channel subsystem should be permitted to use to execute the I/O operation requested by the DIAGNOSE. If the issuer of the DIAGNOSE requires that his I/O be issued down a specific path, he must represent that path in this field. If this field contains zeros, this indicates that the issuer of the DIAGNOSE does not wish the I/O operation to be restricted to a particular path or paths.

Note that there is a positional correspondence between the bit positions in the logical path mask and the channel path IDs in the subchannel.

#### **Options**

Bits 8 through 15 of word 6 contain settings for certain options for this I/O operation.

## DIAGNOSE Code X'A8'

If bit 8 is on, the caller can use the 28-bit extended addressing format and access a minidisk above cylinder 65519.

Bits 9 through 15 are reserved for future use and must be zeros; otherwise an operand exception occurs.

### Reserved

Bits 16 through 31 of word 6 are reserved for future use and must be zeros; otherwise an operand exception occurs.

Bits 0 through 15 of word 7 are reserved for future use and must be zeros; otherwise an operand exception occurs.

### Sense Data Count

Bits 16 through 31 of word 7 contain the amount of sense data present if a unit check is indicated. This is returned to the issuer of the DIAGNOSE. This field is returned unchanged if unit check is not present.

### Reserved

Bits 0 through 31 of words 8 through 13 are reserved for future use and must be zeros; otherwise an operand exception occurs.

### Sense Data

Bits 0 through 31 of words 14 through 21 contain the sense data (as limited by the Sense Data Count) if a unit check is indicated. This is returned to the issuer of the DIAGNOSE. This field is returned unchanged if unit check is not present.

## Usage Notes

1. No I/O interruptions are returned by CP to the virtual machine. The DIAGNOSE instruction is complete only when the channel program associated with the DIAGNOSE is complete.
2. If neither DIAGNOSE code X'A4' nor DIAGNOSE code X'18' can be used, then the channel programming capability of the device being accessed must be determined and the appropriate channel program constructed.
  - a. Use DIAGNOSE code X'24' or X'210' to determine if the device is in an ECKD-capable subsystem.
  - b. Generate a CKD, ECKD or FBA channel program as appropriate for the device being accessed.
  - c. Expand sense error analysis and recovery procedures to include the 32 byte format returned by ECKD subsystems.
3. Use DIAGNOSE code X'A8' to perform synchronous I/O in a nonsynchronous environment.
4. Diagnose I/O operations issued to virtual Parallel Access Volume bases and aliases are randomly scheduled on any available, appropriate real base or alias device. Certain CCWs, such as Reserve and Release, require base or alias real device affinity. This is handled by CP as needed.
5. DIAGNOSE code X'A8' can be used on a minidisk that resides on an Extended Address Volume (EAV).

## Responses

Upon completion of DIAGNOSE code X'A8', the HCPSGIOP is returned with information in the following fields:

- Device status
- Subchannel status
- Residual count
- Address of CCW at interrupt
- Sense data count
- Sense data if a unit check is present in the device status field.

**Condition Codes and Return Codes:** Upon completion of DIAGNOSE code X'A8', you also receive a condition code and, if there is an error, a return code in register 15.

If you receive a condition code of 0, the I/O operation completed successfully and register 15 remains unchanged.

If you receive a condition code of 1, an error condition was detected which prevented execution of the guest virtual machine's channel program. Real I/O may not have been performed. In addition, one of the return codes shown in [Table 18 on page 147](#) is set in the guest's register 15:

*Table 18. DIAGNOSE Code X'A8' Return Codes in the Guest's Register 15 with CC=1*

| Condition Code | Return Code in Register 15 | Meaning                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1              | 1 (X'01')                  | Device not attached.<br><br><b>Note:</b> This indicates that either the device has not been logically attached, or that the physical path to the device has been lost. If the physical path to the device has been lost, then some portion of the channel program may have been executed. This is because CP may have used multiple real channel programs to perform the I/O operation. |
| 1              | 2 (X'02')                  | Device is not supported.                                                                                                                                                                                                                                                                                                                                                                |
| 1              | 5 (X'05')                  | Device is busy, or has an interrupt pending.                                                                                                                                                                                                                                                                                                                                            |

If you receive a condition code of 2, an exception condition was detected. Return code 16 is set in the guest's register 15, indicating that an unsolicited status was pending at the real subchannel or device.

The channel program may not have completed, and thus the ending status may not pertain to this I/O request. This is because CP may have used multiple real channel programs to perform the I/O operation. The channel command word at interrupt field in the HCPSGIOP must be examined to determine how much, if any, of the I/O request was completed. Device verification is required to determine why unsolicited status was pending at the real subchannel or device.

If you receive a condition code of 3, this indicates that an unrecoverable I/O error occurred or the I/O was terminated at the user's request by entering an exigent command. If the I/O error resulted in a unit check, then sense data is stored in the sense data field and the amount of sense data stored is in the sense data count field. Return code 13 is set in the guest's register 15, indicating that a permanent I/O error occurred.

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'A8' is given incorrect input data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                                               | The address of the HCPSGIOP (specified in Rx) is not on a word boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch or store the HCPSGIOP.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## DIAGNOSE Code X'B0' – Access Re-IPL Data

---

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'B0' to obtain diagnostic information about the cause of the automatic re-IPL of your virtual machine. The data returned by the system also includes the IPL statement from the directory entry for the issuing user.

### Entry Values:

#### Rx

Contains the guest real address of the buffer for the output data.

#### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the buffer for the output area. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the buffer is in the host-primary address space.

#### Ry

Contains the length of the buffer. Any nonnegative length is allowed. To avoid possible truncation of data, a buffer of at least 90 bytes is recommended.

### Exit Values:

#### Ry

Contains a completion code, as follows:

#### Code

#### Meaning

0

Re-IPL information and IPL statement information are returned in buffer. (The IPL statement information may be the null string.)

4

No re-IPL information is available. IPL statement information is returned in the buffer. (The IPL statement information may be the null string.) Either the protected application environment is not active, or the IPL was initiated by the user.

8

No information is available. A paging or storage error has occurred.

**Buffer Content:** Successful completion of the request may result in output consisting of re-IPL information, an IPL statement from the directory, both types of information, or neither. Only as much information is returned as fits in the output area supplied.

## Re-IPL Information

If the completion code is zero, the buffer contains re-IPL information consisting of the following:

### Byte 0: Error code

- The codes and the errors to which they correspond are as follows:

#### Code

#### CP Meaning

X'01'

CP entered; Disabled wait PSW is provided in a message in the buffer

X'02'

CP entered; External interrupt loop

X'03'

CP entered; Paging error

**X'04'**

CP entered; Program interrupt loop

**X'07'**

CP entered; Complex interrupt loop

**X'08'**

System soft abend, abend code is provided in a message in the buffer

**X'09'**

CPU ... stopped; Check-stop state entered

**X'0A'**

Page zero damaged

**X'0B'**

An error occurred but CP was unable to provide a message because of a paging error.

**Bytes 1-n:** Variable data

- The additional variable length data, if present, depends on the particular error condition. The variable length data is shown as follows:

**Code****Variable Data****X'01'**

for z/Architecture mode guests, 16-byte binary disabled wait state PSW

for non-z/Architecture mode guests, 8-byte binary disabled wait state PSW

**X'02'**

for z/Architecture mode guests, 16-byte binary external interrupt old PSW

for non-z/Architecture mode guests, 8-byte binary external interrupt old PSW

**X'03'**

None

**X'04'**

for z/Architecture mode guests, 16-byte binary program interrupt old PSW

for non-z/Architecture mode guests, 8-byte binary program interrupt old PSW

**X'07'**

None

**X'08'**

EBCDIC CPU number

EBCDIC abend code

**X'09'**

EBCDIC CPU number

**X'0A'**

None

**X'0B'**

CP module name

EBCDIC offset into module

- EBCDIC variable data items (for codes above X'07') are delimited by 1-byte binary fields. The field between multiple data items is X'00'. The field following the final data item is X'01'. For example, the buffer contents returned for a soft abend is the following (assuming the buffer is large enough):

– X'08'

– CPU number

– X'00'

## DIAGNOSE Code X'B4'

- Abend code
- X'01'.

### IPL Statement Information

If the completion code is 0, the IPL statement information immediately follows the re-IPL information in the buffer. If the completion code is 4, the IPL statement information is placed at the start of the buffer.

**Byte 0:** Length of IPL directory statement

This data is present if a re-IPL occurred. It is zero if the user has no IPL statement in the directory, or if the output area is too small to contain at least one byte of text. If the entire IPL statement does not fit in the area, this length is that of the text truncated to fit in the available space.

**Bytes 1-m:** Text of IPL directory statement

This data is present if the preceding length byte is nonzero.

### Usage Notes

1. If Ry specifies a length of zero on entry, the contents of Rx are not examined. Ry returns with the value zero if an automatic re-IPL has occurred; otherwise, Ry contains the value four.
2. CP does not guarantee the validity of the IPL statement content for the virtual machine environment issuing DIAGNOSE code X'B0'. It is the responsibility of the program issuing DIAGNOSE code X'B0' to use the information contained in it appropriately.

### Responses

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'B0' is given incorrect data:

| Problem Encountered                                                   | Cause                                              |
|-----------------------------------------------------------------------|----------------------------------------------------|
| Specification exception                                               | The buffer length is negative.                     |
| Privileged-operation exception                                        | The virtual machine is in the problem state.       |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to store the re-IPL data. |

## DIAGNOSE Code X'B4' – Read/Write/Erase the Virtual Printer XAB

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'B4' to read, write, and erase the external attribute buffer (XAB) for a spooled printer device. A copy of this external attribute buffer is added to each spool file created on the device. Specific information about the XAB may be found in [“External Attribute Buffer Used by DIAGNOSE Codes X'B4', X'B8', and X'290'”](#) on page 995.

**Entry Values:**

**Rx**

Contains the buffer address

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the buffer. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the buffer is in the host-primary address space.

**Ry**

Bytes 0 and 1 contain the length of the buffer in bytes (0=ERASE). Bytes 2 and 3 contain the device number of the virtual printer.

**Ry+1**

Bytes 2 and 3 contain subcode X'0000' (Read) or X'0004' (Write/Erase).

**Exit Values:****READ - Subcode X'0000'**

CC=0 - Successful

**Ry**

Bytes 0 and 1 contain the length of the XAB read, 0 if there is no XAB. Bytes 2 and 3 are unchanged.

**Ry+1**

Byte 0 is X'00'. Bytes 1 through 3 are unchanged.

**READ - Subcode X'0000'**

CC=2 - Unsuccessful

**Ry**

Bytes 0 and 1 contain the length of the XAB if it is too large for the buffer. Bytes 2 and 3 are unchanged.

**Ry+1**

Byte 0 contains the return code; see [Table 19 on page 151](#). Bytes 1 through 3 are unchanged.

**WRITE/ERASE - Subcode X'0004'**

CC=0 - Successful

**Ry+1**

Byte 0 contains X'00'. Bytes 1 through 3 are unchanged.

**WRITE/ERASE - Subcode X'0004'**

CC=2 - Unsuccessful

**Ry+1**

Byte 0 contains the return code; see [Table 19 on page 151](#). Bytes 1 through 3 are unchanged.

## Responses

**Condition Codes for Normal Exit:** The condition code for a normal exit is 0, indicating that the reading, writing, or erasing of the XAB was successful.

**Condition Codes and Return Codes for Exit with Error:** The condition code for an error exit is 2, indicating that the reading, writing, or erasing of the XAB was unsuccessful. The return code is shown in [Table 19 on page 151](#).

*Table 19. DIAGNOSE Code X'B4' Return Codes*

| Return Code in Ry+1 | Meaning                                                                   |
|---------------------|---------------------------------------------------------------------------|
| 4 (X'04')           | The device does not exist, or is not a spooled virtual printer.           |
| 8 (X'08')           | The buffer is too small. (returned for READ, subcode X'0000', only).      |
| 12 (X'0C')          | The buffer length is invalid.                                             |
| 20 (X'14')          | CP paging or I/O error                                                    |
| 28 (X'1C')          | Invalid subcode                                                           |
| 32 (X'20')          | The buffer address is zero or negative.                                   |
| 36 (X'24')          | Not used                                                                  |
| 40 (X'28')          | No XAB is to be erased (returned for Write/Erase, subcode X'0004', only). |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'B4' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                           |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| Specification exception                                               | Ry is R15.                                                                                      |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                    |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch from (WRITE function) or store to (READ function) the buffer. |

## DIAGNOSE Code X'B8' – Spool File XAB Manipulation

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'B8' to read, write, or erase the external attribute buffer (XAB) of a spool file on the printer queue, or to read the XAB of a file on the reader queue. It also can be used to set user HOLD status or user NOHOLD status.

**Note:** The external attribute buffer (XAB) is a control block that contains data the user creates to specify additional information about a print file. Each print file has its own XAB, and CP has the facilities to maintain the XABs. For more information on the XAB, refer to [“External Attribute Buffer Used by DIAGNOSE Codes X'B4', X'B8', and X'290'”](#) on page 995.

### Entry Values:

#### Rx

Bytes 0 through 3 contain the buffer address

#### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the buffer. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the buffer is in the host-primary address space.

#### Ry

Bytes 0 and 1 contain the length of the buffer in bytes (0=ERASE). Bytes 2 and 3 contain the spool file ID.

#### Ry+1

Byte 1 contains flag bits which have the following meanings:

| Flag  | Meaning                                                           |
|-------|-------------------------------------------------------------------|
| X'01' | Place the spool file in user HOLD status                          |
| X'02' | Place the spool file in user NOHOLD status                        |
| X'04' | Look for the spool file on the reader queue (READ function only). |

Flags X'01' and X'02' may not be specified together. If neither is specified, the file's HOLD status is left unchanged.

Bytes 2 and 3 of Ry+1 contain subcode X'0000' (READ) or X'0004' (WRITE/ERASE).

### Exit Values:

#### READ - Subcode X'0000'

CC=0 - Successful

**Ry**

Bytes 0 and 1 contain the length of the XAB Read; 0 if there is no XAB

**Ry+1**

Byte 0 contains X'00'

**READ - Subcode X'0000'**

CC=2 - Unsuccessful

**Ry**

Bytes 0 and 1 contain the length of the XAB if it is too large for the buffer

**Ry+1**

Byte 0 contains the return code, see [Table 20 on page 153](#).

**WRITE/ERASE - Subcode X'0004'**

CC=0 - Successful

**Ry+1**

Byte 0 contains X'00'

**WRITE/ERASE - Subcode X'0004'**

CC=2 - Unsuccessful

**Ry+1**

Byte 0 contains the return code, see [Table 20 on page 153](#).

## Usage Note

You may not be authorized to issue this DIAGNOSE code if an external security manager is installed on your system. For additional information, contact your security administrator.

## Responses

**Condition Codes for Normal Exit:** A normal exit condition is a condition code of 0, indicating that the reading, writing, or erasing of the XAB of a spool file on the printer queue (or the reading of the XAB of a file on the reader queue) was successful.

**Condition Codes and Return Codes for Exit with Error:** An error exit condition is a condition code of 2, indicating that the reading, writing, or erasing of the XAB of a spool file on the printer queue (or the reading of the XAB of a spool file on the reader queue) was unsuccessful. The return code is shown in [Table 20 on page 153](#).

*Table 20. Return Codes*

| Return Code in Ry+1 | Meaning                                                                              |
|---------------------|--------------------------------------------------------------------------------------|
| 4 (X'04')           | The spool ID is invalid or does not exist.                                           |
| 8 (X'08')           | The length of the XAB buffer is greater than the user buffer. (See note)             |
| 12 (X'0C')          | The buffer length is invalid.                                                        |
| 20 (X'14')          | CP paging or I/O error                                                               |
| 24 (X'18')          | The specified process flag is invalid.                                               |
| 28 (X'1C')          | Invalid subcode                                                                      |
| 32 (X'20')          | The buffer address is zero or negative.                                              |
| 36 (X'24')          | Not used                                                                             |
| 40 (X'28')          | No XAB is to be erased (returned for WRITE/ERASE, subcode X'0004', only).            |
| 44 (X'2C')          | The XAB is not available because the file is marked for purge or has been converted. |

**Note:** Any special processing requested by the flag byte is completed.

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'B8' is given incorrect data:

| Problem Encountered                                  | Cause                                                                                             |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| Specification exception                              | Ry is R15.                                                                                        |
| Privileged-operation exception                       | The virtual machine is in the problem state.                                                      |
| Access exception (See “Access Exceptions” on page 8. | An error occurred trying to fetch from (WRITE function) or store into (READ function) the buffer. |

## DIAGNOSE Code X'BC' – Open and Query Spool File Characteristics

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE code X'BC' opens a spool file (if it is not already open) for a spooled reader device and returns all information about the spool file to a user-specified buffer. CP selects the spool file according to the rules governing the CLASS and HOLD status. For these rules, refer to *z/VM: CP Commands and Utilities Reference* and *z/VM: Virtual Machine Operation*. This means CP opens only spool files with the same class designation as the virtual reader.

**Entry Values:** Set the input registers up as follows when invoking DIAGNOSE code X'BC':

### Rx

contains the guest real address of a buffer. Rx cannot be register 15.

### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the buffer. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the buffer is in the host-primary address space.

### Rx+1

contains the length of the buffer, in bytes.

### Ry

Bytes 0 and 1 contain the subcode. Bytes 2 and 3 contain the virtual device number of the spooled reader device. Ry cannot be register 15.

### Subcode

#### Meaning

#### X'0000'

This subcode provides information in character format only. This subcode is compatible with VM/SP, VM/SP HPO, and VM/ESA (370 Feature).

#### X'0004'

This subcode provides information in character format, where appropriate, and binary format for numeric information. This format is not compatible with VM/SP, VM/SP HPO, and VM/ESA (370 Feature).

### Exit Values:

*Subcode X'0000':* Depending on the specified buffer length, the user's buffer contains as much of the following information shown as possible: (Bytes means character length, in bytes.)

### Bytes

#### Description

#### 4

Spool file ID (EBCDIC)

**8** File originator  
**1** Class  
**3** Type: RDR, PRT, PUN, CON  
**8** Number of records (EBCDIC)  
**3** Number of copies (EBCDIC)  
**12** File name  
**12** File type  
**8** Date: mm/dd/yy  
**8** Time  
**8** Distribution  
**4** Status -- 'NONE'  
**8** FORM -- User forms  
**8** Destination  
**4** Flash name  
**3** Flash count (EBCDIC)  
**4** FCB -- Forms control buffer  
**4** CMOD -- Character modification  
**1** Character modification count (EBCDIC)  
**3** Load 3800 -- 'ANY' 'BEG' 'NO'  
**16** CHARS -- Character Arrangement Tables  
**8** SIZE -- Number of pages  
**8** SECLABEL - Security label of file.  
**10** Full year date: mm/dd/yyyy  
**10** ISO date: yyyy-mm-dd

*Subcode X'0004'*: Depending on the specified buffer length, the user's buffer contains as much of the following information as possible. (Bytes means character length, in bytes.) Note that CP returns character information, where appropriate, and binary format for numeric data.

**Bytes**

## Usage Note

If an external security manager is installed, the user may not receive all the information about the file. If the external security manager denies access to the file, the only fields of the response that will contain information are the spool file ID, user ID, class, date, time and status fields. All other fields will contain asterisks.

## Responses

**Condition Codes and Return Codes:** Upon completion, DIAGNOSE code X'BC' returns the following condition codes (found in the user's PSW) and return codes (found in Ry+1):

| Condition Code | Return Code in Ry+1 | Meaning                                       |
|----------------|---------------------|-----------------------------------------------|
| 0              | 0 (X'00')           | Data transfer successful, file opened         |
| 1              | 0 (X'00')           | Data transfer successful, file already opened |
| 2              | N/A                 | No file is found                              |
| 3              | 4 (X'04')           | The device address is invalid                 |
| 3              | 8 (X'08')           | The device type is invalid                    |
| 3              | 18 (X'12')          | Device busy, not ready, or a real reader      |
| 3              | 22 (X'16')          | A paging I/O error is received.               |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'BC' is given incorrect data:

| Problem Encountered                                   | Cause                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                               | Any of the following: <ul style="list-style-type: none"> <li>• The user's buffer length is less than or equal to 0</li> <li>• Either Rx or Ry is specified as R15</li> <li>• There is any overlap of Rx, Rx+1, Ry, or Ry+1</li> <li>• The subcode specification is not X'00' or X'04'.</li> </ul> |
| Privileged-operation exception                        | The virtual machine is in the problem state.                                                                                                                                                                                                                                                      |
| Access exception (See “Access Exceptions” on page 8.) | An error occurred trying to store into the buffer.                                                                                                                                                                                                                                                |

## DIAGNOSE Code X'C8' – Set Language

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE code X'C8' initiates the SET of the national language for the virtual machine session. It sets only the CP language. CP uses this language to issue most CP system messages.

For CMS applications, the preferred user interface is the CMS SET LANGUAGE command.

For more information on the languages supported on your z/VM system, see *z/VM: Installation Guide*.

**Entry Values:**

**Rx and Rx+1**

Language identifier specifying the language to be set for the virtual machine and the *langid* specified in the message repository. The language identifier is specified using the 1- to 5-character *langid*, left-justified (that is, the first four characters in Rx and fifth character in the high-order byte of Rx+1). If the language identifier is less than five characters, it should be padded on the right with blanks. Rx cannot be register 15.

**Ry**

X'00xxxxx'—the function code (X'00' in the high-order byte, with the remaining bytes unused).

**Exit Values:** When processing of the SET function completes, the first five bytes of the register pair Rx, Rx+1 contain the language identifier for the language that has been set for CP messages (this language may or may not be the same as the language set before the DIAGNOSE code was issued), left-justified and padded on the right with blanks as required.

## Responses

**Return Codes:** The low-order byte of register Ry contains one of the following return codes (the contents of the remaining bytes of Ry are unpredictable):

| Return Code in Ry+1 | Meaning                                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')           | The language requested has been set.                                                                                                                                        |
| 20 (X'14')          | A paging error occurred while an attempt was being made to read the first page of the requested message repository. The current language used for CP messages is unchanged. |
| 28 (X'1C')          | No message repository could be found for the specified language identifier. The current language used for CP messages is unchanged.                                         |
| 32 (X'20')          | The selected repository does not appear to be a valid message repository.                                                                                                   |

| Return Code in Ry+1 | Meaning                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------|
| 36 (X'24')          | Unrecoverable error, causing a soft abend. The current language used for CP messages is unchanged. |
| 40 (X'28')          | The NLS lock could not be obtained. This is a temporary error. Retry the command.                  |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'C8' is given incorrect data:

| Problem Encountered            | Cause                                                                                                                                                                                  |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception        | Any of the following: <ul style="list-style-type: none"> <li>• Rx or Rx+1 is the same register as Ry</li> <li>• Rx is register 15.</li> <li>• The function code is invalid.</li> </ul> |
| Privileged-operation exception | The virtual machine is in the problem state.                                                                                                                                           |

## DIAGNOSE Code X'CC' – Save Message Repository

**Privilege Class:** E

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'CC' to initiate the SAVE function for the CP message repository. If the SAVE operation completes successfully, then DIAGNOSE code X'C8' can be used to set that language.

The preferred user interface is the CMS LANGGEN command.

**Entry Values:**

**Rx and Rx+1**

The language identifiers specifying the language to be saved and the language identifiers specified in the message repository. The language identifiers are specified using the 1- to 5-character language identifier, left-justified (that is, the first four characters in Rx and the fifth character in the high-order byte of Rx+1). If the language identifiers are less than five characters, they should be padded on the right with blanks. Rx cannot be register 15.

**Ry**

X'00xxxxxx' – the function code (X'00' in the high-order byte, with the remaining bytes unused). Ry cannot be register 15.

**Ry+1**

The guest real address where the compiled CP message repository that is to be saved has been loaded. This address must be on a page boundary.

Key-controlled protection does not apply to accesses to the message repository data.

**Ay+1**

Is used only by XC virtual machines in access-register mode. Ay+1 contains the ALET for the address space containing the CP message repository.

## Responses

**Return Codes :** When processing of the SAVE function is completed, the low-order byte of Ry contains the return code (the contents of the remaining bytes being unpredictable).

| Return Code in Ry | Meaning                                                 |
|-------------------|---------------------------------------------------------|
| 0 (X'00')         | The entire CP message repository is successfully saved. |

| Return Code in Ry | Meaning                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------|
| 16 (X'10')        | The repository cannot be saved because of insufficient resources (spool file IDs or spool space).                            |
| 24 (X'18')        | A storage or paging I/O error occurred.                                                                                      |
| 28 (X'1C')        | The language identifier specified does not match the language identifier in the repository at the specified virtual address. |
| 32 (X'20')        | The selected repository does not appear to be a valid message repository.                                                    |
| 40 (X'28')        | An unrecoverable error has occurred. A soft abend has been taken.                                                            |
| 44 (X'2C')        | No system spool file ID is available.                                                                                        |
| 48 (X'30')        | An invalid file name was specified. The language identifier was left blank or contains more than one name.                   |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'CC' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                                               | Any of the following: <ul style="list-style-type: none"> <li>• Rx is the same register as Ry or Ry+1</li> <li>• Rx+1 is the same register as Ry</li> <li>• Rx or Ry is register 15</li> <li>• Function code is invalid</li> <li>• Repository buffer address is not on a 4K-byte boundary.</li> </ul> |
| Privileged-operation exception                                        | Any of the following: <ul style="list-style-type: none"> <li>• The virtual machine is in the problem state.</li> <li>• The user does not have the privilege class required to issue the DIAGNOSE instruction.</li> </ul>                                                                             |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch the message repository data. (Key-controlled protection does not apply.)                                                                                                                                                                                           |

## DIAGNOSE Code X'D0' – Volume Serial Support

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'D0' to pass CP the virtual device number and the volume serial (VOLSER) for a tape device. CP will include the VOLSER in error recording records it creates for that drive.

### Entry Values:

#### Rx

Contains the address of the tape volume serial passed to the DIAGNOSE interface. The tape volume serial should be six bytes long.

#### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the tape volume serial. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the tape volume serial is in the host-primary address space.

**Ry**

Contains the virtual device number passed to the DIAGNOSE interface.

**Exit Values:** Return and condition codes are returned for DIAGNOSE code X'D0'.

## Usage Note

The volume serial of a tape volume is recorded in the OBR and MDR records whenever DIAGNOSE code X'D0' has been successfully executed for the tape volume. The VOLSER is maintained until the tape volume is unloaded. If a tape is manually unloaded, CP clears the VOLSER field following the logging of the required OBR record to avoid the possibility of logging future OBR/MDR records with an incorrect VOLSER.

## Responses

### Condition Codes and Return Codes:

| Condition Code | Return Code in Ry            | Meaning                                                                                                                                                                                                      |
|----------------|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | The original contents of Ry. | DIAGNOSE completed successfully.                                                                                                                                                                             |
| 1              | 1 (X'01')                    | Addressing exception condition.                                                                                                                                                                              |
| 1              | 3 (X'03')                    | Paging or storage error.                                                                                                                                                                                     |
| 1              | 4 (X'04')                    | VOLSER fetch-protected.                                                                                                                                                                                      |
| 1              | 5 (X'05')                    | Invalid virtual device number or device not dedicated                                                                                                                                                        |
| 1              | 6 (X'06')                    | The VOLSER function does not support this device.                                                                                                                                                            |
| 1              | 7 (X'07')                    | ALET-specification exception condition: For an XC virtual machine in access-register mode, Ax contains an ALET that has an unexpected bit setting.                                                           |
| 1              | 8 (X'08')                    | ALEN-translation exception condition: For an XC virtual machine in access-register mode, Ax contains an ALET that cannot be translated.                                                                      |
| 1              | 9 (X'09')                    | Addressing-capability exception condition: For an XC virtual machine in access-register mode, Ax contains an ALET that designates an address space for which your virtual machine's access has been revoked. |

## DIAGNOSE Code X'D4' – Set Alternate User ID

**Privilege Class:** B

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE code X'D4' is used by a virtual machine when scheduling work on one of its worker virtual machines on behalf of an end user. The end user's user ID is considered to be the *alternate user ID*.

CP uses the alternate user ID in the following ways:

- Placed in the IPV MID field of the APPC/VM connection pending interrupt data when the worker issues and APPCVM CONNECT. (See Part 3, “The Advanced Program-to-Program Communication/VM,” on page 385 for more information.)
- Used as a spool file origin ID for spool files created by the worker. It establishes the end user's user ID as the originator of spool files created while the worker machine is processing the end user's request. Special files such as VMDUMP files are not affected as they rightly belong to the worker machine. When

## DIAGNOSE code X'D4'

the worker virtual machine is finished with the end user's request, the master virtual machine can set a new alternate user ID for the next job, or cancel alternate user ID processing for the worker.

### Notes:

1. The parameter list may cross a page boundary.
2. Invoking DIAGNOSE code X'D4' does not change the user ID for existing IUCV/APPC connections.
3. If an external security manager is installed and security label checking is enabled, but no SECLABEL is supplied (for either subcode 0 or 4), then the worker's VMDBK is updated with the alternate user's default SECLABEL.
4. If security label checking is not enabled, the DD4ALTSC value supplied with a subcode 4 is ignored.

### Entry Values for Subcode X'00':

#### Rx

X'00'

#### Ry

Pointer to the parameter list, DD4PARM0. DD4PARM0 COPY is provided in the HCPGPI macro library.

#### Ay

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the parameter list. If Ry designates general register 0, if Ay contains X'00000000', or if the virtual machine is not in XC mode, the parameter list is in the host-primary address space.

### DD4PARM0 DSECT

The parameter list is in this format:

|   |         |
|---|---------|
| 0 | DD4PTGT |
| 8 | DD4PALT |

### DD4PTGT

is the user ID of the worker virtual machine which will run with an alternate user ID. If less than eight characters, it must be padded on the right with blanks.

### DD4PALT

is the user ID of the end user requesting the work from the worker virtual machine. This user ID will appear as the originator of the spool files. If specified and less than eight characters, it must be padded on the right with blanks. If set to zero (not specified), then the alternate user ID and alternate SECLABEL functions are set off (reset to zero).

### Entry Values for Subcode X'04':

#### Rx

X'04'

#### Ry

Pointer to the parameter list, DD4PARM4.

#### Ay

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the parameter list. If Ry designates general register 0, if Ay contains X'00000000', or if the virtual machine is not in XC mode, the parameter list is in the host-primary address space.

### DD4PARM4 DSECT

The parameter list is in this format:

|    |          |
|----|----------|
| 0  | DD4PTGT  |
| 8  | DD4PALT  |
| 10 | DD4ALTSC |

**DD4PTGT**

is the user ID of the worker virtual machine which will run with an alternate user ID. If less than eight characters, it must be padded on the right with blanks.

**DD4PALT**

is the user ID of the end user requesting the work from the worker virtual machine. This user ID will appear as the originator of the spool files. If specified and less than eight characters, it must be padded on the right with blanks. If set to zero (not specified), then the alternate user ID and alternate SECLABEL functions are set off (reset to zero).

**DD4ALTSC**

is the SECLABEL of the end user requesting the work from the worker virtual machine. The worker virtual machine will acquire this SECLABEL value. The SECLABEL is a 1- to 8-character value. If specified and less than eight characters, it must be padded on the right with blanks.

**Exit Values:** Return codes are returned for DIAGNOSE code X'D4'.

## Responses

**Return Codes:** Return codes are returned as follows:

| Return Code in Rx | Meaning                                         |
|-------------------|-------------------------------------------------|
| 0 (X'00')         | Successful completion                           |
| 4 (X'04')         | Paging or storage error on the parameter list   |
| 8 (X'08')         | Worker virtual machine not found                |
| 12 (X'0C')        | ESM authorization denied                        |
| 16 (X'10')        | Alternate user ID currently set through APPC/VM |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'D4' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                                                                                                      |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Privileged-operation exception                                        | Any of the following: <ul style="list-style-type: none"> <li>The virtual machine is in the problem state.</li> <li>The issuer does not have class B privileges.</li> </ul> |
| Specification exception                                               | One of the following: <ul style="list-style-type: none"> <li>Rx and Ry are the same register</li> <li>The Rx register does not contain a valid subcode.</li> </ul>         |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch the parameter list.                                                                                                                      |

## DIAGNOSE Code X'D8' – Read Spool File Blocks on System Queues

**Privilege Class:** D

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'D8' to read information from the spool file descriptor block of any file in the system. This DIAGNOSE code:

- Allows a program to request the first or next spool file block on the specified queue: reader, printer, punch, or system data (NSS/DCSS, UCR, IMG, NLS, and TRF files). Files for a particular user, or any file within the system, can be specified. The descriptor block information is returned in DIAGNOSE code X'14' compatibility format (SFBLOKs), or in z/VM format (SPFBKs).

- Returns a bitmap indicating which CP-owned volumes contain at least one page of a designated spool file.

**Entry Values:**
**Rx**

Points to the parameter list, DD8PARM0. DD8PARM0 COPY is provided in the HCPGPI macro library. The parameter list must be on a doubleword boundary.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing DD8PARM0 and the output buffer for the spool file descriptor blocks. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, DD8PARM0 and the output buffer are in the host-primary address space.

**DD8PARM0 DSECT**

The parameter list, in this format:

|    |          |          |          |          |
|----|----------|----------|----------|----------|
| 0  | DD8PSPID |          | DD8PCODE |          |
| 4  | DD8PBUF  |          |          |          |
| 8  | DD8PUSER |          |          |          |
| 10 | DD8PTYPE | DD8PSIZE | DD8PCLFG | DD8PBMSZ |
| 14 | DD8PRSVD |          |          |          |

**DD8PSPID**

is the spool file ID of the previous file when reading the *next* file. It is zero if the first file is to be read.

**DD8PCODE**
**X'0000'**

Return SFBLOK format (see [Appendix A, "Data Areas Used by DIAGNOSE Codes,"](#) on page 985)

**X'0004'**

Return SPFBK format (see [Appendix A, "Data Areas Used by DIAGNOSE Codes,"](#) on page 985)

**DD8PBUF**

is the address of the storage buffer in the same address space as the parameter list. The buffer must start on a doubleword boundary and must reside in the same host address space as the parameter list.

**DD8PUSER**

is the owner of the file if the selection is by the user. This field must be either zero or blank when requesting the first file on a queue.

**DD8PTYPE**

is the queue to be searched:

**X'80'**

Printer files

**X'40'**

Punch files

**X'20'**

Reader files

**X'10'**

System data

**DD8PSIZE**

is the size of the user buffer in doublewords. If it is zero, the first 20 doublewords are returned. If the address in DD8PBUF plus the length is greater than the size of the address space, the buffer is wrapped to the beginning of the address space.

**DD8PCFLG**

means choose system or individual user files.

**X'00'**

Get the next file for the user.

**X'80'**

Get the next file regardless of the user.

**DD8PBMSZ**

is the size of a guest buffer area to hold the bitmap, in doublewords. If this field is non-zero, up to 32 bytes of the bitmap are returned. The bitmap area is located immediately after the spool file block area in the issuer's buffer.

**DD8PRSVD**

is reserved for IBM use and must be zero.

## Responses

**Condition Codes:** Condition codes are returned as follows:

| Condition Code | Meaning                                                                           |
|----------------|-----------------------------------------------------------------------------------|
| 0              | Successful completion; the spool file block has been copied to the user's buffer. |
| 1              | No files are available after the input file.                                      |
| 2              | The starting file is not found.                                                   |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'D8' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Privileged-operation exception                                        | Any of the following: <ul style="list-style-type: none"> <li>The virtual machine is in the problem state.</li> <li>The issuer of the command does not have class D privileges.</li> </ul>                                                                                                                                                                                                                                                 |
| Specification exception                                               | Any of the following: <ul style="list-style-type: none"> <li>The parameter list or buffer is not doubleword-aligned.</li> <li>The reserved fields are not set to zeros.</li> <li>The subfunction code is not defined.</li> <li>The spool file ID is specified without the corresponding user ID.</li> <li>The user ID was not specified, but the request was for a particular user.</li> <li>The queue specified is not valid.</li> </ul> |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch the parameter list or to store into the spool file block buffer.                                                                                                                                                                                                                                                                                                                                        |

## DIAGNOSE Code X'DC' – Control Application Monitor Record Collection

**Privilege Class:** Any

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

Use DIAGNOSE code X'DC' to control the collection of monitor records for an application. Data is collected by CP from buffers declared using this Diagnose function and may be used to analyze application performance.

**Entry Values:** To issue DIAGNOSE code X'DC', the user's directory must contain an OPTION APPLMON statement.

### Rx

Specifies the guest real address of the parameter list.

### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the parameter list and the product ID. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the parameter list and product ID are in the host-primary address space.

### Ry

Used for responses, no entry value required

Rx and Ry can be the same register.

There are two different formats for the parameter list based on the addressing mode of the caller. For 24-bit and 31-bit addressing mode callers there is a 16 byte parameter list:

|   |          |            |     |                    |
|---|----------|------------|-----|--------------------|
| 0 | DIAG     | FCN        | LEN | PRODUCT-ID-ADDRESS |
| 8 | //////// | BUFFER-LEN |     | BUFFER-ADDRESS     |

### DIAG

is a 2-byte field containing the DIAGNOSE code X'00DC'.

### FCN

is a 1-byte field specifying the function code of the DIAGNOSE:

#### X'00'

##### START INTERVAL RECORDING

Declare the buffer for CP monitoring. Application data is collected from this buffer by CP at each sample interval when application data monitoring is enabled by the MONITOR SAMPLE ENABLE APPLDATA command. For more information on this command, see [z/VM: CP Commands and Utilities Reference](#). The application may place data in the buffer at any time. The application may declare more than one buffer from the same virtual machine. Each START request for a given buffer address and length is treated independently.

#### X'01'

##### STOP INTERVAL OR CONFIGURATION RECORDINGS

Delete the buffer from CP monitoring. Application data is no longer collected from this buffer. Each STOP request for a given buffer address and length is treated independently. If this function is issued for an interval recording buffer then if the APPLDATA domain is enabled for event monitoring, CP generates an event monitor record, indicating that collection of application data has stopped.

#### X'02'

##### GENERATE EVENT RECORD

Collect application data from the buffer immediately as an event record, if the APPLDATA domain is enabled for event recording by the MONITOR EVENT ENABLE APPLDATA command.

**X'03'****START CONFIGURATION RECORDING**

Collect application data from the buffer immediately as an event record, if the APPLDATA domain is enabled for event recording by the MONITOR EVENT ENABLE APPLDATA command. In addition, collect application data from the buffer as a sample configuration record whenever monitor configuration data is generated.

**LEN**

is a 1-byte field specifying the byte length of the parameter list.

The minimum length is X'10'. A length beyond X'10' is allowed, but only the first 16 bytes are used by CP.

**PRODUCT-ID-ADDRESS**

is a 4-byte guest real address in the same address space as the parameter list. This address is treated as a 31-bit address if the guest PSW is in 31- or 64-bit addressing mode. It is treated as a 24-bit address in 24-bit addressing mode. It points to a 16-byte field that identifies the product that is generating the data. The contents of this field are fetched at the time DIAGNOSE code X'DC' START is issued, and are saved for inclusion in subsequent monitor records.

A suggested format for the product ID is *ppppppppffnvvrrmm*, where *pppppppp* is the product number or unique name, *ff* is the function of the product, *n* is the record number of the product, *vv* is the version, *rr* is the release, and *mm* is the modification level.

CP does not check or interpret this data; it is included in all monitor records generated for this buffer. This data may be useful for identification purposes.

**Note:** This field is not specified with function code X'01'.

**////...**

is a 2-byte reserved field.

**BUFFER-LEN**

is a 2-byte field specifying the length of the application data buffer.

The minimum value for BUFFER-LEN is 1; the maximum value is 4012.

**Note:** The maximum figure is derived to provide minimal space in a 4KB page for the static portion (APLSDT\_APHDR) of the monitor record, MRAPLSDT, the end-of-frame monitor record, MRMTREOF, and a 12-byte control area record.

For information on how to access and print the layouts or lengths of the monitor records, see [z/VM: Performance](#).

**BUFFER-ADDRESS**

is the 4-byte guest absolute address in the host-primary address space of the application data buffer. This address is treated as a 31-bit address if the guest PSW is in 31- or 64-bit addressing mode. It is treated as a 24-bit address in 24-bit addressing mode.

A trial fetch is made of the data buffer when DIAGNOSE code X'DC' is executed; this fetch is subject to key-controlled protection, but not to fetch-protection override or storage-protection override. Subsequent to the completion of DIAGNOSE code X'DC', the buffer contents are fetched periodically to be included in monitor records; no storage protection mechanisms apply to these fetches.

In z/Architecture mode the following 32-byte parameter list is preferred for 24-, 31- and 64-bit addressing mode callers:

|    |                    |            |     |              |
|----|--------------------|------------|-----|--------------|
| 0  | DIAG               | FCN        | LEN | -Not Used 1- |
| 8  | //////             | BUFFER-LEN |     | -Not Used 2- |
| 16 | PRODUCT_ID_ADDRESS |            |     |              |
| 24 | BUFFER_ADDRESS     |            |     |              |

**DIAG**

is a 2-byte field containing the DIAGNOSE code X'00DC'.

**FCN**

is a 1-byte field specifying the function code of the DIAGNOSE:

**X'80'****START INTERVAL RECORDING**

Declare the buffer for CP monitoring. Application data is collected from this buffer by CP at each sample interval when application data monitoring is enabled by the MONITOR SAMPLE ENABLE APPLDATA command. For more information on this command, see [z/VM: CP Commands and Utilities Reference](#). The application may place data in the buffer at any time. The application may declare more than one buffer from the same virtual machine. Each START request for a given buffer address and length is treated independently.

**X'81'****STOP INTERVAL OR CONFIGURATION RECORDINGS**

Delete the buffer from CP monitoring. Application data is no longer collected from this buffer. Each STOP request for a given buffer address and length is treated independently. If this function is issued for an interval recording buffer, then if the APPLDATA domain is enabled for event monitoring, CP generates an event monitor record indicating that collection of application data has stopped.

**X'82'****GENERATE EVENT RECORD**

Collect application data from the buffer immediately as an event record if the APPLDATA domain is enabled for event recording by the MONITOR EVENT ENABLE APPLDATA command.

**X'83'****START CONFIGURATION RECORDING**

Collect application data from the buffer immediately as an event record if the APPLDATA domain is enabled for event recording by the MONITOR EVENT ENABLE APPLDATA command. In addition, collect application data from the buffer as a sample configuration record whenever monitor configuration data is generated.

**LEN**

is a 1-byte field specifying the byte length of the parameter list. The minimum length for 64-bit addressing mode access is X'20'. A length beyond X'20' is allowed, but only the first 32 bytes are used by CP.

**-Not used 1-**

is a 4-byte field not used under 64-bit addressing mode.

**////...**

is a 2-byte reserved field.

**BUFFER\_LEN**

is a 2-byte field specifying the length of the application data buffer. The minimum value for BUFFER\_LEN is 1; the maximum value is 4012.

**Note:** The maximum figure is derived to provide minimal space in a 4KB page for the static portion (APLSDT\_APHDR) of the monitor record, MRAPLSDT, the end-of-frame monitor record, MRMTREOF, and a 12-byte control area record.

For information on how to access and print the layouts or lengths of the monitor records, see [z/VM: Performance](#).

**-Not used 2-**

is a 4-byte field not used under 64-bit addressing mode.

**PRODUCT\_ID\_ADDRESS**

is an 8-byte guest real address in the same address space as the parameter list. The addressing mode of the guest PSW determines whether this address is a 24-bit, 31-bit, or 64-bit address. It points to

a 16-byte field that identifies the product that is generating the data. The contents of this field are fetched at the time DIAGNOSE code X'DC' START is issued, and are saved for inclusion in subsequent monitor records.

A suggested format for the product ID is *ppppppppffnvrrmm*, where:

***pppppppp***

is the product number or unique name

***ff***

is the function of the product

***n***

is the record number of the product

***vv***

is the version

***rr***

is the release

***mm***

is the modification level

CP does not check or interpret this data; it is included in all monitor records generated for this buffer. This data may be useful for identification purposes.

**Note:** This field is not specified with function code X'01'.

#### **BUFFER\_ADDRESS**

is the 8-byte guest absolute address in the host-primary address space of the application data buffer. This address is always treated as a 64-bit address regardless of the guest PSW addressing mode.

A trial fetch is made of the data buffer when DIAGNOSE code X'DC' is executed; this fetch is subject to key-controlled protection, but not to fetch-protection override or storage-protection override. Subsequent to the completion of DIAGNOSE code X'DC', the buffer contents are fetched periodically to be included in monitor records; no storage protection mechanisms apply to these fetches.

**Exit Values:** Ry contains the return code and the condition code is set in the guest's PSW. See the Responses section for descriptions.

## **Usage Notes**

1. Recording of application data takes effect only when the application has issued DIAGNOSE code X'DC' to declare the buffer, its user has been enabled (through the CP MONITOR command) for monitoring in the APPLDATA domain, the CP monitor has been started, and at least one user is connected to the \*MONITOR IUCV system service.
2. If a buffer, or any part of it, resides within a saved segment and the segment is then purged, CP performs a DIAGNOSE code X'DC' STOP operation for this buffer, thereby stopping application data collection from this buffer.
3. If an application neglects to use the STOP function for its declared buffers then monitor data collection continues until the virtual machine logs off or performs a system reset. This may cause unexpected results.

## **Responses**

**Return Codes:** Upon completion of DIAGNOSE code X'DC', the following return codes are placed in Ry:

| Condition Code | Return Code in Ry | Meaning                                                           |
|----------------|-------------------|-------------------------------------------------------------------|
| 0              | 0 (X'00')         | The request was successfully completed.                           |
| 1              | 1 (X'01')         | The DIAGNOSE code is not X'00DC'.                                 |
| 1              | 2 (X'02')         | The function code is invalid (not X'00', X'01', X'02', or X'03'). |

| Condition Code | Return Code in Ry | Meaning                                                                                                                                                                                                                                                                                                          |
|----------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1              | 3 (X'03')         | The length of the parameter list is invalid.                                                                                                                                                                                                                                                                     |
| 1              | 4 (X'04')         | The parameter list could not be accessed because of a CP paging or storage error trying to read one of the following: <ul style="list-style-type: none"> <li>• DIAGNOSE code X'DC' parameter list</li> <li>• Application buffer</li> <li>• Product ID field.</li> </ul>                                          |
| 1              | 5 (X'05')         | The virtual machine is not authorized to issue DIAGNOSE code X'DC'.                                                                                                                                                                                                                                              |
| 1              | 6 (X'06')         | The BUFFER-LEN is not within the valid range.                                                                                                                                                                                                                                                                    |
| 1              | 7 (X'07')         | The address contained in the PRODUCT-ID-ADDRESS field is not within the address space specified in Ax (applicable for function code X'00' only).                                                                                                                                                                 |
| 1              | 8 (X'08')         | The address contained in the BUFFER-ADDRESS field is not within the addressable storage of the virtual machine's primary address space (applicable for function code X'00' only).                                                                                                                                |
| 1              | 9 (X'09')         | A DIAGNOSE code X'DC' STOP (function code X'01') was issued for a buffer that had not been declared to CP for monitoring. That is, no DIAGNOSE code X'DC' START had been issued for the buffer whose address and length correspond to the BUFFER-ADDRESS and BUFFER-LEN of the DIAGNOSE code X'DC' STOP request. |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'DC' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to <ul style="list-style-type: none"> <li>• Fetch the parameter list or product ID (except that an addressing exception condition on the product ID is reported through return code 7).</li> <li>• Perform a trial fetch from the application data buffer (except that an addressing exception condition on the buffer is reported through return code 8). Fetch-protection override and storage-protection override do not apply to the trial fetch.</li> </ul> |

## DIAGNOSE Code X'E0' – System Trace File Interface

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

DIAGNOSE code X'E0' provides a virtual machine access to system trace files. It allows the virtual machine to pass a buffer containing trace records to CP to be recorded in a system trace file. The trace files created by DIAGNOSE code X'E0' may be read using the CP TRACERED utility. For more information on TRACERED, see [z/VM: CP Commands and Utilities Reference](#).

**Entry Values:****Rx**

Is not used for the WRITE function. Rx may not be specified as register 15.

**Rx+1**

Contains the guest real address of the block of data to be written. The contents of this block are described in [“Content and Format of Trace Blocks” on page 172](#). The block, including its header, may be up to 32KB in length.

**Ax+1**

Is used only by XC virtual machines in access-register mode. Ax+1 contains the ALET for the address space containing the block of data.

**Ry**

Is subcode X'00000004' for the Write function. Ry may not be specified as register 15.

The other subcodes of DIAGNOSE code X'E0' are not programming interfaces, therefore, they are described in [Appendix F, “Reserved DIAGNOSE Codes,” on page 1031](#).

**Exit Values:** On return from the DIAGNOSE processor, a return code is set in the Ry+1 register. The return codes are right-justified in the register and padded with zeros. Only the right-most byte value is given in Responses below.

**Usage Notes**

1. Write requests using this DIAGNOSE code are ignored if TRSOURCE...BLOCK had not been enabled.
2. When a program writes a block of trace data, the first two bytes of each record must be the length of that record so that a read routine can determine the length of each record.
3. An addressing-capability exception condition (RC=X'44') can occur after writing has begun.

**Responses**

**Return Codes:** The following return codes are returned for subcode X'00000004', the Write function:

| Return Code in Ry+1 | Meaning                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')           | Successful write of trace data                                                                                                                                                                               |
| 4 (X'04')           | Trace not enabled for this user or user ID not in BLOCK mode                                                                                                                                                 |
| 12 (X'0C')          | I/O error                                                                                                                                                                                                    |
| 28 (X'1C')          | Invalid buffer address                                                                                                                                                                                       |
| 32 (X'20')          | Invalid buffer length                                                                                                                                                                                        |
| 36 (X'24')          | Protection exception condition                                                                                                                                                                               |
| 40 (X'28')          | Invalid header fields                                                                                                                                                                                        |
| 48 (X'30')          | Invalid subcode                                                                                                                                                                                              |
| 52 (X'34')          | Rx+1, Ry, and Ry+1 overlap or Rx is register 15                                                                                                                                                              |
| 56 (X'38')          | Severe error                                                                                                                                                                                                 |
| 60 (X'3C')          | ALET-specification exception condition: For an XC virtual machine in access-register mode, Ax+1 contains an ALET that has an unexpected bit setting. See the <a href="#">“Access Exceptions” on page 8</a> . |
| 64 (X'40')          | ALEN-translation exception condition: For an XC virtual machine in access-register mode, Ax+1 contains an ALET that cannot be translated. See the <a href="#">“Access Exceptions” on page 8</a> .            |

| Return Code in Ry+1 | Meaning                                                                                                                                                                                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 68 (X'44')          | Addressing-capability exception condition: For an XC virtual machine in access-register mode, Ax+1 contains an ALET that designates an address space for which your virtual machine's access has been revoked. (See usage note “3” on page 171.) See the “Access Exceptions” on page 8 |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'04' is given incorrect input data:

| Problem Encountered     | Cause              |
|-------------------------|--------------------|
| Specification exception | Ry is register 15. |

Content and Format of Trace Blocks

**Trace Blocks Containing Virtual Machine Trace Entries:** The following diagram describes the format of a block of trace data collected by CP as a result of a TRSOURCE command and saved in a system data file or the block of trace data passed to CP through DIAGNOSE code X'E0' write interface. (When a TRSOURCE...BLOCK request is made, CP inserts its own identifier into the block descriptor record and saves the time zone differential.)

|    |                                     |            |                        |          |
|----|-------------------------------------|------------|------------------------|----------|
| 0  | Blength                             | ////////   | Rlength                | //////// |
| 8  | Merge-Routine-Name                  |            |                        |          |
| 10 | Format-Routine-Name                 |            |                        |          |
| 18 | Bdesc                               | ////////// | Time zone differential |          |
| 20 | Variable length trace entry records |            |                        |          |

- Blength**

Is the 2-byte field containing the number of bytes in the block. On a write request it must be less than or equal to 32KB and not less than 32 bytes (X'0020').
- ////

Is a 2-byte reserved field. This field must contain zeros. It is reserved for system use.
- Rlength**

Is a 2-byte length of the first record, a block descriptor record used by TRACERED. This length is 28 (X'001C').
- ////

Is a 2-byte reserved field. This field must contain zeros. It is reserved for system use.
- Merge-routine-name**

is the 8-character name of the user exit routine that can be called for each trace entry record in this block to determine its TOD clock value. This routine is used for merging entries. If no name is provided

(that is, the field is blank), the records in this block cannot be merged with other trace output. On a write, this field is not checked by CP.

**Note:** The method used to create the merge routine user exit can be found in the [z/VM: CP Commands and Utilities Reference](#) under the TRACERED utility.

#### Format-routine-name

is the 8-character name of the user exit routine that can be called for each trace entry record in this block to provide formatted output. If no name is provided (that is, the field is blank), the records in this block cannot be formatted. On a write, this field is not checked by CP.

**Note:** The method used to create the format routine user exit can be found in the [z/VM: CP Commands and Utilities Reference](#) under the TRACERED utility.

#### Bdesc

This block descriptor code is reserved for system use. It is set by CP to indicate what kind of trace data the block contains.

- C'D' — Data type trace
- C'E' — Guest type trace, event mode
- C'B' — Guest type trace, block mode
- C'I' — I/O type trace
- C'L' — LAN type trace

//////

Is a 3-byte reserved field.

#### Time Zone Differential

is a 4-byte field reserved for system use. When the record is written, CP places the time zone differential here.

#### Trace Entry Records

contains trace records from the guest virtual machine. In order for these records to be processed by the CP TRACERED utility, each record must begin with a record descriptor word consisting of a 2-byte record length followed by the record.

## DIAGNOSE Code X'E4' – Return Minidisk Information/Define Full-Pack Overlay

---

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'E4' to get information about a user's minidisk or to create a full-pack overlay.

The functions are:

#### Code

##### Function

#### X'00'

To get information about the device currently linked by a logged-on user.

#### X'01'

To get information about the device as defined in the directory when the device is attached to the system.

#### X'02'

To create a full-pack overlay minidisk of the volume on which a given user's specified minidisk resides.

#### X'03'

To create for the authorized user a full-pack overlay minidisk of the volume when given the real device and cylinder/block number.

## DIAGNOSE code X'E4'

To issue function X'00' or X'01' with a user ID other than your own, your virtual machine's directory entry must include OPTION DEVINFO or DEVMAINT. To issue function X'02' or X'03', your virtual machine's directory entry must include OPTION DEVMAINT. If External Security Manager (ESM) protection is enabled for DIAGNOSE code X'E4', then the ESM's criteria are used rather than the directory options.

### Entry Values:

#### Rx

Contains the address of a parameter list. This must be on a doubleword boundary. The format of this parameter list is function dependent. References to the parameter list are not subject to key-controlled protection and low-address protection.

#### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the parameter list. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the parameter list is in the host-primary address space.

#### Ry

Is not examined as input. Rx and Ry can be the same register.

### Exit Values:

#### Rx

Contains the address of the parameter list supplied as input. If sufficient length LEN is specified, the parameter list output area contains the output values of the DIAGNOSE function. The format of this parameter list is function dependent. If Rx and Ry are the same register, the address of the parameter list will be overlaid by the return code.

#### Ry

Contains a return code. Rx and Ry can be the same register.

## Function X'00' and Function X'01'

These functions of this DIAGNOSE let a user get relocation and real device information about the minidisk of another user. If ESM (External Security Manager) protection for DIAGNOSE code X'E4' is not enabled, then the DEVINFO or DEVMAINT options of the OPTION directory control statement are required for authorization. For more information on the OPTION directory control statement, see [z/VM: CP Planning and Administration](#).

This DIAGNOSE also allows a user to get relocation information about the user's own minidisk. No special authorization is required. For input, you have to supply the following parameter list:

|    |             |     |     |        |            |
|----|-------------|-----|-----|--------|------------|
| 0  | DIAG        | FCN | LEN | VDEVNO | ////////// |
| 8  | USERID      |     |     |        |            |
| 10 | OUTPUT AREA |     |     |        |            |
| 18 | OUTPUT AREA |     |     |        |            |
| 20 | OUTPUT AREA |     |     |        |            |
| 28 | OUTPUT AREA |     |     |        |            |

**DIAG**

is the halfword DIAGNOSE code. It must contain the halfword X'00E4'.

**FCN**

is the byte function code.

**Code**

**Function**

**X'00'**

To get information about the device currently linked by a logged-on user.

**X'01'**

To get information about the device as defined in the directory.

**LEN**

is the byte length, in bytes, of the parameter list. The minimum value is X'10'. The recommended value is X'30' to accommodate the output area.

**VDEVNO**

is the halfword virtual device number of the minidisk for which information is to be returned.

**////...**

is a halfword reserved area.

**USERID**

is the user ID of the virtual machine that owns, or has a link to, the minidisk specified in VDEVNO. This is a doubleword of 8 characters. An asterisk (\*) implies the issuer's user ID. The asterisk or user ID must be left-aligned and padded with blanks.

**OUTPUT AREA**

is the four doubleword parameter list output area. It is not checked or used as input.

For output, the following information is returned in the parameter list:

|    |              |       |        |                                      |
|----|--------------|-------|--------|--------------------------------------|
| 0  | (input area) |       |        |                                      |
| 8  | (input area) |       |        |                                      |
| 10 | VOLSER       |       |        | RDEVNO                               |
| 18 | BEGINNING    |       | EXTENT |                                      |
| 20 | FLAGS        | ///// | OVDEV  | //////////////////////////////////// |
| 28 | OUSER        |       |        |                                      |

**(input area)**

is the two doublewords of the input area. This area is not used for output and is not changed from the user's input specified values.

**VOLSER**

is the 6-character volume serial number of the real volume that contains the minidisk. If the minidisk is a virtual disk in storage, it is not mapped to a real device, and the value (VDSK) is returned in this field.

**RDEVNO**

is the halfword real device number of the device containing the minidisk. If the minidisk is a virtual disk in storage, zeros are returned in this field.

**BEGINNING**

is the fullword relocation factor of the minidisk. This factor is specified in cylinders for CKD and ECKD devices or in blocks for FBA devices. The relocation factor is the number of the cylinder or block where the minidisk starts on the real volume.

**EXTENT**

is the fullword number of cylinders/blocks allocated to the minidisk. To get the number of the last cylinder or block, add the beginning cylinder/block to the total number of cylinders/blocks (extent) minus one.

**FLAGS**

is the device information:

**Code****Meaning****X'80'**

The real device associated with the specified virtual device is dedicated.

**X'40'**

The specified virtual device is a full-pack minidisk.

**Note:** The relocation factor is zero, and the extent is the number of cylinders or blocks apparently available to CP. The number of cylinders or blocks might be less than the full number of cylinders or blocks on the real volume if CP is running as a guest on another VM system in which less than a full-pack is defined.

**X'20'**

The specified virtual device is a non-full-pack minidisk.

**X'10'**

The device is a minidisk defined using the DEVNO operand of the MDISK directory control statement.

**X'08'**

The device is the primary device of a duplex pair.

**X'04'**

The device is the secondary device of a duplex pair.

**X'02'**

The scope of device is local.

**X'01'**

The scope of local is from DEFINE MDISK.

////...

is a 1-byte reserved area.

**OVDEV**

is the halfword virtual device number as defined for the virtual device owner.

////...

is a fullword reserved area.

**OUSER**

is the doubleword user ID of the virtual device owner. If the virtual device is a minidisk that was defined in terms of the source directory, OVDEV is the virtual device number that was found on the MDISK directory control statement and OUSER is the user ID of the user in whose directory entry it was found; otherwise, the OUSER-OVDEV pair is the same as was given as input.

## Function X'02'

This function of DIAGNOSE code X'E4' creates for the invoker a full-pack overlay minidisk of the volume on which a given user's specified minidisk resides. If ESM (External Security Manager) protection for DIAGNOSE code X'E4' is not enabled, then the DEVMAINT option of the OPTION directory control statement is required for authorization. For more information on the OPTION directory control statement, see [z/VM: CP Planning and Administration](#). For input, you have to supply the following parameter list:

|    |             |                                      |     |         |         |
|----|-------------|--------------------------------------|-----|---------|---------|
| 0  | DIAG        | FCN                                  | LEN | VDEVNO1 | VDEVNO2 |
| 8  | USERID      |                                      |     |         |         |
| 10 | MODE        | //////////////////////////////////// |     |         |         |
| 18 | OUTPUT AREA |                                      |     |         |         |

### DIAG

is the halfword DIAGNOSE code. It must contain the halfword X'00E4'.

### FCN

is the byte function code. It must contain the byte X'02'.

### LEN

is the byte length, in bytes, of the parameter list. The minimum value is X'12'. The recommended value is X'20' to accommodate the output area.

### VDEVNO1

Is the halfword virtual device number of the minidisk in the other user's virtual machine configuration.

### VDEVNO2

Is the halfword virtual device number in the invoker's virtual machine configuration which is to be assigned to the full-pack overlay minidisk created by this function.

### USERID

is the user ID of the virtual machine that owns, or has a link to, the minidisk you specified in VDEVNO1. This is a doubleword of 8 characters. An asterisk (\*) implies the issuer's user ID. The asterisk and user ID must be left-aligned and padded with blanks.

### MODE

is the halfword access mode for LINK.

The valid 2-character modes are:

1. *R* specifies Read-Only access. The full-pack overlay request will not be granted if any other user has write or exclusive (read or write) access to the minidisk identified as VDEVNO1. *R* must be left-aligned and padded with a blank.
2. *W* specifies Write access. The full-pack overlay request will not be granted if any other user has read or write access to the minidisk identified as VDEVNO1. *W* must be left-aligned and padded with a blank.
3. *M* specifies Multiple access. The full-pack overlay request will be granted as a write link unless another user has an existing write, stable (read or write) or exclusive (read or write) access to the minidisk identified as VDEVNO1. *M* must be left-aligned and padded with a blank.
4. *RR* specifies Read Only access. The full-pack overlay request will always be granted as a read link unless another user has an existing exclusive (read or write) access.

5. *WR* specifies Write access desired, Read access acceptable. The full-pack overlay request will be granted as a write access unless another user holds an existing read or write access to the minidisk identified as VDEVNO1, in which case the request will be granted as a read access, unless the existing access is an exclusive (read or write) access.
6. *MR* specifies Write access desired, Read access acceptable. The full-pack overlay request will be granted as a write access unless another user has an existing write, stable or exclusive access to the minidisk identified as VDEVNO1, in which case the request will be granted as a read link, unless the existing access is an exclusive access.
7. *MW* specifies Write access is desired. The full-pack overlay request will always be granted as a write link, unless another user has an existing stable or exclusive access to the minidisk identified as VDEVNO1.
8. *SR* specifies stable Read-only access is desired. The full-pack overlay request will be granted unless another user has an existing write or exclusive access to the minidisk identified as VDEVNO1. No other write access requests for this minidisk will be granted while this access is held.
9. *SW* specifies stable Write access. The full-pack overlay request will be granted as a write access unless another user has an existing access to the minidisk identified as VDEVNO1. No other write access requests for this minidisk will be granted while this access is held.
10. *SM* specifies stable Multiple access. The full-pack overlay request will be granted as a write access unless another user has an existing write, stable or exclusive access to the minidisk identified as VDEVNO1. No other write access requests for this minidisk will be granted while this access is held.
11. *ER* specifies Exclusive Read-only access. The full-pack overlay request will be granted as read-only unless another user has an existing read or write access to the minidisk identified as VDEVNO1. No other access requests for this minidisk will be granted while this access is held.
12. *EW* specifies Exclusive Write access. The full-pack overlay request will be granted as a write access unless another user has an existing read or write access to the minidisk identified as VDEVNO1. No other access requests for this minidisk will be granted while this access is held.

////...

is a 6-byte reserved area.

## **OUTPUT AREA**

is the doubleword parameter list output area. It is not checked or used as input.

## **Notes:**

1. If VDEVNO1 represents a LINK in the target user's directory, a maximum of 50 indirect directory iterations are attempted to find the MDISK definition.
2. If VDEVNO1 is a virtual disk in storage, this function fails with a return code of 0302. A virtual disk in storage is allocated from host storage rather than mapped to a real DASD, and therefore cannot be used to generate a full-pack overlay minidisk.
3. To use the stable and exclusive LINK access modes it is necessary for the user to have the appropriate option(s), LNKStabl or LNKExclu, specified on the OPTION directory control statement in the user's directory definition.
4. Function X'02' checks for conflicting links against all active minidisks that share any cylinders with the specified minidisk. For example, a user with a full-pack minidisk on the same volume might cause function X'02' to give return code 307.
5. Based on the state of the DASD and the target directory entry, function X'02' behaves as described by the following table:

| DASD state                                           | Directory MDISK statement | Result                                                                         |
|------------------------------------------------------|---------------------------|--------------------------------------------------------------------------------|
| Free                                                 | Defined by DEVNO          | The device is attached to the system and a DEVNO full-pack overlay is defined. |
| Free                                                 | Defined by VOLSER         | Error condition.                                                               |
| Attached to the system as a DEVNO-defined minidisk.  | Defined by DEVNO          | Define a DEVNO-defined full-pack overlay.                                      |
| Attached to the system as a DEVNO-defined minidisk.  | Defined by VOLSER         | Error condition.                                                               |
| Attached to the system as a VOLSER-defined minidisk. | Defined by DEVNO          | Error condition.                                                               |
| Attached to the system as a VOLSER-defined minidisk. | Defined by VOLSER         | Define a VOLSER-defined full-pack overlay.                                     |

6. This full-pack overlay appears to its owner as an ordinary full-pack minidisk, but is intended for access to only the specified minidisk.

For output, the following information is returned in the parameter list:

|    |              |
|----|--------------|
| 0  | (input area) |
| 8  | (input area) |
| 10 | (input area) |
| 18 | USERID       |

**(input area)**

contains the three doublewords of the input area. This area is not used for output and is not changed from the user's input specified values.

**USERID**

is the user ID of a virtual machine that has a link to the minidisk and is preventing the full-pack overlay from being defined. This field is filled in only if the return code is 307. This is a doubleword of 8 characters. The user ID is left-aligned and padded to the right with blanks.

## Function X'03'

This function of DIAGNOSE code X'E4' creates a full-pack overlay read/write minidisk for the invoker, giving the volume real device number and the CYLINDER/BLOCK number. If ESM (External Security Manager) protection for DIAGNOSE code X'E4' is not enabled, then the DEVMAINT option of the OPTION directory control statement is required for authorization. For more information on the OPTION directory control statement, see [z/VM: CP Planning and Administration](#).

For input, you have to supply the following parameter list:

|    |                |                                      |     |                                      |        |
|----|----------------|--------------------------------------|-----|--------------------------------------|--------|
| 0  | DIAG           | FCN                                  | LEN | RDEVNO                               | VDEVNO |
| 8  | CYLINDER/BLOCK |                                      |     | //////////////////////////////////// |        |
| 10 | MODE           | //////////////////////////////////// |     |                                      |        |
| 18 | OUTPUT AREA    |                                      |     |                                      |        |

**DIAG**

is the halfword DIAGNOSE code. It must contain the halfword X'00E4'.

**FCN**

is the byte function code. It must contain the byte X'03'.

**LEN**

is the byte parameter list length, in bytes. The minimum value is X'12'. The recommended value is X'20' to accommodate the output area.

**RDEVNO**

Is the halfword real device number of the volume.

**VDEVNO**

Is the halfword virtual device number in the invoker's virtual machine configuration which is to be assigned to the full-pack overlay minidisk created by this function.

**CYLINDER/BLOCK**

is one word and contains the real cylinder/block number.

**///...**

is a 4-byte reserved area

**MODE**

is the halfword access mode for LINK.

The valid 2-character modes are:

1. *R* specifies Read-Only access. The full-pack overlay request will not be granted if there is an existing write or exclusive access to the minidisk that includes CYLINDER/BLOCK on volume RDEVNO. *R* must be left-aligned and padded with a blank.
2. *W* specifies Write access. The full-pack overlay request will not be granted if there is any existing read or write access to the minidisk that includes CYLINDER/BLOCK on volume RDEVNO. *W* must be left-aligned and padded with a blank.
3. *M* specifies Multiple access. The full-pack overlay request will be granted as a write link unless another user has an existing write, stable or exclusive access to the minidisk that includes CYLINDER/BLOCK on volume RDEVNO. *M* must be left-aligned and padded with a blank.
4. *RR* specifies Read-Only access. The full-pack overlay request will always be granted as a read link unless another user has an existing exclusive access to the minidisk that includes CYLINDER/BLOCK on volume RDEVNO.
5. *WR* specifies Write access desired, Read access acceptable. The full-pack overlay request will be granted as a write link unless another user has an existing read or write access to the minidisk that includes CYLINDER/BLOCK on volume RDEVNO, in which case the request will be granted as a read access unless the existing access is an exclusive access.

6. *MR* specifies Write access desired, Read access acceptable. The full-pack overlay request will be granted as a write link unless another user has an existing write access to the minidisk identified as CYLINDER/BLOCK on volume RDEVNO, in which case the request will be granted as a read access unless the existing access is an exclusive access.
7. *MW* specifies Write access. The full-pack overlay request will always be granted as a write link, unless there is an existing stable or exclusive access to the minidisk that includes CYLINDER/BLOCK on volume RDEVNO.
8. *SR* specifies stable Read-only access. The full-pack overlay request will not be granted if any other user has write or exclusive access to the minidisk that includes CYLINDER/BLOCK on volume RDEVNO. No other write access requests that include this cylinder/block will be granted while this access is held.
9. *SW* specifies stable Write access. The full-pack overlay request will be granted as a write access unless another user has an existing access to the minidisk that includes CYLINDER/BLOCK on volume RDEVNO. No other write access requests that include this cylinder/block will be granted while this access is held.
10. *SM* specifies stable Multiple access. The full-pack overlay request will be granted as a write access unless another user has an existing write, stable or exclusive access to the minidisk that includes CYLINDER/BLOCK on volume RDEVNO. No other write access requests that include this cylinder/block will be granted while this access is held.
11. *ER* specifies Exclusive Read-only access. The full-pack overlay request will not be granted if any other user has an existing read or write access to the minidisk that includes CYLINDER/BLOCK on volume RDEVNO. No other access requests that include this cylinder/block will be granted while this access is held.
12. *EW* specifies Exclusive Write access. The full-pack overlay request will not be granted if any other user has an existing read or write access to the minidisk that includes CYLINDER/BLOCK on volume RDEVNO. No other access requests that include this cylinder/block will be granted while this access is held.

////...

is a 6-byte reserved area.

#### OUTPUT AREA

is a 14-byte parameter list output area. It is not checked or used as input.

#### Note:

1. To use the stable and exclusive LINK access modes it is necessary for the user to have the appropriate option(s), LNKStabl and/or LNKExclu, specified on the OPTION directory control statement in the user's directory definition.
2. Function X'03' checks for conflicting links against all active minidisks that include the specified cylinder. For example, a user with a full-pack minidisk on the specified volume might cause function X'03' to give return code 407.
3. This full-pack overlay appears to its owner as an ordinary full-pack minidisk, but is intended for access to only the specified cylinder or block.
4. Based on the state of the DASD, function X'03' behaves as described by the following table:

| DASD state                                           | Result                                                                         |
|------------------------------------------------------|--------------------------------------------------------------------------------|
| Free                                                 | The device is attached to the system and a DEVNO full-pack overlay is defined. |
| Attached to the system as a DEVNO-defined minidisk.  | Define a DEVNO-defined full-pack overlay.                                      |
| Attached to the system as a VOLSER-defined minidisk. | Define a VOLSER-defined full-pack overlay.                                     |

For output, the following information is returned in the parameter list:

|    |              |
|----|--------------|
| 0  | (input area) |
| 8  | (input area) |
| 10 | (input area) |
| 18 | USERID       |

**(input area)**

contains the three doublewords of the input area. This area is not used for output and is not changed from the user's input specified values.

**USERID**

is the user ID of a virtual machine that has a link to the minidisk and is preventing the full-pack overlay from being defined. This field is filled in only if the return code is 407. This is a doubleword of 8 characters. The user ID is left-aligned and padded to the right with blanks.

## Usage Notes

1. For customers running RACF/VM, please see [z/VM: RACF Security Server Security Administrator's Guide](#), for procedures on how to protect the invocation of DIAGNOSE code X'E4'.
2. For functions X'00' and X'01', when the secondary device of a duplex pair is specified, the minidisk information for the corresponding primary will be returned except for the *rdev* field. This must occur because two volumes in a duplex, duplex pending, or suspended state allow only the primary volume to be fully functional. I/O operations to the secondary are limited.
3. The maximum allowed link indirections is 50.
4. You may not be authorized to issue this DIAGNOSE code if an external security manager is installed on your system. For additional information, contact your security administrator.

## Responses

**Condition Codes and Return Codes:** Upon successful completion of DIAGNOSE code X'E4', the condition code is set to 0 and Ry is set to 0.

Upon failure of DIAGNOSE code X'E4', the condition code is set to 1 and Ry is assigned one of the following return codes:

| Return Code  | Meaning                                                                                                               |
|--------------|-----------------------------------------------------------------------------------------------------------------------|
| 0001 (X'01') | The parameter list contains the wrong DIAGNOSE code. The DIAGNOSE code must be X'00E4'.                               |
| 0002 (X'02') | The parameter list contains an invalid function code. The function code must be one of X'00', X'01', X'02', or X'03'. |
| 0003 (X'03') | The parameter list specifies a length that is too short to contain the input parameters.                              |
| 0004 (X'04') | The parameter list could not be accessed because of a system error.                                                   |

| Return Code   | Meaning                                                                                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0005 (X'05')  | The user does not have directory authorization or ESM authorization. You must have the appropriate options (such as DEVINFO, DEVMAINT, LNKStabl, LNKExclu, and so forth) specified on your OPTION directory control statement and if RACF/VM is installed, the appropriate RACF PERMITS executed on your behalf. |
| 0100 (X'64')  | For function code 00, user ID USERID is not logged on.                                                                                                                                                                                                                                                           |
| 0101 (X'65')  | For function code 00, virtual device VDEVNO is not in the specified user's current virtual I/O configuration.                                                                                                                                                                                                    |
| 0102 (X'66')  | For function code 00, virtual device VDEVNO is not a minidisk or a temporary disk.                                                                                                                                                                                                                               |
| 0200 (X'C8')  | For function code 01, user ID USERID is not defined to the system.                                                                                                                                                                                                                                               |
| 0201 (X'C9')  | For function code 01, virtual device VDEVNO is not in the specified user's current virtual I/O configuration.                                                                                                                                                                                                    |
| 0202 (X'CA')  | For function code 01, virtual device VDEVNO is not a minidisk.                                                                                                                                                                                                                                                   |
| 0203 (X'CB')  | For function code 01, virtual device VDEVNO is on an unmounted real volume.                                                                                                                                                                                                                                      |
| 0204 (X'CC')  | For function code 01, the directory blocks could not be accessed because of system error.                                                                                                                                                                                                                        |
| 0211 (X'D3')  | For function code 01, there is an excessive number of indirect links.                                                                                                                                                                                                                                            |
| 0300 (X'12C') | For function code 02, user ID USERID is not defined to the system.                                                                                                                                                                                                                                               |
| 0301 (X'12D') | For function code 02, virtual device VDEVNO1 is not in the specified user's current virtual I/O configuration.                                                                                                                                                                                                   |
| 0302 (X'12E') | For function code 02, virtual device VDEVNO1 must be a regular minidisk, not a T-disk or a virtual disk in storage.                                                                                                                                                                                              |
| 0303 (X'12F') | For function code 02, virtual device VDEVNO1 is on an unmounted real volume.                                                                                                                                                                                                                                     |
| 0304 (X'130') | For function code 02, the directory blocks could not be accessed because of system error.                                                                                                                                                                                                                        |
| 0305 (X'131') | For function code 02, a full-pack overlay already exists.                                                                                                                                                                                                                                                        |
| 0306 (X'132') | For function code 02, virtual device VDEVNO1 is not accepted because it is a minidisk that contains CP system space (for example, paging, spooling, directory, or T-disk).                                                                                                                                       |
| 0307 (X'133') | For function code 02, minidisk has existing links to it that prevent linking with the access mode requested. The USERID returned identifies the holder of the "strongest" conflicting link (the first in the series EW, ER, SW, SR, R/W, R/O) to the minidisk identified by VDEVNO.                              |
| 0308 (X'134') | For function code 02, LINK unsuccessful.                                                                                                                                                                                                                                                                         |
| 0309 (X'135') | For function code 02, access mode invalid.                                                                                                                                                                                                                                                                       |
| 0310 (X'136') | For function code 02, reserved for IBM use.                                                                                                                                                                                                                                                                      |
| 0311 (X'137') | For function code 02, there is an excessive number of indirect links.                                                                                                                                                                                                                                            |
| 0400 (X'190') | For function code 03, reserved for IBM use.                                                                                                                                                                                                                                                                      |
| 0401 (X'191') | For function code 03, reserved for IBM use.                                                                                                                                                                                                                                                                      |
| 0402 (X'192') | For function code 03, real device RDEVNO is not a DASD.                                                                                                                                                                                                                                                          |
| 0403 (X'193') | For function code 03, real device RDEVNO is dedicated, off-line, or unmounted.                                                                                                                                                                                                                                   |

## DIAGNOSE Code X'EC'

| Return Code   | Meaning                                                                                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0404 (X'194') | Reserved.                                                                                                                                                                                                                                                                                                        |
| 0405 (X'195') | For function code 03, a full-pack overlay already exists.                                                                                                                                                                                                                                                        |
| 0406 (X'196') | For function code 03, real device RDEVNO is not accepted because it lies within CP system space (for example, paging, spooling, directory, or T-disk).                                                                                                                                                           |
| 0407 (X'197') | For function code 03, minidisk has existing links to it that prevent linking with the access mode requested. The USERID returned identifies the holder of the strongest conflicting link (the first in the series EW, ER, SW, SR, R/W, R/O) to the minidisk defined on the real volume RDEVNO at CYLINDER/BLOCK. |
| 0408 (X'198') | For function code 03, LINK unsuccessful.                                                                                                                                                                                                                                                                         |
| 0409 (X'199') | For function code 03, access mode invalid.                                                                                                                                                                                                                                                                       |
| 0410 (X'19A') | For function code 03, CYLINDER/BLOCK number invalid.                                                                                                                                                                                                                                                             |
| 0411 (X'19B') | For function code 03, real device RDEVNO is a PAV or HyperPAV alias device.                                                                                                                                                                                                                                      |

**Program Exceptions:** These program exceptions can occur if the DIAGNOSE X'E4' is given incorrect input data:

| Problem Encountered                                                   | Cause                                                                              |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------|
| Specification exception                                               | The address of the parameter list specified in Rx is not on a doubleword boundary. |
| Privileged-operation exception                                        | The virtual machine is in the problem state.                                       |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch from or store into the parameter list.           |

## DIAGNOSE Code X'EC' – Query GUEST Trace Status

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'EC' to determine whether data transmitted by a virtual machine through a Query GUEST Trace command is placed in a system trace file.

**Entry Values:**

**Rx**

Contains the address of the input buffer.

The input buffer should be in the following format:

**Byte 0**

is the subcode and must be X'00'

**Byte 1**

can be

- X'00' — Non-group trace entries
- X'01' — Group trace entries

**Note:** This value is not used by z/VM. It exists only for compatibility with VM/SP, VM/SP HPO, and VM/ESA (370 Feature).

**Note:** The minimum input length is 2 bytes.

#### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the input buffer. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the input buffer is in the host-primary address space.

#### Rx+1

Contains the length in bytes of the input buffer. The length must be at least 1 and no more than 255 bytes.

#### Ry

Contains the address of the output buffer. An output buffer must be provided.

#### Ay

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the output buffer. If Ry designates general register 0, if Ay contains X'00000000', or if the virtual machine is not in XC mode, the output buffer is in the host-primary address space.

#### Ry+1

Contains the length in bytes of the output buffer. The length must be at least 1 and no more than 255 bytes.

#### Exit Values:

#### Ry+1

Contains the return code when an error occurred.

Information returned from DIAGNOSE code X'EC' is as follows:

#### Byte 0

X'00'

Byte 0 is in the following format:

**X...** ....

Reserved (always on)

**.X..** ....

Indicates TRSOURCE has been issued for this user

**..X.** ....

Indicates TRSOURCE ENABLE has been issued in EVENT mode for this user

**...X** ....

Indicates TRSOURCE ENABLE has been issued in BLOCK mode for this user

**.... XXXX**

Reserved

**Note:** The minimum output length is 1 byte.

## Responses

**Condition Codes and Return Codes:** Upon completion, DIAGNOSE code X'EC' sets the following condition and return codes:

| Condition Code | Return Code in Ry+1 | Meaning                                                                                    |
|----------------|---------------------|--------------------------------------------------------------------------------------------|
| 0              |                     | Query completed without error. Rx, Rx+1, Ry, Ry+1 not changed.                             |
| 1              | 4 (X'04')           | Reserved. Not used by z/VM.                                                                |
| 1              | 8 (X'08')           | An error occurred. The input buffer size is invalid; it is either too small or too large.  |
| 1              | 12 (X'0C')          | An error occurred. The output buffer size is invalid; it is either too small or too large. |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'EC' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                            |
|-----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception                                               | Any of the following: <ul style="list-style-type: none"> <li>• Rx or Ry is register 15.</li> <li>• Rx is the same register as Ry or Ry+1</li> <li>• Rx+1 is the same register as Ry</li> <li>• The subcode (input byte 0) is invalid.</li> </ul> |
| Privileged-operation exception                                        | Any of the following: <ul style="list-style-type: none"> <li>• The virtual machine is in the problem state.</li> </ul>                                                                                                                           |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch input data or store output data.                                                                                                                                                                               |

## DIAGNOSE Code X'F8' – Spool File Origin Information

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'F8' to have your virtual machine associate the originating node and the user ID information with a virtual output device, or retrieve the stored information for one of your virtual machine's spool files.

**Subcodes:**

- X'00' for the function to associate originating node and user ID with a virtual output device. This can be done only if you are authorized with the SETORIG operand on the OPTION control statement in your virtual machine's directory entry.
- X'01' for the general user function to retrieve the stored originating node and user ID information for a spool file.

**Entry Values:**

**Rx**

Contains the subcode.

**Ry**

Contains the guest real address of the doubleword-aligned parameter list, DF8PARM. DF8PARM COPY may be found in the HCPGPI macro library. The parameter list is used differently for each subcode.

**Ay**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the DF8PARM. If Ry designates general register 0, if Ay contains

X'00000000', or if the virtual machine is not in XC mode, the DF8PARM is in the host-primary address space.

The DF8PARM parameter list for subcode X'00' is as follows:

#### DF8PARM DSECT

|    |          |          |
|----|----------|----------|
| 0  | DF8VCODE | DF8DVNUM |
| 4  | DF8ONODE |          |
| 8  |          |          |
| C  | DF8OUSER |          |
| 10 |          |          |

#### DF8VCODE

is reserved for IBM use. It must be binary zeros.

#### DF8DVNUM

is the output unit record device number (in hexadecimal).

#### DF8ONODE

is the originating node for the spool file creation (in EBCDIC). This is left-aligned and padded on the right with blanks.

#### DF8OUSER

is the originating user ID for the spool file created (in EBCDIC). This is left-aligned and padded on the right with blanks.

The DF8PARM parameter list for subcode X'01' is as follows:

#### DF8PARM DSECT

|    |          |         |
|----|----------|---------|
| 0  | DF8VCODE | DF8SPID |
| 4  | DF8ONODE |         |
| 8  |          |         |
| C  | DF8OUSER |         |
| 10 |          |         |

#### DF8VCODE

is reserved for IBM use. It must be binary zeros.

#### DF8SPID

is the spool file ID for which the originating node and the user ID information is retrieved (in hexadecimal).

#### DF8ONODE

is the originating node for the spool file (to be filled in by CP). This is left-aligned and padded on the right with blanks.

#### DF8OUSER

is the originating user ID for the spool file (to be filled in by CP). This is left-aligned and padded on the right with blanks.

#### Exit Values:

**Rx**

On return, Rx contains the return code for the subcode.

**Usage Notes**

1. If subcode X'00' is issued for a virtual output device, all files generated on that output device contain the originating node and user ID information. To change the originating node and user ID information for a virtual output device, subcode X'00' must be issued again. To clear the originating node and user ID information, subcode X'00' must be issued again for the virtual output device, specifying blanks for the originating information.
2. When subcode X'00' is issued for a virtual output device, the originating node and user ID information is stored with the next file to be opened on that device. If there is an open file on the device when subcode X'00' is issued, that file does not contain the originating node and user ID information specified on the DIAGNOSE issued after the file is opened. You must issue subcode X'00', then open the file on the specified device.
3. Subcode X'01' may not be used for an open spool file. A return code will be set indicating that the spool file was not found (RC=8).

**Responses**

**Return Codes:** Return codes for subcode X'00' are as follows:

| Return Code in Rx | Meaning                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')         | Successful completion; the originating node and user ID information has been associated with the virtual output device. |
| 8 (X'08')         | Device not found                                                                                                        |
| 12 (X'0C')        | The device is not a unit record output device.                                                                          |

Return codes for subcode X'01':

| Return Code in Rx | Meaning                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')         | Successful completion; the originating node and user ID information has been stored in the parameter list.                                                  |
| 4 (X'04')         | The originating node and user ID information were not stored for this file; DF8OUSER contains the user ID of the originator of the spool file on this node. |
| 8 (X'08')         | Spool file not found                                                                                                                                        |
| 16 (X'10')        | Fatal paging I/O error                                                                                                                                      |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'F8' is given incorrect data:

| Problem Encountered            | Cause                                                                                                                                                                                                                                                                                           |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception        | Any of the following: <ul style="list-style-type: none"> <li>• The subcode is not defined.</li> <li>• The parameter list is not doubleword-aligned.</li> <li>• The DF8VCODE is invalid.</li> <li>• The issuer of the privileged subcode X'00' is not authorized in the CP directory.</li> </ul> |
| Privileged-operation exception | The virtual machine is in the problem state.                                                                                                                                                                                                                                                    |

| Problem Encountered                                                   | Cause                                                                    |
|-----------------------------------------------------------------------|--------------------------------------------------------------------------|
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch from or store into the parameter list. |

## DIAGNOSE Code X'210' – Retrieve Device Information

**Privilege Class:** G

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'210' to request identifying information and status information about a particular virtual device. DIAGNOSE code X'210' replaces DIAGNOSE code X'24' for new applications. Your virtual machine must specify the address of the virtual device for which information is requested. DIAGNOSE code X'24' should still be used in order to determine the address of the virtual console.

**Entry Values:**

**Rx**

contains the guest real address of the Virtual/Real Device Characteristics Block (VRDCBLOK), which includes the input parameter list and an area for the output data.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the buffer. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the buffer is in the host-primary address space.

**Virtual/Real Device Characteristics Block (VRDCBLOK)**

is the buffer containing the address of the virtual device (bytes 0 and 1) and the length of the buffer (bytes 2 and 3). The block must be on a fullword boundary and if a length of 16 bytes or more is specified, then bytes 14-15 must be zeros; otherwise, a specification exception occurs.

**Exit Values:**

**Virtual/Real Device Characteristics Block**

contains virtual device, real device, and control unit information.

### Virtual/Real Device Characteristics Block

The Virtual/Real Device Characteristics Block contains virtual device, real device, and control unit information, and data from READ DEVICE CHARACTERISTICS. The symbolic names in [Table 21 on page 191](#) describe the corresponding fields. See [Appendix A, “Data Areas Used by DIAGNOSE Codes,” on page 985](#) for a description and for bit definitions of the fields in the diagram.

You can use the VRDCBLOK DSECT, which is in the VRDCBLOK COPY file (found in the HCPGPI macro library), to map the buffer.

The VRDCBLOK DSECT fields are shown in [Figure 15 on page 190](#) and are described in the table following the figure.

Figure 15. Fields in the VRDCBLOK DSECT

<sup>2</sup> For the meanings of these bytes, refer to [Appendix A, “Data Areas Used by DIAGNOSE Codes,”](#) on page 985.

Table 21. Fields in the VRDCBLOK DSECT

| Displace-<br>ment | Name     | Length                                                        | Description                                                                                                                                         |
|-------------------|----------|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 000               | VRDCDVNO | XL2                                                           | Virtual device number (input field)                                                                                                                 |
| 002               | VRDCLEN  | XL2                                                           | VRDCBLOK length (input)                                                                                                                             |

| 00E               | VRDCRSVD | XL2    | Reserved. This value must be zero on z/VM 5.3.0 and earlier.                                                                                                                                                                                            |
| 060               | VRDCVERS | XL1    | Specifies version of output buffer. Should be 0 on input. On output, if this value is X'00' only the first 96B of output data are valid.                                                                                                                |
| 061               | VRDCRSIO | XL31   | Reserved for future Input/Output fields. Should be set to zero for input.                                                                                                                                                                               |
| 080               | VRDCRDEV | XL2    | Contains the device number of the underlying real device. This value is only valid when the diagnose returns with a CC of 0 and the VRDCEMRD bit is OFF. If there is a nonzero CC or the VRDCEMRD bit is ON, then VRDCRDEV will be X'0000' but invalid. |
| 082               | VRDRRCC  | XL1    | Contains condition codes explaining reasons why a real device may not be able to be reserved. If this field is zero, real Reserve CCWs will be issued to the underlying real device.                                                                    |
|                   |          |        | <b>VRDSUPRR X'80'</b><br>Underlying device does not support reserve/release.                                                                                                                                                                            |
|                   |          |        | <b>VRDMDWOV X'40'</b><br>Minidisk without the 'v' suffix.                                                                                                                                                                                               |

## Usage Notes

1. The field VRDCVERS should be cleared before issuing DIAGNOSE X'210'. This field will be updated as output from the DIAGNOSE, such that:
  - The field will remain unchanged if the value of VRDCLEN is not greater than X'60'.
  - The field will remain unchanged if z/VM is version 5.3.0 or earlier.
  - The field will be set to X'01' if z/VM is version 5.4.0 or greater and the value of VRDCLEN is greater than X'60'. This implies that the data returned beginning at offset X'60' is valid up until VRDCLEN.
2. It is strongly recommended that the field VRDCRSIO be cleared prior to issuing the DIAGNOSE. IBM presently does not check these fields for input, but may do so in future releases.

3. The device information in bytes X'004' through X'009', and X'00B', is returned in a format consistent with DIAGNOSE code X'24'. However, the real device model field in DIAGNOSE code X'24' and the corresponding byte (X'00A') in DIAGNOSE code X'210' return different information. For a 3380 DASD, DIAGNOSE code X'24' returns the high-order 4 bits of the control unit model number in its high-order 4 bits, and the low-order 4 bits of the device model number in its low-order 4 bits in the real device model field. For a 3390 and 9345, DASD, the model number does not apply for DIAGNOSE code X'24'. Instead, byte X'00A' in DIAGNOSE code X'210' contains only device model information for all devices.
4. Refer to the hardware manuals for content descriptions of the sense ID or the READ DEVICE CHARACTERISTICS channel command results.
5. If DIAGNOSE code X'210' is issued for a device that does not support RDC, the RDC data bytes starting with Byte X'015' show the static device information and do not necessarily conform to the format given.
6. When DIAGNOSE code X'210' is issued for a minidisk, the number of primary cylinders or blocks is set to the size of the minidisk. The alternate, diagnostic, and device support cylinder or block addresses, and number of tracks, are all set to zero.
7. DIAGNOSE code X'210' returns as much information to the virtual machine as possible in the VRDCBLOK. For example, if the length is only 8 bytes, then only the virtual device information is returned.
8. If the virtual device is a virtual disk in storage, it is not mapped to a real device. However, condition code 0 is returned for successful completion, and VRDCBLOK contains information about the simulated real device.
9. When issued for a virtual console and the user is logged on to the system console, CP will return real device information indicating that the real device is an undefined line mode terminal.

## Responses

**Condition Codes:** Upon completion of DIAGNOSE code X'210', the condition codes are:

| Condition Code | Meaning                                                              |
|----------------|----------------------------------------------------------------------|
| 0              | Normal completion.                                                   |
| 1              | CP paging error, no data returned.                                   |
| 2              | The virtual device exists, but is not associated with a real device. |
| 3              | Invalid device address, or the virtual device does not exist.        |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'210' is given incorrect data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                               |
|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                                                                                                                                        |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to fetch from or store into the VRDCBLOK.                                                                                                                                                                                  |

## DIAGNOSE Code X'218' – Retrieve Real CPU Identification

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'218' to request the real CPU identification. The information is stored in a buffer address supplied in the Ry register.

**Entry Values:**

**Rx**

Contains a function code:

- Function code 0  
The CPU identification is returned to an 8-byte buffer address in Ry. The data returned is the same as supplied by the STIDP instruction on the real machine.
- Function code 1  
The CPU identification is returned in 16-byte character format to the second half of a 32-byte buffer addressed by Ry. The first half of the 32-byte buffer contains a 16-byte translation string supplied by the calling program. Each byte of the translation string corresponds in sequence to the characters 0 (zero) through F.

**Ry**

Contains a guest real address of a buffer in the following format:

- Function code 0 in Rx: CPU identification; for format, see the description of STORE CPU ID in [z/Architecture Principles of Operation, SA22-7832](#).
- Function code 1 in Rx:

A 32-byte buffer; the first 16 bytes contains a translation string supplied by the calling program. The translated CPU identification is stored in character format in the second half of the buffer.

The 8-byte binary CPU ID (STIDP instruction format) is converted to a 16-byte character string by translating each 4-bit nibble to one byte, picking the byte at the corresponding offset (0-15) in the given 16-byte translation string.

For example, specifying the translation string '0123456789ABCDEF' results in the CPU identification being returned in character format in the second half of the 32-byte buffer.

**Ay**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the buffer. If Ry designates general register 0, if Ay contains X'00000000', or if the virtual machine is not in XC mode, the buffer is in the host-primary address space.

**Exit Values:**

**Rx**

Contains a return code

**Ry**

Does not change.

Results are stored in the CPU identification buffer.

**Usage Notes**

1. In a multiprocessor configuration, this DIAGNOSE may execute on different processors in subsequent calls, resulting in different a CPU identification being returned.

## DIAGNOSE Code X'218'

- As is the case for all programs that run in virtual machines, the execution of a program that uses this DIAGNOSE code, and the results of the DIAGNOSE code that the program observes, can be altered through the use of CP debugging commands (such as TRACE).

## Responses

**Return Codes:** Upon completion of DIAGNOSE code X'218', the following return codes are placed in Rx:

| Return Code in Rx | Meaning                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')         | Real CPU identification is successfully returned to the buffer address supplied in Ry.                                                   |
| 4 (X'04')         | DIAGNOSE is not supported on a lower level Control Program. Virtual CPU identification is returned to the buffer address supplied in Ry. |

## Examples

The following code shows how DIAGNOSE code X'218' can be called to get the binary CPU ID from the real processor:

## DIAGNOSE Code X'238' – Time-Based Unique Identifiers

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'238' to obtain a time stamp value and clock sequence number to form unique time-based serial numbers.

The time stamp value is defined as a 60 bit number. It represents the number of 100-nanosecond intervals of time that have passed since the standard time origin. The standard time origin, the time which corresponds to a TOD clock value of zero, is January 1, 1900 0 a.m. Coordinated Universal Time (UTC).

The clock sequence number is defined as a 14 bit value. It is given a random non-zero value on the first IPL of the system or when the system is IPLed with no valid checkpoint data. It is incremented (modulo 16384) every time the system is IPLed or every time diagnose X'238' is issued and the system clock appears to have been set backwards. The range of values for the clock sequence number is from 1 to 16383. When the clock sequence number reaches 16383, the value on the subsequent IPL would be 1.

### Entry Values:

**Rx**

Contents must be 0.

**Ry**

Contents must be 0.

### Exit Values:

**Rx**

The low order 28 bits (4-31) are set to the high order 28 bits of the time stamp value. The high order 4 bits (0-3) are set to zero.

**Rx+1**

Set to the low order 32 bits of the time stamp value.

**Ry**

The clock sequence number is placed in the low order 14 bits (18-31). The high order 18 bits (0-17) are set to zero.

## Usage Notes

1. No two invocations of this diagnose instruction will return the same 60 bit time stamp value unless the time on the system clock is set backwards. This is true even when the diagnose instruction is issued simultaneously by multiple virtual CPUs.
2. The clock sequence number is maintained over a system shutdown. Thus, along with the 60 bit time stamp value, the clock sequence number can be used to ensure that a unique time-based serial number is returned to the issuer of the diagnose.
3. Although the time stamp value returned by this diagnose is derived from the TOD clock, this diagnose is not intended to be used as a timing mechanism for application programs.

## Responses

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'238' is given incorrect data:

| Problem Encountered            | Cause                                                                                                                                                                                                                                                                         |

| Privileged-operation exception | The virtual machine is in the problem state.                                                                                                                                                                                                                                  |

## DIAGNOSE Code X'248' – Copy-To-Primary Service

**Privilege Class:** Any (XA, ESA, and Z virtual machines only)

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'248' to copy data from an address space designated by a host access-list entry (ALE) on your virtual machine's host access list into your virtual machine's host-primary address space. An XA, ESA, or Z virtual machine must use this DIAGNOSE to access address spaces on its host access list because the host access-register translation process of the XC architecture is not available to it.

This DIAGNOSE code copies data from an ALET-specified source address space into the host-primary address space. The source location is specified by an address and an ALET contained in an even-odd general-register pair. The target location is specified by an address contained in the even register of an even-odd general-register pair, and the number of bytes to be copied is specified in the odd register of that even-odd register pair.

The ALET identifying the source address space is translated through host access-register translation as if the virtual machine was an XC virtual machine operating in the access-register mode. An ALEN-translation, ALET-specification, or addressing-capability exception may possibly be recognized on this DIAGNOSE code as a result of host access-register translation, even though these exceptions cannot normally occur for an XA or DAT-off ESA or Z virtual machine. If an ALEN-translation or addressing-capability exception occurs, zeros will be stored at location 160 and the ALET being translated will be stored at locations 168-171.

Movement of data from the source area to the target area starts at the left end (lowest-numbered address) of both areas and proceeds to the right. The storage-operand-consistency specification for the storage accesses and the handling of destructive overlap conditions is the same as is defined for the MOVE CHARACTER (MVC) instruction. For destructive-overlap purposes, the target is considered to be specified by ALET X'00000000'; thus, if a non-zero source ALET is used to access the host-primary space, destructive overlap may not be recognized and may yield unpredictable results.

### Entry Values:

#### Rx

Contains the real address of the first byte of the target storage area. This target-area address is treated as a 24-bit or 31-bit real address as appropriate.

The target area always resides within the host-primary address space.

Address wraparound for the target addresses occurs according to the ESA rules for 24-bit address wraparound when the target addresses are treated as 24-bit addresses, and according to the ESA rules for 31-bit address wraparound when the target addresses are treated as 31-bit addresses.

Rx must designate the even register of an even-odd pair of general registers; otherwise a specification exception is recognized.

#### Rx+1

Bits 8-31 of the Rx+1 register contain the number of bytes to be copied from the source address space into the host-primary address space, starting at the addresses contained in the Rx and Ry registers.

## DIAGNOSE Code X'250'

Bits 0-7 of the Rx+1 register are ignored.

### Ry

Contains the real address of the first byte of the source storage area. This source-area address is always treated as a 31-bit real address.

The source area resides within the host-address space designated by the ALET in register Ry+1.

Address wraparound for the source addresses occurs according to the ESA rules for 31-bit address wraparound.

Ry must designate the even register of an even-odd pair of general registers; otherwise a specification exception is recognized.

### Ry+1

Contains an ALET designating the source address space. This ALET must designate a valid ALE in your virtual machine's host access list, or be an ALET of X'00000000' designating your virtual machine's host-primary address space. If the ALET does not designate a valid ALE, then host-ART-related exceptions will be recognized as in ESA/XC or z/XC architecture (ALEN-translation, ALET-specification, or addressing-capability) depending on the particular exception condition.

The Rx and Ry fields must designate different registers; otherwise a specification exception is recognized.

**Exit Values:** None.

## Usage Note

The target addresses are treated as 24-bit or 31-bit real addresses based on the setting of the addressing-mode bit, bit 32 of the PSW.

See [“How Addresses Are Processed”](#) on page 5.

## Responses

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'248' is given incorrect data:

| Problem Encountered                                                                                                  | Cause                                                                                                                                                                                                                                                                                                                               |

## DIAGNOSE Code X'250' – Block I/O (Standard Blocksize)

**Privilege Class:** Any

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

Use DIAGNOSE code X'250' to perform input/output operations to a direct-access storage device with consistent block sizes and supported by z/VM. DIAGNOSE code X'250' provides a virtual machine with device independent access to its virtual DASD devices either synchronously or asynchronously.

DIAGNOSE code X'250' also supports input/output operations to and from data spaces. Status of the DIAGNOSE is contained in the condition code, the Rx+1 register and the block I/O entry list.

#### Entry Values:

##### Rx

is the general register that contains the guest real address of the block I/O parameter list (HCPBIOPL). The BIOPL must be on a doubleword boundary.

The entire BIOPL will be replaced in guest storage when this function completes.

##### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the block I/O parameter list (BIOPL). If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the parameter list is in the host-primary address space.

##### Ry

In z/Architecture and z/XC mode the high order word of register Ry is ignored. The low order register word contains a function code in the low order byte. The possible function codes are:

- X'00' - Initialize the environment to perform block I/O to a virtual DASD
- X'01' - Read/Write to a virtual DASD
- X'02' - Remove the block I/O environment for a virtual DASD

The remaining three bytes must contain binary zeros.

#### Exit Values:

##### Rx+1

Contains the return code indicating the result of this request. Refer to [“Responses” on page 211](#) for a description of the possible values of this field. In z/Architecture mode the high order word of register Rx+1 is unaltered.

## Initialize Block I/O to a Device

This function establishes the necessary environment to invoke subsequent read/write functions of DIAGNOSE code X'250' on a virtual device.

The function code for an initialization request is X'00', and the BIOPL is defined by one of the following formats determined by bit 0 of byte X'02'.

If bit 0 of byte X'02' is zero:

|    |                                  |                  |                                  |
|----|----------------------------------|------------------|----------------------------------|
| 00 | Device Number                    | FlagA   00000000 | 00000000000000000000000000000000 |
| 08 | 00000000000000000000000000000000 |                  | 00000000000000000000000000000000 |
| 10 | 00000000000000000000000000000000 |                  | 00000000000000000000000000000000 |
| 18 | Block Size                       |                  | Offset                           |
| 20 | Start Block                      |                  | End Block                        |
| 28 | 00000000000000000000000000000000 |                  | 00000000000000000000000000000000 |
| 30 | 00000000000000000000000000000000 |                  | 00000000000000000000000000000000 |
| 38 | 00000000000000000000000000000000 |                  | 00000000000000000000000000000000 |

If bit 0 of byte X'02' is one:

|    |                                  |                  |                                  |
|----|----------------------------------|------------------|----------------------------------|
| 00 | Device Number                    | FlagA   00000000 | 00000000000000000000000000000000 |
| 08 | 00000000000000000000000000000000 |                  | 00000000000000000000000000000000 |
| 10 | 00000000000000000000000000000000 |                  | 00000000000000000000000000000000 |
| 18 | Block Size                       |                  | 00000000000000000000000000000000 |
| 20 | Offset                           |                  |                                  |
| 28 | Start Block                      |                  |                                  |
| 30 | End Block                        |                  |                                  |
| 38 | 00000000000000000000000000000000 |                  | 00000000000000000000000000000000 |

**Device Number**

is a halfword field containing the virtual device number of the DASD to which subsequent DIAGNOSE code X'250' read/write requests will be targeted. The DASD must be fully supported by z/VM. The device number must be in the range X'0000'-X'FFFF'.

**Flag A**

Bit 0 of byte X'02' indicates the format of the parameter list.

Bits 1-7 of byte X'02' must contain binary zeros.

### Block Size

is a fullword field containing an unsigned binary number that specifies the size of the storage blocks for this request. The block size must be one of the following:

- 512
- 1024
- 2048
- 4096

### Offset

is a fullword or doubleword field containing the number of sequential blocks used at the beginning of the disk by the file system to implement its structure.

This DIAGNOSE does not check the validity of this number; therefore the application can change the number if desired, but you could overlay blocks used by the file system.

### Start Block

is a fullword or doubleword field set by this function to contain a signed integer representing 1 minus the offset specified on input. Start block and end block specify the range of block numbers allowable on subsequent invocations of the read/write function of DIAGNOSE code X'250' for this virtual device.

### End Block

is a fullword or doubleword field set by this function to contain the number of blocks on the specified device minus the offset specified on input. Start block and end block specify the range of block numbers allowable on subsequent invocations of the read/write function of DIAGNOSE code X'250' for this virtual device.

### Reserved

The rest of the fields in this block are reserved for IBM use and must contain binary zeros.

### Usage Notes:

1. If the disk is in CMS format, the CMS RESERVE command may be used to allocate all available blocks of the minidisk to a unique CMS file, although this is not required.
2. If the minidisk is in CMS format, and has been reserved, an application can use the CMS function DISKID to obtain the device number, block size, and offset information. DISKID is described in [\*z/VM: CMS Macros and Functions Reference\*](#).
3. The use of bit 0 of byte X'02' in the BIOPL is restricted to guests in z/Architecture or z/XC mode.

## Read/Write to DASD

Once block I/O initialization for a virtual DASD has completed, you can use the read/write function of DIAGNOSE code X'250' to perform I/O to that virtual device.

The function code for a read/write request is X'01', and the BIOPL is defined by one of the following formats determined by bit 0 of byte X'02'.

If bit 0 of byte X'02' is zero:

|    |                                  |       |                  |                                        |
|----|----------------------------------|-------|------------------|----------------------------------------|
| 00 | Device Number                    | FlagA | 00000000         | 00000000000000000000000000000000       |
| 08 | 00000000000000000000000000000000 |       |                  | 00000000000000000000000000000000       |
| 10 | 00000000000000000000000000000000 |       |                  | 00000000000000000000000000000000       |
| 18 | Key                              | Flags | 0000000000000000 | Block Count                            |
| 20 | ALET of the block-entry list     |       |                  | 31 bit address of the block-entry list |
| 28 | 32 bit Interruption parameter    |       |                  | 00000000000000000000000000000000       |
| 30 | 00000000000000000000000000000000 |       |                  | 00000000000000000000000000000000       |
| 38 | 00000000000000000000000000000000 |       |                  | 00000000000000000000000000000000       |

If bit 0 of byte X'02' is one:

|    |                                        |       |                  |                                  |
|----|----------------------------------------|-------|------------------|----------------------------------|
| 00 | Device Number                          | FlagA | 00000000         | 00000000000000000000000000000000 |
| 08 | 00000000000000000000000000000000       |       |                  | 00000000000000000000000000000000 |
| 10 | 00000000000000000000000000000000       |       |                  | 00000000000000000000000000000000 |
| 18 | Key                                    | Flags | 0000000000000000 | Block Count                      |
| 20 | ALET of the block-entry list           |       |                  | 00000000000000000000000000000000 |
| 28 | 64 bit Interruption parameter          |       |                  |                                  |
| 30 | 64 bit address of the block-entry list |       |                  |                                  |
| 38 | 00000000000000000000000000000000       |       |                  | 00000000000000000000000000000000 |

**Device Number**

is a halfword field containing the virtual device number of the DASD to which the read/write operation is targeted.

**Flag A**

Bit 0 of byte X'02' indicates the format of the parameter list, and the block I/O entries, see [“Format of a Block I/O Entry”](#) on page 208.

Bits 1-7 of byte X'02' must contain binary zeros.

### Key

Bits 0-3 of byte X'18' contain the subchannel key for fetching of output data and for storing of input data associated with this read/write request. This key is matched with a storage key during these storage references.

Bits 4-7 of this field must contain binary zeros.

### Flags

Bits 0-5 of byte X'19' must contain binary zeros.

Bit 6 of byte X'19' indicates whether this is a synchronous or an asynchronous request. If the bit is zero, then the read/write operation is to be performed synchronously. The condition code and return code returned by this function will indicate the results of the operation.

If the bit is one, then the I/O may be performed asynchronously. Status of the I/O request will be presented by a block I/O external interruption. However, if the asynchronous request can be serviced entirely from minidisk cache, and bit 7 of byte X'19' is zero to indicate that minidisk cache should be interrogated, then a condition code and return code are returned by this function and no block I/O external interruption is generated.

*Table 22. Summary of the Effects of Byte X'19' Bits 6 and 7 on Read/Write Processing*

| Bit 6 | Bit 7 | Effect                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | 0     | The request will be performed synchronously; minidisk cache may be interrogated. The condition code and return code will indicate the results of the operation.                                                                                                                                                                                                                               |
| 0     | 1     | The request will be performed synchronously; minidisk cache will not be interrogated. The condition code and return code will indicate the results of the operation. This option is ignored for write requests.                                                                                                                                                                               |
| 1     | 0     | The request may be performed asynchronously; minidisk cache may be interrogated. The condition code and return code must be examined to determine if the requested was performed asynchronously; if it was, the results of the I/O request will be presented via a block I/O external interruption; otherwise, the condition code and return code will indicate the results of the operation. |
| 1     | 1     | The request will be performed asynchronously; minidisk cache will not be interrogated. The results of the I/O operation will be presented by a block I/O external interruption. This option is ignored for write requests.                                                                                                                                                                    |

Bit 7 of byte X'19' indicates whether minidisk cache should be bypassed for the read request. If the bit is zero, then the request will be satisfied from minidisk cache if possible. If the bit is one, then minidisk cache will not be interrogated. I/O will be performed even if the request could be satisfied from cache.

Use the minidisk cache bypass option when reading data that is not referenced frequently. This prevents infrequently-used data from filling the cache and flushing out frequently referenced data.

**Note:** This option is ignored for write requests.

### Block Count

is a fullword field containing an unsigned binary number specifying the count of entries in the block I/O entry list. The minimum number of entries is 1, and the maximum is 256.

### ALET of the block I/O entry list

If your virtual machine is an XC virtual machine executing in host-access-register mode, then this fullword field contains the access-list-entry token (ALET) designating the address space containing the block I/O entry list. If the virtual CPU of your XC virtual machine is executing in host-primary-

space mode or your virtual machine is not an XC virtual machine, then this field is ignored, and the block I/O entry list is contained in the host-primary address space.

The system performs host access-register translation for the ALETs contained within the BIOPL during the execution of DIAGNOSE code X'250'. When asynchronous I/O has been requested, the resulting ASITs are used to reference the data buffers during the ensuing asynchronous process.

**31 bit address of block I/O entry list**

If bit 0 of byte X'02' is zero, then bytes X'24' - X'27' is a fullword field containing the guest real address of a contiguous list of block I/O entries. Each entry in the list identifies a read or write request for the virtual device. The data within an individual entry is described in [“Format of a Block I/O Entry” on page 208](#).

The address of the block I/O entry list must be an address on a doubleword boundary.

If bit 0 of byte X'02' is one, bytes X'24' - X'27' must contain zeros.

**32 bit Interruption Parameter**

If bit 0 of byte X'02' is zero, then this fullword field contains user data to be stored at guest real storage locations 128-131 in the host-primary address space upon presentation of the block I/O external interruption at the completion of an asynchronous read/write request.

**64 bit Interruption Parameter**

If bit 0 of byte X'02' is one, then this doubleword field contains user data to be stored at guest real storage locations 4536-4543 in the host-primary address space upon presentation of the block I/O external interruption at the completion of an asynchronous read/write request.

**64 bit address of block I/O entry list**

If bit 0 of byte X'02' is one, then bytes X'30' - X'37' are a doubleword field containing the guest real address of a contiguous list of block I/O entries. Each entry in the list identifies a read or write request for the virtual device. The data within an individual entry is described in [“Format of a Block I/O Entry” on page 208](#).

The address of the block I/O entry list must be an address on a doubleword boundary.

If bit 0 of byte X'02' is zero, bytes X'30' - X'37' must contain zeros.

**Reserved**

The rest of the fields in this block are reserved for IBM use and must contain binary zeros.

**Format of a Block I/O Entry**

The block I/O entry list is a contiguous list of entries, each defining a read or write request. The starting address of the list is specified in the block I/O parameter list (BIOPL). If your virtual machine is an XC virtual machine that is executing in host-access-register mode, then the ALET at offset X'20' of the BIOPL identifies the address space containing the block I/O entry list. Otherwise, the block I/O entry list resides in the host-primary address space. For performance reasons, try not to let the block I/O entry list cross a page boundary.

The status code field in each entry is updated in guest storage to reflect the status of the corresponding operation; it is unpredictable whether the remainder of the block I/O entry list is stored back into guest storage.

Each entry within the block I/O entry list is mapped by HCPBELBK to one the following formats.

If bit 0 of byte X'02' in the BIOPL is zero:

|    |                  |        |                  |                              |
|----|------------------|--------|------------------|------------------------------|
| 00 | Type             | Status | 0000000000000000 | Block Number (32 bit)        |
| 08 | Data-Buffer ALET |        |                  | Data-Buffer Address (31 bit) |

If bit of byte X'02' in the BIOPL is one:

|    |                              |        |                  |                  |
|----|------------------------------|--------|------------------|------------------|
| 00 | Type                         | Status | 0000000000000000 | Data-Buffer ALET |
| 08 | Block Number (64 bit)        |        |                  |                  |
| 10 | Data-Buffer Address (64 bit) |        |                  |                  |

**Type**

is the one-byte request type for this I/O operation:

X'01' Write request

X'02' Read request

**Status**

is a byte set by this function to contain a status code for this read or write request. See [“Status Codes” on page 209](#) for a description of the values assigned to this field.

**Block Number**

is a fullword or doubleword field containing the DASD block number for this request. Block numbers are assigned sequentially to DASD records.

**Data-Buffer ALET**

If your virtual machine is an XC virtual machine that executes in host-access-register mode, then this fullword field contains the access-list-entry token (ALET) designating the address space containing the data buffer. If the virtual CPU of your XC virtual machine executes in host-primary-space mode or your virtual machine is not an XC virtual machine, then this field is ignored, and the data buffer is contained in the host-primary address space.

**Data-Buffer Address**

is a fullword or doubleword field containing the guest absolute address of the data for this request. For a *write* request this is the location in storage from which the data is written to DASD. For a *read* request this is the location in storage where the data read from DASD is placed.

**Reserved**

The rest of this block is reserved for IBM use and must contain binary zeros.

**Status Codes**

One of the following status codes is set within each block I/O entry. Since an error on a single block I/O entry does not prevent processing of other block I/O entries, you should check both the return code in Rx+1 and the status codes in each entry for the status of your request.

*Table 23. Status codes for block I/O entries*

| Status Code in Block I/O Entry | Description                                                                                                                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'00'                          | The read or write request was successful.                                                                                                                                                       |
| X'01'                          | An invalid block number is specified in this block I/O entry.                                                                                                                                   |
| X'02'                          | An addressing exception condition occurred because the data buffer addressed by this block I/O entry extends into storage locations not available in the designated address space.              |
| X'03'                          | This block I/O entry indicates a write request; however, the target virtual DASD is read-only.                                                                                                  |
| X'04' <sup>1</sup>             | The block I/O was initiated at the device; however, the block size specified was not consistent with the block size on the virtual DASD. (This status code is valid only for CKD/ECKD devices.) |

*Table 23. Status codes for block I/O entries (continued)*

| <b>Status Code in Block I/O Entry</b> | <b>Description</b>                                                                                                                                                                                                                                                                                              |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'05' <sup>1</sup>                    | An irrecoverable I/O error was encountered on the virtual DASD.                                                                                                                                                                                                                                                 |
| X'06'                                 | The request type specified in this block I/O entry is invalid.                                                                                                                                                                                                                                                  |
| X'07' <sup>1</sup>                    | A protection exception condition occurred.                                                                                                                                                                                                                                                                      |
| X'08' <sup>1</sup>                    | An addressing-capability exception condition occurred because the address space containing the data buffer is in the revoked state (no longer accessible to your virtual machine).                                                                                                                              |
| X'09' <sup>1</sup>                    | An ALEN-translation exception condition occurred; the ALET in the block I/O entry for the data buffer designates an ALET that is in neither the valid nor the revoked state.                                                                                                                                    |
| X'0A' <sup>1</sup>                    | An ALET-specification exception condition occurred; the ALET in the block I/O entry for the data buffer is invalid.                                                                                                                                                                                             |
| X'0B' <sup>1</sup>                    | Reserved fields in the block I/O entry are not zeros.                                                                                                                                                                                                                                                           |
| X'0C' <sup>1</sup>                    | This block I/O entry was not processed. Rx+1 contains the return code that indicates the condition that occurred to cause partial processing of the block I/O entry list.<br><br><b>Note:</b> This status code will only occur if a condition for which CC1 is returned on the DIAGNOSE code invocation occurs. |

**Note:**
**1**

Some I/O for this request may have been performed to the device.

**Usage Notes:**

1. You can use the interruption parameter in the BIOPL to associate a block I/O external interruption with a particular invocation of the read/write function.
2. You can attempt to terminate a synchronous read/write operation by entering an exigent command from the virtual machine console as the first or only command on a CP command line (that is, while TERMINAL MODE is CP, or CP READ is displayed, or the command begins with the #CP prefix).
3. No I/O interruptions are returned by CP to the virtual machine for DIAGNOSE code X'250' I/O.
4. The use of bit 0 of byte X'02' in the BIOPL is restricted to guests in z/Architecture mode. This is because a 64 bit interruption parameter may be stored in the second page of the prefix area.
5. The format of the fields in the BIOPL and block I/O entries is determined by bit 0 of byte X'02' in the BIOPL and is independent of the PSW addressing mode.
6. The length of the individual block I/O entries is determined by bit 0 of byte X'02' in the BIOPL. If bit 0 of byte X'02' in the BIOPL is zero, the block I/O entries are 2 doublewords in length. If bit 0 of byte X'02' in the BIOPL is one, the block I/O entries are 3 doublewords in length.
7. The I/O for the DASD blocks specified in the block I/O entries of the BELBK may not occur in the same order that they are listed. If the application requires that the DASD blocks or I/O data buffers be updated in a particular order, then that I/O request should be implemented with separate DIAGNOSE X'250' invocations.
8. This DIAGNOSE code does not support HyperPAV alias devices.
9. The \*BLOCKIO IUCV system service and Diagnose X'250' do not honor DASD reserves managed by VM's virtual reserve/release function. Therefore, do not use these I/O interfaces if a minidisk is shared by multiple guests on the same VM image where another guest is expecting to use reserve/release I/O to serialize its data access. Also, \*BLOCKIO and Diagnose X'250' do not use reserve/release.

Table 24. DIAGNOSE X'250' condition codes

| Condition Code | Meaning                                                                                                                                                              |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | Function completed successfully.                                                                                                                                     |
| 1              | Function partially completed. Some of the I/O completed successfully. A return code in Rx+1 indicates the condition that caused the partial completion.              |
| 2              | Function failed. The environment has not been set up or removed, or no I/O has completed successfully. The return code in Rx+1 indicates the reason for the failure. |

Return codes and their corresponding condition codes for the **INITIALIZE** function are listed in [Table 25 on page 212](#).

Table 25. Condition codes and return codes for the Initialize function

| Condition Code | Return Code in Rx+1 | Meaning                                                                                                                                                                                                      |
|----------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | 0 (X'00')           | Initialization for DIAGNOSE code X'250' to the specified virtual DASD is complete. The virtual device is not read-only. The starting block number and the ending block number have been stored in the BIOPL. |
| 0              | 4 (X'04')           | Initialization for DIAGNOSE code X'250' to the specified virtual device is complete. The virtual device is read-only. The starting block number and the ending block number have been stored in the BIOPL.   |
| 2              | 16 (X'10')          | The virtual device is not defined.                                                                                                                                                                           |
| 2              | 20 (X'14')          | The virtual device is not a supported DASD.                                                                                                                                                                  |
| 2              | 24 (X'18')          | The block size is not supported.                                                                                                                                                                             |
| 2              | 28 (X'1C')          | A DIAGNOSE code X'250' environment already exists for this virtual device.                                                                                                                                   |
| 2              | 255 (X'FF')         | An irrecoverable error occurred while processing the DIAGNOSE and a soft abend may have been taken. The environment was not initialized.                                                                     |

Return codes and their corresponding condition codes for the **READ/WRITE** function are listed in [Table 26 on page 212](#).

Table 26. Condition codes and return codes for the Read/Write function

| Condition Code | Return Code in Rx+1 | Meaning                                                                                                                     |
|----------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------|
| 0              | 0 (X'00')           | A synchronous request has completed successfully, or an asynchronous request was successfully serviced from minidisk cache. |
| 0              | 8 (X'08')           | The asynchronous request has been initiated. The BIOPL used for the initiated request is now available for re-use.          |

Table 26. Condition codes and return codes for the Read/Write function (continued)

| Condition Code | Return Code in Rx+1 | Meaning                                                                                                                                                                                                                                                                                                         |
|----------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1              | 12 (X'0C')          | A synchronous request was partially successful; you must check each individual block I/O entry for the status code. This return code also applies to an asynchronous request that could be serviced from minidisk cache, however, an error occurred preventing the entire request from completing successfully. |
| 2              | 16 (X'10')          | The virtual device is not defined.                                                                                                                                                                                                                                                                              |
| 2              | 28 (X'1C')          | The DIAGNOSE code X'250' environment does not exist for this virtual device.                                                                                                                                                                                                                                    |
| 2              | 32 (X'20')          | A CP paging error occurred while accessing the block I/O entry list.                                                                                                                                                                                                                                            |
| 2              | 36 (X'24')          | The number of buffer list entries was not a positive number within the range of 1 to 256.                                                                                                                                                                                                                       |
| 2              | 40 (X'28')          | Every block I/O entry list entry is in error. You must check the status code in each block I/O entry list entry.                                                                                                                                                                                                |
| 1              | 44 (X'2C')          | The remove function has terminated a synchronous read/write request. Some I/O may have been performed.                                                                                                                                                                                                          |
| 1              | 48 (X'30')          | A synchronous read/write was terminated at the user's request (for example, by an exigent command). Some I/O may have been performed.                                                                                                                                                                           |
| 1, 2           | 255 (X'FF')         | An irrecoverable error occurred while processing the DIAGNOSE and a soft abend may have been taken. If this return code is returned with condition code 1, some I/O may have been performed.                                                                                                                    |

Return codes and their corresponding condition codes for the **REMOVE** function are listed in [Table 27 on page 213](#).

Table 27. Condition codes and return codes for the Remove function

| Condition Code | Return Code in Rx+1 | Meaning                                                                                                                          |
|----------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------|
| 0              | 0 (X'00')           | Any pending DIAGNOSE code X'250' block I/O to this virtual device has been cleared. The block I/O environment has been deleted.  |
| 2              | 16 (X'10')          | The virtual device is not defined.                                                                                               |
| 2              | 28 (X'1C')          | Block I/O to the virtual device was not previously established using the initialization function of DIAGNOSE code X'250'.        |
| 0              | 255 (X'FF')         | An irrecoverable error occurred while processing the DIAGNOSE and a soft abend may have been taken. The environment was removed. |

**Program Exceptions:** DIAGNOSE code X'250' may result in one of the following program exceptions:

*Table 28. Program exceptions*

| <b>Problem Encountered</b>                                             | <b>Cause</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access exceptions (See <a href="#">“Access Exceptions”</a> on page 8.) | <p>An error occurred trying to</p> <ul style="list-style-type: none"> <li>• Fetch or store the block I/O parameter list (BIOPL) while processing an initialize function</li> <li>• Fetch the BIOPL while processing a read/write or remove function (it is unpredictable whether store-protection violations are reported for the read/write and remove functions)</li> <li>• Fetch or store the block I/O entry list while processing a read/write function.</li> </ul>                                |

## Block I/O External Interruption

A block I/O external interruption is generated when an asynchronous DIAGNOSE code X'250' read/write request has completed normally, or when I/O is cancelled because of either a device reset on a device that has a DIAGNOSE code X'250' environment active, or a REMOVE request for the device. The interruption is a floating interruption condition and is presented to the first virtual CPU in the virtual configuration that is enabled for the interruption. The condition is cleared once the interruption is presented and also by a virtual subsystem reset (for example, a SYSTEM RESET or IPL command).

The subclass mask to enable for the interruption is bit 22 of control register 0.

The block I/O condition is indicated by an external-interruption code of X'2603' stored at guest real location 134-135, and a sub-interruption code of X'03' or X'07' stored at guest real location 132. If the interruption is the result of a read/write request, then an interruption parameter (as specified in the BIOPL on a DIAGNOSE code X'250' read/write request) is stored at guest real locations 128-131 for sub-interruption code X'03' or at guest real locations 4536-4543 for sub-interruption code X'07'; otherwise, binary zeros are stored at guest real locations 128-131 or 4536-4543. In addition, one of the following status codes will be stored at guest real location 133:

### **X'00'**

All requested I/O completed successfully.

### **X'01'**

One or more errors occurred which prevented all of the I/O requests from completing successfully. You must check each entry in the block I/O entry list to determine which requests were successfully processed.

### **X'02'**

The updated block I/O entry list could not be stored into guest storage. The results of the I/O operations are indeterminate.

### **X'03'**

The virtual device was reset or the environment removed. Any pending I/O to the device has been cleared. The results of the I/O operations can be determined by examining the entries in the block I/O entry list.

**Notes:**

1. All locations updated as a result of the external interruption are in the host-primary address space.
2. If the guest turned on bit 0 of byte X'02' in the BIOPL and is no longer in z/Architecture mode at the completion of an asynchronous request, the external interruption will not be presented.

## DIAGNOSE Code X'258' – Page-Reference Services

---

### Page-Reference Services

**Privilege Class:** Any

DIAGNOSE X'258' is invoked from the guest PFAULT macro and REFPAGE macro to perform page reference service functions.

**Note:** The preferred method of invocation for the page-reference services is the PFAULT and REFPAGE macros. For more information, refer to [“PFAULT Macro -- Page-Fault Handshaking Services” on page 866](#) and [“REFPAGE — Page Reference Services” on page 877](#).

The following page-reference-service functions can be invoked using this DIAGNOSE:

- Page-fault-token
- Page-fault-cancel
- Page-reference-inform, list form
- Page-reference-inform, block form.

**Entry Values:**

**Rx**

The address of a function parameter list, the format of which is determined by the function code in the parameter list. The parameter list is built by the PFAULT macro or the REFPAGE macro in the macro's work area.

**Ax**

Is used only in access-register mode. Ax contains the ALET for the address space containing the parameter list.

When Rx is general register 0, Ax is not examined. The ALET is assumed to be X'00000000', which indicates the host-primary address space.

**Exit Values:**

**Ry**

On return, register Ry contains a return code, as defined for the PFAULT or REFPAGE macros; refer to [“PFAULT Macro -- Page-Fault Handshaking Services” on page 866](#) and [“REFPAGE — Page Reference Services” on page 877](#).

### Page-Fault-Token Function

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

The TOKEN function of the PFAULT macro establishes the guest real storage location of the page-fault handshaking token. If the VERSION=2 parameter is specified, then it also provides the masks used to determine if a page-fault is eligible for page-fault handshaking.

Register Rx contains the address of a doubleword-aligned parameter list in the following format when VERSION=2 is **not** specified :

|     |            |          |          |          |
|-----|------------|----------|----------|----------|
| Dec |            |          |          |          |
| 00  | REFDIAGC   | REFFCODE | REFDWLEN | REFVERSN |
| 08  | Reserved-Z |          | REFADDR  |          |
| 16  | Reserved-Z |          |          |          |
| 24  |            |          |          |          |
| 32  |            |          |          |          |

**REFDIAGC**

Bytes 0 and 1 of the parameter list contain the hexadecimal code, X'0258'.

**REFFCODE**

Bytes 2 and 3 of the parameter list contain the hexadecimal function code for the diagnose. A function code of X'0000' indicates the TOKEN function of the PFAULT macro.

**REFDWLEN**

Bytes 4 and 5 of the parameter list contain the length of this parameter list in doublewords. The value must be at least X'0005.'

**REFVERSN**

Bytes 6 and 7 of the parameter list contain a version code of X'0001'.

**Reserved-Z**

Bytes 8-11 and 16-39 of the parameter list are reserved and contain binary zeros.

**REFADDR**

Bytes 12 through 15 of the parameter list contain the guest real address which will contain the token to be associated with AR-specified page fault handshaking. This address is always in the host-primary address space.

Register Rx contains the address of a doubleword-aligned parameter list in the following format when VERSION=2 is specified:

|           |          |            |          |          |
|-----------|----------|------------|----------|----------|
| Dec<br>00 | REFDIAGC | REFFCODE   | REFDWLEN | REFVERSN |
| 08        | REFGADDR |            |          |          |
| 16        | REFSELMK |            |          |          |
| 24        | REFCMPMK |            |          |          |
| 32        | Z        | Reserved-Z |          |          |

**REFDIAGC**

Bytes 0 and 1 of the parameter list contain the hexadecimal code X'0258'.

**REFFCODE**

Bytes 2 and 3 of the parameter list contain the hexadecimal diagnose function code. A function code of X'0000' indicates the TOKEN function of the PFAULT macro.

**REFDWLEN**

Bytes 4 and 5 of the parameter list contain the length of this parameter list in doublewords. The value must be at least X'0005.'

**REFVERSN**

Bytes 6 and 7 of the parameter list contains a version code of X'0002.'

**REFGADDR**

Bytes 8 through 15 of the parameter list contain the guest real address of the token area to be associated with page-fault handshaking. REFGADDR is always in the host-primary address space. If the virtual machine is in z/Architecture mode, this is an 8 byte doubleword aligned area. If the virtual machine is not in z/Architecture mode, this is a 4 byte fullword aligned area. This 64-bit field is used as an address in the addressing mode of the virtual CPU when the diagnose is executed and the storage it points to must be accessible. At page fault time, this address is used to fetch the token to present on the initial interruption. This same token is presented on the subsequent completion interruption.

**REFSELMK**

Bytes 16 through 23 of the parameter list contain the 64-bit **selection mask**. At the time of a page fault, bits from the current PSW corresponding to bits set to 1 in this mask are selected for comparison against the compare mask. In z/Architecture mode, all 64 bits are used. When not in z/Architecture mode, bits 0 through 32 of this mask are used; bits 33 through 63 are ignored and assumed to be zero.

**REFCMPMK**

Bytes 24 through 31 of the parameter list contain the 64-bit **compare mask**. When there is a bit that is 1 in this compare mask, it must also be 1 in the selection mask, or a specification exception is presented to the virtual CPU. If the selected bits in the PSW at the time of a page fault exactly match the compare mask, then the page fault is eligible for page-fault handshaking and an initial interruption may be presented. Note that the compare mask is not used when presenting the completion interruption.

**Z**

This is bit 0 of this doubleword. When this bit is 0, the interface is ESA, which means the token area address points to a 4-byte field and the interruption parameters are in the format from PFAULT TOKEN being specified without including the VERSION=2 parameter. When this bit is 1, the interface is z/Architecture and the token area address points to an 8-byte field and the interruption parameters are in the format from the VERSION=2 and ARCHITECTURE=z parameters being specified with the PFAULT TOKEN macro. The setting of this bit must match the architecture of the virtual CPU executing the diagnose. This bit corresponds to the PFAULT macro ARCHITECTURE parameter.

**Reserved-Z**

Bytes 32 (bits 1–7 only) through 39 of the parameter list are reserved and contain binary zeros.

**Comparison and Selection Mask Example**

The program has determined that the PSW must be in the problem state for an initial interruption to be presented. One way of accomplishing this is for the selection mask to have a 1 in bit position 15 and to have the compare mask be the exact same mask.

**Usage Notes**

1. The address that is provided in the REFGADDR field is a real address. This address points to a token area in the host-primary address space. This address is saved and associated with the invoking virtual CPU. The length of the token area depends on whether or not the virtual CPU is in z/Architecture mode. If this address does not meet alignment restrictions, a specification exception is presented to the virtual CPU.
2. The masks in the parameter list are saved and associated with the invoking virtual CPU.

3. When VERSION=2 is in effect, this diagnose may be issued in any architecture and any addressing mode supported by CP.
4. If SIGP Set-Architecture is executed by the virtual configuration, page-fault handshaking is reset.
5. Using the PFAULT TOKEN macro is the preferred interface from assembly language to this diagnose. Refer to [“PFAULT TOKEN” on page 873](#) for additional information regarding parameters.
6. Refer to [“PFAULT Macro -- Page-Fault Handshaking Services” on page 866](#) for information about page-fault handshaking and the use of the token area, interruptions, and eligibility.
7. If the token area or parameter list are not accessible, then a program check is presented to the virtual CPU.
8. If any fields do not contain the value specified for them, then a specification exception is presented to the virtual CPU.
9. If the specification of the "Z" bit does not match the architecture of the invoking virtual CPU, then a specification exception is presented to the virtual CPU.

## Page-Fault-Cancel Function

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

The CANCEL function of the PFAULT macro cancels the location of the page-fault handshaking token. Register Rx contains the address of a doubleword-aligned parameter list in the following format:

|     |            |          |          |          |
|-----|------------|----------|----------|----------|
| Dec |            |          |          |          |
| 00  | REFDIAGC   | REFFCODE | REFDWLEN | REFVERSN |
| 08  | Reserved-Z |          |          |          |
| 16  |            |          |          |          |
| 24  |            |          |          |          |
| 32  |            |          |          |          |

### REFDIAGC

Bytes 0 and 1 of the parameter list contain the hexadecimal code, X'0258'.

### REFFCODE

Bytes 2 and 3 of the parameter list contain the hexadecimal function code for the diagnose. A function code of X'0001' indicates the CANCEL function of the PFAULT macro.

### REFDWLEN

Bytes 4 and 5 of the parameter list contain the length of this parameter list in doublewords. The value must be at least X'0005.'

### REFVERSN

Bytes 6 and 7 of the parameter list contain a version code of X'0001' or X'0002.' In either case, page-fault handshaking (invoked by PFAULT TOKEN) is cancelled for the invoking virtual CPU.

### Reserved-Z

Bytes 8 through 39 of the parameter list are reserved and contain binary zeros.

## Page-Reference-Inform Function

**Addressing Mode:** 24-bit or 31-bit

The INFORM function of the REFPAGE macro identifies a range of pages that are about to be referenced in a specific order.

### List Form

For the list-form INFORM function, register Rx contains the address of a doubleword-aligned parameter list in the following format:

|     |            |          |            |          |
|-----|------------|----------|------------|----------|
| Dec |            |          |            |          |
| 00  | REFDIAGC   | REFFCODE | REFDWLEN   | REFVERSN |
| 08  | REFALET    |          | REFADDR    |          |
| 16  | REFCOUNT   |          | Reserved-Z |          |
| 24  | Reserved-Z |          |            |          |
| 32  |            |          |            |          |

#### REFDIAGC

Bytes 0 and 1 of the parameter list contain the hexadecimal code, X'0258'.

#### REFFCODE

Bytes 2 and 3 of the parameter list contain the hexadecimal function code. A function code of X'0002' indicates the list form of the INFORM function.

#### REFDWLEN

Bytes 4 and 5 of the parameter list contain the length of this parameter list in doublewords. The value must be at least X'0005'.

#### REFVERSN

Bytes 6 and 7 of the parameter list contain a version code of X'0001'.

#### REFALET

Bytes 8 through 11 of the parameter list contain the ALET designating the address space that contains the page list addressed by REFADDR. This field is ignored in primary space mode.

#### REFADDR

Bytes 12 through 15 of the parameter list contain the guest real storage address of the page list. The page list is the set of ALET/Page numbers.

#### REFCOUNT

Bytes 16 through 19 of the parameter list contain the count of ALET/Page-number pairs in the list pointed to by REFADDR.

**Note:** The ALETs in this list are meaningful even in primary-space mode.

#### Reserved-Z

Bytes 20 through 39 of the parameter list are reserved and contain binary zeros.

### Block Form

For the block-form INFORM function, register Rx contains the address of a doubleword-aligned parameter list in the following format:

|     |          |            |            |          |
|-----|----------|------------|------------|----------|
| Dec |          |            |            |          |
| 00  | REFDIAGC | REFFCODE   | REFDWLEN   | REFVERSN |
| 08  | REFALET  |            | REFADDR    |          |
| 16  | REFGROUP |            | REFSBGRP   |          |
| 24  | REFSPAN  |            | REFSKIP    |          |
| 32  | D        | Reserved-Z | Reserved-Z |          |

**REFDIAGC**

Bytes 0 through 1 of the parameter list contain the hexadecimal code, X'0258'.

**REFFCODE**

Bytes 2 through 3 of the parameter list contain the hexadecimal function code. A function code of X'0003' indicates the block form of the INFORM function.

**REFDWLEN**

Bytes 4 through 5 of the parameter list contain the length of this parameter list in doublewords. The value must be at least X'0005'.

**REFVERSN**

Bytes 6 through 7 of the parameter list contain a version code of X'0001'.

**REFALET**

Bytes 8 through 11 of the parameter list contain the ALET of the address space that contains the page addressed by REFADDR.

**REFADDR**

Bytes 12 through 15 of the parameter list contain the starting page address in the page-reference-pattern. The starting address is the lowest address when the direction is ascending, or it is the highest address when the direction is descending.

**REFGROUP**

Bytes 16 through 19 of the parameter list contain the number of subgroups contained in the page-reference-pattern.

**REFSBGRP**

Bytes 20 through 23 of the parameter list contain the number of spans within a single subgroup.

**REFSPAN**

Bytes 24 through 27 of the parameter list contain the number of consecutive pages that should be considered as a single span of pages within the range of pages.

**REFSKIP**

Bytes 28 through 31 of the parameter list contain the number of pages to be skipped from the last page of a given span to the starting page of the next span.

**D**

Byte 32 of the parameter list contains the direction indicator. This byte should contain a value of 1 for ascending or -1 for descending, but the actual value is not validated. Bit 0 is checked to determine if it is ascending (0) or descending (1).

**Reserved-Z**

Bytes 33 through 39 of the parameter list are reserved and contain binary zeros.

**Program Exceptions:**

The program exceptions for DIAGNOSE X'258' are the same as those documented for the PFAULT and REFPAGE macros; refer to “PFAULT Macro -- Page-Fault Handshaking Services” on page 866 and “REFPAGE — Page Reference Services” on page 877.

## DIAGNOSE Code X'260' – Access Certain Virtual Machine Information

---

**Privilege Class:** Any

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

Use DIAGNOSE code X'260' to access certain virtual machine information.

**Entry Values:**

**Rx**

Depends on the subcode specified in Ry (see description below).

**Rx+1**

Depends on the subcode specified in Ry.

**Ry**

In z/Architecture mode, the high-order word of register Ry is ignored. The 4 bytes of the low-order register word contain the function subcode.

The function subcodes are as follows:

### Subcode X'00000000'

Return the highest addressable byte of virtual storage in the host-primary space, including named saved systems and saved segments. This subcode is valid only for 24-bit or 31-bit addressing mode.

**Entry Values:**

**Ry**

Must be X'00000000'.

**Exit Values:**

**Rx**

Equal to the highest addressable byte of virtual storage in the host-primary space, including named saved systems and saved segments. For example, for a 2047 MB address space, Rx would be X'7FEFFFFF'. For an 8 MB address space with the highest addressable saved segment loaded in MB X'19', Rx would be X'019FFFFF'.

**Usage Note:** XC virtual machines in access register mode can execute DIAGNOSE code X'260' Subcode X'00000000', but only the host-primary address space is implied.

### Subcode X'00000004'

Return the BYUSER ID for the user issuing this diagnose. This subcode is valid only for 24-bit or 31-bit addressing mode.

**Entry Values:**

**Rx**

Contains the address of a doubleword that may contain the BYUSER ID (left-justified, followed by spaces). The output buffer is only used if there is a BYUSER (return code 0).

**Ax**

Used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the output doubleword. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the output doubleword is in the host-primary address space.

**Ry**

Must be X'00000004'. Ry cannot be the same as Rx.

**Exit Values:****Ry+1**

Contains a return code.

| Return Code in Ry+1 | Meaning                                                             |
|---------------------|---------------------------------------------------------------------|
| 0 (X'00')           | BYUSER ID was successfully returned in the specified output buffer. |
| 4 (X'04')           | BYUSER ID was not returned. There is no BYUSER ID for this user ID. |

**Usage Notes:**

1. Rx and Ry cannot be the same register.
2. Ry must be an even-numbered register.
3. A BYUSER ID is only defined for a virtual machine that is logged on with the BY option of the LOGON command.
4. When a virtual machine is disconnected, its BYUSER ID remains unchanged.
5. A virtual machine's BYUSER ID is updated on a successful reconnect.

**Subcode X'00000008'**

Return the lines per page (LPP) value for the virtual printer or virtual console. This subcode is valid only for 24-bit or 31-bit addressing mode.

**Entry Values:****Rx**

Contains the virtual printer or virtual console device address.

**Ry**

Must be X'00000008'.

**Exit Values:****Rx**

Contains zero if the lines-per-page (LPP) value for the virtual printer or virtual console has been set to OFF either by use of the SPOOL LPP option or through the global system setting. Rx contains the binary value of the virtual LPP if it has been specified for the device. The binary value has a range of (decimal) 30 to 255.

**Ry**

Contains a return code.

| Return Code in Ry | Meaning                                                        |
|-------------------|----------------------------------------------------------------|
| 0 (X'00')         | A valid LPP value was returned (including zero if LPP is OFF). |
| 4 (X'04')         | Rx is not a valid virtual printer address                      |

**Subcode X'0000000C'**

Return the highest addressable byte of virtual storage in the host-primary address space, including named saved systems and saved segments. This subcode is valid only for a z/Architecture virtual machine.

**Entry Values:****Ry**

Must be X'0000000C' (the high-order word is ignored).

**Exit Values:****Rx**

Equal to the highest addressable byte of virtual storage in the first defined storage extent of the host-primary space, including named saved systems and saved segments. For example, for an 8.5G address space, Rx would be X'000000021FFFFFFF'.

**Ry**

Equal to the highest addressable byte of virtual storage in the host-primary address space, including named saved systems and saved segments. For example, for a guest with DEFINE STORAGE CONFIG 0.1G 8G.1G in effect, Rx would be X'000000003FFFFFFF' and Ry would be X'000000023FFFFFFF'.

**Usage Notes:**

1. The CONFIGURATION option on the DEFINE STORAGE command allows the definition of multiple noncontiguous storage extents. If the CONFIGURATION, RESERVED, and STANDBY options were not used on the DEFINE STORAGE command, the defined storage is one extent, and Rx and Ry will be identical.
2. If the RESERVED or STANDBY option was used on the DEFINE STORAGE command to configure reserved or standby storage for a guest, the values returned in Rx and Ry will be the current values, but these values can change dynamically depending on the options specified and any dynamic storage reconfiguration (DSR) changes initiated by the guest.

**Subcode X'00000010'**

Return information about a guest's storage configuration.

**Entry Values:****Rx**

Guest logical address of storage configuration output area.

**Rx+1**

Length of storage configuration output area.

**Ry**

Must be X'00000010'.

**Exit Values:****Rx**

Unchanged.

**Rx+1**

Unchanged.

**Ry**

Number of storage configuration extents.

**Usage Note:** If the CONFIGURATION option was not used on the DEFINE STORAGE command, the defined storage is one extent, and the value of Ry will be 1.

| Condition Code | Meaning                                             |
|----------------|-----------------------------------------------------|
| 0              | All extents returned in output area                 |
| 1              | More extents exist than will fit in the output area |

**Output Area:** The output area consists of one or more pairs of 64-bit values giving the start (first byte) and end (last byte) addresses of a guest storage extent. The area must be aligned on a quadword boundary.

**Responses**

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'260' is given incorrect data:

| <b>Problem Encountered</b>     | <b>Cause</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception        | <p>Ry does not contain a valid function subcode or does not contain a function subcode that is allowed with the virtual machine's current addressing mode.</p> <p>For subcode X'04':</p> <ul style="list-style-type: none"> <li>• Rx and Ry are the same register.</li> <li>• Ry is not an even-numbered register.</li> <li>• The output buffer is not on a doubleword boundary.</li> </ul> <p>For subcode X'10':</p> <ul style="list-style-type: none"> <li>• Rx is not an even-numbered register.</li> <li>• The address contained in Rx is not on a quadword boundary.</li> <li>• The length contained in Rx+1 is not a positive multiple of 16.</li> </ul> |
| Access exception               | <p>For subcode X'04' only, an error occurred trying to store BYUSER information into the output buffer.</p> <p>For subcode X'10', an error occurred trying to store the extent information into the guest's output area.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Privileged-operation exception | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## **DIAGNOSE Code X'268' – 370 Accommodation Services**

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'268' to access services in support of the 370 Accommodation facility. For more information on the 370 Accommodation facility, see [Part 6, "Architectural Extensions and Accommodations for Virtual Machines,"](#) on page 895.

### **Entry Values:**

#### **Rx**

Contains a function subcode. This subcode selects the service to be performed. The rest of the entry values and the exit values depend upon the specific subcode. A specification exception is recognized if an unassigned subcode is given. The following subcode is recognized:

**0**

Convert a BC-mode or mapped PSW to EC-mode

### **Subcode 0 – Convert a BC-mode or mapped PSW to EC mode**

This function converts a PSW which is in BC mode or which has been "mapped" by the 370 Accommodation facility to an EC-mode PSW.

### **Entry Values:**

#### **Rx**

Contains function subcode 0.

#### **Ry**

Contains bytes 0-3 of the PSW to be converted. R15 must not be specified as the Ry register, or a specification exception will result.

#### **Ry+1**

Contains bytes 4-7 of the PSW to be converted.

**Exit Values:****Ry**

If the condition code is zero, Ry contains bytes 0-3 of the converted PSW. If the condition code is non-zero, Ry is unchanged.

**Ry+1**

If the condition code is zero, Ry+1 contains bytes 4-7 of the converted PSW. If the condition code is non-zero, Ry+1 is unchanged.

**Condition Codes:** The following condition codes are set by subcode 0:

| Condition Code | Status                                                                                                                                                 |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | The conversion was successful. The contents of the Ry and Ry+1 general registers are replaced with the converted PSW.                                  |
| 1              | The conversion was unsuccessful because the input PSW is not a BC-mode or mapped PSW. The contents of the Ry and Ry+1 general registers are unchanged. |

**Program Exceptions:** These program exceptions may be recognized for subcode 0 of DIAGNOSE code X'268':

| Problem Encountered     | Cause                    |
|-------------------------|--------------------------|
| Specification exception | R15 is specified for Ry. |

## Responses

**Program Exceptions:** These program exceptions may be recognized for any subcode of DIAGNOSE code X'268':

| Problem Encountered            | Cause                                        |
|--------------------------------|----------------------------------------------|
| Specification exception        | An unknown subcode is specified in Rx.       |
| Privileged-operation exception | The virtual machine is in the problem state. |

## DIAGNOSE Code X'26C' – Access Certain System Information

**Privilege Class:** B, E; Subcode X'00000024' and Subcode X'00000030' - G

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'26C' to access certain system information.

**Entry Values:****Rx**

Contents depend on the value of subcode. Rx must be an even-numbered register and cannot be the same as Ry.

**Rx+1**

Contains the address of an output buffer on a doubleword boundary.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the doubleword passed as input. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the input doubleword is in the host-primary address space.

**Ry**

The second data register contains the function subcode. Ry must be an even-numbered register and cannot be the same as Rx.

- Subcode X'00000004' Return the BYUSER ID for a given user ID.
- Subcode X'00000008' Return virtual LAN system information.
- Subcode X'0000000C' Return controller list.
- Subcode X'00000010' Return controller information.
- Subcode X'00000014' Return guest LAN list.
- Subcode X'00000018' Return guest LAN information.
- Subcode X'0000001C' Return virtual switch list.
- Subcode X'00000020' Return virtual switch information.
- Subcode X'00000024' Return virtual port, virtual NIC or HiperSockets logical port information.
- Subcode X'00000030' MAC Services.

**Ax+1**

Is used only by XC virtual machines in access-register mode. Ax+1 contains the ALET for the address space containing the output doubleword. If an XC-mode virtual machine is not in access register mode, or if the virtual machine is not in XC mode, Ax+1 is ignored.

**Exit Values:**
**Ry+1**

Contains a return code value. Meaning is determined by subcode.

**Common Usage Notes:**

1. Rx and Ry cannot be the same register.
2. Rx and Ry must be even-numbered registers.
3. Many subcodes use *version* as input parameter. *Version* indicates the desired format of the information in the **output** buffer. Note that the version defines the length of the output data, not the content of reserved fields. For example, reserved fields in version N may actually contain some content defined for level N+1.

Use CSI66823 to provide information in the format described below.

Valid versions are defined by HCPCSI BK COPY and include:

*Table 29. Version definitions.* This describes the versions that may be specified on subcodes that accept a version indicator on input.

| Value     | HCPCSI BK equate | Description                   |
|-----------|------------------|-------------------------------|
| 0000 0001 | CSICPVER         | z/VM 5.3.0, no service        |
| 0000 0001 | CSIVERS1         | z/VM 5.3.0, no service        |
| 0001 0001 | CSI64281         | z/VM 5.3.0, with APAR VM64281 |
| 0002 0001 | CSI64277         | z/VM 5.3.0, with APAR VM64277 |
| 0000 0002 | CSIVERS2         | z/VM 5.4.0, no service        |
| 0000 0003 | CSIVERS3         | z/VM 6.1.0, no service        |
| 0001 0003 | CSI64780         | z/VM 6.1.0, with APAR VM64780 |
| 0000 0004 | CSIVERS4         | z/VM 6.2.0, no service        |
| 0001 0004 | CSI65042         | z/VM 6.2.0, with APAR VM65042 |
| 0000 0005 | CSIVERS5         | z/VM 6.3.0, no service        |
| 0001 0005 | CSI65583         | z/VM 6.3.0, with APAR VM65583 |
| 0000 0006 | CSIVERS6         | z/VM 6.4.0 no service         |

Table 29. *Version definitions.* This describes the versions that may be specified on subcodes that accept a version indicator on input. (continued)

| Value     | HPCCSIBK equate | Description                  |
|-----------|-----------------|------------------------------|
| 0001 0006 | CSI65925        | z/VM 6.4.0 with APAR VM65925 |
| 0002 0006 | CSI65918        | z/VM 6.4.0 with APAR VM65918 |
| 0000 0007 | CSIVERS7        | z/VM 7.1.0, no service       |
| 0001 0007 | CSI66219        | z/VM 7.1.0 with APAR VM66219 |
| 0000 0008 | CSIVERS8        | z/VM 7.2.0, no service       |
| 0000 0009 | CSIVERS9        | z/VM 7.3.0, no service       |
| 0001 0009 | CSI66823        | z/VM 7.3.0 with APAR VM66823 |

Programs written to use HPCCSIBK COPY on one release of z/VM can be executed on a new release of z/VM without change. To exploit the function provided by a follow-on release, examine your program for necessary changes and use the new value for version.

An error is returned if the version supplied is not supported by the current level of CP.

## Subcode X'00000004'—Return the BYUSER ID For a Given User ID

### Entry Values:

#### Rx

Contains the address of an input buffer two fullwords in length. The input buffer contains the user ID (left-justified, followed by blanks) whose BYUSER value is to be returned.

#### Rx+1

Contains the address of a doubleword that may contain the BYUSER ID (left-justified, followed by blanks) of the specified user ID. The output buffer is only used if there is a BYUSER for the user ID (return code 0).

Table 30. *Subcode X'00000004' Return Codes*

| Return Code in Ry+1 | Meaning                                                             |
|---------------------|---------------------------------------------------------------------|
| 0 (X'00')           | BYUSER ID was successfully returned in the specified output buffer. |
| 4 (X'04')           | BYUSER ID was not returned. There is no BYUSER ID for this user ID. |
| 8 (X'08')           | BYUSER ID was not returned. The user ID is not logged on.           |

### Usage Notes:

1. A BYUSER ID is only defined for a virtual machine that is logged on with the BY option of the LOGON command.
2. When a virtual machine is disconnected, its BYUSER ID remains unchanged.
3. A virtual machine's BYUSER ID is updated on a successful reconnect.

## Subcode X'00000008'—Return Virtual LAN System Information

### Entry Values:

#### Rx

Contains the address of an input buffer two fullwords in length. The first word of the buffer contains the length of the output buffer (Rx+1). The second word contains the version. Valid version numbers are defined in HPCCSIBK COPY.

This address must be aligned on a doubleword boundary.

**Rx+1**

Contains the address of an output buffer to contain the virtual LAN system information. This structure is mapped by HCPCSIBK COPY. The output buffer is modified only if Ry+1 contains return 0 or return code 16 (X'10').

This address must be aligned on a doubleword boundary.

**Output Buffer Format**

*Table 31. Return Virtual LAN System Information (DSECT CSISRESP) . Length CSISOL51, X'68'. Length for versions prior to CSI65583 was CSISOL31, X'50'. Length for versions prior to CSI64780 was CSISOSIZ, X'30'.*

Table 33. Subcode X'00000008' Return Codes

| Return Code in Ry+1 | Meaning                                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')           | Virtual LAN system information was successfully returned in the specified output buffer. The fullword at the address pointed to by Rx is modified to contain the total length of the data returned in the buffer.         |
| 12 (X'0C')          | The requested version is not supported by CP.                                                                                                                                                                             |
| 16 (X'10')          | The buffer provided is not large enough to contain the virtual LAN system information. The fullword at the address pointed to by Rx is modified to contain the size of the buffer needed to return all information.       |
| 20 (X'14')          | Error obtaining storage. The buffer size provided is too large. Issue the request using a smaller buffer size. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer required. |

**Usage Notes:** None.**Subcode X'0000000C'—Return Controller List****Entry values:****Rx**

Contains the address of an input buffer one fullword in length. The input buffer contains the length of the output buffer (Rx+1).

This address must be aligned on a doubleword boundary.

#### Rx+1

Contains the address of an output buffer to contain the list of controller virtual machine names. Each name is padded to 8 bytes. The output buffer is modified only if Ry+1 contains return 0 or return code 16 (X'10').

This address must be aligned on a doubleword boundary.

#### Exit Values:

| 0 (X'00')           | Controller names were successfully returned in the specified output buffer. The fullword at the address pointed to by Rx is modified to contain the total length of the data returned in the buffer.                                          |
| 4 (X'04')           | Controller names were not returned. No controllers exist.                                                                                                                                                                                     |
| 16 (X'10')          | The buffer provided is not large enough to contain the controller names. Some information may be returned. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer needed to return all information. |
| 20 (X'14')          | Error obtaining storage. The buffer size provided is too large. Issue the request using a smaller buffer size. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer required.                     |

**Usage Notes:** None.

## Subcode X'00000010'—Return Controller Information

#### Entry Values:

#### Rx

Contains the address of an input buffer four fullwords in length. The first word of the buffer contains the length of the output buffer (Rx+1). The second fullword contains the version. Valid version numbers are defined in HCPCSIK COPY. The third and fourth words contain a controller name (left-justified, padded with blanks) to obtain information about a specific controller. If the controller name provided is all blanks, information is returned for all controllers.

This address must be aligned on a doubleword boundary.

#### Rx+1

Contains the address of an output buffer to contain the controller information. This structure is mapped by HCPCSIK COPY. The output buffer is modified only if Ry+1 contains return 0 or return code 16 (X'10').

This address must be aligned on a doubleword boundary.

#### Output Buffer Format

| Return Code in Ry+1 | Meaning                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')           | Controller information was successfully returned in the specified output buffer. The fullword at the address pointed to by Rx is modified to contain the total length of the data returned in the buffer.                                                                                                                                                                              |
| 4 (X'04')           | Controller information was not returned. The specified user ID is not a controller or no controllers exist.                                                                                                                                                                                                                                                                            |
| 12 (X'0C')          | The requested version is not supported by CP.                                                                                                                                                                                                                                                                                                                                          |
| 16 (X'10')          | The buffer provided is not large enough to contain the controller information. Some information may be returned. The value of <i>controller count</i> in the output buffer indicates how many complete sets of controller information are returned. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer needed to return all information. |
| 20 (X'14')          | Error obtaining storage. The buffer size provided is too large. Issue the request using a smaller buffer size. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer required.                                                                                                                                                              |
| 28 (X'1C')          | Controller information was not returned. Internal error.                                                                                                                                                                                                                                                                                                                               |

**Usage Notes:** None.

## Subcode X'00000014'—Return Guest LAN List

### Entry Values:

#### Rx

Contains the address of an input buffer one fullword in length. The input buffer contains the length of the output buffer (Rx+1).

This address must be aligned on a doubleword boundary.

#### Rx+1

Contains the address of an output buffer to contain the guest LAN names. For each guest LAN, the guest LAN owner is returned in the first 8 bytes padded with blanks, followed by the guest LAN name in the next 8 bytes padded with blanks. The output buffer is modified only if Ry+1 contains return code 0 or return code 16 (X'10').

The address must be aligned on a doubleword boundary.

### Exit Values:

Table 39. Subcode X'00000014' Return Codes

| Return Code in Ry+1 | Meaning                                                                                                                                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')           | Guest LAN names were successfully returned in the specified output buffer. The fullword at the address pointed to by Rx is modified to contain the total length of the data returned in the buffer.                                          |
| 4 (X'04')           | Guest LAN names were not returned. No guest LANs exist.                                                                                                                                                                                      |
| 16 (X'10')          | The buffer provided is not large enough to contain the guest LAN names. Some information may be returned. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer needed to return all information. |

Table 39. Subcode X'00000014' Return Codes (continued)

| Return Code in Ry+1 | Meaning                                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20 (X'14')          | Error obtaining storage. The buffer size provided is too large. Issue the request using a smaller buffer size. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer required. |

**Usage Note:** The list of guest LAN names returned can include virtual switches, which are a special kind of guest LAN.

## Subcode X'00000018'—Return Guest LAN Information

### Entry Values:

#### Rx

Contains the address of an input buffer six fullwords in length. The first word of the buffer contains the length of the output buffer (Rx+1). The second word contains the version. Valid version numbers are defined in HCPCSIBK COPY. The third and fourth words contain the guest LAN owner (left-justified, padded with blanks). The remaining words contain the guest LAN name (left-justified, padded with blanks).

Providing blanks for guest LAN owner or guest LAN name can return all guest LANs with a given name, or all guest LANs with a given owner, or all guest LANs.

This address must be aligned on a doubleword boundary.

#### Rx+1

Contains the address of an output buffer to contain the guest LAN information. This structure is mapped by HCPCSIBK COPY. The output buffer is modified only if Ry+1 contains return code 0 or return code 16 (X'10').

The address must be aligned on a doubleword boundary.

### Output Buffer Format

Table 40. Return Guest LAN Information (DSECT CSIGRESP). Length CSIGOSIZ, X'08'. This structure also includes CSIGGCTR Entries of Type CSIGGSTR.

Table 44. Subcode X'00000018' Return Codes

| Return Code in Ry+1 | Meaning                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')           | Guest LAN information was successfully returned in the specified output buffer. The fullword at the address pointed to by Rx is modified to contain the total length of the data returned in the buffer.                                                                                                                                                                            |
| 4 (X'04')           | Guest LAN information was not returned. No guest LANs exist to match the specified guest LAN owner and guest LAN name, or no guest LANs exist.                                                                                                                                                                                                                                      |
| 12 (X'0C')          | The requested version is not supported by CP.                                                                                                                                                                                                                                                                                                                                       |
| 16 (X'10')          | The buffer provided is not large enough to contain the guest LAN information. Some information may be returned. The value of <i>guest LAN count</i> in the output buffer indicates how many complete sets of guest LAN information are returned. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer needed to return all information. |
| 20 (X'14')          | Error obtaining storage. The buffer size provided is too large. Issue the request using a smaller buffer size. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer required.                                                                                                                                                           |

**Usage Note:** The guest LAN information returned can be for a virtual switch, which is a special kind of guest LAN. Use subcode X'00000020' to obtain information specific to virtual switches.

## Subcode X'0000001C'—Return Virtual Switch List

**Entry Values:**

**Rx**

Contains the address of an input buffer one fullword in length. The input buffer contains the length of the output buffer (Rx+1).

This address must be aligned on a doubleword boundary.

**Rx+1**

Contains the address of an output buffer to contain the list of virtual switch names. Each name is padded to 8 bytes. The output buffer is modified only if Ry+1 contains return code 0 or return code 16 (X'10').

The address must be aligned on a doubleword boundary.

**Exit Values:**

*Table 45. Subcode X'0000001C' Return Codes*

| Return Code in Ry+1 | Meaning                                                                                                                                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')           | Virtual switch names were successfully returned in the specified output buffer. The fullword at the address pointed to by Rx is modified to contain the total length of the data returned in the buffer.                                          |
| 4 (X'04')           | Virtual switch names were not returned. No virtual switches exist.                                                                                                                                                                                |
| 16 (X'10')          | The buffer provided is not large enough to contain the virtual switch names. Some information may be returned. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer needed to return all information. |
| 20 (X'14')          | Error obtaining storage. The buffer size provided is too large. Issue the request using a smaller buffer size. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer required.                         |

**Usage Note:** None.

## Subcode X'00000020'—Return Virtual Switch Information

**Entry Values:**
**Rx**

Contains the address of an input buffer four fullwords in length. The first word of the buffer contains the length of the output buffer (Rx+1). The second word contains the version. Valid version numbers are defined in HCPCSI BK COPY.

The third and fourth words contain a VSWITCH name (left-justified, padded with blanks). If the VSWITCH name provided is all blanks, information is returned for all virtual switches.

**OR**

The third word contains a virtual switch management IP address in hexadecimal format and the fourth word contains hex zeroes. If the third and fourth words contain zeroes, information is returned for all virtual switches.

This address must be aligned on a doubleword boundary.

**Rx+1**

Contains the address of an output buffer to contain the virtual switch information. The structure is mapped by HCPCSI BK COPY. The output buffer is modified only if Ry+1 contains return code 0 or return code 16 (X'10').

The address must be aligned on a doubleword boundary.

**Output Buffer Format**

The following diagram shows the layout of structures that are returned in the output buffer CSIVRESP. The individual structures are shown in subsequent tables.

|                            |         |
|----------------------------|---------|
| CSIVRESP                   |         |

| Return Code in Ry+1 | Meaning                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')           | Virtual switch information was successfully returned in the specified output buffer. The fullword at the address pointed to by Rx is modified to contain the total length of the data returned in the buffer.                                                                                                                                                                                      |
| 4 (X'04')           | Virtual switch information was not returned. The specified VSWITCH does not exist, or no virtual switch has a management IP address matching the IP address provided, or no virtual switches exist.                                                                                                                                                                                                |
| 12 (X'0C')          | The requested version is not supported by CP.                                                                                                                                                                                                                                                                                                                                                      |
| 16 (X'10')          | The buffer provided is not large enough to contain the virtual switch information. Some information may be returned. The value of <i>virtual switch count</i> in the output buffer indicates how many complete sets of virtual switch information are returned. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer needed to return all information. |
| 20 (X'14')          | Error obtaining storage. The buffer size provided is too large. Issue the request using a smaller buffer size. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer required.                                                                                                                                                                          |

**Usage Notes:** None.

## Subcode X'00000024'—Return Virtual Port, Virtual NIC or HiperSockets Logical Port Information

#### Entry Values:

##### Rx

Contains the address of an input buffer six fullwords in length. This is mapped by the CSIPPLST structure in HPCPSIBK COPY. The first word of the buffer contains the length of the output buffer (Rx+1). The second fullword contains the version. Valid version numbers are defined in HPCPSIBK COPY. The high order half word of the third word contains an input parameter list type which defines the format of the remaining input.

The following formats return Virtual Port or Virtual NIC Information. This information is obtained for guests on the VSWITCH itself.

- 0 (X'0000') - CSIPITYU. Return port information by user ID, optionally filtered by VLAN ID and NIC addresses. The low order half word of the third word contains a VLAN ID or hex zeroes. If the halfword contains zeroes, information is returned for all active VLAN IDs.

The fourth and fifth fullwords contain the name of the virtual machine ID. Use the user ID of the controller to obtain information about the active virtual switch RDEV ports.

The sixth fullword contains the coupled guest NIC in the two low-order bytes, or use the RDEV to obtain information about an active virtual switch RDEV port. The two high-order bytes must contain zeroes. If the two low-order bytes contain X'FFFF' (CSIPINON), information is returned for all coupled NICs defined for the specified user and all active RDEV ports for which the virtual machine is a VSWITCH controller.

- 1 (X'0001') - CSIPITYI. Return port information by virtual switch management IP address, optionally filtering by VLAN ID and port number. The low order half word of the third word contains a VLAN ID or hex zeroes. If the halfword contain zeroes, information is returned for all active VLAN IDs defined for the virtual switch.

The fourth word contains a virtual switch management IP address in hexadecimal format.

The fifth word must contain hex zeroes.

The sixth fullword contains the port number in hexadecimal format. If the sixth fullword contains zeroes, information is returned for all ports defined for the specified virtual switch. Ports include all virtual NICs coupled to the virtual switch, as well as the VSWITCH's active RDEVs.

- 2 (X'0002') - CSIPITYN. Return virtual NIC information by user ID, optionally filtered by VLAN ID and NIC address. The low order half word of the third word contains a VLAN ID or hex zeroes. If the halfword contains zeroes, information is returned for all active VLAN IDs.

The fourth and fifth fullwords contain the name of the virtual machine ID for which virtual NICs are defined.

The sixth fullword contains the NIC in the two low-order bytes. The two high-order bytes must contain zeroes. If the two low-order bytes also contain x'FFFF' (CSIPINON), information is returned for all NICs defined for the specified user.

The following formats return HiperSockets Logical Port Information. This information is obtained for guests on the HiperSockets channel that are bridge capable.

- 20 (X'0014') - CSIPITYH. Return HiperSockets logical port information by VSWITCH name.

The low order halfword of the third word is unused.

The fourth and fifth fullwords contain the name of the VSWITCH.

The sixth fullword is not used and contains zero.

This address must be aligned on a doubleword boundary.

#### **Rx+1**

Contains the address of an output buffer to contain the guest LAN information. This structure is mapped by HCPCSIBK COPY. The output buffer is modified only if Ry+1 contains return code 0 or return code 16 (X'10').

The address must be aligned on a doubleword boundary.

#### **Output Buffer Format**

| 16 (X'10')          | The buffer provided is not large enough to contain the information. Some information may be returned. The value of <i>port</i> or <i>NIC count</i> in the output buffer indicates how many complete sets of information are returned. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer needed to return all information.                                                                                                                                                                                                                                                                                                                                  |
| 20 (X'14')          | Error obtaining storage. The buffer size provided is too large. Issue the request using a smaller buffer size. The first fullword at the address pointed to by Rx is modified to contain the size of the buffer required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 24 (X'18')          | Incorrect parameter list type (CSIPITYP) or reserved field not zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 28 (X'1C')          | The issuer has G privilege class and is not authorized to obtain information for the virtual machine name specified (CSIIPIUSR) in plist CSIPPLST structure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Usage Notes:** Privilege class G users are able to obtain information for their virtual machine. Information pertaining to other users will not be returned.

## Subcode X'00000030'—MAC Services

### Entry Values:

#### Rx

Contains the address of a buffer four fullwords in length. This is mapped by the CSIMPLST structure in HCPCSIBK COPY.

The first word of the buffer contains the length of the output buffer (Rx+1). The second fullword contains the version. Valid version numbers are defined in HCPCSIBK COPY.

The high order halfword of the third word contains the MAC services operation code.

X'0000' - Return MAC address

The low order halfword contains the virtual device number in hexadecimal format.

The fourth fullword is reserved.

#### Rx+1

Contains the address of an output buffer to contain the results of the MAC Service requested. This structure is mapped by HCPCSIBK COPY. The output buffer is modified only if Ry+1 contains return 0 or return code 16 (X'10').

This address must be aligned on a doubleword boundary.

## DIAGNOSE Code X'270' – Pseudo Timer Extended

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'270' to cause CP to store the number of bytes of time information specified in the Ry register at the address specified in the Rx register. DIAGNOSE code X'270' replaces DIAGNOSE code X'0C' for new applications.

**Entry Values:**

**Rx**

Contains the address of an area where the time information is to be stored. The address must be in second-level storage (that is, in the storage that appears real to your virtual machine) and must be on a doubleword boundary.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the buffer where the time information is to be stored. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the buffer is in the host-primary address space.

**Ry**

Contains the length of the buffer in bytes. If Ry is 0, the same output as the DIAGNOSE X'0C' will be given. 48 bytes are necessary to contain the same output from the DIAGNOSE X'0C' and the date in the full-year format. 64 bytes are needed to contain the same output from the DIAGNOSE X'0C', the date in full-year format and the date in ISO format.

**Exit Values:** The output area contains the following information:

| Hex | 1          | 2 | 3  | 4  | 5  | 6        | 7 |
|-----|------------|---|----|----|----|----------|---|
| 0   | MM/DD/YY   |   |    |    |    |          |   |
| 8   | HH:MM:SS   |   |    |    |    |          |   |
| 10  | VIRTCPU    |   |    |    |    |          |   |
| 18  | TOTALPROC  |   |    |    |    |          |   |
| 20  | MM/DD/YYYY |   |    |    |    |          |   |
| 28  | Reserved   |   |    |    |    |          |   |
| 30  | YYYY-MM-DD |   |    |    |    |          |   |
| 38  |            |   | F1 | F2 | F3 | Reserved |   |

The byte definitions for F1, F2, and F3 are as follows:

**F1**

Version of DIAGNOSE 270 (Currently 1)

**F2**

User's default date format

**F3**

System default data format

The bit settings in F2 and F3 are as follows:

**X'80'**

SHORTdate format — mm/dd/yy

**X'40'**

FULLdate format — mm/dd/yyyy

**X'20'**

ISOdate format — yyyy-mm-dd

**X'10'**

Use the system-wide default setting (F2 only). If this bit is on, one of the other bits will be on also. The combination of these bits indicates the value of the system-wide default setting.

The first eight bytes (0 through 7) of the output area contain the date (*mm/dd/yy*) in EBCDIC. The next eight bytes (8 through 15) contain the time of day (*hh:mm:ss*) in EBCDIC. The next eight bytes, VIRTCPU (16 through 23), contain the virtual time consumed by the virtual CPU that issued the DIAGNOSE instruction. The next eight bytes, TOTALPROC (24 through 31), contain the total of the virtual time (VIRTCPU) and the simulation time spent on behalf of the virtual CPU that issued the DIAGNOSE instruction. Thus, TOTALPROC is always greater than or equal to VIRTCPU. The difference between them represents the time that CP has spent specifically on behalf of the virtual CPU. The next 10 bytes (32 through 41) contain the date in full year format (*mm/dd/yyyy*). The next 6 bytes (42 through 47) are reserved. The next 10 bytes (48 through 57) contain the date in ISO date format (*yyyy-mm-dd*). The next three bytes are three one-byte fields. The first byte is the version of the Diagnose 270. The second byte is the user's default date format. The third byte is the system default date format. The last three bytes are reserved.

These values are also part of the response for the CP INDICATE USER command. Bytes 16 through 31 contain the virtual and total processor time used by the virtual machine that issued the DIAGNOSE instruction. VIRTCPU and TOTALPROC are doubleword, unsigned integers; the time is expressed in microseconds, not as TOD clock units.

## Usage Note

For a discussion of how z/VM processes addresses, refer to [“How Addresses Are Processed”](#) on page 5.

## Responses

**Program Exceptions:** These program exceptions can occur if DIAGNOSE X'270' is given incorrect input data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                                                                       |

| Privileged-operation exception                                        | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                                                                                                |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | An error occurred trying to store into the time-information area.                                                                                                                                                                                                                                                                                                                           |

## DIAGNOSE Code X'274' – Set Timezone Interrupt Flag

**Privilege Class:** G

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'274' to instruct CP to reflect an external interrupt, X'2004', to the issuer's virtual machine when an operator enters the SET TIMEZONE command.

**Entry Values:**

**Rx**

contains the subfunction code.

**Ry**

is reserved and must be specified as 0.

**Subfunction Code****Meaning****0**

Turns off the normal timezone interrupt flag.

**1**

Turns on the normal timezone interrupt flag.

**2**

Turns off the control program timezone interrupt flag. This flag should only be used by the virtual machine's operating system.

**3**

Turns on the control program timezone interrupt flag. This flag should only be used by the virtual machine's operating system. Starting with CMS Level 11, CMS uses this flag in order to monitor time zone changes on VM.

If either the normal or the control program timezone interrupt flag is turned on and control register 0 bit 19 is on, the floating external interrupt is presented to the virtual machine.

**Exit Values:****Guest Cond. Code****Meaning****0**

DIAGNOSE completed with no errors.

**3**

DIAGNOSE failed due to one of the following errors:

- Ry was not specified as 0.
- The subfunction code was not valid.

**Usage Notes**

1. Interrupt X'2004' is masked by the TOD - clock sync-check subclass mask, control register 0 bit 19. When the interruption is received, DIAGNOSE code X'00' may be used to obtain the new time zone differential.
2. A Subsystem Reset resets both timezone interrupt flags. Such a reset occurs during the processing of commands like IPL, DEFINE STORAGE, SET MACHINE, SYSTEM RESET, SYSTEM CLEAR, and DETACH CPU.
3. HNDEXT SET for interrupt X'2004' can be used by CMS applications wanting to monitor time zone changes. Starting with CMS Level 11, control register 0 bit 19 (CR0.19) is turned on during CMS initialization to enable the X'2004' interruption. Applications which turn CR0.19 off prohibit recognition of the time zone change. The CMS application receives control after CMS processes the X'2004' interrupt.

**DIAGNOSE Code X'27C' –Product Enablement Verification**

**Privilege Class:** Any

**Addressing Mode:** 24-bit or 31-bit

Use DIAGNOSE code X'27C' to perform product enablement verification. This DIAGNOSE code tests information relating to the product definition within the system. DIAGNOSE code X'27C' requests information regarding the enablement status of a single product or feature. The return code and output area produced by DIAGNOSE code X'27C' contain the following information:

- Whether the product or feature is defined to the system. The product can be defined using a PRODUCT statement within the system configuration file or a SET PRODUCT command.
- The current state of the product (ENABLED or DISABLED).

- The contents of the optional DESCRIPTION operand specified on the PRODUCT statement or SET PRODUCT command.

### Entry Values:

#### Rx

Is the guest real address of a product parameter list. This area is mapped by the HCPPPLBK member in HCPGPI MACLIB. This address must be on a doubleword boundary. The required entry values of the product parameter list are described under **Product Parameter List Entry Values**.

#### Ax

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the product parameter list and the description return area. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the product parameter list and the description return area are in the host-primary address space.

#### Ry

Is the length of the product parameter list. This length must be equal to X'20' (PPLBKSZ).

### HCPPPLBK — Product Parameter List Format:

### HCPPPLBK — Product Parameter List Entry Values:

The required entry values of the product parameter list are:

- The PPLTYPE field must be set to PPLPROD (X'01') to explicitly indicate this is a product query.
- The PPLFLAG1 field must be set to X'00'.
- The reserved fields must be set to X'00'.
- The PPLPRDID field must be set to the VMSES/E product identifier of the product or feature the issuer wanted to query. A seven character product identifier must be padded on the right with a blank.
- To receive any product description data:
  - The PPLDESCL field must contain the number of bytes of the product description the issuer wants to store. It is an unsigned binary number between 0 and 255 (X'00' to X'FF'). If PPLDESCL is not zero, the product description is stored at the guest real address specified by PPLDESCA. If PPLDESCL is zero, the product description is not stored even if one exists.
  - The PPLDESCA field must contain the guest real address where the product description is to be stored. It must be aligned on a doubleword boundary.

### Exit Values:

#### Rx

Is unchanged. The exit values of the product parameter list are described under **Product Parameter List Exit Values**.

#### Ax

Is unchanged.

#### Ry

Is the return code from the product enablement verification. The return codes are as follows:

| Return Code in Ry | Status                                                                                                                                                                                                                  |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (X'00')         | The specified product is defined to the z/VM system, and the current status of the product is ENABLED. The fields in the product parameter list are updated as described in <b>Product Parameter List Exit Values</b> . |

| Return Code in Ry | Status                                                                                                                                                                                                                   |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4 (X'04')         | The specified product is defined to the z/VM system, but the current status of the product is DISABLED. The fields of the product parameter list are updated as described in <b>Product Parameter List Exit Values</b> . |
| 8 (X'08')         | The specified product is not defined to the z/VM system. The fields in the product parameter list are not updated.                                                                                                       |
| 12 (X'0C')        | An unknown error occurred. The fields in the product parameter list are not updated.                                                                                                                                     |

#### HCPPPLBK — Product Parameter List Exit Values:

If the Ry return code is 8 or 12, the fields within the product parameter list are not changed.

If the Ry return code is 0 or 4, the fields within the product parameter list are updated as follows:

- PPLTYPE field is unchanged.
- PPLFLAG1 field is updated as appropriate. Either the PPLENABL bit (X'80') or the PPLDISAB bit (X'40') is set depending on the state of the product within the system. The PPLDESCR bit (X'10') is set if the specified product contains a decryption.
- PPLPRDID field is unchanged.
- PPLDESCL field may be changed. It contains the actual number of bytes of the product description that was stored. This is either the number of bytes of the actual product description or the value of the input PPLDESCL, whichever is smaller.
- PPLDESCA field is unchanged.

## Usage Note

For a discussion of how z/VM processes addresses, refer to [“How Addresses Are Processed”](#) on page 5.

## Responses

**Program Exceptions:** These program exceptions can occur if the DIAGNOSE code X'27C' is given incorrect input data:

| Problem Encountered            | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

The only valid length is X'20'.</li> <li>• Reserved fields in the product parameter list are not zero.</li> </ul> |

## DIAGNOSE Code X'288' - Control Virtual Machine Time Bomb

**Privilege Class:** Any

**Addressing Mode:** 31-bit or 64-bit

Use DIAGNOSE code X'288' to set, change, or cancel a virtual machine time bomb. A time bomb explodes after an interval defined by the Diagnose issuer unless it is changed or cancelled. In practice, this interface is used to ensure that the virtual machine remains responsive, as indicated by its issuance of the Diagnose before the interval expires. For example, if the virtual machine issues the Diagnose every 10 seconds and specifies an interval of 15 seconds, it will avoid the explosion indefinitely.

### Entry Values:

#### Rx

is a 32-bit value comprising a 16-bit flag field followed by a 16-bit integer function code. In z/Architecture mode, the high-order word of the register is ignored. The following function codes are supported:

**0**

Initialize

**1**

Change

**2**

Cancel

The following flags are supported:

#### X'8000'

For the Initialize function, enable SET CONCEAL ON for the virtual machine and arm the time bomb for conditions it detects

#### Rx+1

For the Initialize or Change function, contains the 32-bit interval in seconds that must elapse before the time bomb explodes. In z/Architecture mode, the high-order word of the register is ignored.

#### Ry

For the Initialize function, contains the 31-bit or 64-bit real address of the command string to be executed if the time bomb explodes.

#### Ry+1

For the Initialize function, contains the 32-bit length of the command string. In z/Architecture mode, the high-order word of the register is ignored.

## Usage Notes

1. The time bomb interval must not be less than 15 seconds, unless it is zero, in which case the time bomb is disarmed.
2. The command string may consist of one or more commands separated by line-end characters (X'15').
3. Registers that are not used by a particular function code are ignored.
4. Flags that are defined but are not used by a particular function code are ignored.
5. The Initialize function must be the first one used by a virtual machine after it IPLs or issues a Cancel function. Thereafter, the Initialize and Change functions may be used as desired until either a system reset occurs (for example, as part of an IPL) or a Cancel function is used, after which another Initialize function is required.

## Responses

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'288' is given incorrect input data:

| Problem Encountered            | Cause                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Privileged-operation exception | The virtual machine is in the problem state.                                                                                                                                                                                                                                                                                                                                                      |
| Addressing exception           | The time bomb command string is not addressable.                                                                                                                                                                                                                                                                                                                                                  |
| Specification exception        | Any of the following: <ul style="list-style-type: none"> <li>An undefined flag bit is turned on.</li> <li>An undefined function code is used.</li> <li>The time bomb interval is less than 15 seconds and is not zero (Initialize, Change).</li> <li>The time bomb command string length exceeds 240 bytes or is zero (Initialize).</li> <li>No time bomb is defined (Change, Cancel).</li> </ul> |

## DIAGNOSE Code X'290' – Perform Privileged Spool Functions

**Privilege Class:** D

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

Use DIAGNOSE code X'290' to perform the privileged spool functions identified by the following subcodes:

- **X'0000'** fetches the page currently being built in a spool file that is open for creation. This data page contains the records most recently added to the file and has not been written to spool. The spool file may be owned by a user other than the issuer of this Diagnose.
- **X'0004'** fetches the external attribute buffer (XAB) data associated with a particular virtual unit record output device. The owner of the device may be any user currently logged on to the system. For more information on the XAB, refer to [“External Attribute Buffer Used by DIAGNOSE Codes X'B4', X'B8', and X'290'”](#) on page 995.

**Entry Values:**

**Rx**

Contains the guest real storage address of the input parameter block. This block must be aligned on a doubleword boundary.

**Ax**

Is used only for XC virtual machines in access-register mode, in which case it contains the ALET for the address space containing the input parameter block. If Rx designates general register 0, if Ax contains X'00000000', or if the virtual machine is not in XC mode, the input parameter block is in the host-primary address space.

**Ry**

(32-bit) Bytes 0 and 1 contain the length of the input parameter block in bytes. Bytes 2 and 3 contain the subcode.

### Subcode X'0000' – Fetch Current Page of Open Spool File

**Input Parameter Block:** The input parameter block for DIAGNOSE code X'290' subcode X'0000' is defined in the D29000 DSECT (in HCPD290P COPY) and contains the following input parameters:

**D29000VN**

(displacement 0, length 1) Version number (must be X'01').

**D29000Q**

(displacement 1, length 1) Queue on which the target spool file exists:

**D29000PU**

X'40' punch queue

**D29000PR**

X'20' printer queue

**D29000ID**

(displacement 2, length 2) Spool file ID of the target file.

**D29000PN**

(displacement 4, length 4) Relative page number of the data page that the program expects is the active page in the open spool file; that is, the page where records are currently being written during creation of the spool file. The first data page in the file is relative page number 0. If the page number of the currently active page does not match this value, a nonzero return code is given (see Responses). This mismatch can occur because new records can be written by the owner between the time the application determines the page number and the time this Diagnose executes.

**D29000UI**

(displacement 8, length 8) User ID of the owner of the target spool file.

**D29000BA**

(displacement 16, length 8) Buffer address - the 64-bit guest real address of the output buffer where the data page contents should be stored. This buffer is in the same address space that contains the input parameter block, and it must start on a 4 KB boundary.

**D29000BL**

(displacement 24, length 4) Buffer length in bytes (must be 4096).

**D29000R1**

(displacement 28, length 4) Reserved (must be zero for future compatibility).

**Exit Values:**

- Successful:
  - CC = 0
  - Ry (32-bit) = 0
  - The contents of the current spool file page are in the buffer.
- Unsuccessful:
  - CC = 1
  - Ry (32-bit) = nonzero return code (see Responses)
  - The buffer does not contain the requested data.

**Usage Note**

For a discussion of how z/VM processes addresses, refer to [“How Addresses Are Processed”](#) on page 5.

**Responses****Condition Codes:**

| Condition Code | Meaning                                                                                                                                          |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | The contents of the specified open spool file's currently active page buffer have been stored in the guest's buffer. The return code in Ry is 0. |
| 1              | The data has not been stored in the buffer. The exact error is defined by the return code.                                                       |

**Return Codes:**

| Return Code in Ry | Meaning                |
|-------------------|------------------------|
| 0 (X'00')         | Successful completion. |

| Return Code in Ry            | Meaning                                                         |
|------------------------------|-----------------------------------------------------------------|
| 4 (X'04')<br>D29000UIDNTLG   | The user ID specified is not logged on.                         |
| 8 (X'08')<br>D29000SFDNTEX   | The spool file specified does not exist on the specified queue. |
| 12 (X'0C')<br>D29000SFNTOPN  | The spool file specified is not currently open.                 |
| 16 (X'10')<br>D29000RBNTCUR  | The requested block number is not the current page.             |
| 20 (X'14')<br>D29000BFLNTVAL | The buffer length is not 4096.                                  |
| 24 (X'18')<br>D29000BFADNT4K | The buffer is not on a 4 KB boundary.                           |
| 28 (X'1C')<br>D29000CPIOERR  | A CP paging or I/O error occurred.                              |
| 32 (X'20')<br>D29000QNTVAL   | The spool queue specified is not valid.                         |
| 36 (X'24')<br>D29000ESMFAIL  | DIAGNOSE code X'290' use is not authorized.                     |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE X'290' is given incorrect input data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                                                                              |

## Subcode X'0004' – Fetch XAB Data from Virtual Printer

**Input Parameter Block:** The input parameter block for DIAGNOSE code X'290' subcode X'0004' is defined in the D29004 DSECT (in HCPD290P COPY) and contains the following input parameters:

### D29004VN

(displacement 0, length 1) Version number (must be X'01').

### D29004R1

(displacement 1, length 1) Reserved (must be zero for future compatibility).

**D29004DN**

(displacement 2, length 2) Virtual address of the target device.

**D29004R2**

(displacement 4, length 4) Reserved (must be zero for future compatibility).

**D29004UI**

(displacement 8, length 8) User ID of the owner of the target device.

**D29004BA**

(displacement 16, length 8) Buffer address - the 64-bit guest real address of the output buffer where the XAB data should be stored. This buffer is in the same address space that contains the input parameter block, and it must start on a 4 KB boundary.

**D29004BL**

(displacement 24, length 4) Buffer length in bytes (must be 32768).

**D29004R3**

(displacement 28, length 4) Reserved (must be zero for future compatibility).

**Exit Values:**

- Successful:
  - CC = 0
  - Rx (32-bit) = actual length of XAB data stored in the buffer
  - Ry (32-bit) = 0
  - The contents of the XABs are in the buffer.
- Unsuccessful:
  - CC = 1
  - Ry (32-bit) = nonzero return code (see Responses)
  - The buffer does not contain the requested XAB data.

**Usage Note**

For a discussion of how z/VM processes addresses, refer to [“How Addresses Are Processed”](#) on page 5.

**Responses****Condition Codes:**

| Condition Code | Meaning                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | The contents of the specified virtual output device's associated XABs have been stored in the guest's buffer. The return code in Ry is 0. |
| 1              | The XAB data has not been stored in the buffer. The exact error is defined by the return code.                                            |

**Return Codes:**

| Return Code in Ry            | Meaning                                 |
|------------------------------|-----------------------------------------|
| 0 (X'00')                    | Successful completion.                  |
| 4 (X'04')<br>D29004UIDNTLG   | The user ID specified is not logged on. |
| 8 (X'08')<br>D29004DEVNTEX   | The device specified does not exist.    |
| 12 (X'0C')<br>D29004DEVNTPRT | The device specified is not a printer.  |

| Return Code in Ry            | Meaning                                     |
|------------------------------|---------------------------------------------|
| 16 (X'10')<br>D29004DEVNOXAB | The device has no associated XABs.          |
| 20 (X'14')<br>D29004BFLNTVAL | The buffer length is not 32768.             |
| 24 (X'18')<br>D29004BFADNT4K | The buffer is not on a 4 KB boundary.       |
| 28 (X'1C')<br>D29004CPIOERR  | A CP paging or I/O error occurred.          |
| 36 (X'24')<br>D29004ESMFAIL  | DIAGNOSE code X'290' use is not authorized. |

**Program Exceptions:** These program exceptions can occur if DIAGNOSE X'290' is given incorrect input data:

| Problem Encountered                                                   | Cause                                                                                                                                                                                                                                                                                                                                                                                                        |

| Privileged-operation exception                                        | The issuer of the instruction does not have class D privileges.                                                                                                                                                                                                                                                                                                                                              |
| Access exception (See <a href="#">“Access Exceptions”</a> on page 8.) | Any of the following: <ul style="list-style-type: none"> <li>• An error occurred trying to fetch the input parameter block.</li> <li>• An error occurred trying to store the XAB data into the guest's buffer.</li> </ul>                                                                                                                                                                                    |

## DIAGNOSE Code X'2A8' – Network Diagnose

**Privilege Class:** Any

**Addressing Mode:** 31-bit or 64-bit

DIAGNOSE code X'2A8' establishes a network connection on a z/VM simulated network device in order to transmit and receive Ethernet frames. It provides a virtual machine with device-independent access to a simulated NIC created with a CP DEFINE NIC command that is coupled with a CP COUPLE command to either an Ethernet VSWITCH or Ethernet QDIO guest LAN.

### Entry Values:

#### Rx

The general register that contains the guest real address of a DIAGNOSE code X'2A8' request block. The request block must be on a doubleword boundary and cannot cross a 4K boundary. The size and format of the request block is determined by the specified operation code in Ry.

#### Ax

Is not used. The DIAGNOSE code X'2A8' request block must be in the host-primary address space.

#### Ry

The operation, as follows:

**Bits****Function****0-31**

Zero

**32-39**

Operation code:

**X'00'**

Query Interface

**X'01'**

Establish Device Connection

**X'02'**

Send Data Request

**X'03'**

Receive Data Request

**X'04'**

Multicast MAC Registration

**X'05'**

Network Device Options

**40-47**

Zero

**48-63**

Device number

**Exit Values:****Rx + 1**

Contains the response code indicating the results of the request. Refer to [“Responses” on page 283](#) for the response codes that may be returned.

## Operation code X'00' - Query Interface

This function returns the information required to establish and activate a network device connection using an operation code X'01' - Establish Device Connection.

The operation code in bits 32-39 of the Ry operand for this query request is X'00'. The Rx operand must specify the guest real address of a 64-byte storage area in which this operation code will store the following information for the virtual device number specified in Ry operand bits 48-63:

|    | 0                   | 1 | 2                | 3 | 4        | 5 | 6         | 7        |
|----|---------------------|---|------------------|---|----------|---|-----------|----------|
| 00 | MAC Address         |   |                  |   |          |   | Format    | Features |
| 08 | Frames              |   | Below 2GB Frames |   | Reserved |   | MAC Limit |          |

## Operation code X'01' - Establish Device Connection

This function will establish a network connection on a virtual NIC, defined by a CP DEFINE NIC command that is coupled with a CP COUPLE command to either an Ethernet VSWITCH or Ethernet QDIO guest LAN. Prior to establishing a connection, an operation code X'00' - Query Interface must be issued to obtain the information needed to establish and activate this connection.

Prior to issuing an operation code X'01' - Establish Device Connection, the number of guest absolute frames required for Diagnose use (as returned by operation code X'00' - Query Interface) must be provided in guest storage and not modified while the device connection is in use. Unpredictable results can occur if these frames are modified while the device connection is established or activated.

The operation code in bits 32-39 of the Ry operand for this query request is X'01'. The Rx operand must specify the guest real address of a variable-size establish device connection parameter list (EDCPL) that provides the following information for the virtual device number specified in Ry operand bits 48-63:

|    | 0                   | 1 | 2     | 3 | 4        | 5 | 6 | 7 |
|----|---------------------|---|-------|---|----------|---|---|---|

| 18 | Reserved            |   |       |   |          |   |   |   |
| 20 | Frame Address Array |   |       |   |          |   |   |   |
|    |                     |   |       |   |          |   |   |   |
|    |                     |   |       |   |          |   |   |   |
| xx |                     |   |       |   |          |   |   |   |

Once a connection is established, it must be activated by issuing a SSCH instruction to the device specified in Ry with the CCW returned by the operation code X'00' - Query Interface. The I/O request will remain active until it is either terminated by the adapter due to an unexpected error condition or terminated by the guest with either a CSCH or HSCH instruction. As long as the device connection is

active, data can be sent to the LAN by an operation code X'02' - Send Data Request or received with an operation code X'03' - Receive Data Request.

| <b>Field</b>               | <b>Length</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Frames</b>              | 2             | The number of guest real frames given to DIAGNOSE Code X'2A8' to manage the device connection. The number of frames required to establish a device connection is returned by operation code X'00' - Query Interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Index</b>               | 2             | When a response code returned in Rx+1 indicates a problem with an entry in the Frame Address Array, the index (0 to x) of the entry in error is set in this field. The field is ignored on entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Reserved</b>            | 28            | Reserved (set to binary zeros). Note that programs which place nonzero values in these fields may not operate compatibly in the future.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Frame Address Array</b> | Frames X 8    | <p>Variable-size array of 64-bit frames being given to the Network Diagnose to manage the device connection. The size of the array must equal the Frames field multiplied by eight bytes. Each entry must contain the non-zero 64-bit guest absolute address of a frame for the exclusive use of this Diagnose. The frames must remain resident and unmodified in guest storage until the activation CCW terminates.</p> <p><b>Note:</b> The Frame Address Array contains a list of both frames below and above 2GB to be given to the Network Diagnose. The required number of frames below 2GB returned by operation code X'00' Query Interface must be the first frames specified in the Frame Address Array. Failure to specify the frames below 2GB first within the Frame Address Array will result in a response code 32 error. The rest of the frames in the Frame Address Array may reside anywhere in storage.</p> |

## Operation code X'02' - Send Data Request

This function transmits the specified Ethernet frames to the LAN connection established with operation code X'01' - Establish Device Connection and activated with a SSCH of the I/O activation CCW provided by operation code X'00' - Query Interface. As long as the connection is active, data can be sent to the LAN by an operation code X'02' - Send Data Request.

The operation code in bits 32-39 of the Ry operand for this request is X'02'. The Rx operand must specify the 64- or 31-bit guest real address of a network parameter list (NETPL) to transmit Ethernet frames on the device connection activated on the virtual device number specified in Ry operand bits 48-63:

### Network Parameter List (NETPL)

The NETPL is a variable-size control block and is divided into two sections. The first 32 bytes is a fixed-size header that is followed by a variable-size array of data request blocks (DRBs). The address of the NETPL must be on a doubleword boundary and cannot cross a 4K boundary. The NETPL specifies the following information for the virtual device number in Ry operand bits 48-63:

|    |                           |       |          |   |   |   |   |   |

### Data Request Block (DRB)

Appended to the NETPL is an array of data request blocks. Each DRB maps a single packet to be transmitted or received. The number of DRBs to be processed is specified in the Entries field of the NETPL. The maximum number of DRBs that may be specified in a particular NETPL is determined by its starting address. An entire NETPL including the array of DRBs must reside within a single 4K frame. If any portion of the NETPL crosses a 4K boundary, the request will fail.

|-------------------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Reserved</b>               | 4      | Reserved (set to binary zeros). Note that programs which place nonzero values in these fields may not operate compatibly in the future.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Count</b>                  | 2      | An unsigned half word that specifies the size of the frame to be transmitted for an operation code X'02' - Send Data Request or the size of the buffer for an operation code X'03' - Receive Data Request. For a Receive Data, this count field will indicate the number of bytes filled in the DGRs on completion of the Diagnose.                                                                                                                                                                                                                                                                |
| <b>Ethernet Frame Address</b> | 8      | Guest real 64-bit address of a Ethernet frame for an operation code X'02' - Send Data Request or an empty buffer for operation code X'03' - Receive Data Request. The Ethernet and VLAN frame headers specified within a SEND Ethernet frame may not cross a 4K boundary. An Ethernet or VLAN frame header crossing a 4K boundary will result in a response code 40 error.<br><br><b>Note:</b> For performance reasons, it's advisable to keep the entire Ethernet frame within a single 4K frame. Additional Diagnose logic is necessary to process a Ethernet frame which crosses a 4K boundary. |

## Operation code X'03' - Receive Data Request

This function is used to retrieve Ethernet frames received from the LAN connection established with operation code X'01' - Establish Device Connection. After the network connection is activated, the arrival of inbound frames is signaled by a PCI I/O Interruption on the subchannel on which the I/O CCW provided by operation code X'00' - Query Interface was started via SSCH.

On receipt of a PCI I/O Interruption, an operation code X'03' - Receive Data Request should be issued with an array of empty data request buffers (DGRs). The size of each buffer must be large enough to contain an entire Ethernet frame (equal to or greater than the MTU size for the interface). On completion of the Diagnose instruction, the NETPL Entries field will indicate the number of DGR entries filled with Ethernet frames. The Count field in each filled-in DGR is updated to reflect the number of bytes stored in the Ethernet frame. Operation code X'03' - Receive Data Request should be reissued until all pending Ethernet frames are received. As long as the connection is active, data can be received from the LAN by an operation code X'03' - Receive Data Request.

The operation code in bits 32-39 of the Ry operand for this Receive Data request is X'03'. The Rx operand must specify a 64- or 31-bit guest real address of a network parameter list (NETPL) in order to receive pending Ethernet frames on the device connection activated on the virtual device number specified in Ry operand bits 48-63.

The NETPL is a variable-size control block and is divided into two sections. The first 32 bytes is a fixed-size header and is followed by a variable-size array of Data Request Blocks (DRB). The address of the NETPL must be on a doubleword boundary and cannot cross a 4K boundary. Refer to [“Network Parameter List \(NETPL\)”](#) on page 278 for the format of the NETPL for a Receive Data request.

## Operation code X'04' - Multicast MAC Registration

This function is used to register a multicast MAC address on a LAN connection established with an operation code X'01' - Establish Device Connection. After the network connection is activated, inbound multicast Ethernet frames may only be received when their multicast MAC address is registered on the LAN. Operation code X'04' allows a program to either register a multicast MAC address or to remove a previously registered multicast address from an activated network connection.

A multicast MAC address may only be registered after the device connection is activated. A MAC address registration will remain in effect until either it is removed by this operation code or the device connection is deactivated by a CSCH.

The operation code in bits 32-39 of the Ry operand for this registration request is X'04'. The Rx operand must specify a 64- or 31-bit guest real address of a multicast MAC address parameter list (MACPL) in order to receive multicast Ethernet frames on the device connection activated on the virtual device:

| <b>Reserved</b>              | 18     | Reserved (set to binary zeros). Note that programs which place nonzero values in these fields may not operate compatibly in the future.                                                         |

## Operation code X'05' - Network Device Options

This function is used to examine or modify options for a network device connection established with an operation code X'01' - Establish Device Connection. A device options parameter list (DOPL) is specified when the operation code is executed. The first 32 bytes of the DOPL specify the function to be performed. The trailing 32 bytes of the DOPL return the active device settings at completion of the operation code X'05' - Network Device Options.

A device option may be modified after the device connection is activated. Any change made will remain in effect until it is either modified by this operation code or the device connection is deactivated.

The operation code in bits 32-39 of the Ry operand for this Network Device Options request is X'05'. The Rx operand must specify the 64- or 31-bit guest real address of a device options parameter list (DOPL).

**Device Options Parameter List (DOPL)**

## Responses

### Condition Codes:

Upon completion of DIAGNOSE code X'2A8', control is returned to the invoker with a condition code set to indicate the status of both input parameter list processing and the function requested. A response code in Rx+1 further defines the results (see the response code tables that follow).

| Condition Code | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | Function completed successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 1              | Function partially completed. Some of the I/O completed successfully. A response code in Rx+1 indicates the condition that caused the partial completion and the Index field in the EDCPL or NETPL indicates the entry in error.                                                                                                                                                                                                                                                                  |
| 2              | Function failed. No I/O has completed successfully. The response code in Rx+1 indicates the reason for the failure.                                                                                                                                                                                                                                                                                                                                                                               |
| 3              | <p>One of the following conditions occurred:</p> <ul style="list-style-type: none"> <li>• The device number specified in bits 48 to 63 in Ry doesn't exist or its subchannel is not enabled.</li> <li>• The device number is not a virtual NIC coupled to an Ethernet VSWITCH or Ethernet QDIO Guest LAN.</li> <li>• A nonrecoverable error occurred while processing the instruction – a soft ABEND was taken.</li> </ul> <p>The response code in Rx+1 indicates the reason for the failure.</p> |

Response codes for operation code X'00' - Query Interface are as follows:

| Condition Code | Response Code in Rx+1 (decimal) | Meaning                                                                                                                                                                                                                                                                                                                                   |

**Program Exceptions:** DIAGNOSE code X'2A8' may result in one of the following program exceptions:

| Program Exception    | Cause                                        |
|----------------------|----------------------------------------------|
| Privileged-operation | The virtual machine is in the problem state. |

| Program Exception | Cause                                                                                                                                                                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access            | An error occurred trying to: <ul style="list-style-type: none"> <li>• Store Query Interface information</li> <li>• Fetch or store the establish device connection parameter list (EDCPL)</li> <li>• Fetch or store the network parameter list (NETPL)</li> <li>• Fetch or store the device options parameter list (DOPL).</li> </ul> |
| Specification     | One of the following: <ul style="list-style-type: none"> <li>• Rx is not on a doubleword boundary or it crosses a 4K boundary</li> <li>• Rx equals Ry</li> <li>• Register 15 specified for Rx</li> <li>• Rx+1 overlays Ry</li> <li>• Rx specifies an address of zero</li> </ul>                                                      |
| Operand           | An invalid operation code is specified in bits 32-39 of Ry.                                                                                                                                                                                                                                                                          |

## DIAGNOSE Code X'2CC' – SSI Interface

**Privilege Class:** B, E

**Addressing Mode:** 24-, 31-, or 64-bit

Use DIAGNOSE code X'2CC' to perform certain SSI-related functions. DIAGNOSE code X'2CC' provides a virtual machine with access to SSI information.

**Entry Values:**

**Rx**

Function code.

| Bits  | Function                                                                                                                               |
|-------|----------------------------------------------------------------------------------------------------------------------------------------|
| 00-31 | Ignored                                                                                                                                |
| 32-63 | Function Code: <ul style="list-style-type: none"> <li>0 – Obtain Local System SSI Identifiers</li> <li>1 – Query membership</li> </ul> |

**Ry**

Contains a function-specific value and must be an even-numbered register.

**Exit Values:**

**Ry + 1**

Contains the response code indicating the results of the request. Refer to the section for each function code to determine the response codes that can be returned.

## Responses

**Condition Codes and Response Codes:**

Upon completion of DIAGNOSE code X'2CC', control is returned to the invoker with the condition code set to indicate the status of both input parameter processing and the function requested. A response code is set in Ry+1 and might further define the results.

If the function code in Rx is not recognized, condition code 3 is set and Ry+1 contains a response code of 256.

Refer to the individual function code descriptions for specific explanations of the meanings of condition codes 0, 1, and 2, as well as for the associated response code values and meanings.

#### Program Exceptions:

DIAGNOSE code X'2CC' might result in one of the following program exceptions:

| Program Exception    | Cause                                                                                                                                                                                   |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Privileged-operation | Any of the following: <ul style="list-style-type: none"> <li>The virtual machine is in the problem state.</li> <li>The virtual machine does not have privilege class B or E.</li> </ul> |
| Access               | An error occurred trying to fetch or store a parameter.                                                                                                                                 |
| Specification        | Any of the following: <ul style="list-style-type: none"> <li>Rx and Ry are the same register.</li> <li>Ry is not an even-numbered register.</li> </ul>                                  |

### Function Code 0: Obtain Local System SSI Identifiers

This function sets the condition code based on whether the local system is a member of the SSI cluster and, if so, returns cluster-related information.

The function code in bits 32-63 of the Rx operand for the Obtain Local System SSI Identifiers request is 0.

The Ry operand must specify the guest logical address of a 32-byte storage area that contains, if the response code is zero:

- The name of the SSI cluster, left-justified and padded with blanks, if necessary, in bytes 0-7
- The name of the local system, left-justified and padded with blanks, if necessary, in bytes 8-15
- A bitmap indicating the slot number of the local system (from left to right), in bytes 16-19
- The slot number of the local system in bytes 20-21
- Zeroes in bytes 22-31.

If the system is not a member of an SSI cluster, condition code 2 is set and the designated 32-byte storage area contains:

- Blanks in bytes 0-7
- The system name, left-justified and padded with blanks, if necessary, in bytes 8-15
- Zeroes in bytes 16-31.

#### Condition Codes and Response Codes for Obtain Local System SSI Identifiers Function:

| Condition code | Response Code in Ry+1 | Response Code Meaning                                                                                                                                            |
|----------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | 0                     | The local system is an SSI cluster member.                                                                                                                       |
| 2              | 248                   | The local system is not a member of an SSI cluster because it is not configured for an SSI cluster.                                                              |
| 2              | 252                   | The local system is not a member of an SSI cluster because it was IPLed with the REPAIR parameter, which causes any SSI configuration information to be ignored. |

## Function Code 1: Query SSI Membership

This function sets the condition code based on whether the system name, whose address is in Ry, is configured as a member of the SSI cluster to which the local system belongs.

The function code in bits 32-63 of the Rx operand for the Query Membership request is 1.

The Ry operand must specify the guest logical address of an eight-byte storage area containing the name of the system whose cluster membership is to be determined. The name of the system must be left-justified and padded with blanks, if necessary.

### Condition Codes and Response Codes for Query Membership Function:

| Condition code | Response Code in Ry+1 | Response Code Meaning                                                                                                                                            |
|----------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | 0                     | The specified system is a member of the SSI cluster.                                                                                                             |
| 1              | 4                     | The specified system is not a member of the SSI cluster.                                                                                                         |
| 2              | 248                   | The local system is not a member of an SSI cluster because it is not configured for an SSI cluster.                                                              |
| 2              | 252                   | The local system is not a member of an SSI cluster because it was IPLed with the REPAIR parameter, which causes any SSI configuration information to be ignored. |

## DIAGNOSE Code X'2E0' – SYSEVENT Query Virtual Server (QVS)

**Privilege Class:** Any

**Addressing Mode:** 24-bit, 31-bit, or 64-bit

Use DIAGNOSE code X'2E0' to return information about system, logical partition, and virtual machine capacity. It is equivalent to the MVS™ SYSEVENT QVS interface, as described in *z/OS MVS Programming: Authorized Assembler Services Reference, Volume 4 (SET-WTO)*, SA22-7612.

### Entry Values:

#### Rx

Contains the guest logical address of QVS parameter list.

#### Ry

Contents must be 0.

### Exit Values:

#### Rx

Does not change.

#### Ry

Contains a return code.

**Parameter List:** The parameter list consists of an input area followed by an output area. The area must be aligned on a doubleword boundary. This area is mapped by the IRAQVS macro in HCPGPI MACLIB.

## Usage Notes

1. SYSEVENT QVS does not report capacity information when z/VM is running on IFL processor engines.
2. Virtual and real specialty engines that may be part of the virtual machine, logical partition, or machine configuration are not included in the capacity values returned by SYSEVENT QVS.

## Responses

Upon completion, DIAGNOSE code X'2E0' sets one of the following return codes in Ry:

**Return Code**  
**Explanation**

**0**

Successful.

**4**

Parameter list too short.

The output area is set to zeros with a return code of zero if z/VM is running in a Linux®-only partition, or the DIAGNOSE is issued on a virtual processor that is not a virtual CP.

The virtual machine capacity value returned by DIAGNOSE code X'2E0' is not affected by any SHARE HARDLIMIT setting and reflects the capacity of the lowest-level virtual machine. That is, if the DIAGNOSE is issued by a guest of a z/VM guest, the virtual machine capacity value reflects the capacity of the z/VM guest and not the one issuing the DIAGNOSE instruction.

**Program Exceptions:** These program exceptions can occur if DIAGNOSE code X'2E0' is given incorrect data:

| Problem Encountered     | Cause                                                                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification exception | <ul style="list-style-type: none"> <li>The address contained in Rx is not on a doubleword boundary.</li> <li>The value contained in Ry is not zero.</li> </ul> |
| Access exception        | An error occurred trying to store the capacity information into the guest's output area.                                                                       |

## DIAGNOSE Code X'2FC' – Obtain Certain Guest Performance Data

**Privilege Class:** Any, B.

**Addressing Mode:** 24-bit, 31-bit or 64-bit

Use DIAGNOSE code X'2FC' to obtain certain guest performance data.

**Entry Values:**

**Rx**

Contains the guest logical address of the parameter list.

**Ax**

Is used only for virtual machines in access register mode and contains the ALET for the address space containing the parameter list and the response area. When Rx is general register 0, Ax is not examined; the ALET is assumed to be X'00000000', which indicates the guest host-primary address space.

**Exit Values:**

**Rx**

Contains the response buffer residual length.

**Ax**

Does not change.

**Ry**

Contains a return code.

**Parameter List Definition:** The parameter list must be aligned on a doubleword boundary. Its format is as follows:

Where:

**User identifier selection string (EBCDIC value)** This string:

- (Class Any) must be eight blanks to indicate that the issuer's performance data is to be obtained.
- (Class B) must identify a user whose performance data is to be obtained.
- (Class B) must identify a set of users by designating zero or more of the leading characters of their user identifiers, followed by an asterisk (i.e., \*) to indicate that any arbitrary subsequent characters are allowed.

**ACI Group identifier selection string (EBCDIC value)** This string:

- (Class Any) is ignored.
- (Class B) must identify the ACI group name of the users whose performance data is to be obtained.
- (Class B) must identify a set of users by designating zero or more of their ACI group name leading characters, followed by an asterisk (i.e., \*) to indicate that any arbitrary subsequent characters are allowed.

Performance data is returned only for users who satisfy both the user identifier and the ACI Group identifier conditions.

**Response area address:** This is the guest logical address of the doubleword-aligned area in storage where the performance data is to be returned. For a virtual machine in access register mode, the ALET for the address space is contained in Ax. See Ax under [Entry Values](#), for more information.

**Response area length:** This is the signed 32-bit binary length of the response area.

**Response area format:** This is the response format and must have the binary integer value 2.

## Responses

At the completion of the instruction, the response area contains zero or more sets of performance data. The first word of each set of data in the response is a binary version number indicating its format.

The Format 2, Version 1 response is X'70' (112) bytes long and has the following format:

| Offset | Type (Length) | Field Description |
|--------|---------------|-------------------|
| 0x00   | Binary(4)     | Version           |

| Offset | Type (Length) | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Offset | Type (Length)  | Field Description                              |
|--------|----------------|------------------------------------------------|
| 0x60   | Binary(4)      | Other Samples; times user found in other state |
| 0x64   | Binary(4)      | Total Samples; times user state sampled        |
| 0x68   | Char(8) EBCDIC | User Identifier                                |

**Notes:**

1. The fields that contain samples (from x'50' through x'64') are calculated only for virtual CPUs of the same type as the primary virtual CPU.
2. For more information about specialty engines and CPU types, see Chapter 1 of *z/VM: Running Guest Operating Systems*.

**Condition Code:** The condition code is unchanged.

**Return Codes:** At the completion of the Diagnose instruction, the following return codes are provided in Ry:

| Return Code | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 0           | SUCCESS<br><br>Rx contains the residual response area length. Subtract its value from the original response area length to determine the amount of performance data returned. The result could be zero.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -1          | FORMAT_NOT_SUPPORTED<br><br>The Response format value is not 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| -2          | RECEIVE_BUFFER_TOO_SMALL<br><br>The response area is too small to hold all the performance data and contains only as many complete responses as would fit. Rx contains the residual response area length and will be negative, its complement indicating how much larger the area must be to contain the entire response. Since the size of the response area may change between two invocations of the Diagnose, increasing the area size by this amount might make it either too large or too small to hold a subsequent response. This error will also be returned if the initial response area length is not positive. |
| -3          | INCORRECT_RECEIVE_ADDRESS<br><br>The response area is not doubleword-aligned, is protected, or is not addressable. The contents of any accessible portion of the response area are unpredictable.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| -4          | API_EXCEPTION<br><br>An error occurred fetching the parameter list or storing into the response area. An attempt was made to access another user's performance data without the appropriate (privilege class B) authorization.                                                                                                                                                                                                                                                                                                                                                                                             |

## Part 2. The Inter-User Communications Vehicle

This part contains the following chapters:

- Chapter 3, “[IUCV Overview](#),” on [page 297](#) which gives an overview of the Inter-User Communications Vehicle (IUCV), and a high-level description of using IUCV to pass information from one virtual machine to another.
- Chapter 4, “[IUCV Protocols](#),” on [page 311](#) which gives reference information on IUCV protocol.
- Chapter 5, “[IUCV Function Descriptions](#),” on [page 317](#) which gives reference information needed to code IUCV functions.

---

## Chapter 3. IUCV Overview

The Inter-User Communications Vehicle (IUCV) is a communications facility that allows a program running in a virtual machine to communicate with other virtual machines, with a CP system service, and with itself.

An IUCV communication takes place between a source communicator and a target communicator. The communication takes place over a predefined linkage called a path. Each communicator can have multiple paths, and can receive or send multiple messages on the same path simultaneously.

IUCV provides functions, through the IUCV macro, to:

- Create and dismantle paths
- Send and reply to messages
- Receive or reject messages
- Control the sequence of IUCV events.

Communicators receive information about IUCV events by handling IUCV external interrupts.

To use the IUCV macro, issue the CMS GLOBAL command for HCPGPI MACLIB before assembling your program.

**Note:** Advanced Program-to-Program Communication/VM (APPC/VM) is based on the IUCV support described in this chapter. Using APPC/VM, a user application program can communicate with a resource manager program in the same system, as with IUCV. With APPC/VM however, an application program can also communicate with a program in another system. This other system could reside in the same TSAF collection (a defined group of z/VM systems), CS collection, or anywhere within a network defined by IBM's Systems Network Architecture (SNA). IUCV connections are restricted to the CS collection, and by default to only virtual machines on the same system.

This chapter only describes communication using IUCV—it does not include information about APPC/VM. Please refer to [Part 3, “The Advanced Program-to-Program Communication/VM,” on page 385](#) for details about APPC/VM and communications outside a single system.

You can write programs that use just the IUCV support described in this chapter, however, CMS IUCV applications should use the CMS support for IUCV and APPC/VM as described in [z/VM: CMS Application Development Guide for Assembler](#) and [z/VM: CMS Macros and Functions Reference](#). The CMS Shared File System, Session Services, private resources, CPI Communications (also known as SAA communications interface), and Coordinated Resource Recovery are just some of the functions and products that require this CMS support.

---

### How Addresses Are Processed

z/VM processes addresses (24-bit or 31-bit) according to the addressing mode being used by the virtual machine. When the guest PSW is in 64-bit addressing mode, IUCV treats addresses as 31-bit addresses.

**Note:** The IUCV instruction is not supported in access-register mode in an XC virtual machine. It results in a special-operation exception.

The address of the IUCV parameter list is a guest real address in the host-primary address space. All other addresses processed by IUCV are guest absolute addresses in the host-primary address space.

---

### IUCV Paths

The IUCV directory control statement authorizes the establishment of paths between virtual machines, or between a virtual machine and a CP system service. If the maximum number of paths is not specified by the MAXCONN keyword of the OPTION statement in the user's directory, a communicator can establish a maximum of 64 paths.

Once authorized, users establish a path when the source communicator invokes the CONNECT function and the target communicator invokes the ACCEPT function. Either communicator can terminate an established path through the SEVER function. The target communicator can also prevent the establishment of a path by invoking the SEVER function instead of the ACCEPT function. In addition, communication over a path can be temporarily suspended when a communicator invokes the QUIESCE function. The quiesced path can be reactivated when a communicator invokes the RESUME function.

A single communicator can have multiple paths defined, and virtual machines may have multiple paths between them. The communicator could be a source communicator on some of its defined paths, a target communicator on other paths, and both a source and a target communicator on still other paths. Communication over any and all paths can occur simultaneously.

Every path has two ends: the source communicator's end and the target communicator's end. The source communicator has a description of the path from the source's perspective and the target communicator has a description of the same path from the target's perspective.

Each path description has a path ID that is unique for each communicator. IUCV assigns path IDs when communicators invoke the CONNECT and ACCEPT functions. When invoking IUCV functions, the source communicator identifies the path by using the source's path ID. The target communicator identifies the same path to IUCV by using the target's path ID. A path ID is IUCV's method of distinguishing among the paths available to a communicator.

## IUCV Messages

An IUCV communication is called a message. The source communicator invoking the SEND function initiates communication and creates a message. The target communicator obtains the message by invoking the RECEIVE function.

The target communicator can optionally request information about messages sent to it by invoking the DESCRIBE function or the INTERRUPT POLL function, and can refuse a message sent to it by invoking the REJECT function. The target communicator can respond to a message through the REPLY function.

Communication is terminated and the message is destroyed when the source communicator issues the TEST COMPLETION function, the INTERRUPT POLL function, or handles an IUCV message complete external interrupt.

## Message Data Transfer

When the target communicator issues the RECEIVE function, IUCV moves the message data from the source communicator's SEND virtual address space to the target communicator's RECEIVE virtual address space. When the target communicator issues the REPLY function during a two-way communication, IUCV moves data from the target communicator's REPLY virtual address space to the source communicator's ANSWER virtual address space.

Figure 16 on page 298 illustrates the movement of message data during an IUCV two-way communication.

Figure 16. IUCV Two-Way Data Transfer

The source communicator's SEND and ANSWER areas may overlap. Similarly, the target communicator's RECEIVE and REPLY areas may overlap.

CP performs storage protection checking for all data moved during an IUCV communication.

## Message Identification

A message is fully identified to a virtual machine by three values. IUCV functions allow one or more of these values to be specified to process messages selectively.

- Message ID

IUCV assigns a message ID when the source communicator invokes the SEND function. The message ID is generated by a sequential counter value and is unique for the system IPL.

- Message class

The source communicator identifies a message by using the source message class and target communicator identifies a message by using the target message class. The message classes are arbitrary values that the source communicator specifies when invoking the SEND function. The meaning of the message classes is agreed to in advance by the two communicators. IUCV places no restrictions on the values specified for message class. The communicators can use the message class to handle messages selectively.

- Path ID

IUCV assigns the path ID when a path is established with the CONNECT function.

There is no defined relationship between the values of the source and target path IDs IUCV assigns, or between the message classes the source and the target communicators use. None of these values need to be the same although they refer to the same message.

The message ID always has the same value for both target and source communicators.

When invoking IUCV functions, the source communicator may refer to a message by a combination of its source path ID, source message class, and message ID. The target communicator may refer to the same message by a combination of its target path ID, target message class, and message ID.

The message tag information may optionally be used by the source communicator to further identify a message. Since IUCV presents the tag to the source communicator when the message completes, the tag may be used to tie the completed message to the original SEND request.

Since a message can be identified as a priority message, the source communicator may also use this as an indication to the target communicator that special handling is required. IUCV queues a priority message ahead of any nonpriority messages and behind any earlier priority messages. A communicator must be authorized to handle priority messages in the IUCV directory control statement.

## IUCV External Interrupts

---

The IUCV external interrupt notifies a virtual machine about IUCV events.

To enable IUCV external interruptions, communicators must:

- Invoke the DECLARE BUFFER function to indicate to IUCV where to store data associated with an external interruption.
- Set bit 7 in the virtual machine's PSW to 1.
- Set submask bit 30 of control register 0 to 1.

IUCV functions generate a type X'4000' external interruption. When a virtual machine in EC mode receives an IUCV external interruption, IUCV places the interruption code in locations X'86' and X'87' of the virtual machine's storage. For a virtual machine in BC mode, IUCV places the code in the external old PSW. In addition, IUCV stores an external interrupt buffer containing information about the message or IUCV function at the address specified when the communicator invoked the DECLARE BUFFER function. One field of this buffer is an external interrupt subtype that indicates why the external interrupt occurred. The possible values of this field are:

- 01 - Connection pending
- 02 - Connection complete
- 03 - Connection severed
- 04 - Connection quiesced
- 05 - Connection resumed
- 06 - Priority message completion
- 07 - Nonpriority message completion
- 08 - Priority message pending
- 09 - Nonpriority message pending.

The first five types are called *control interrupts*, and the last four types are called *message interrupts*.

Whenever there are multiple IUCV interrupts queued for the virtual machine, control interrupts are always reflected to the virtual machine in first-in-first-out (FIFO) order before message interrupts. Message interrupts of the same subtype are reflected in first-in-first-out (FIFO), but message interrupts of different subtypes are reflected in the order shown above.

Interrupts are reflected to the virtual machine in this order regardless of the order in which the interrupts were queued for the virtual machine. There are many conditions which can cause more than one interrupt to be queued for a virtual machine, some of which are beyond the control of the application. For example, if the virtual machine disables for IUCV interrupts for a period of time or if the virtual machine is communicating with multiple partners, then often multiple IUCV interrupts will be on the virtual machine's queue. Also, the relative priorities and time slices given to the communicating virtual machines can affect the order in which IUCV interrupts are presented. For example, if virtual machine A sends a one-way message to virtual machine B, and B receives the message, a message complete interrupt is queued for A. If B then severs the IUCV path, then a sever interrupt is queued for A. If A is not dispatched, or doesn't enable for IUCV interrupts until after the sever interrupt is queued, then A would see the sever interrupt first. If A is dispatched and is enabled for IUCV interrupts before the sever interrupt is queued, then A would see the message complete interrupt first.

A virtual machine can use the SET MASK function to enable or disable external interrupts selectively for IUCV communications. The SET MASK function has mask bits that enable or disable external interruptions for:

- Priority message pending
- Nonpriority message pending
- Priority message completion
- Nonpriority message completion
- IUCV control functions.

To divide and handle the control type interrupts even further, the SET CONTROL MASK function may be used on the IUCV macro. The types of control interrupts may be separately enabled and disabled. These control type interrupts are:

- Connection pending
- Connection complete
- Connection severed
- Connection quiesced
- Connection resumed.

The SET MASK function is interrogated before the SET CONTROL MASK function. If you specify that all control interrupts are disabled using the SET MASK function, then the SET CONTROL MASK settings are not interrogated. If you specify that all control interrupts are enabled using the SET MASK function, then the SET CONTROL MASK settings are interrogated to determine how to handle the individual types of control interrupts.

After IUCV initialization and until you issue the SET MASK or SET CONTROL MASK functions, all IUCV submask bits are on, enabling all IUCV external interrupts.

## Avoiding IUCV External Interrupts

A virtual machine can only be notified about an IUCV control function by receiving an external interruption. However, a virtual machine can handle pending messages either by an external interrupts or by using the DESCRIBE function. Message completions can be handled either by an external interrupt or with the TEST COMPLETION function. The INTERRUPT POLL function allows a user to handle message completions and pending messages at the same time.

IUCV also provides the TEST MESSAGE function to determine the presence of any pending messages or message completions. If neither is pending, the virtual machine goes into a wait state until one is pending.

For example, if a source communicator sends a priority message, IUCV queues an external interrupt for the target communicator. If the target virtual machine is enabled for external interrupts, then the target virtual machine receives an external interrupt. However, if the target virtual machine is not enabled, the message remains pending for the virtual machine, and the target virtual machine can issue the DESCRIBE function or the INTERRUPT POLL function to obtain information about the message in the parameter list. The message pending external interrupt is cleared. The target virtual machine can continue processing the message with the RECEIVE or REJECT functions.

**Note:** If a communicator is enabled for external interrupts and issues the DESCRIBE, INTERRUPT POLL or TEST COMPLETION function, results are unpredictable. However, IUCV supplies information about a message only once.

Two IUCV functions, QUIESCE and RESUME, let a virtual machine control the arrival of message pending external interrupts. The QUIESCE function suspends incoming messages on one or all IUCV paths. Any communicator trying to send a message over a path that has been quiesced receives a return code indicating a quiesced path. No message is created and thus no external interrupt is reflected. The RESUME function restores normal communications.

## Security Considerations

Installations control how IUCV is used through the virtual machine directory entries. If the installation has not authorized a user for IUCV communications in the directory, all requests for IUCV communications to virtual machines other than the user's own are denied. Service virtual machines and CP system services defined with the ALLOW (any virtual machine to connect) option do their own authorization checking, and individual directory entries are not needed.

IUCV moves data from one virtual machine address space to another. A virtual machine never has access to the storage or registers of CP or another virtual machine. When the user invokes the RECEIVE or REPLY functions, the data to be moved is described by a starting address and a length, or a list of starting addresses and lengths. The length specified in the parameter list is the maximum amount of data moved. No requirements are placed on a virtual machine as to the location of these buffers.

IUCV assigns path IDs and records the path ID of each communicator. A given communicator can reference only the paths that have been established for his virtual machine.

IUCV assigns the message ID for each message. IUCV does not use this identifier as a direct reference, but only as an operand in a comparison. It is conceivable that a virtual machine could generate a valid message identifier and use this to request a message. However, when a message ID is used to request a message, a user must also specify a message class and a path ID. If the specified message is not associated with the specified path ID and message class, the user cannot access the messages. If the message ID, path ID, and message class do match, the user could legitimately access the message by specifying simply path ID and/or message class without the generated message ID.

The installation can limit the number of connections for a particular virtual machine by using the MAXCONN parameter of the OPTION control statement in the virtual machine's directory entry.

## Virtual Machine-to-Virtual Machine Communication

Three ways of accomplishing virtual machine-to-virtual machine communications are:

- Using data in a buffer
- Using data in a parameter list
- Using control paths.

### Using Data in a Buffer

Table 66 on page 302 illustrates a typical sequence of functions invoked when a virtual machine communicates with another virtual machine. The functions include initializing, connecting to another virtual machine, sending and receiving messages, replying to and waiting for messages, severing communications with the other virtual machine, and terminating communications.

**Note:** Remember, in Table 66 on page 302 data for the messages is stored in a buffer. Refer to [“Using Data in a Parameter List”](#) on page 303 for an example of using parameter list data.

#### Virtual Machine X Communicating to Virtual Machine Y

| Table 66. Sequence of Functions                                                                                                                                                                                      |                                                                                                                                                                                                                           |

Get External Interrupt<br>14. SEVER<br>15. RETRIEVE BUFFER |

1. Virtual machine X wishes to communicate with virtual machine Y. Both virtual machines must independently invoke the DECLARE BUFFER function. The buffer provides the virtual machine with information about incoming external interrupts concerning IUCV functions.
2. Virtual machine X invokes the CONNECT function, indicating Y as the target. IUCV checks the directory to determine if this connection is authorized. If it is, IUCV queues an external interrupt for Y indicating that there is a connection pending for it. IUCV returns control to X at the next instruction after the CONNECT.
3. The external interrupt queued by step “2” on page 302 is reflected to Y indicating a connection pending. IUCV places the external interrupt information in the buffer that Y provided in step “1” on page 302. IUCV passes control to the external interrupt handler of Y.
4. Virtual machine Y interprets the external interrupt and responds with an ACCEPT to complete the connection. IUCV then completes the connection and queues a Connection Complete external interrupt for X. IUCV returns control to Y at the next instruction after the ACCEPT.
5. The external interrupt queued by step “4” on page 302 is reflected to X, indicating that the connection is complete, and the communication path is available for use. IUCV places the external interrupt information in the buffer that X provided in step “1” on page 302. IUCV passes control to the external interrupt handler of X.

6. Virtual machine X issues a SEND. The SEND function queues an external interrupt for Y indicating that a message is pending. Control returns in X at the next instruction after the SEND.
7. If virtual machine Y is enabled for external interrupts and for IUCV messages (through SET MASK), the external interrupt queued by step “6” on page 303 is reflected to Y, indicating that a message is pending. IUCV places external interrupt information in the buffer specified in step “1” on page 302. IUCV passes control to the external interrupt handler of Y. If virtual machine Y is disabled for external interrupts or IUCV messages and invokes the DESCRIBE function, IUCV places the message information in the DESCRIBE parameter list, and the Message Pending external interrupt for this message is cleared. IUCV passes control to the next instruction after the DESCRIBE.
8. While virtual machine Y is processing the message, virtual machine X can decide to check if the communication has been completed by issuing the TEST COMPLETION function. The condition code indicates that (in this example) the communication is not complete.
9. With the message description from step “7” on page 303, virtual machine Y starts processing the message and issues a RECEIVE. The parameter list associated with RECEIVE specifies where the message data is stored in virtual machine Y.  
  
If the message was one-way, the RECEIVE function queues an external interrupt for X indicating that the message had completed. REPLY processing in step “10” on page 303 would not be required for one-way messages. Control returns to Y at the next instruction after the RECEIVE.
10. When processing the message is complete, virtual machine Y responds to X by invoking the REPLY function. The REPLY function queues an external interrupt for X indicating that the message has completed. Control returns to Y at the next instruction after the REPLY.
11. If virtual machine X is both enabled for external interrupts and enabled for IUCV replies, the external interrupt queued by step “10” on page 303 is reflected to X, indicating a reply pending. To identify the reply, the external interrupt information is placed in the buffer specified in step “1” on page 302. IUCV passes control to the external interrupt handler of X. If virtual machine X is disabled for external interrupts and issues a TEST COMPLETION, IUCV places the message information in the TEST COMPLETION parameter list, and the Message Completion external interrupt is cleared. IUCV passes control to the next instruction after the TEST COMPLETION.
12. Virtual machine X has now completed its communications with virtual machine Y and issues a SEVER to break the communications path. The SEVER function queues an external interrupt for Y indicating that the communication link has been broken. Control returns in X at the next instruction after the SEVER.
13. The external interrupt queued by step “12” on page 303 is reflected to Y indicating that the path has been broken by virtual machine X. Virtual machine Y can now do any cleanup needed in its storage.
14. After virtual machine Y has completed processing, the virtual machine issues a SEVER notifying IUCV that it also is finished with the communication path. IUCV can then clean up its control blocks.
15. When all communications are complete and all communication paths have been severed, both virtual machines independently invoke the RETRIEVE BUFFER function.

## Using Data in a Parameter List

Most IUCV functions require a **parameter list** which contains information necessary for IUCV to perform the requested function. The IUCV macro assists you in filling in the parameter list properly. The parameters used with each function are described with the individual function descriptions later in this chapter.

The parameters let you specify 8 bytes of data in the parameter list. To understand better how data specified in the parameter list is handled, the IUCV functions are covered in a typical scenario.

1. The IUCV DECLARE BUFFER, CONNECT, and ACCEPT sequence must be invoked to establish the user's external interrupt buffer and a path to the target virtual machine (or CP). If you expect to receive data in the parameter list, you must authorize such communication on the CONNECT or ACCEPT by specifying PRMDATA=YES. The external interrupt information to the target communicator includes a bit indicating if PRMDATA=YES was chosen.

2. Issue an IUCV SEND request. When the data is to be passed in the parameter list, the DATA=PRMSG option is used on the IUCV macro, and the PRMSG= option is used to move the data into the parameter list. The sender of the message should be prepared to handle a return code indicating that DATA=PRMSG is not allowed if the target communicator has not specified PRMDATA=YES at connection time. IUCV saves the message data until it is to be presented to the target.
3. If the target is enabled for IUCV Message Pending external interrupts, the target virtual machine receives an IUCV Message Pending external interrupt because of the SEND request in the previous step. The message data is stored in the external interrupt buffer. A flag is set in the IPFLAGS1 field of the buffer (in the IPARML DSECT) indicating that the data is in the parameter list. Since the message data has been presented to the target, the target does not have to issue an IUCV RECEIVE for this message. If the message was a one-way message, communication is complete. There is no asynchronous return of message completion given to the source (sending) virtual machine on a one-way message.
4. If the target is disabled for IUCV Message Pending external interrupts and issues the IUCV DESCRIBE or RECEIVE functions, the message data is stored in the parameter list. A flag is set in the IPFLAGS1 field of the parameter list (in the IPARML DSECT) indicating that the data is in the parameter list. Since the message data is presented to the target on a DESCRIBE, the target does not have to issue an IUCV RECEIVE for this message. If the message was a one-way message, the communication is complete. There is no asynchronous return of message completion given to the source (sending) virtual machine on a one-way message.
5. If the communication in the previous steps was a two-way message, a REPLY is issued by the target virtual machine. When the REPLY data is to be passed in the parameter list, the DATA=PRMSG option is used on the IUCV macro, and the PRMSG= option is used to move the data into the parameter list. The REPLYer of the message should be prepared to handle a return code indicating that DATA=PRMSG is not allowed if the source communicator has not specified PRMDATA=YES at connection time. IUCV saves the message data until it is to be presented to the source communicator.
6. If the source communicator is enabled for IUCV Message Completion external interrupts, the source virtual machine receives an IUCV Message Completion external interrupt because of the REPLY in the previous step. The message data is stored in the external interrupt buffer. A flag is set in the IPFLAGS1 field of the buffer indicating that the data is in the parameter list. The communication is complete.
7. If the target is disabled for IUCV Message Completion external interrupts, and issues the IUCV TEST COMPLETE function, the message data is stored in the parameter list. A flag is set in the IPFLAGS1 field of the parameter list indicating that the data is in the parameter list. The communication is complete.
8. SEVER and RETRIEVE BUFFER cause any messages pending to be destroyed for that virtual machine. Since no asynchronous Message Completion external interrupt is returned to the source communicator for one-way messages using the DATA=PRMSG option, the source communicator must realize upon receiving an IUCV Connection Severed external interrupt from the target communicator that messages may not have been received by the target.

## Using Control Paths

IUCV control paths and buffers allow a control program (like CMS) running in a virtual machine to use the IUCV functions without interfering with a user application that is also using IUCV. Applications would not be coded using the CONTROL parameter on the IUCV DECLARE BUFFER, IUCV CONNECT, and IUCV ACCEPT functions.

To understand better how control paths would be handled, the IUCV functions are covered in a typical user scenario. In the scenario, CMS is used as the control program running in a virtual machine executing a normal IUCV application.

1. When CMS is IPLed in the virtual machine, CMS issues an IUCV DECLARE BUFFER with the CONTROL=YES parameter. This establishes a control buffer for CMS to use. All IUCV external interrupt information for control paths is presented in this buffer.

2. After CMS has defined a control buffer, CMS may establish control paths to other virtual machines by issuing an IUCV CONNECT with the CONTROL=YES parameter. All paths used by CMS should be specified as control paths.
3. If the target virtual machine accepts the connection request, an IUCV Connection Complete external interrupt is presented to the CMS control program. The IPCNTRL bit in IPFLAGS1 of the external interrupt (in the IPARML DSECT) indicates that a control path was accepted. CMS may now start communications on this path.
4. Just as it can establish control paths through IUCV CONNECT, CMS can also accept connections and specify that they be managed as control paths. CMS does this by issuing IUCV ACCEPT with the CONTROL=YES parameter. All paths accepted by CMS should be accepted as control paths.
5. When CMS allows the application program to run, the application issues an IUCV DECLARE BUFFER with the CONTROL=NO parameter. All application paths are established using IUCV CONNECT with the CONTROL=NO parameter. These are the functions that the application uses today so no changes are required to the application.
6. The application starts communicating over its established paths.
7. Since both CMS and its application have established paths, both are expecting and handling external interrupts.

If an external interrupt is on a control path, the IUCV information about the interrupt is stored in the control buffer when the interrupt is presented to CMS. CMS interrogates the control buffer, recognizes the path ID as belonging to a control path, and handles the IUCV interrupt. The application's buffer remains unchanged.

If the external interrupt is on an application path, the IUCV information about the interrupt is stored in the application's buffer when the interrupt is presented to CMS. Since CMS only has access to the control buffer, IUCV stores the path ID in the control buffer and clears (to 0) the remainder of the buffer. CMS interrogates the control buffer, recognizes the path ID as belonging to an application path, and passes the IUCV external interrupt to the application for handling.

8. When the application wishes to terminate a path that it established or to terminate all IUCV communications, it uses the IUCV SEVER or RETRIEVE BUFFER functions. Neither of these functions affects the control paths being used by CMS.

Certain IUCV functions result in an operation exception if executed with only a control buffer declared. These functions are:

- DESCRIBE
- INTERRUPT POLL
- RETRIEVE BUFFER
- SET CONTROL MASK
- SET MASK
- TEST COMPLETION
- TEST MESSAGE.

The ALL=YES parameter on the IUCV functions of SEVER, QUIESCE, and RESUME does not affect control paths.

When handling IUCV messages with the IUCV functions of RECEIVE, REPLY, REJECT, and PURGE on control paths, the message must be fully qualified. The message ID, path ID, and class of the message must be specified in the parameter list to reference the message.

The IUCV functions affecting IUCV external interrupts do not operate on interrupts for control paths. These functions are TEST MESSAGE, DESCRIBE, INTERRUPT POLL, TEST COMPLETION, SET MASK, and SET CONTROL MASK. These functions are never used by a control program since they have no affect on control paths.

Since IUCV cannot tell what part of the virtual machine issued an IUCV function, it is possible for an application to issue an IUCV function on a control path. This reference to a control path by an application, whether intentional or accidental, is considered a user application error. For example, the SEVER function

specifying a control path terminates that path even though the function was issued by the application program.

## Invoking IUCV Functions

You can invoke all IUCV functions through the IUCV macro. In general, specify the name of the IUCV function you wish to perform, the address of a parameter list to contain input to the function, and keyword parameters. IUCV moves the values specified on the keyword parameters into the specified parameter list.

The parameter list must be defined on a doubleword boundary.

You can specify IUCV parameters in two ways:

- By coding keyword parameters on the IUCV macro. IUCV stores values in the parameter list based on values you specify on the macro.
- By storing required input to the function in the function parameter list before invoking the IUCV macro. To store input in an IUCV parameter list, use labels generated by the IPARML DSECT in HCPGPI MACLIB.

You may use a combination of these methods to supply input to a single IUCV function. If you specify any optional parameters on the IUCV macro, you are responsible for providing the USING for the IPARML DSECT when the macro is invoked. If you do not specify an optional parameter to initialize the parameter list, the macro assumes that you have stored a value in the parameter list before invoking the IUCV macro.

**Note:** The IUCV macro does NOT clear parameter list fields since values may have been stored by the user already. Therefore, it is the user's responsibility to insure that all unused fields are cleared (set to 0). All reserved fields in the parameter list should always be set to 0.

An advantage of using the IUCV macro is that IUCV provides extensive error checking of parameter combinations when input is supplied on the macro. Many invalid parameter combinations can be detected by IUCV when you assemble the program.

For more information on the CMS IUCV applications, see [z/VM: CMS Application Development Guide for Assembler](#) and [z/VM: CMS Macros and Functions Reference](#).

## General Description of IUCV Functions

---

In the description of IUCV functions the following terms are used:

### Address

A guest real address (real to the virtual machine). It can be specified on the IUCV macro in one of the following ways:

- *Label* of the storage location
- Number of a register in parentheses that contains the address, (*reg*).

Every address field in the IUCV parameter list is a 4-byte reserved field. The address of the parameter list must be a guest real address, and it must be on a doubleword boundary.

Specify the address of the parameter list as a relocatable label or the number of a register that contains the address.

### Address List

A virtual machine defined area used on an IUCV SEND, RECEIVE, or REPLY that allows data to be moved from discontinuous areas. The address list must be on a doubleword boundary in the following format:

|           |          |
|-----------|----------|
| address 1 | length 1 |
| address 2 | length 2 |
| ▪<br>▪    | ▪<br>▪   |
| address n | length n |

Each entry contains two fullwords; the guest real address of the data to be transferred and the number of bytes to be transferred from that address.

**Label**

An addressable label in the user's program. The IPARML DSECT provides common labels for referencing fields in an IUCV parameter list.

**Length**

The amount of data to be transferred on an IUCV request. It can be specified on the IUCV macro in one of the following ways:

- *Label* of the storage location containing the length
- Number of a register that contains the length, *(reg)*.

The IUCV macro assumes a halfword value for the length at the storage location, or the low-order halfword of the register specified. A length modifier of 2 or 4 may be used, *(label,2)* or *((reg),2)*, or *(label,4)* or *((reg),4)*. If a length modifier of 4 is used, the macro uses the fullword value for the length at the storage location or in the register specified.

The descriptions of the IUCV functions are presented in alphabetic order in [Chapter 5, “IUCV Function Descriptions,”](#) on page 317:

ACCEPT — Complete a path  
CONNECT — Establish a path  
DECLARE BUFFER\* — Initialize for IUCV communications  
DESCRIBE\* — Avoid Message pending interrupt  
IPOLL\* — Check for pending replies or incoming messages  
PURGE — Cancel a message  
QUERY — Get IUCV information  
QUIESCE — Suspend message pending interrupts  
RECEIVE — Receive a message  
REJECT — Refuse a message  
REPLY — Respond to a message  
RESUME — Restore message pending interrupts  
RETRIEVE BUFFER\* — Terminate all IUCV communications

SEND — Transmit a message  
 SET CONTROL MASK\* — Disable all IUCV control interrupts  
 SET MASK\* — Disable all types of IUCV interrupts  
 SEVER — Terminate a path  
 TEST COMPLETION\* — Avoid Message complete interrupt  
 TEST MESSAGE\* — Check for interrupts or wait.

\*These functions have different meanings in a virtual MP environment. For more information about a virtual MP environment, see the following section on "Virtual MP Considerations for IUCV Applications".

## Virtual MP Considerations for IUCV Applications

---

IUCV applications can be written to work in a virtual MP environment. The following list is intended to provide some guidance on using IUCV in a virtual MP environment.

- IUCV functions may be invoked by any virtual processor in the virtual configuration as long as one of the processors has issued a DECLARE BUFFER function.
- The DECLARE BUFFER function defines an interrupt buffer for the virtual processor that invokes it.
- In the virtual MP environment, IUCV interrupts are treated as "floating" interrupts. Any virtual processor that has:
  - issued an IUCV Declare Buffer
  - enabled to receive IUCV interrupts with the CR0 setting
  - enabled for IUCV interrupts with the SETMASK and SETCMASK functions
 may receive an IUCV interrupt.
- The IUCV RETRIEVE BUFFER function will only retrieve the buffer for the currently running virtual processor. IUCV paths will not be SEVERed until the last virtual processor issues a RETRIEVE BUFFER.
- The SETMASK and SETCMASK functions will apply only to the virtual processor on which they are invoked. This will allow an application to force different types of IUCV interrupts to different virtual processors in the complex, if so desired.
- The following are associated with the virtual configuration:
  - IUCV directory specifications
  - IUCV paths
  - IUCV interrupts
  - IUCV messages.
- The following are associated with the virtual CPU:
  - the application buffer, the control buffer, and the interrupt buffer extension
  - interrupt enablement masks in the virtual PSW and virtual control register 0 (bit 30)
  - the interrupt enablement masks of SETMASK and SETCMASK.
- The DESCRIBE, TEST COMPLETE, and IPOLL functions will complete on any processor in the virtual complex as long as one virtual processor has issued a DECLARE BUFFER (it does not have to be the virtual processor that issued the DESCRIBE, TEST COMPLETE, or IPOLL function).
- If multiple virtual processors in the complex issue the TEST MESSAGE function, it is unpredictable in which order the virtual processors will be taken out of their wait states.
- All addresses specified with IUCV parameter lists are guest absolute addresses.
- Without appropriate guest operating system support, it is difficult or impossible to use IUCV in a virtual MP environment. This support would allow your application to:
  - declare buffers on different processors
  - enable for IUCV interrupts on the needed processors
  - handle the interrupts and route them to the appropriate virtual processor

Note that CMS does not currently support IUCV virtual MP functions.

## IUCV in a Distributed Environment

---

Distributed IUCV is supported across a Communication Services (CS) collection. Participating systems must include the DISTRIBUTE IUCV statement in their SYSTEM CONFIG files. Depending on what you specify, distributed IUCV will either:

- attempt to satisfy a CONNECT on the local system, then attempt to locate the target on a system within the CS collection. The only exceptions being if the application specifies that the connect must be satisfied either locally or on a particular target system.
- or, be supported only when an application explicitly specifies the target system for a CONNECT.

IUCV applications will behave the same in a distributed environment as they do on a local system with the following exceptions:

- PURGE and REJECT will only be honored on the local system. Once a message is sent to the other system it is considered to be delivered.
- The PRIORITY and MSGLIMIT directory specifications must be present on both systems if they are to be honored.
- The default maximum data length is 16M per message. The maximum can be altered via the SYSTEM CONFIG file by using the DISTRIBUTE statement.

As with distributed APPC/VM through ISFC, distributed IUCV will SEVER both sides of the conversation if it receives an IPRCODE or IPAUDIT code on function completion. Because ISFC is a transport mechanism, it can not rely on information received on a function that completes with an error and because ISFC is unsure of the disposition of the conversation, it SEVERs the path. This is the normal procedure for an application that receives an IUCV error.

At this time, no system services are able to operate in a distributed IUCV environment.

See [\*z/VM: CP Planning and Administration\*](#) for information on the DISTRIBUTE IUCV system configuration statement.

## Chapter 4. IUCV Protocols

The following protocols are defined for IUCV data communication:

### CONNECT/ACCEPT

Establishes a path between two communicators

### SEND/RECEIVE

Sends one-way messages with data in one or more buffers

### SEND/RECEIVE/REPLY

Sends two-way messages with data in one or more buffers

### SEND

Sends one-way messages with data in a parameter list

### SEND/REPLY

Sends two-way messages with data in a parameter list.

**IUCV CONNECT/ACCEPT Protocol:** A virtual machine uses the CONNECT/ACCEPT protocol (shown in Figure 17 on page 311) to establish a connection with another virtual machine or with a CP system service. The IUCV parameter list specified on the CONNECT request indicates the user ID of the intended target virtual machine or CP system service and, optionally:

- A message limit that indicates the number of outstanding messages permitted for the path
- The path's ability to handle priority communications
- Whether data is to be sent in a parameter list or in one or more buffers
- A user doubleword of data.

The condition code and the return code for the CONNECT request indicate to the source virtual machine the success or failure of the sending of the request. IUCV also returns the (IUCV-assigned) path ID and message limit to the source virtual machine in the IUCV parameter list.

Figure 17. Flow of the IUCV CONNECT/ACCEPT Protocol

The target communicator specified in a successful CONNECT request has a connection-pending external interrupt queued for it by CP. Identification of the request (the source virtual machine's path ID and user ID) is placed in the external interrupt buffer that is stored in the target virtual machine's virtual storage at the time the target virtual machine receives the connection-pending external interrupt. The target virtual machine can then send an ACCEPT function that specifies the path ID of the path to be accepted and optionally modifies the characteristics of the path, such as its message limit and priority handling.

If the ACCEPT function is incorrectly specified, the target virtual machine is notified immediately by way of a condition code and return code and the acceptance of the path does not take place. If correctly

specified, the ACCEPT function causes CP to establish the path. When the path is established, CP notifies the target virtual machine by way of a condition code and return code for the ACCEPT function that indicates a successful or unsuccessful operation.

The source virtual machine is notified of the completion of its CONNECT request by way of a connection-complete external interrupt. The external interrupt buffer identifies the completed request by way of its path ID, indicates the path's characteristics, and optionally, contains a user doubleword of data specified by the target virtual machine.

If the target virtual machine to which a CONNECT request is directed does not wish to establish the path, it can enter a SEVER function that specifies the path being rejected. CP then posts a connection-severed external interrupt for the source virtual machine. The external interrupt buffer indicates the path ID of the severed path, and optionally, a user doubleword of data specified by the target virtual machine. The source virtual machine can also sever a path by using the SEVER function.

**IUCV SEND/RECEIVE Protocol:** The SEND/RECEIVE protocol defines a one-way transfer of data from virtual storage of the source virtual machine to virtual storage of the target virtual machine, as shown in Figure 18 on page 312. The IUCV parameter list specified on the SEND request indicates:

- Path ID of the path on which the message is to be sent
- This is a one-way message
- Data is in one or more buffers
- Length of the data
- Address of the data or the address of a list of buffers that contain the data in the source virtual machine.

Optionally, the priority of the message, the source message class, the target message class, and a message tag may be specified. The condition code and the return code for the SEND request indicate to the source virtual machine the success or failure of the sending of the request. IUCV also returns the (IUCV-assigned) message ID to the source virtual machine in the IUCV parameter list. The source virtual machine can then continue with other processing while the data transfer operation takes place.

Figure 18. Flow of the IUCV SEND/RECEIVE Protocol

The target communicator specified in a successful SEND request has a message-pending external interrupt queued for it by CP. Identification of the request (path ID and message ID) and data length are placed in the external interrupt buffer that is stored in the target virtual machine's virtual storage when the target virtual machine receives the message-pending external interrupt. The target virtual machine can then send a RECEIVE function that specifies the path ID and message ID the request to be received and the address and length of the buffer in its own virtual storage in which the data to be received is to be placed. If more than one buffer is required, the address of a list of discontinuous buffers may be specified

instead. Use of the message ID in the RECEIVE function enables a virtual machine with more than one data transfer request queued to process them in the order desired.

If the RECEIVE function is incorrectly specified, the target virtual machine is notified immediately by way of a condition code and a return code. The requested data transfer does not take place. If correctly specified, the RECEIVE function causes CP to begin transferring the data from virtual storage of the source to virtual storage of the target virtual machine. When the data transfer is completed, CP notifies the target virtual machine by way of a condition code and a return code for the RECEIVE function that indicates a successful or unsuccessful operation.

The source virtual machine is notified of the completion of its SEND request by way of a message-complete external interrupt. The external interrupt buffer:

- Indicates whether the data transfer occurred successfully (by way of the audit trail bits)
- Identifies the completed request (by way of its path ID and message ID)
- Contains a residual count for a partial transfer operation (as a result of a data transfer error).

If the target virtual machine to which a SEND request is directed does not wish to receive the data, it can issue a REJECT function that specifies the request being rejected. The external interrupt buffer stored for the message-complete external interrupt for the source virtual machine indicates that the request was rejected by way of an audit trail bit. The source virtual machine can purge a SEND request using the PURGE function.

**IUCV SEND/RECEIVE/REPLY Protocol:** The SEND/RECEIVE/REPLY protocol provides the means for a virtual machine to perform a send and receive operation using a single request. That is, while data is being transferred from the source virtual machine to the target virtual machine, data can also be transferred from the target virtual machine to the source virtual machine.

As shown in [Figure 19 on page 314](#), the source virtual machine issues a SEND function to initiate the two-way transfer request. The IUCV parameter list of the SEND function specifies the following:

- The path ID of the path on which the message is to be sent
- That this is a two-way message
- That the data is in one or more buffers
- The address and length of the data to be sent (or list of buffers that contain the data) in the source virtual machine
- The address and length of the reply area (or list of reply buffers) in the source virtual machine.

Optionally, the priority of the message, the source message class, the target message class, and a message tag may be specified.

Figure 19. Flow of the IUCV SEND/RECEIVE/REPLY Protocol

The condition code and the return code for the SEND request indicate whether the request was sent successfully. IUCV also returns the (IUCV-assigned) message ID to the source virtual machine in the IUCV parameter list and processing in the source virtual machine continues. A message-pending external interrupt is queued for the target virtual machine by CP. When the target virtual machine receives the interrupt, the request is identified in the external interrupt buffer by its path ID and message ID. The length and location of the buffer in the source virtual machine that is to receive data sent by the target virtual machine by way of a REPLY (or the address of a list of buffers) is also stored.

After receiving the message-pending external interrupt, the target virtual machine can respond with a RECEIVE or REJECT function, with parameters specified as for a SEND/RECEIVE transaction. The REJECT function causes the entire SEND/RECEIVE/REPLY transaction to be cancelled. The RECEIVE function causes a data transfer from the source virtual machine to the target virtual machine, as for a SEND/RECEIVE transaction. However, after the RECEIVE function is sent, the target virtual machine receives control to send a REPLY function that specifies the path ID and message ID for this REPLY request, and the address and length of the data to be sent to the source virtual machine. This causes CP to start transferring data from the target virtual machine to the source virtual machine. The data is placed in the reply buffers in the source virtual machine that were specified in the SEND function.

When both data transfer operations have completed, the source virtual machine receives a message-complete external interrupt and the target virtual machine receives a condition code and return code in response to the REPLY function. The source virtual machine can use the REPLY data length field in the stored external interrupt buffer to determine the amount of data sent by the target virtual machine.

A SEND/RECEIVE/REPLY request can be terminated by the source virtual machine by way of a PURGE function.

**IUCV SEND Protocol:** The SEND protocol defines a one-way transfer of data from a source virtual machine to a target virtual machine without the use of the RECEIVE function, as shown in [Figure 20 on page 315](#). The data that may be transferred in this way is limited to 8 bytes and is stored in the IUCV parameter list. The path to be used must be authorized to handle data in the parameter list during the CONNECT/ACCEPT protocol that establishes it. If a SEND is directed to a virtual machine that has not authorized receipt of data in a parameter list on this path, it is indicated by a return code to the SEND request and the request is cancelled by CP.

The IUCV parameter list for a SEND request with data in the parameter list specifies the path ID of the path on which the message is to be sent, that this is a one-way message, and that the data is in the parameter list. Optionally, the priority of the message, the source message class, the target message class, and a message tag may be specified. When correctly specified, the SEND causes CP to transfer data from the source to the external interrupt buffer of the target virtual machine. After the data transfer is complete, a message-pending external interrupt is queued for the target virtual machine. Note that no message-complete external interrupt is queued for the source virtual machine.

A SEND request can be purged by the source virtual machine through the PURGE function. The target virtual machine can reject a SEND request through the REJECT function.

Figure 20. Flow of the IUCV SEND Protocol

**IUCV SEND/REPLY Protocol:** The SEND/REPLY protocol defines a two-way transfer of data from a source virtual machine to a target virtual machine without the use of the RECEIVE function, as shown in [Figure 21 on page 315](#). The data that may be transferred in this way is limited to 8 bytes and is stored in the IUCV parameter list. The path to be used must be authorized to handle data in the parameter list during the CONNECT/ACCEPT protocol that establishes it. If a SEND/REPLY request is directed to a virtual machine that has not authorized receipt of data in a parameter list on this path, it is indicated by a return code to the SEND/REPLY request and the request is cancelled by CP.

Figure 21. Flow of the IUCV SEND/REPLY Protocol

The IUCV parameter list for a SEND/REPLY request with data in the parameter list specifies the path ID of the path on which the message is to be sent, that this is a two-way message, and that the data is in the parameter list. Optionally, the priority of the message, the source message class, the target message class, and a message tag may be specified. When correctly specified, the SEND causes CP to transfer data from the source virtual machine to the external interrupt buffer of the target virtual machine. After the data transfer is complete, a message-pending external interrupt is queued for the target virtual machine.

Note that no message-complete external interrupt is queued for the source virtual machine after the SEND.

After receiving the message-pending external interrupt, the target virtual machine receives control to send a REPLY function that specifies the path ID and message ID for this REPLY request, and that the reply is in the parameter list. CP transfers the data from the target virtual machine's parameter list to the external interrupt buffer of the source virtual machine. When the data transfer from the REPLY is complete, the source virtual machine receives a message-complete external interrupt and the target virtual machine receives a condition code and return code in response to the REPLY function.

The target virtual machine can also REPLY with data in one or more buffers as is described under the SEND/RECEIVE/REPLY protocol.

A SEND request can be purged by the source virtual machine using the PURGE function. The target virtual machine can reject a SEND request using the REJECT function.

---

## Chapter 5. IUCV Function Descriptions

This chapter contains information on the following IUCV functions and external interrupts:

- Accept and the Connection Complete Interrupt
- Connect and the Connection Pending External Interrupt
- Declare Buffer
- Describe
- Interrupt Poll
- Purge
- Query
- Quiesce and the Connection Quiesced External Interrupt
- Receive
- Reply and the Message Complete External Interrupt
- Resume and the Connection Resumed External Interrupt
- Retrieve Buffer
- Send and the Message Pending External Interrupt
- Set Control Mask
- Set Mask
- Sever and the Connection Severed External Interrupt
- Test Completion
- Test Message.

If you are unfamiliar with reading syntax diagrams, see [“Syntax, Message, and Response Conventions”](#) on page xxxv.

---

### CP System Services

IUCV treats communications with CP as if CP were a single virtual machine. IUCV gathers information about a message and routes it to the specified system service for processing.

IUCV provides:

- Routing of connections to CP system services
- Routing of messages to CP system services
- Routing of message completions to the CP system service that issued the SEND
- Severing of connections to CP system services.

Each CP system service that interfaces with virtual machines is uniquely defined to IUCV. The following table shows the corresponding user ID for each of the CP system services. This user ID must be specified on the USERID= parameter when invoking the IUCV CONNECT function.

**Note:** Use of any IUCV service within a transaction will cause the transaction to abort with either a restricted-instruction transaction-abort code or a transaction-constraint exception. (See [z/Architecture Principles of Operation \(https://publibfp.dhe.ibm.com/epubs/pdf/a227832d.pdf\)](#) for details on transactional execution.)

CP system services and their user IDs are as follows:

Table 67. CP System Services and Their User IDs

| <b>System Service User ID</b> | <b>System Service</b>                                                                                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| *ACCOUNT                      | Accounting System Service (See page <a href="#">Chapter 12, “Account System Service (*ACCOUNT),”</a> on page 697.)                                                |
| *ASYNCMD                      | Asynchronous CP Command Response System Service (See page <a href="#">Chapter 13, “Asynchronous CP Command Response System Service (*ASYNCMD),”</a> on page 717.) |
| *BLOCKIO                      | DASD Block I/O System Service (See page <a href="#">Chapter 14, “DASD Block I/O System Service (*BLOCKIO),”</a> on page 719>.)                                    |
| *IDENT                        | Identify System Service (See page <a href="#">Chapter 16, “Identify System Service (*IDENT),”</a> on page 729.)                                                   |
| *LOGREC                       | Error Recording System Service (See page <a href="#">Chapter 15, “Error Logging System Service (*LOGREC),”</a> on page 727.)                                      |
| *MONITOR                      | Monitor System Service (See <a href="#">z/VM: Performance.</a> )                                                                                                  |
| *MSG                          | Message System Service (See page <a href="#">Chapter 17, “Message System Service (*MSG),”</a> on page 737.)                                                       |
| *MSGALL                       | Message All System Service (See page <a href="#">Chapter 18, “Message All System Service (*MSGALL),”</a> on page 739.)                                            |
| *RPI                          | Access Verification System Service (See page <a href="#">Chapter 11, “Access Verification System Service (*RPI),”</a> on page 589.)                               |
| *SIGNAL                       | Signal System Service (See page <a href="#">Chapter 20, “Signal System Service (*SIGNAL),”</a> on page 745.)                                                      |
| *SPL                          | Spool System Service (See page <a href="#">Chapter 21, “Spool System Service (*SPL),”</a> on page 749.)                                                           |
| *SYMPTOM                      | Symptom System Service (See page <a href="#">Chapter 22, “Symptom System Service (*SYMPTOM),”</a> on page 771.)                                                   |
| *VMEVENT                      | VM Event System Service (See page <a href="#">Chapter 23, “VM Event System Service (*VMEVENT),”</a> on page 773.)                                                 |

## ACCEPT Function

### Purpose

The ACCEPT function is issued after the user receives a Connection Pending external interrupt and now wishes to complete the IUCV communication path.

### Parameters

#### Required Parameters:

##### ACCEPT

Requests that CP perform the IUCV ACCEPT function.

##### PRMLIST=

Specifies the *address* of the ACCEPT parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

##### MF=L

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

**MSGLIM=**

Specifies the limit of outstanding messages to be allowed on the path completing this ACCEPT. The *address* of the MSGLIM points to a 2-byte field.

Upon executing the IUCV instruction, the message limit specified is checked to insure that the maximum limit of 65535 has not been exceeded. The actual limit assigned to the invoker's path established by this connection depends on the value specified for MSGLIM and the value specified for MSGLIMIT (if any) on the IUCV control statement of the invoker's directory entry. The IUCV control statement authorizes the invoker to establish the path.

When the ACCEPT function is invoked, the directory entries are searched in a definite order:

1. The invoker's IUCV control statements are searched for an entry for the target's user ID.
2. The invoker's IUCV control statements are searched for an ANY entry.

The first entry found, that applies establishes the message limit for the path according to the following table:

| <b>MSGLIM specified<br/>on ACCEPT</b> | <b>MSGLIMIT specified<br/>on applicable IUCV<br/>control statement</b> | <b>Actual message limit</b>      |
|---------------------------------------|------------------------------------------------------------------------|----------------------------------|
| No                                    | No                                                                     | Default value of 10              |
| No                                    | Yes                                                                    | Directory entry value            |
| Yes                                   | No                                                                     | MSGLIM value                     |
| Yes                                   | Yes                                                                    | Lower value of the two specified |

After executing the IUCV instruction, the IPMSGLIM field in the output parameter list reflects the actual message limit established for the path.

**PATHID=**

Specifies the path identification number on which you wish to communicate. This path ID is presented to the virtual machine in the Connection Pending external interrupt.

**PRTY=**

Specifies if you want to send priority messages on this path. It does not affect the program's ability to receive priority messages.

PRTY=YES indicates that you want to send priority messages. Priority must be authorized in the IUCV directory control statement for this parameter to be effective. After executing the IUCV instruction, the IPPRTY bit in IPFLAGS1 should be checked to insure that priority messages were authorized.

PRTY=NO indicates that you cannot send priority messages.

If your program is unauthorized or if PRTY=NO is specified, IUCV prevents your program from sending priority messages.

**PRMDATA=**

Specifies whether your program can handle message data in the parameter list.

PRMDATA=YES indicates that your program can handle message data in the parameter list (those messages sent using the parameter DATA=PRMMSG on an IUCV SEND).

PRMDATA=NO indicates that your program can only handle message data presented in a buffer (sent using the parameter DATA=BUFFER on an IUCV SEND).

**QUIESCE=**

Specifies whether you want to quiesce the path being established.

QUIESCE=YES prevents messages from coming across the path until your program is ready to process them. You can restore the path to full communication by invoking the IUCV RESUME function.

QUIESCE=NO indicates that the path will become active as soon as the IUCV ACCEPT completes.

**USERDTA=**

Specifies the data area containing the 16 bytes of user data that IUCV is to reflect to the source virtual machine. The user data is reflected as part of the IUCV Connection Complete external interrupt.

**CONTROL=**

Specifies whether this connection is to be associated with the external interrupt buffer for control paths or application paths.

CONTROL=YES indicates that this path is to be associated with the external interrupt buffer for control paths. CONTROL=NO indicates that this path is to be associated with the external interrupt buffer for application paths.

**Parameter List Format:**

| IPARML DSECT |                                      |   |          |         |          |   |          |   |  |
|--------------|--------------------------------------|---|----------|---------|----------|---|----------|---|--|
|              | 0                                    | 1 | 2        | 3       | 4        | 5 | 6        | 7 |  |
| 0            | IPPATHID                             |   | IPFLAGS1 | IPRCODE | IPMSGLIM |   | //////// |   |  |
| 8            | //////////////////////////////////// |   |          |         |          |   |          |   |  |
| 10           | IPUSER                               |   |          |         |          |   |          |   |  |
| 18           |                                      |   |          |         |          |   |          |   |  |
| 20           |                                      |   |          |         |          |   |          |   |  |
|              | //////////////////////////////////// |   |          |         |          |   |          |   |  |

**Parameter List Input Fields:****IPPATHID**

Contains the path identification number of the path you are completing.

**IPFLAGS1**

Contains options for the ACCEPT function.

**IPRMDATA (X'80')**

Indicates that you are prepared to handle message data in the parameter list.

**IPQUSCE (X'40')**

Indicates that you do not want to receive messages on this path until an IUCV RESUME is issued.

**IPPRTY (X'20')**

Indicates that you want to send priority messages on this path.

**IPCNTL (X'04')**

Indicates that you want this to be a control path.

**IPMSG LIM**

Contains the limit of outstanding messages that IUCV is to allow the invoker to send on the path.

**IPUSER**

Contains the user data that IUCV reflects to the target virtual machine.

**Condition Codes and Return Codes****CONDITION CODES**

0 - Normal completion

1 - Nonzero value stored in IPRCODE.

**Parameter List Output Fields:****IPMSG LIM**

Contains the message limit for this path.

**IPFLAGS1**

Contains specific information about this connection.

## IUCV ACCEPT

### IPPRTY (X'20')

Indicates that you may send priority messages.

### IPRCODE

Contains the return code describing how this function completed.

### RETURN CODES in IPRCODE

- 0 - X'00' - Normal return
- 1 - X'01' - Connection is not pending on this path
- 20 - X'14' - Originator has severed this path
- 30 - X'1E' - IPAPPC flag in IPFLAGS1 not 0.

**Note:** If you get a return code that is not documented here, it is an APPC/VM return code. An APPC/VM return code can result if the IPAPPC bit is set on during an IUCV CONNECT. For a description of the APPC/VM return code, refer to [“IUCV ACCEPT” on page 524](#).

## Program Exceptions

The program exceptions for IUCV ACCEPT are:

### Specification Exception

The parameter list is not on a doubleword boundary.

### Operation Exception

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

### Addressing Exception

The parameter list address that you specified is outside the virtual machine's storage.

### Protection Exception

The storage key of the specified parameter list address does not match the key of the user.

## Completion Conditions

**Connection Complete External Interrupt:** To notify the source virtual machine that you have accepted the connection and completed a new IUCV path, IUCV reflects an IUCV Connection Complete external interrupt to the source virtual machine.

The source virtual machine receives this external interrupt if it is enabled for IUCV interrupts in Control Register 0 and the PSW. The functions of SET MASK and SET CONTROL MASK also control the presentation of this type of interrupt.

### IPPATHID

Contains the path ID of the path which has now been established.

### IPFLAGS1

Contains options for this path.

### IPRMDATA (X'80')

Indicates that the connecting virtual machine can handle message data in the parameter list.

**IPQUSCE (X'40')**

Indicates that IUCV will not allow messages to be sent on this path until an IUCV RESUME is issued by the connecting virtual machine.

**IPPRTY (X'20')**

Indicates that the virtual machine may receive priority messages on this path.

**IPCNTL (X'04')**

Indicates that this is a control path.

**IPTYPE**

Indicates a Connection Complete external interrupt with a value of X'02'.

**IPMSGLIM**

Contains the maximum number of messages that IUCV allows the virtual machine that issued the ACCEPT function to send on this path.

**IPUSER**

Contains the user data specified by the target virtual machine when it accepted this connection.

**IPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

## CONNECT Function

### Purpose

The CONNECT function establishes an IUCV path to another virtual machine. Although the CONNECT may complete successfully, you are not able to use the path until you receive an IUCV Connection Complete external interrupt (the target has accepted your connection) for this path.

If you receive an IUCV Connection Severed external interrupt (the target has severed your connection) for this path, you may not use this path since the connection has been refused by the target virtual machine.

If the CONNECT function completes successfully, the count of active connections is incremented for both virtual machines. If a virtual machine is connecting to itself, the active connection count is incremented by two. The count is not decremented until the virtual machine issues an IUCV SEVER for a particular path.

**Note:** If an external security manager is installed on your system, you may not be authorized to use this function. For additional information, contact your security administrator.

### Parameters

#### Required Parameters:

**CONNECT**

Requests that CP perform the IUCV CONNECT function.

**PRMLIST=**

Specifies the *address* of the CONNECT parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

**MF=L**

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

**CONTROL=**

Specifies whether this connection is to be associated with the external interrupt buffer for control paths or application paths.

CONTROL=YES indicates that this path is to be associated with the external interrupt buffer for control paths. For a complete discussion on using control paths and buffers, see [“Using Control Paths” on page 304](#).

CONTROL=NO indicates that this path is to be associated with the external interrupt buffer for application paths.

**LOCAL=****YES**

Allows an application to force the partner to be on the local system. LOCAL=YES and TARGET=*address* cannot be specified together.

**NO**

Indicates that if the partner is not found on the local system, IUCV may try to locate the partner within the CS collection if DISTRIBUTE IUCV YES is specified in the system configuration file.

**MSGLIM=**

Specifies the limit of outstanding messages to be allowed on the path established by this CONNECT. The *address* of the MSGLIM points to a 2-byte field.

Upon executing the IUCV instruction, the message limit specified is checked to insure that the maximum limit of 65535 has not been exceeded. The actual limit assigned to the invoker's path established by this connection depends on the value specified for MSGLIM and the value specified for MSGLIMIT (if any) on the IUCV control statement of the invoker's directory entry. The IUCV control statement authorizes the invoker to establish the path.

When the CONNECT function is invoked, the directory entries are searched in a definite order:

1. The invoker's IUCV control statements are searched for an entry for the target's user ID.
2. The invoker's IUCV control statements are searched for an ANY entry.
3. The target's IUCV control statements are searched for an ALLOW entry.

The first entry found, that applies establishes the message limit for the path according to the following table:

| MSGLIM specified<br>on CONNECT | MSGLIMIT specified<br>on applicable IUCV<br>control statement | Actual message limit  |
|--------------------------------|---------------------------------------------------------------|-----------------------|
| No                             | No                                                            | Default value of 10   |
| No                             | Yes                                                           | Directory entry value |
| Yes                            | No                                                            | MSGLIM value          |

| <b>MSGLIM specified<br/>on CONNECT</b> | <b>MSGLIMIT specified<br/>on applicable IUCV<br/>control statement</b> | <b>Actual message limit</b>      |
|----------------------------------------|------------------------------------------------------------------------|----------------------------------|
| Yes                                    | Yes                                                                    | Lower value of the two specified |

After executing the IUCV instruction, the IPMSGLIM field in the output parameter list reflects the actual message limit established for the path.

If the SEND function completes successfully, the count of active messages is incremented for the sending virtual machine. The count is not decremented until the message complete external interrupt is returned. For one-way messages using data in the parameter list, the count is decremented when the message pending external interrupt is presented to the target virtual machine.

#### **PRMDATA=**

Specifies whether your program can handle message data in the parameter list.

PRMDATA=YES indicates that your program can handle message data in the parameter list (those messages sent using the parameter DATA=PRMMSG on an IUCV SEND).

PRMDATA=NO indicates that your program can only handle message data presented in a buffer (sent using the parameter DATA=BUFFER on an IUCV SEND).

#### **PRTY=**

Specifies if you want to send priority messages on this path. It does not affect the program's ability to receive priority messages.

PRTY=YES indicates that you want to send priority messages. Priority must be authorized on the IUCV directory control statement for this parameter to be effective. After executing the IUCV instruction, the IPPRTY bit in IPFLAGS1 should be checked to insure that priority messages were authorized.

If the IUCV CONNECT is routed via ISFC, PRIORITY status for the CONNECT is determined by the initial CONNECT invoker's IUCV directory control statement.

PRTY=NO indicates that you do not want to send priority messages.

If your program is unauthorized or if PRTY=NO is specified, IUCV prevents your program from sending priority messages.

#### **TARGET=**

Specifies which system the target must be on. LOCAL=YES and TARGET=address cannot be specified together.

This option allows a remote connection within the CS collection if DISTRIBUTE IUCV YES or TOLERATE has been specified in the system configuration file. If DISTRIBUTE IUCV NO has been specified, a remote connection is allowed only if the source and target node are members of the same SSI cluster.

#### **QUIESCE=**

Specifies whether you want to quiesce the path being established.

QUIESCE=YES prevents messages from coming across this path until your program is ready to process them. You can restore the path to full communication by invoking the IUCV RESUME function.

QUIESCE=NO indicates that the path is to become active as soon as the corresponding IUCV ACCEPT is done by the target communicator.

#### **USERDTA=**

Specifies the data area containing the 16 bytes of user data that IUCV is to reflect to the target virtual machine. The user data is reflected as part of the IUCV Connection Pending external interrupt.

#### **USERID=**

Specifies the 8-character user ID of the target virtual machine or the IUCV system service to which you want to establish this path.

By default USERID is resolved within the local VM system.

When TARGET is specified, USERID is resolved on the designated target VM system. This requires:

- Configure DISTRIBUTE IUCV YES or TOLERATE on both systems. For more information on the SYSTEM CONFIG statement, see *z/VM: CP Planning and Administration*. Note that if the source and target node reside within the same SSI cluster, the DISTRIBUTE IUCV restrictions do not apply.
- Configure ISFC links connecting both VM systems. For more information on the ACTIVATE ISLINK, see *z/VM: CP Commands and Utilities Reference* and *z/VM: CP Planning and Administration*.
- The LOCAL=YES option must not be specified.

When TARGET is not specified, USERID is resolved according to the following rules:

- If USERID is logged on the local VM system (the one the invoker is on) a local connection is initiated.
- If an ISFC link is active, and DISTRIBUTE IUCV YES is configured, ISFC will perform a search for USERID logged on within the ISFC collection. If USERID is found on a node within the collection, a connection is attempted via ISFC.

If DISTRIBUTE IUCV NO or TOLERATE is configured and USERID is a single-configuration user online within the same SSI cluster, a remote connection is initiated because the user is configured to operate on any node in the cluster. If DISTRIBUTE IUCV NO or TOLERATE is configured and USERID is a multiconfiguration (IDENTITY) user, the IUCV CONNECT fails without a TARGET node.

- Otherwise, the IUCV CONNECT fails.

#### Parameter List Format:

| IPARML DSECT |          |   |          |         |           |   |            |   |
|--------------|----------|---|----------|---------|-----------|---|------------|---|
|              | 0        | 1 | 2        | 3       | 4         | 5 | 6          | 7 |
| 0            | IPPATHID |   | IPFLAGS1 | IPRCODE | IPMSGGLIM |   | ////////// |   |
| 8            | IPVMID   |   |          |         |           |   |            |   |
| 10           | IPUSER   |   |          |         |           |   |            |   |
| 18           |          |   |          |         |           |   |            |   |
| 20           | IPTARGET |   |          |         |           |   |            |   |
| 28           |          |   |          |         |           |   |            |   |

#### Parameter List Input Fields:

##### IPFLAGS1

Contains options for the CONNECT function.

##### IPRMDATA (X'80')

Indicates that your program can handle message data in the parameter list.

##### IPQUSCE (X'40')

Indicates that you do not want to receive messages on this path until an IUCV RESUME is issued.

##### IPPRTY (X'20')

Indicates that you want to send priority messages on this path.

##### IPAPPC (X'08')

Indicates the protocol to be used on this path. This bit must be set to 0.

##### IPCNTL (X'04')

Indicates that you want this to be a control path.

##### IPLOCAL (X'01')

Indicates that the connect can only be satisfied on the local system

##### IPMSGGLIM

Contains the limit of outstanding messages that IUCV is to allow the invoker to send on the path.

##### IPVMID

Contains the user ID of the virtual machine or IUCV system service to which you want to establish this path.

### IPUSER

Contains the user data that IUCV reflects to the target virtual machine.

### IPTARGET

Contains the system name where the connect is to be satisfied.

## Condition Codes and Return Codes

### CONDITION CODES

0 - Normal completion

1 - Nonzero value stored in IPRCODE.

### Parameter List Output Fields:

#### IPPATHID

Contains the path ID that IUCV assigns the new path.

#### IPMSG LIM

Contains the message limit for this path.

#### IPFLAGS1

Contains specific information about this connection.

#### IPPRTY (X'20')

Indicates that you may send priority messages on this path.

#### IPRCODE

Contains the return code describing how this function completed.

### RETURN CODES in IPRCODE

0 - X'00' - Normal return

11 - X'0B' - Target communicator is not logged on.

Also see note 2 below.

12 - X'0C' - Target communicator has not invoked the DECLARE BUFFER function

13 - X'0D' - Maximum number of connections for this communicator exceeded

14 - X'0E' - Maximum number of connections for the target exceeded

15 - X'0F' - No authorization found (See Note 3.)

16 - X'10' - Invalid IUCV system service name

### Notes:

1. If you get a return code that is not documented here, it is an APPC/VM return code. An APPC/VM return code can result if the IPAPPC bit is set on during an IUCV CONNECT. For a description of the APPC/VM return code, refer to [“APPCVM CONNECT”](#) on page 412.
2. IPRCODE 11 - X'0B' may also be returned if Distributed IUCV is active (either DISTRIBUTE IUCV TOLERATE or DISTRIBUTE IUCV YES is specified in the SYSTEM CONFIG file for the z/VM system) and one of the following occurs:
  - IPLOCAL is specified but IPTARGET is non-zero.
  - IPLOCAL is specified but the target VM id (IPVMID) is not logged on locally.
  - IPTARGET is blanks.
  - IPTARGET specifies a remote system but no ISFC link exists.

- DISTRIBUTE IUCV TOLERATE is specified in SYSTEM CONFIG and IPTARGET is zero but the VM id (IPVMID) is not logged on locally.
  - DISTRIBUTE IUCV YES is specified in SYSTEM CONFIG and IPTARGET is zero but the VM id (IPVMID) is not logged on locally or remotely.
3. IPRCODE 15 - X'0F' may also be returned if a problem was detected with internal CP control structures. Consequently, a CP soft abend will be generated.

## Program Exceptions

The program exceptions for IUCV CONNECT are:

### Specification Exception

The parameter list is not on a doubleword boundary.

### Operation Exception

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

### Addressing Exception

The parameter list address that you specified is outside the virtual machine's storage.

### Protection Exception

The storage key of the specified parameter list address does not match the key of the user.

## Completion Conditions

**Connection Pending External Interrupt:** To notify the target virtual machine that you wish to establish a new path (through the CONNECT), IUCV reflects an IUCV Connection Pending external interrupt to the target virtual machine.

The target virtual machine receives this external interrupt if it is enabled for IUCV interrupts in Control Register 0 and the PSW. The functions of SET MASK and SET CONTROL MASK also control the presentation of this type of interrupt.

The external interrupt contains the information that the target virtual machine needs to either ACCEPT or SEVER the pending connection.

|    |                                  |   |          |          |                                  |   |          |
|----|----------------------------------|---|----------|----------|----------------------------------|---|----------|
| 0  | 1                                | 2 | 3        | 4        | 5                                | 6 | 7        |
| 0  | IPPATHID                         |   | IPFLAGS1 | IPTYPE   | IPMSGGLIM                        |   | //////// |
| 8  | IPVMID                           |   |          |          |                                  |   |          |
| 10 | IPUSER                           |   |          |          |                                  |   |          |
| 18 |                                  |   |          |          |                                  |   |          |
| 20 | //////////////////////////////// |   |          | IPPOLLFG | //////////////////////////////// |   |          |

### IPPATHID

Contains the path ID that IUCV assigns the new path.

### IPFLAGS1

Contains options for this path.

### IPRMDATA (X'80')

Indicates that the connecting virtual machine can handle message data in the parameter list.

### IPQUSCE (X'40')

Indicates that IUCV will not allow messages to be sent on this path until an IUCV RESUME is issued by the connecting virtual machine.

### IPPRTY (X'20')

Indicates that the virtual machine may receive priority messages on this path.

### IPTYPE

Indicates a Connection Pending external interrupt with a value of X'01'.

### **IPMSGLIM**

Contains the maximum number of messages that IUCV allows the virtual machine that issued the CONNECT function to send on this path.

### **IPVMID**

Contains the user ID of the virtual machine or IUCV system service specified by the virtual machine that wants to establish this path.

### **IPUSER**

Contains the user data specified by the virtual machine that wants to establish this path.

### **IPPOLLFG**

Contains a flag returned by IUCV.

### **IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

## DECLARE BUFFER Function

### Purpose

The `DECLARE BUFFER` function specifies the guest real address of an external interrupt buffer where IUCV can store information. When a virtual machine receives an IUCV external interruption, IUCV stores in this buffer information about the message, reply, or control function that caused the interruption.

The `DECLARE BUFFER` function must be invoked before any other IUCV function can be used (except `QUERY`).

After invoking the `DECLARE BUFFER` function and if enabled for IUCV interrupts, the virtual machine can now start receiving IUCV external interrupts.

This function has a different meaning in a virtual MP environment. For more information about a virtual MP environment, see [“Virtual MP Considerations for IUCV Applications”](#) on page 308.

### Parameters

#### Required Parameters:

##### DCLBFR

requests that CP perform the IUCV `DECLARE BUFFER` function.

##### PRMLIST=

specifies the *address* of the `DECLARE BUFFER` parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

##### MF=L

lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

##### BUFFER=

specifies the *address* of the external interrupt buffer.

##### CONTROL=

specifies whether this buffer is to be used with control paths or application paths.

## IUCV DECLARE BUFFER

CONTROL=YES indicates that this buffer is to be used with control paths. For a complete discussion on using control buffers and paths, see [“Using Control Paths”](#) on page 304.

CONTROL=NO indicates that this buffer is to be used with application paths.

### Parameter List Format:

IPARML DSECT

|    |                                      |          |         |                                      |
|----|--------------------------------------|----------|---------|--------------------------------------|
| 0  | //////////                           | IPFLAGS1 | IPRCODE | //////////////////////////////////// |
| 8  | //////////////////////////////////// |          |         | IPBFADR1                             |
| 10 | //////////////////////////////////// |          |         |                                      |
| 18 | //////////////////////////////////// |          |         |                                      |
| 20 | //////////////////////////////////// |          |         |                                      |

### Parameter List Input Fields:

#### IPFLAGS1

contains options for the DECLARE BUFFER function.

#### IPCNTRL (X'04')

indicates that you want this to be a control buffer.

#### IPBFADR1

contains the address of your external interrupt buffer.

## Condition Codes and Return Codes

### CONDITION CODES

- 0 - Normal completion
- 1 - Nonzero value stored at IPRCODE
- 3 - Errors encountered in reading directory.

### Parameter List Output Fields:

#### IPRCODE

Contains the return code describing how this function completed.

### RETURN CODES in IPRCODE

- 0 - X'00' - Normal return
- 10 - X'0A' - Invalid length for the interrupt buffer extension.
- 19 - X'13' - A previously declared buffer is still in use  
or an IUCV RETRIEVE BUFFER is in progress.
- 62 - X'3E' - Two of the following buffers overlap:
  - Control buffer
  - External interrupt buffer
  - Interrupt buffer extension
- 92 - X'5C' - A paging or storage error was detected.

## Program Exceptions

The program exceptions for IUCV DECLARE BUFFER are:

### Specification Exception

The parameter list is not on a doubleword boundary.

### Addressing Exception

The parameter list or buffer address that you specified is outside the virtual machine's storage.

**Operation Exception**

Your virtual machine is not in supervisor state.

**Protection Exception**

The storage key of the specified parameter list address does not match the key of the user.

The buffer is outside the user's address space when CP checks to see that the user is entitled to access the area of space assigned to the buffer.

# DESCRIBE Function

## Purpose

The DESCRIBE function determines whether you have a message pending for your virtual machine. If there is a message pending, information about the message is returned in the parameter list. Since you now have the message information, there is no need for IUCV to reflect an IUCV Message Pending external interrupt and you do not receive one for this message.

Since IUCV normally informs you of the message by reflecting a Message Pending external interrupt, you should not use the DESCRIBE function unless you have disabled for this type of interrupt. The IUCV SET MASK function can be used to disable your virtual machine for Message Pending external interrupts.

A message is described only once, either in the parameter list of a DESCRIBE or by a Message Pending external interrupt.

This function has a different meaning in a virtual MP environment. For more information about a virtual MP environment, see [“Virtual MP Considerations for IUCV Applications”](#) on page 308.

## Parameters

### Required Parameters:

- DESCRIBE**  
Requests that CP perform the IUCV DESCRIBE function.
- PRMLIST=**  
Specifies the *address* of the DESCRIBE parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.
- Optional Parameter:** If you do not specify this parameter, the macro assumes that you have stored the desired value into the parameter list before invoking the IUCV macro.
- MF=L**  
Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

### Parameter List Format:

| IPARML DSECT |                                  |   |          |         |                                  |                                  |   |   |
|--------------|----------------------------------|---|----------|---------|----------------------------------|----------------------------------|---|---|
|              | 0                                | 1 | 2        | 3       | 4                                | 5                                | 6 | 7 |
| 0            | IPPATHID                         |   | IPFLAGS1 | IPRCODE | IPMSGID                          |                                  |   |   |
| 8            | IPTRGCLS                         |   |          |         | IPRMMMSG1                        |                                  |   |   |
| 10           | IPBFLN1F / IPRMMSG2              |   |          |         | //////////////////////////////// |                                  |   |   |
| 18           | //////////////////////////////// |   |          |         |                                  |                                  |   |   |
| 20           | IPBFLN2F                         |   |          |         | IPPOLLFG                         | //////////////////////////////// |   |   |

## Condition Codes and Return Codes

**CONDITION CODES**

- 0 - Normal completion
- 2 - No message found.

**Parameter List Output Fields:****IPPATHID**

Contains the path on which the message was sent.

**IPFLAGS1**

Contains specific information about the message.

**IPRMDATA (X'80')**

Indicates that the 8-byte message is in the parameter list at IPRMMSG.

**IPPRTY (X'20')**

Indicates that this is a priority message.

**IPNORPY (X'10')**

Indicates that this is a one-way message and no REPLY is expected.

**IPFGMID (X'04')**

Is always set to 1 indicating that the message ID has been stored at IPMSGID.

**IPFGPID (X'02')**

Is always set to 1 indicating that the path ID has been stored at IPPATHID.

**IPFGMCL (X'01')**

Is always set to 1 indicating that the target message class has been stored at IPTRGCLS.

**IPMSGID**

Contains the message ID.

**IPTRGCLS**

Contains the target message class.

**IPRMMMSG1/IPRMMMSG2**

Contains the message when it is stored in the parameter list (indicated by IPRMDATA in IPFLAGS1). The label IPRMMSG refers to the combined IPRMMMSG1 and IPRMMMSG2 fields.

**IPBFLN1F**

Contains the length of the message.

**IPBFLN2F**

Contains the length of the maximum expected reply.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that another iteration of this function will probably not find a message waiting at this time.

**IPRCODE**

Contains the return code describing how this function completed.

**RETURN CODES in IPRCODE**

- 0 - X'00' - Normal return.

**Program Exceptions**

The program exceptions for IUCV DESCRIBE are:

**Specification Exception**

The parameter list is not on a doubleword boundary.

**Operation Exception**

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

**Addressing Exception**

The parameter list address that you specified is outside the virtual machine's storage.

**Protection Exception**

The storage key of the specified parameter list address does not match the key of the user.

## INTERRUPT POLL Function

### Purpose

The INTERRUPT POLL (IPOLL) function determines whether you have any replies or incoming messages pending. If IUCV finds any replies or incoming messages pending, it returns the information about them in the buffer provided. The maximum number of pending interrupts that can be retrieved on a single request is the number of IUCV external interrupt buffers which can fit on one 4K page.

### Notes:

1. Unless you disable your virtual machine for IUCV message-complete and message-pending interrupts, you should not use the INTERRUPT POLL function. When the virtual machine is enabled for these interrupts, IUCV automatically informs you of message completion or arrival of an incoming message by reflecting an external interrupt to your virtual machine.
2. No external interrupt will occur for a reply represented by a message-complete returned by the INTERRUPT POLL function.
3. No external interrupt will occur for a message represented by a message-pending returned by the INTERRUPT POLL function. It is your responsibility to use the RECEIVE or REJECT function to process a message obtained using the INTERRUPT POLL function.

This function has a different meaning in a virtual MP environment. For more information about a virtual MP environment, see [“Virtual MP Considerations for IUCV Applications”](#) on page 308.

### Parameters

#### Required Parameters:

##### IPOLL

Requests that CP perform the IUCV INTERRUPT POLL function.

##### PRMLIST=

Specifies the *address* of the INTERRUPT POLL parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

##### MF=L

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

##### BUFFER=

Specifies the address of the INTERRUPT POLL buffer for interrupt data.

## BUFLEN=

Specifies the length of the INTERRUPT POLL buffer for interrupt data. This length must be at least the size of an IUCV interrupt buffer and not more than 4096 bytes, and the buffer may not cross a 4K page boundary. The length need not be an exact multiple of the length of an IPARML.

## Parameter List Format:

| IPARML DSECT |                                  |   |   |                                  |                                  |   |   |   |
|--------------|----------------------------------|---|---|----------------------------------|----------------------------------|---|---|---|
|              | 0                                | 1 | 2 | 3                                | 4                                | 5 | 6 | 7 |
| 0            | //////////////////////////////// |   |   | IPRCODE                          | //////////////////////////////// |   |   |   |
| 8            | //////////////////////////////// |   |   | IPBFADR1                         |                                  |   |   |   |
| 10           | IPBFLN1F                         |   |   | //////////////////////////////// |                                  |   |   |   |
| 18           | //////////////////////////////// |   |   |                                  |                                  |   |   |   |
| 20           | //////////////////////////////// |   |   |                                  |                                  |   |   |   |

## Parameter List Input Fields:

### IPBFADR1

contains the address of the input buffer.

### IPBFLN1F

contains the length of the input buffer.

## Condition Codes and Return Codes

### CONDITION CODES

- 0 - Normal completion
- 1 - Nonzero value stored at IPRCODE
- 2 - No message found.

## Parameter List Output Fields:

### IPBFLN1F

contains the length of the output data returned by the INTERRUPT POLL function. This value will always be a multiple of the length of an IUCV external interrupt buffer (IPARML).

### IPRCODE

contains the return code describing how this function completed.

### RETURN CODES in IPRCODE

- 0 - X'00' - Normal return
- 92 - X'5C' - A paging or storage error was detected.

## Program Exceptions

The program exceptions for IUCV INTERRUPT POLL are:

### Specification Exception

- The parameter list is not on a doubleword boundary.
- The buffer length specified is less than the size of an IUCV interrupt buffer.
- The buffer specified spans a 4K page boundary.

### Operation Exception

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

**Addressing Exception**

The parameter list address that you specified is outside the virtual machine's storage.

**Completion Conditions**

**Output Buffer Format:** When the condition code is zero, the buffer contains one or more interrupt data areas for replies and messages. See [Message Complete External Interrupt](#), and [Message Pending External Interrupt](#). The remainder of the buffer not occupied by the external interrupt data remains unchanged.

If no more replies or messages are pending for the invoker, the last interrupt placed in the output buffer will have the IPNOPOLL flag set.

If INTERRUPT POLL is issued in an APPC/VM environment you may receive interrupt information both for IUCV and APPC/VM paths.

## PURGE Function

### Purpose

The PURGE function cancels a message that you have sent. When you purge a message, one of the following actions takes place:

- If you purge a message before the target virtual machine has received an IUCV Message Pending external interrupt for this message, the target virtual machine is never aware that you sent the message.
- If you purge a message after the target virtual machine has received the IUCV Message Pending external interrupt, but before the target has completed handling the message, the target receives a return code indicating that the message has been purged the next time it references the message (normally, on a RECEIVE or a REPLY). The target is given only one such indication about the purged message. Any future references to the purged message results in a *no message found* condition.
- If you purge a message on which the target virtual machine has already completed its processing, the IUCV Message Complete external interrupt is avoided, but the target virtual machine is never aware that the message was purged.

When purging a message, you can completely identify the message by specifying the message ID, path ID, and source message class. You can also identify the message by the path ID with or without the message class.

### Parameters

#### Required Parameters:

##### PURGE

Requests that CP perform the IUCV PURGE function.

##### PRMLIST=

Specifies the *address* of the PURGE parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

##### MF=L

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

**MSGID=**

Specifies the message ID of the message to be purged. If the message ID is used to identify the message, the path ID and the source class must also be correctly specified in the parameter list.

**PATHID=**

Specifies the path ID on which the message was sent. The *address* of the PATHID is a halfword value.

**SRCCLS=**

Specifies the source message class associated with a message.

**Parameter List Format:**

| IPARML DSECT |                                      |   |          |                                      |                                      |   |   |   |
|--------------|--------------------------------------|---|----------|--------------------------------------|--------------------------------------|---|---|---|
|              | 0                                    | 1 | 2        | 3                                    | 4                                    | 5 | 6 | 7 |
| 0            | IPPATHID                             |   | IPFLAGS1 | IPRCODE                              | IPMSGID                              |   |   |   |
| 8            | IPAUDIT                              |   |          | //////////////////////////////////// |                                      |   |   |   |
| 10           | //////////////////////////////////// |   |          |                                      | IPSRCCLS                             |   |   |   |
| 18           | IPMSGTAG                             |   |          |                                      | //////////////////////////////////// |   |   |   |
| 20           | //////////////////////////////////// |   |          |                                      |                                      |   |   |   |

**Parameter List Input Fields:****IPPATHID**

Contains the path ID of the message you are purging.

**IPFLAGS1**

Specifies options for the PURGE function.

**IPFGMID (X'04')**

Indicates that you have specified a message ID (IPMSGID) for the message you are purging.

**IPFGPID (X'02')**

Indicates that you have specified a path ID (IPPATHID) for the message you are purging.

**IPFGMCL (X'01')**

Indicates that you have specified a source message class (IPSRCCLS) to identify the message you are trying to purge.

**IPMSGID**

Contains the message ID of the message you are purging.

**IPSRCCLS**

Contains the source message class of the message you are purging.

**Condition Codes and Return Codes****CONDITION CODES**

- 0 - Normal completion
- 1 - Nonzero value stored at IPRCODE
- 2 - No message found.

**Parameter List Output Fields:****IPPATHID**

Contains the path ID of the message you purged.

**IPFLAGS1**

Contains specific information about the message purged.

**IPNORPY (X'10')**

Indicates that the message purged is a one-way message.

**IPPRTY (X'20')**

Indicates that the message purged is a priority message.

**IPMSGID**

Contains the message ID of the message you purged.

**IPAUDIT**

Contains information about possible asynchronous error conditions which may have affected the normal completion of this message. If this field is 0, the message has completed successfully.

The meanings of the bits in the audit trail are:

**IPADRPLE (X'800000')**

Reply too long for buffer

**IPADSNPX (X'400000')**

Protection exception on send buffer

**IPADSNAX (X'200000')**

Addressing exception on send buffer

**IPADANPX (X'100000')**

Protection exception on answer buffer

**IPADANAX (X'080000')**

Addressing exception on answer buffer

**IPADRJCT (X'040000')**

Message was rejected

**IPADPRMD (X'020000')**

Reply specified DATA=PRMMSG, but this path cannot handle data in the parameter list.

**IPADPGNR (X'010000')**

Message purged on send or receive queue.

**IPADRCPX (X'008000')**

Protection exception on receive buffer

**IPADRCAX (X'004000')**

Addressing exception on receive buffer

**IPADRPPX (X'002000')**

Protection exception on reply buffer

**IPADRPAX (X'001000')**

Addressing exception on reply buffer

**IPADSVRD (X'000800')**

Path was severed

**IPADRLST (X'000400')**

Invalid RECEIVE or REPLY address list

**(X'000200')**

Reserved

**(X'000100')**

Reserved

**IPADBLEN (X'000080')**

Bad length in SEND buffer list

**IPADALEN (X'000040')**

Bad length in SEND answer list

**IPADBTOT (X'000020')**

Invalid total SEND buffer length

**IPADATOT (X'000010')**

Invalid total SEND answer length

**(X'000008')**

Reserved

**(X'000004')**

Reserved

**(X'000002')**

Reserved

**(X'000001')**

Reserved.

**IPSRCCLS**

Contains the message class of the message you purged.

**IPMSGTAG**

Contains the message tag of the message you purged.

**IPRCODE**

Contains the return code describing how this function completed.

**RETURN CODES in IPRCODE**

0 - X'00' - Normal return

1 - X'01' - Path ID specified is not an established path

8 - X'08' - Message found but message class invalid

31 - X'1F' - IUCV function specified on an APPC/VM path.

**Program Exceptions**

The program exceptions for IUCV PURGE are:

**Specification Exception**

The parameter list is not on a doubleword boundary, or the message ID was specified without the path ID or the message class.

**Operation Exception**

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

**Addressing Exception**

The parameter list address that you specified is outside the virtual machine's storage.

**Protection Exception**

The storage key of the specified parameter list address does not match the key of the user.

## QUERY Function

---

### Purpose

The QUERY function determines how large an external interrupt buffer IUCV requires to store information, and determines the maximum number of communication paths you can establish in your virtual machine.

QUERY can be issued before DECLARE BUFFER to determine the buffer size and allocate the buffer before it is declared to IUCV. The maximum number of paths facilitates the allocation of a user-defined path table. This function is useful to virtual machines that have dynamic storage allocations routines. For those programs that must allocate fixed storage, the buffer size is 40 bytes (X'28'), and the maximum number of paths available would be the default of four or the number on the user's OPTION directory control statement, the MAXCONN option.

### Parameters

#### Required Parameter:

##### QUERY

Requests that CP perform the IUCV QUERY function.

### Condition Codes and Return Codes

#### CONDITION CODES

- 0 - Normal completion
- 2 - Error - IUCV RETRIEVE BUFFER in progress.
- 3 - Errors were encountered reading directory.

**Output from QUERY:** When you invoke the QUERY function, IUCV returns:

- The size of the IUCV external interrupt buffer in general register 0.
- The maximum number of connections that can be outstanding for this virtual machine in general register 1.

### Program Exceptions

The program exceptions for IUCV QUERY are:

#### Operation Exception

Your virtual machine is not in supervisor state.

## QUIESCE Function

### Purpose

The QUIESCE function temporarily suspends incoming messages on an IUCV path. You can later reactivate the path by invoking the RESUME function or you may leave the path quiesced, making it a one-way path. You are still allowed to send messages as the path is only quiesced for incoming messages.

If a message is sent to you on a quiesced path, a return code is returned to the sender, and the message is not sent. Each end of a path can be quiesced independently.

### Parameters

#### Required Parameters:

##### QUIESCE

Requests that CP perform the IUCV QUIESCE function.

##### PRMLIST=

Specifies the *address* of the QUIESCE parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

##### MF=L

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

##### ALL=

Specifies whether all paths for this virtual machine are to be quiesced.

ALL=YES indicates that all of your paths are to be quiesced.

ALL=NO indicates that you do not want all of your paths quiesced, only the one specified by PATHID.

##### PATHID=

Specifies the path ID of the path you want to quiesce.

## IUCV QUIESCE

### USERDTA=

Specifies the data area containing the 16 bytes of user data to be reflected across the path. The user data is reflected as part of the IUCV Connection Quiesced external interrupt.

### Parameter List Format:

| IPARML DSECT |                                      |   |          |         |                                      |   |   |   |
|--------------|--------------------------------------|---|----------|---------|--------------------------------------|---|---|---|
|              | 0                                    | 1 | 2        | 3       | 4                                    | 5 | 6 | 7 |
| 0            | IPPATHID                             |   | IPFLAGS1 | IPRCODE | //////////////////////////////////// |   |   |   |
| 8            | //////////////////////////////////// |   |          |         |                                      |   |   |   |
| 10           | IPUSER                               |   |          |         |                                      |   |   |   |
| 18           |                                      |   |          |         |                                      |   |   |   |
| 20           | //////////////////////////////////// |   |          |         |                                      |   |   |   |

### Parameter List Input Fields:

#### IPPATHID

Contains the path ID of the path you are quiescing.

#### IPFLAGS1

Contains options for the QUIESCE function.

#### IPALL (X'80')

Indicates that you want to quiesce all paths for this virtual machine.

#### IPUSER

Contains the user data that is reflected across the path.

## Condition Codes and Return Codes

### CONDITION CODES

0 - Normal completion

1 - Nonzero value stored at IPRCODE

### Parameter List Output Fields:

#### IPRCODE

Contains the return code describing how this function completed.

### RETURN CODES in IPRCODE

0 - X'00' - Normal return

1 - X'01' - Path ID specified is not an established path

31 - X'1F' - IUCV function specified on an APPC/VM path.

48 - X'30' - Partner system service does not support this function.

## Program Exceptions

The program exceptions for IUCV QUIESCE are:

### Specification Exception

The parameter list is not on a doubleword boundary.

### Operation Exception

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

### Addressing Exception

The parameter list address that you specified is outside the virtual machine's storage.

**Protection Exception**

The storage key of the specified parameter list address does not match the key of the user.

**Completion Conditions**

**Connection Quiesced External Interrupt:** To notify the other side of the path that the path has been quiesced, IUCV reflects an IUCV Connection Quiesced external interrupt.

The target virtual machine receives this external interrupt if it is enabled for IUCV interrupts in Control Register 0 and the PSW. The functions of SET MASK and SET CONTROL MASK also control the presentation of this type of interrupt.

**IPPATHID**

Contains the path ID of the path quiesced.

**IPTYPE**

Indicates a Connection Quiesced external interrupt with a value of X'04'.

**IPUSER**

Contains the user data specified by the virtual machine that quiesced the path.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

## RECEIVE Function

### Purpose

The RECEIVE function receives messages that are being sent to you over established paths. The RECEIVE function moves the message data from the source virtual machine to your virtual machine.

When receiving a message, you can completely identify the message by specifying the message ID, path ID, and target class. You can also identify the message by either the path ID or the target class, or both. If you do not specify any identifiers when invoking the RECEIVE function, you receive the first message that has not been partially received.

If your receive area cannot contain the complete message, you can issue another RECEIVE to obtain the remainder of the message. If you use the same parameter list on the subsequent RECEIVE, the message ID, path ID, and message class that are already stored in the parameter list completely identify the message. These fields are required on any subsequent RECEIVES for the same message. You must initialize the receive area and length for the subsequent RECEIVES.

The RECEIVE function completes a one-way communication when all the data has been received.

### Parameters

#### Required Parameters:

##### RECEIVE

Requests that CP perform the IUCV RECEIVE function.

##### PRMLIST=

Specifies the *address* of the RECEIVE parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

**MF=L**

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

**MSGID=**

Specifies the message ID of the message to be received. If the message ID is used to locate the message, the path ID and the target class must also be correctly specified in the parameter list.

**PATHID=**

Specifies the path over which you wish to receive the message. The *address* of the PATHID is to a halfword value.

**TRGCLS=**

Specifies the target message class associated with this message.

**BUFLIST=**

Specifies that the list format is being used.

BUFLIST=NO indicates that the list format is not being used. The BUFFER parameter is the address of the complete message.

BUFLIST=YES indicates that the address on the BUFFER parameter identifies the address of a list of addresses and lengths of discontiguous buffers that hold the message text.

**BUFFER=**

Specifies the *address* or the *list* of addresses into which IUCV moves the message.

**BUFLEN=**

Specifies the total length of the message to RECEIVE. If BUFFER specifies an address list (BUFLIST=YES), the value specified with BUFLEN is the total of the individual buffer lengths in the list.

**Parameter List Format:**

| IPARML DSECT |                                      |   |          |         |                                      |   |   |   |
|--------------|--------------------------------------|---|----------|---------|--------------------------------------|---|---|---|
|              | 0                                    | 1 | 2        | 3       | 4                                    | 5 | 6 | 7 |
| 0            | IPPATHID                             |   | IPFLAGS1 | IPRCODE | IPMSGID                              |   |   |   |
| 8            | IPTRGCLS                             |   |          |         | IPBFADR1 / IPRMMMSG1                 |   |   |   |
| 10           | IPBFLN1F / IPRMMMSG2                 |   |          |         | //////////////////////////////////// |   |   |   |
| 18           | //////////////////////////////////// |   |          |         |                                      |   |   |   |
| 20           | IPBFLN2F                             |   |          |         | //////////////////////////////////// |   |   |   |

**Parameter List Input Fields:****IPPATHID**

Contains the path ID of the path to receive the message.

**IPFLAGS1**

Contains options for the RECEIVE function.

**IPBUFLST (X'40')**

Indicates that you are using an address list for the message data.

**IPAPPC (X'08')**

Indicates the protocol to be used on this path. This bit must be set to 0.

**IPFGMID (X'04')**

Indicates that you have specified a message ID (IPMSGID) for the messages you are trying to receive.

**IPFGPID (X'02')**

Indicates that you have specified a path ID (IPPATHID) for the message you are trying to receive.

**IPFGMCL (X'01')**

Indicates that you have specified a target message class (IPTRGCLS) to identify the message you are trying to receive.

**IPMSGID**

Contains the message ID of the message you are trying to receive.

**IPTRGCLS**

Contains the target message class of the message you are trying to receive.

**IPBFADR1**

Contains the address of the receive buffer.

**IPBFLN1F**

Contains the length of the receive buffer. Use this label with a fullword value. Use IPBFLN1 with a halfword value.

**Condition Codes and Return Codes****CONDITION CODES**

0 - Normal completion

1 - Nonzero value stored at IPRCODE

2 - No message found.

**Parameter List Output Fields:****IPPATHID**

Contains the path ID of the message you received.

**IPFLAGS1**

Contains specific information about the message received.

**IPRMDATA (X'80')**

Indicates that the 8-byte message is contained in the parameter list at IPRMSG.

**IPPTY (X'20')**

Indicates that this is a priority message.

**IPNORPY (X'10')**

Indicates that this is a one-way message and no reply is expected.

**IPFGMID (X'04')**

Is always set to 1 indicating that the message ID has been stored at IPMSGID.

**IPFGPID (X'02')**

Is always set to 1 indicating that the path ID has been stored at IPPATHID.

**IPFGMCL (X'01')**

Is always set to 1 indicating that the target message class has been stored at IPTRGCLS.

**IPMSGID**

Contains the message ID.

**IPTRGCLS**

Contains the target message class.

**IPBFADR1**

If BUFLIST=NO, contains the address of the buffer updated by the number of bytes you have received.

If BUFLIST=YES, the address points to the current list entry IUCV is working on.

**IPRMSG1/IPRMSG2**

Contains the message when it is stored in the parameter list (indicated by IPRMDATA in IPFLAGS1).

The label IPRMSG refers to the combined IPRMSG1 and IPRMSG2 fields.

**IPBFLN1F**

Contains one of the following values, if the receive buffer is:

The same length as the message, this field contains 0.

Longer than the message, this field contains the number of bytes remaining in the buffer.

Shorter than the message, this field contains a residual count (that is, the number of bytes remaining in the message that does not fit into the buffer).

#### **IPBFLN2F**

Contains the length of the expected reply. Use this label with a fullword value. Use IPBFLN2 with a halfword value.

#### **IPRCODE**

Contains the return code describing how this function completed.

#### **RETURN CODES in IPRCODE**

- 0 - X'00' - Normal return
- 1 - X'01' - Path ID specified is not an established path
- 5 - X'05' - Receive buffer too short to contain message
- 6 - X'06' - Fetch protection exception on send buffer
- 7 - X'07' - Addressing exception on the send buffer
- 8 - X'08' - Message ID found but message class or path ID invalid
- 9 - X'09' - Message has been purged
- 10 - X'0A' - Message length is negative
- 22 - X'16' - Send buffer list invalid
- 23 - X'17' - Negative length in buffer list
- 24 - X'18' - Incorrect total length of buffer list lengths
- 26 - X'1A' - Buffer list not on a doubleword boundary
- 30 - X'1E' - IPAPPC flag in IPFLAGS1 not 0
- 31 - X'1F' - IUCV function specified on an APPC/VM path
- 91 - X'5B' - A paging or storage error was detected in the SEND data area
- 92 - X'5C' - A paging or storage error was detected in the RECEIVE data area.

**Note:** If you get a return code that is not documented here, it is an APPC/VM return code. An APPC/VM return code can result if the IPAPPC bit is set on during an IUCV CONNECT. For a description of the APPC/VM return code, refer to [“APPCVM RECEIVE” on page 451](#).

### **Program Exceptions**

The program exceptions for IUCV RECEIVE are:

#### **Specification Exception**

The parameter list is not on a doubleword boundary, or the message ID was specified without the path ID and the message class.

#### **Operation Exception**

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

#### **Addressing Exception**

The parameter list, the buffer address, or the buffer list address that you specified is outside the virtual machine's storage.

#### **Protection Exception**

The storage key of the specified parameter list address, buffer list address, or buffer address in the parameter list or the buffer list does not match the key of the user.

## REJECT Function

### Purpose

The REJECT function refuses a specified message. Between the time that you are notified of a message and the time that you complete the message, the message may be rejected.

When a message is rejected, an IUCV Message Complete external interrupt is reflected to the source virtual machine with an indication in the audit trail (IPAUDIT) that the message was rejected. Depending on when the message was rejected and the type of message, message data may or may not have been moved. When a message is rejected, the sender has no way to determine if any data has been transmitted.

When rejecting a message, you can completely identify the message by specifying the message ID, path ID, and target message class. You can also identify the message by either the path ID or the target message class, or both.

### Parameters

#### Required Parameters:

##### REJECT

Requests that CP perform the IUCV REJECT function.

##### PRMLIST=

Specifies the *address* of the REJECT parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

##### MF=L

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

##### MSGID=

Specifies the message ID of the message to be rejected. If the message ID is used to locate the message, the path ID and the target class must also be correctly specified in the parameter list.

##### PATHID=

Specifies the path ID of the message to be rejected.

##### TRGCLS=

Specifies the target message class of the message to be rejected.

**Parameter List Format:**

| IPARML DSECT |                                  |   |          |         |                                  |   |   |   |
|--------------|----------------------------------|---|----------|---------|----------------------------------|---|---|---|
|              | 0                                | 1 | 2        | 3       | 4                                | 5 | 6 | 7 |
| 0            | IPPATHID                         |   | IPFLAGS1 | IPRCODE | IPMSGID                          |   |   |   |
| 8            | IPTRGCLS                         |   |          |         | //////////////////////////////// |   |   |   |
| 10           | //////////////////////////////// |   |          |         |                                  |   |   |   |
| 18           | //////////////////////////////// |   |          |         |                                  |   |   |   |
| 20           | //////////////////////////////// |   |          |         |                                  |   |   |   |

**Parameter List Input Fields:****IPPATHID**

Contains the path ID of the message you are rejecting.

**IPFLAGS1**

Contains options for the REJECT function.

**IPFGMID (X'04')**

Indicates that you have specified a message ID (IPMSGID) for the message you are rejecting.

**IPFGPID (X'02')**

Indicates that you have specified a path ID (IPPATHID) for the message you are rejecting.

**IPFGMCL (X'01')**

Indicates that you have specified a target message class (IPTRGCLS) for the message you are rejecting.

**IPMSGID**

Contains the message ID of the message you are rejecting.

**IPTRGCLS**

Contains the target message class of the message you are rejecting.

**Condition Codes and Return Codes****CONDITION CODES**

- 0 - Normal completion
- 1 - Nonzero value stored in IPRCODE
- 2 - No message found.

**Parameter List Output Fields:****IPPATHID**

Contains the path ID of the message you rejected.

**IPMSGID**

Contains the message ID of the message you rejected.

**IPTRGCLS**

Contains the target message class of the message you rejected.

**IPRCODE**

Contains the return code describing how this function completed.

### RETURN CODES in IPRCODE

- 0 - X'00' - Normal return
- 1 - X'01' - Path ID specified is not an established path
- 8 - X'08' - Message ID found but message class or path ID invalid
- 31 - X'1F' - IUCV function specified on an APPC/VM path.

### Program Exceptions

The program exceptions for IUCV REJECT are:

#### Specification Exception

The parameter list is not on a doubleword boundary, or the message ID was specified without the path ID and the message class.

#### Operation Exception

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

#### Addressing Exception

The parameter list address that you specified is outside the virtual machine's storage.

#### Protection Exception

The storage key of the specified parameter list address does not match the key of the user.

## REPLY Function

### Purpose

The REPLY function responds to the two-way messages that you receive. The previous IUCV functions will have identified the message to which you are replying by providing the message ID, the path ID, and the target class. You must identify completely the message to which you wish to reply.

The REPLY function moves the reply data from your virtual machine to the source virtual machine.

### Parameters

#### Required Parameters:

##### REPLY

Requests that CP perform the IUCV REPLY function.

##### PRMLIST=

Specifies the *address* of the REPLY parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

**MF=L**

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

**MSGID=**

Specifies the message ID of the message to which you are replying.

**PATHID=**

Specifies the path associated with the message.

**TRGCLS=**

Specifies the target message class associated with the message.

With the reply function you have an option of replying to the message in a buffer or in the parameter list. The size of a parameter list message is very limited, but then the originator of the message (sender) does not have to maintain an answer buffer (ANSBUF parameter on SEND). The protocol you chose may be different from that used to send you the message.

**DATA=**

Specifies the location of your message data for this IUCV communication.

DATA=BUFFER indicates that your reply data is in a buffer. You can use the ANSBUF, ANSLEN, or ANSLIST macro options to help you fill in the parameter list.

DATA=PRMMSG indicates that your reply data is in the parameter list. Use the PRMMSG parameter if you want the macro to fill in the parameter list.

**ANSLIST=**

Specifies whether the list format is being used.

ANSLIST=NO indicates that the list format is not being used. The ANSBUF parameter is the address of the complete reply.

ANSLIST=YES indicates that the address on the ANSBUF parameter identifies a list of addresses and lengths of discontiguous buffers that contains the reply data.

**ANSBUF=**

Specifies the *address* or the address of a list of addresses (*address-list*) from which IUCV moves the reply data.

Since the data is moved as part of the REPLY function, all buffer areas may be reused when the REPLY function completes.

**ANSLEN=**

Specifies the total *length* of the reply data. If ANSBUF specifies an address list (ANSLIST=YES), the value specified with ANSLEN is the total of the individual buffer lengths in the list.

**PRMMSG=**

Specifies the 8 bytes of message data that are moved into the parameter list.

An additional option on REPLY lets you define priority messages.

**PRTY=**

Specifies whether this response is a priority message.

PRTY=YES indicates that this response is a priority message.

PRTY=NO indicates that this response is not a priority message.

**Parameter List Format:**

| IPARML DSECT |                                      |   |          |         |                                      |   |   |   |
|--------------|--------------------------------------|---|----------|---------|--------------------------------------|---|---|---|

| 10           | IPRMMMSG2                            |   |          |         | //////////////////////////////////// |   |   |   |
| 18           | //////////////////////////////////// |   |          |         | IPBFADR2                             |   |   |   |
| 20           | IPBFLN2F                             |   |          |         | //////////////////////////////////// |   |   |   |

**Parameter List Input Fields:****IPPATHID**

Contains the path ID of the message to which you are replying.

**IPFLAGS1**

Contains the options for the REPLY function.

**IPRMDATA (X'80')**

Indicates that the reply is in the parameter list.

**IPPRTY (X'20')**

Indicates that this is a priority response.

**IPANSLST (X'08')**

Indicates that you are using an address list for the reply data.

**IPMSGID**

Contains the message ID of the message to which you are replying.

**IPTRGCLS**

Contains the message class of the message to which you are replying.

**IPRMMSG1/IPRMMSG2**

Contain the reply data when it is stored in the parameter list rather than a buffer. The label IPRMMSG refers to the combined IPRMMSG1 and IPRMMSG2 fields.

**IPBFADR2**

Contains the address of the reply data.

**IPBFLN2F**

Contains the length of the reply data. Use this label with a fullword value. Use IPBFLN2 with a halfword value.

**Condition Codes and Return Codes****CONDITION CODES**

- 0 - Normal completion
- 1 - Nonzero value stored in IPRCODE
- 2 - No message found.

**Parameter List Output Fields:****IPBFADR2**

Contains the address of the reply data, when ANSLIST=NO, updated by the number of bytes of data that IUCV moved. If ANSLIST=YES is specified, the address points to the current list entry IUCV is working on.

**IPBFLN2F**

Contains one of the following values:

If the answer buffer is the same length as the reply, this field contains 0.

If the answer buffer is longer than the reply, this field contains the number of bytes remaining in the buffer.

If the answer buffer shorter than the reply, this field contains a residual count (that is, the number of bytes remaining in the reply that does not fit into the buffer).

### IPRCODE

Contains the return code describing how this function completed.

### RETURN CODES in IPRCODE

- 0 - X'00' - Normal return
- 1 - X'01' - Path ID specified is not an established path
- 5 - X'05' - Answer buffer too short to contain message
- 6 - X'06' - Storage protection exception on answer buffer
- 7 - X'07' - Addressing exception on answer buffer
- 8 - X'08' - Message ID found but message class or path ID invalid
- 9 - X'09' - Message has been purged
- 10 - X'0A' - Message length is negative
- 21 - X'15' - Parameter list data not allowed on this path
- 22 - X'16' - Send/Answer buffer list invalid
- 23 - X'17' - Negative length in buffer list
- 24 - X'18' - Incorrect total length of buffer list lengths
- 25 - X'19' - PRMSG option invalid with ANSLIST option
- 27 - X'1B' - Answer list not on a doubleword boundary
- 31 - X'1F' - IUCV function specified on an APPC/VM path
- 93 - X'5D' - A paging or storage error was detected in the ANSWER data area
- 94 - X'5E' - A paging or storage error was detected in the REPLY data area.

## Program Exceptions

The program exceptions for IUCV REPLY are:

### Specification Exception

The parameter list is not on a doubleword boundary.

### Operation Exception

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

### Addressing Exception

The parameter list address, the answer list address, the answer buffer address, or an answer buffer address in the answer list is outside the virtual machine's storage.

### Protection Exception

The storage key of the specified parameter list address, answer list address, answer buffer address, or an answer buffer address in the answer list does not match the key of the user.

## Completion Conditions

Message Complete External Interrupt:

To notify the originator of the message (the sender) that you have replied to the message, IUCV reflects an IUCV Message Complete external interrupt to the originator's virtual machine. If the sender had reserved buffers or address lists for use with this message, they can now be reused.

### Notes:

1. Even though the user may not be dependent on the information contained in this interrupt, it should be processed as the message is not considered complete until the interrupt is reflected to the virtual machine.
2. A message complete interrupt is also reflected to the sender of the message when a one-way message with data specified in a buffer is received by the target. No message complete external interrupt is reflected for a one-way message with data specified in the parameter list.

|    | 0        | 1 | 2        | 3      | 4                    | 5                    | 6 | 7 |
|----|----------|---|----------|--------|----------------------|----------------------|---|---|
| 0  | IPPATHID |   | IPFLAGS1 | IPTPYE | IPMSGID              |                      |   |   |
| 8  | IPAUDIT  |   |          |        | IPRMMSG1             |                      |   |   |
| 10 | IPRMMSG2 |   |          |        | IPSRCCLS             |                      |   |   |
| 18 | IPMSGTAG |   |          |        | //////////////////// |                      |   |   |
| 20 | IPBFLN2F |   |          |        | IPPOLLFG             | //////////////////// |   |   |

**IPPATHID**

Contains the path on which the message was sent.

**IPFLAGS1**

Contains specific information about the message.

**IPRMDATA (X'80')**

Indicates that the 8-byte reply is in the interrupt information.

**IPPRTY (X'20')**

Indicates that this is a priority reply.

**IPNORPY (X'10')**

Indicates that this is a one-way message.

**IPTYPE**

Indicates a Message Complete external interrupt. If this is an incoming priority message completion, the interrupt type is X'06'. If this is an incoming nonpriority message completion, the interrupt type is X'07'.

**IPMSGID**

Contains the message ID.

**IPAUDIT**

Contains information about possible asynchronous error conditions which may have affected the normal completion of this message. If this field is 0, the message has completed successfully.

The meanings of the bits in the audit trail are:

**IPADRPLE (X'800000')**

Reply too long for buffer

**IPADSNPX (X'400000')**

Protection exception on send buffer

**IPADSNAX (X'200000')**

Addressing exception on send buffer

**IPADANPX (X'100000')**

Protection exception on answer buffer

**IPADANAX (X'080000')**

Addressing exception on answer buffer

**IPADRJCT (X'040000')**

Message was rejected

**IPADPRMD (X'020000')**

Reply specified DATA=PRMMSG, but this path cannot handle data in the parameter list.

**IPADPGNR (X'010000')**

Message purged on send or receive queue.

**IPADRCPX (X'008000')**

Protection exception on receive buffer

**IPADRCAX (X'004000')**

Addressing exception on receive buffer

**IPADRPPX (X'002000')**

Protection exception on reply buffer

**IPADRPAX (X'001000')**

Addressing exception on reply buffer

**IPADSVRD (X'000800')**

Path was severed

**IPADRLST (X'000400')**

Invalid RECEIVE or REPLY address list

**(X'000200')**

Reserved

**(X'000100')**

Reserved

**IPADBLEN (X'000080')**

Bad length in SEND buffer list

**IPADALEN (X'000040')**

Invalid Send/Answer buffer list such as bad address or length

**IPADBTOT (X'000020')**

Invalid total SEND buffer length

**IPADATOT (X'000010')**

Invalid total SEND answer length

**(X'000008')**

Reserved

**(X'000004')**

Reserved

**(X'000002')**

Reserved

**(X'000001')**

Reserved.

The fourth byte of IPAUDIT, IPASYRC, may contain one of the following error codes (for which an appropriate IPRCODE was given to your communications partner).

**IPMCSNDA, 91 (X'00005B')**

Paging or storage error was detected in SEND data area

**IPMCRECA, 92 (X'00005C')**

Paging or storage error was detected in RECEIVE data area

**IPMCANSA, 93 (X'00005D')**

Paging or storage error was detected in ANSWER data area

**IPMCRPYA, 94 (X'00005E')**

Paging or storage error was detected in REPLY data area.

**IPRMMSG1/IPRMMSG2**

Contains the message when it is stored with the interrupt information (indicated by IPRMDATA in IPFLAGS1). The label IPRMMSG refers to the combined IPRMMSG1 and IPRMMSG2 fields.

**IPSRCCLS**

Contains the source message class.

**IPMSGTAG**

Contains the tag data of the message.

**IPBFLN2F**

Contains one of the following values, if the answer buffer is:

The same length as the reply, this field contains 0.

Longer than the reply, this field contains the number of bytes remaining in the buffer.

Shorter than the reply, this field contains a residual count (that is, the number of bytes remaining in the reply that does not fit into the buffer). The IPADRPLE bit is set in the audit trail on this condition.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

## RESUME Function

### Purpose

The RESUME function restores communications over a quiesced path.

### Parameters

#### Required Parameters:

##### RESUME

Requests that CP perform the IUCV RESUME function.

##### PRMLIST=

Specifies the *address* of the RESUME parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

##### MF=L

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

##### PATHID=

Specifies the path ID of the path on which you want to resume getting messages.

##### ALL=

Specifies whether communications should be restored for all paths for this virtual machine.

ALL=YES indicates that communications should be restored on all paths.

ALL=NO indicates that communications should be restored only on the path specified by PATHID.

##### USERDTA=

Specifies the data area containing the 16 bytes of user data that is to be reflected across the path. The user data is reflected as part of the IUCV Connection Resumed external interrupt.

#### Parameter List Format:

**Parameter List Input Fields:****IPPATHID**

Contains the path ID of the path you are resuming.

**IPFLAGS1**

Contains options for the RESUME function.

**IPALL (X'80')**

Indicates that you want to resume all paths for this virtual machine.

**IPUSER**

Contains the user data that is reflected across the path.

**Condition Codes and Return Codes****CONDITION CODES**

0 - Normal completion

1 - Nonzero value stored at IPRCODE.

**Parameter List Output Fields:****IPRCODE**

Contains the return code describing how this function completed.

**RETURN CODES in IPRCODE**

0 - X'00' - Normal return

1 - X'01' - Path ID specified is not an established path

31 - X'1F' - IUCV function specified on an APPC/VM path.

48 - X'30' - Partner system service does not support this function.

**Program Exceptions**

The program exceptions for IUCV RESUME are:

**Specification Exception**

The parameter list is not on a doubleword boundary.

**Operation Exception**

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

**Addressing Exception**

The parameter list address that you specified is outside the virtual machine's storage.

**Protection Exception**

The storage key of the specified parameter list address does not match the key of the user.

## Completion Conditions

**Connection Resumed External Interrupt:** To notify the other side of the path that the path has been resumed, IUCV reflects an IUCV Connection Resumed external interrupt.

The target virtual machine receives this external interrupt if it is enabled for IUCV interrupts in Control Register 0 and the PSW. The functions of SET MASK and SET CONTROL MASK also control the presentation of this type of interrupt.

### IPPATHID

Contains the path ID of the path quiesced.

### IPTYPE

Indicates a Connection Resumed external interrupt with a value of X'05'.

### IPUSER

Contains the user data specified by the virtual machine that quiesced the path.

### IPPOLLFG

Contains a flag returned by IUCV.

### IPNOPOLL (X'80')

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

## RETRIEVE BUFFER Function

### Purpose

The RETRIEVE BUFFER function terminates all use of IUCV. After the RETRIEVE BUFFER function completes, you may reuse the storage allocated for the IUCV external interrupt buffer since you will no longer receive IUCV external interrupts.

Since this function results in a sever of all IUCV paths, all outstanding IUCV communications are terminated as if each path has been individually severed.

When issued by a virtual machine, the RETRIEVE BUFFER function causes all paths except control paths to be severed. For example, if a program using CMSIUCV support issues HNDIUCV CLR, CMS issues the RETRIEVE BUFFER function and all paths are severed **except control paths**.

When issued by CP, the RETRIEVE BUFFER function severs **all** paths.

**Note:** Be aware that CP issues the RETRIEVE BUFFER function for the following commands:

- SYSTEM RESET
- IPL, which issues SYSTEM RESET
- LOGOFF.

This severs **all** paths, including control paths.

This function has a different meaning in a virtual MP environment. For more information about a virtual MP environment, see [“Virtual MP Considerations for IUCV Applications”](#) on page 308.

### Parameters

**Required Parameter:**

#### RTRVBFR

Requests that CP perform the IUCV RETRIEVE BUFFER function.

### Condition Codes and Return Codes

#### CONDITION CODES

0 - Normal completion.

### Program Exceptions

The program exceptions for IUCV RETRIEVE BUFFER are:

#### Operation Exception

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

## SEND Function

### Purpose

The **SEND** function transmits data to another virtual machine. This data is called a *message* and may be specified in the parameter list or in a buffer. The message is sent over a path that has been established by the **CONNECT** function.

## Parameters

### Required Parameters:

#### SEND

Requests that CP perform the IUCV SEND function.

#### PRMLIST=

Specifies the *address* of the SEND parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

#### MF=L

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

#### PATHID=

Specifies the path over which you wish to send the message. The *address* of the PATHID is to a halfword value.

#### TRGCLS=

Specifies the target message class associated with this message. This value, which is user defined, is considered part of the message identification (along with the PATHID and the MSGID field returned by IUCV). It can be used by the target virtual machine to receive particular messages.

With the SEND function you have an option of sending the message in a buffer or in the parameter list. The size of a parameter list message is very limited (only 8 bytes), but the overhead of an IUCV RECEIVE is avoided, which simplifies the communication process. The protocol that you chose on SEND does not affect the protocol chosen if the target must REPLY.

#### DATA=

Specifies the location of your message data for this IUCV communication.

DATA=BUFFER indicates that your message is in a buffer. You can use the BUFFER, BUFLLEN, or BUFLIST macro parameter to help you fill in the parameter list.

DATA=PRMSG indicates that your message is in the parameter list. Use the PRMSG parameter if you want the macro to fill in the parameter list.

#### BUFLIST=

Specifies if the list format is being used.

BUFLIST=NO indicates that the list format is not being used. The BUFFER parameter is the address of the complete message.

BUFLIST=YES indicates that the address on the BUFFER parameter identifies a list of addresses and lengths of discontiguous buffers that hold the message text.

#### BUFFER=

Specifies the *address* or the address of a list of addresses (*address-list*) from which IUCV moves the message. Any message buffers should not be reused until you receive a Message Complete external interrupt for this message.

#### BUFLLEN=

Specifies the total *length* of the message. If BUFFER specifies an address list (BUFLIST=YES), the value specified with BUFLLEN is the total of the individual buffer lengths in the list.

#### PRMSG=

Specifies the eight bytes of message data that are moved into the parameter list.

With the SEND function you have an option of sending the message with and without a reply. If you depend on the target virtual machine processing the message (for example, updating a database), you should use the 2-WAY protocol with a REPLY.

#### TYPE=

Specifies whether a reply is expected to this message.

TYPE=1WAY indicates that this is a one-way message and that the receiver will not reply to the message.

TYPE=2WAY indicates that this is a two-way messages and that the receiver is expected to reply to the message. You can use the ANSBUF, ANSLEN, or ANSLIST macro parameter to help you fill in the parameter list.

#### **ANSLIST=**

Specifies whether the list format is being used.

ANSLIST=NO indicates that the list format is not being used. The ANSBUF parameter is the address to contain the complete reply.

ANSLIST=YES indicates that the address on the ANSBUF parameter identifies a list of addresses and lengths of discontiguous buffers that contains the reply.

#### **ANSBUF=**

Specifies the *address* or the address of a list of addresses (*address-list*) into which IUCV moves the reply to this message. You do not know that the reply has been stored into this area until you receive a Message Complete external interrupt.

#### **ANSLEN=**

Specifies the total *length* of the expected reply. If ANSBUF specifies an address list (ANSLIST=YES), the value specified with ANSLEN is the total of the individual buffer lengths in the list.

Additional options for SEND include tagging the messages, sending priority messages, and defining a source class.

#### **MSGTAG=**

Specifies a tag to be associated with this message. This tag is returned to you on the IUCV Message Complete external interrupt. IUCV does not reference this tag so it may be used for any purpose that you desire. The tag information is not presented to the target user.

#### **PRTY=**

Specifies whether this is a priority message.

PRTY=YES indicates that this is a priority message.

PRTY=NO indicates that this is not a priority message.

#### **SRCCLS=**

Specifies the source message class associated with this message.

The tag information is not presented to the target user. The source class is returned on the Message Complete external interrupt. You can use this field to identify different types of messages.

#### **SYNC=**

Designates a synchronous send request.

#### **Parameter List Format:**

| IPARML DSECT |                      |   |          |         |                                      |   |     |
|--------------|----------------------|---|----------|---------|--------------------------------------|---|-----|
|              | 0                    | 1 | 2        | 3       | 4                                    | 5 | 6 7 |
| 0            | IPPATHID             |   | IPFLAGS1 | IPRCODE | IPMSGID                              |   |     |
| 8            | IPTRGCLS             |   |          |         | IPBFADR1 / IPRMMMSG1                 |   |     |
| 10           | IPBFLN1F / IPRMMMSG2 |   |          |         | IPSRCCLS                             |   |     |
| 18           | IPMSGTAG             |   |          |         | IPBFADR2                             |   |     |
| 20           | IPBFLN2F             |   |          |         | //////////////////////////////////// |   |     |

#### **Parameter List Input Fields:**

##### **IPPATHID**

Contains the path ID on which to send the message.

##### **IPFLAGS1**

Contains options for the SEND function.

**IPRMDATA (X'80')**

Indicates that the message is in the parameter list.

**IPBUFLST (X'40')**

Indicates that you are using an address list for the message data.

**IPPRTY (X'20')**

Indicates that you are sending a priority message.

**IPNORPY (X'10')**

Indicates that this is a one-way message. No reply expected.

**IPANSLST (X'08')**

Indicates that you are using an address list for the reply data.

**IPSYNC (X'04')**

Indicates that you are requesting a synchronous send.

**IPAPPCSN (X'02')**

Indicates the protocol to be used on this path. This bit must be set to 0.

**IPTRGCLS**

Contains the target message class.

**IPBFADR1**

Contains the address of the message.

**IPBFLN1F**

Contains the length of the message buffer. Use this label with a fullword value. Use IPBFLN1 with a halfword value.

**IPRMMSG1/IPRMMSG2**

Contains the message when it is stored in the parameter list rather than a buffer. The label IPRMMSG refers to the combined IPRMMSG1 and IPRMMSG2 fields.

**IPSRCCLS**

Contains the source message class.

**IPMSGTAG**

Contains the tag data of the message.

**IPBFADR2**

Contains the address to hold the reply.

**IPBFLN2F**

Contains the length of the reply area. Use this label with a fullword value. Use IPBFLN2 with a halfword value.

**Condition Codes and Return Codes**

The condition codes are:

|   |                                                                                                    |
|---|----------------------------------------------------------------------------------------------------|
| 0 | Normal completion                                                                                  |
| 1 | Nonzero value stored in IPRCODE                                                                    |
| 2 | Synchronous send request (IPSYNC) to the DASD Block I/O System Service has completed successfully. |

**Parameter List Output Fields:****IPMSGID**

Contains a message ID that IUCV assigns the message.

**IPRCODE**

Contains the return code describing how this function completed.

|           |               |
|-----------|---------------|
| 0 - X'00' | Normal return |
|-----------|---------------|

## IUCV SEND

|            |                                                                                                   |
|------------|---------------------------------------------------------------------------------------------------|
| 1 - X'01'  | Path ID specified is not an established path                                                      |
| 2 - X'02'  | Path quiesced - SENDs not allowed                                                                 |
| 3 - X'03'  | Message limit exceeded                                                                            |
| 4 - X'04'  | Priority messages not allowed on this path                                                        |
| 10 - X'0A' | Message length is negative                                                                        |
| 21 - X'15' | Message in parameter list not allowed on this path                                                |
| 25 - X'19' | PRMMMSG invalid with BUFLIST parameter                                                            |
| 26 - X'1A' | Buffer list not on a doubleword boundary                                                          |
| 27 - X'1B' | Answer list not on a doubleword boundary                                                          |
| 30 - X'1E' | IPAPPCSN flag in IPFLAGS1 not 0                                                                   |
| 31 - X'1F' | IUCV function specified on an APPC/VM path                                                        |
| 48 - X'30' | Partner system service does not support this function.                                            |
| 96 - X'60' | The send was going to be routed via ISFC but the length was greater than the maximum allowed      |
| 97 - X'61' | The send was going to be routed via ISFC but the answer area was greater than the maximum allowed |

**Note:** If you get a return code that is not documented here, it is an APPC/VM return code. An APPC/VM return code can result if the IPAPPC bit is set on during an IUCV CONNECT. For a description of the APPC/VM return code, refer to [“APPCVM SENDDATA” on page 475](#).

## Program Exceptions

The program exceptions for IUCV SEND are:

### Specification Exception

The parameter list is not on a doubleword boundary.

### Operation Exception

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

### Addressing Exception

The parameter list or buffer address that you specified is outside the virtual machine's storage.

### Protection Exception

The storage key of the specified parameter list address does not match the key of the user.

## Completion Conditions

**Message Pending External Interrupt:** To notify the target virtual machine that you have sent a message, IUCV reflects an IUCV Message Pending external interrupt to the target virtual machine.

The target virtual machine receives this external interrupt if it is enabled for IUCV interrupts in Control Register 0 and the PSW. The SET MASK function also controls the presentation of this type of interrupt.

The external interrupt contains the information that the target virtual machine needs to continue processing the message. If the message is being sent in a buffer, the target continues processing by issuing a RECEIVE or a REJECT. If the message is contained in the interrupt information (IPRMDATA in IPFLAGS1 is on), a RECEIVE is not needed. If the interrupt indicates a one-way message with the data in the parameter list, no further IUCV processing is necessary. Therefore, no message complete external interrupt is generated for the sender of the message.

|    |                                  |   |          |        |                                  |                                  |   |   |
|----|----------------------------------|---|----------|--------|----------------------------------|----------------------------------|---|---|
|    | 0                                | 1 | 2        | 3      | 4                                | 5                                | 6 | 7 |
| 0  | IPPATHID                         |   | IPFLAGS1 | IPTYPE | IPMSGID                          |                                  |   |   |
| 8  | IPTRGCLS                         |   |          |        | IPRMSG1                          |                                  |   |   |
| 10 | IPBFLN1F / IPRMSG2               |   |          |        | //////////////////////////////// |                                  |   |   |
| 18 | //////////////////////////////// |   |          |        |                                  |                                  |   |   |
| 20 | IPBFLN2F                         |   |          |        | IPPOLLFG                         | //////////////////////////////// |   |   |

**IPPATHID**

Contains the path on which the message was sent.

**IPFLAGS1**

Contains options for this message.

**IPRMDATA (X'80')**

Indicates that the 8-byte message is in the interrupt information.

**X'40'**

This value is reserved for IBM use only.

**IPPRTY (X'20')**

Indicates that this is a priority message.

**IPNORPY (X'10')**

Indicates that this is a one-way message and no REPLY is expected.

**IPFGMID (X'04')**

Is always set to 1 indicating that the message ID has been stored at IPMSGID.

**IPFGPID (X'02')**

Is always set to 1 indicating that the path ID has been stored at IPPATHID.

**IPFGMCL (X'01')**

Is always set to 1 indicating that the target message class has been stored at IPTRGCLS.

**IPTYPE**

Indicates an Incoming Message external interrupt. If this is an incoming priority message, the interrupt type is X'08'. If this is an incoming nonpriority message, the interrupt type is X'09'.

**IPMSGID**

Contains the message ID.

**IPTRGCLS**

Contains the target message class.

**IPRMSG1/IPRMSG2**

Contains the message when it is stored with the interrupt information (indicated by IPRMDATA in IPFLAGS1). The label IPRMSG refers to the combined IPRMSG1 and IPRMSG2 fields.

**IPBFLN1F**

Contains the length of the message.

**IPBFLN2F**

Contains the length of the maximum expected reply.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

## SET CONTROL MASK Function

### Purpose

The SET CONTROL MASK function enables or disables the following IUCV external interruptions:

- Pending Connection
- Connection Complete
- Connection Severed
- Connection Quiesced
- Connection Resumed.

IUCV external interrupts are controlled by several masks in the following priority order:

1. Submask bit 30 of Control Register 0
2. Bit 7 of the virtual machine PSW
3. Bits defined by the SET MASK function
4. Bits defined by the SET CONTROL MASK function.

This function has a different meaning in a virtual MP environment. For more information about a virtual MP environment, see [“Virtual MP Considerations for IUCV Applications” on page 308.](#)

### Parameters

#### Required Parameters:

##### SETCMASK

Requests that CP perform the IUCV SET CONTROL MASK function.

##### PRMLIST=

Specifies the *address* of the SET parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

##### MF=L

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

##### MASK=

Specifies the mask byte to determine for which, if any, IUCV external interrupts a virtual machine is enabled.

#### Parameter List Format:

| IPARML DSECT |          |   |          |   |         |   |          |   |
|--------------|----------|---|----------|---|---------|---|----------|---|
|              | 0        | 1 | 2        | 3 | 4       | 5 | 6        | 7 |
| 0            | IPMASK   |   | //////// |   | IPRCODE |   | //////// |   |
| 8            | //////// |   |          |   |         |   |          |   |
| 10           | //////// |   |          |   |         |   |          |   |
| 18           | //////// |   |          |   |         |   |          |   |
| 20           | //////// |   |          |   |         |   |          |   |

**Parameter List Input Fields:****IPMASK**

Contains the mask that specifies for which, if any, IUCV interrupts your virtual machine is enabled. The meanings of the bits in the mask are:

**IPCLPC (X'80')**

Enable for pending connections interrupts

**IPCLCC (X'40')**

Enable for connection complete interrupts

**IPCLPS (X'20')**

Enable for connection severed interrupts

**IPCLPQ (X'10')**

Enable for connection quiesced interrupts

**IPCLPR (X'08')**

Enable for connection resumed interrupts.

**Condition Codes and Return Codes****CONDITION CODES**

0 - Normal completion

**Parameter List Output Fields:****IPRCODE**

Contains the return code describing how this function completed.

**RETURN CODES in IPRCODE**

0 - X'00' - Normal return

**Program Exceptions**

The program exceptions for IUCV SET CONTROL MASK are:

**Operation Exception**

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

**Protection Exception**

The storage key of the specified parameter list does not match the key of the user.

## SET MASK Function

### Purpose

The SET MASK function enables or disables the following IUCV external interruptions:

- Nonpriority message interrupts
- Priority message interrupts
- Priority reply interrupts
- Nonpriority reply interrupts
- IUCV control interrupts.

Individual IUCV control interrupts can be controlled by using the SET CONTROL MASK function.

IUCV external interrupts are controlled by several masks in the following priority order:

1. Submask bit 30 of Control Register 0
2. Bit 7 of the virtual machine PSW
3. Bits defined by the SET MASK function
4. Bits defined by the SET CONTROL MASK function.

This function has a different meaning in a virtual MP environment. For more information about a virtual MP environment, see [“Virtual MP Considerations for IUCV Applications” on page 308](#).

### Parameters

#### Required Parameters:

##### SET MASK

Requests that CP perform the IUCV SET MASK function.

##### PRMLIST=

Specifies the *address* of the SET parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

##### MF=L

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

##### MASK=

Specifies the mask byte to determine for which, if any, IUCV external interrupts a virtual machine is enabled.

**Parameter List Format:**

| IPARML DSECT |                                      |   |            |   |         |   |                                      |   |  |  |
|--------------|--------------------------------------|---|------------|---|---------|---|--------------------------------------|---|--|--|
|              | 0                                    | 1 | 2          | 3 | 4       | 5 | 6                                    | 7 |  |  |
| 0            | IPMASK                               |   | ////////// |   | IPRCODE |   | //////////////////////////////////// |   |  |  |
| 8            | //////////////////////////////////// |   |            |   |         |   |                                      |   |  |  |
| 10           | //////////////////////////////////// |   |            |   |         |   |                                      |   |  |  |
| 18           | //////////////////////////////////// |   |            |   |         |   |                                      |   |  |  |
| 20           | //////////////////////////////////// |   |            |   |         |   |                                      |   |  |  |

**Parameter List Input Fields:****IPMASK**

Contains the mask that specifies for which, if any, IUCV interrupts your virtual machine is enabled. The meanings of the bits in the mask are:

**IPSNDN (X'80')**

Enable for nonpriority message interrupts

**IPSNDP (X'40')**

Enable for priority message interrupts

**IPRPYN (X'20')**

Enable for nonpriority message completion interrupts

**IPRPYP (X'10')**

Enable for priority message completion interrupts

**IPCTRL (X'08')**

Enable for IUCV control interrupts

**Condition Codes and Return Codes****CONDITION CODES**

0 - Normal completion.

**Parameter List Output Fields:****IPRCODE**

Contains the return code describing how this function completed.

**RETURN CODES in IPRCODE**

0 - X'00' - Normal return.

**Program Exceptions**

The program exceptions for IUCV SET MASK are:

**Operation Exception**

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

**Protection Exception**

The storage key of the specified parameter list does not match the key of the user.

## SEVER Function

### Purpose

The SEVER function terminates an IUCV path to another virtual machine. You can terminate an established path or a pending connection. When you SEVER an established path, all of your outstanding messages on that path are purged, and any incoming messages on that path are rejected. When you have severed a path, communications on that path are no longer allowed and no communication, in either direction, can occur. The path ID may be reused by IUCV when new paths are established.

When you receive an IUCV Connection Severed external interrupt, you can no longer send on that path, but you can process outstanding messages. You should always issue a SEVER in response to a Connection Severed interrupt to terminate your use of the path.

### Parameters

#### Required Parameters:

##### SEVER

Requests that CP perform the IUCV SEVER function.

##### PRMLIST=

Specifies the *address* of the SEVER parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

##### MF=L

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

##### ALL=

Specifies whether all paths for this virtual machine are to be severed.

ALL=YES indicates that all of your paths are to be severed.

ALL=NO indicates that you do not want all of your paths severed, only the one specified by PATHID.

**PATHID=**

Specifies the path ID to be severed.

**USERDTA=**

Specifies the data area containing the 16 bytes of user data that IUCV is to reflect across the path. The user data is reflected as part of the IUCV Connection Severed external interrupt.

**Parameter List Format:**

| IPARML DSECT |                                      |   |          |         |                                      |   |   |   |
|--------------|--------------------------------------|---|----------|---------|--------------------------------------|---|---|---|
|              | 0                                    | 1 | 2        | 3       | 4                                    | 5 | 6 | 7 |
| 0            | IPPATHID                             |   | IPFLAGS1 | IPRCODE | //////////////////////////////////// |   |   |   |
| 8            | //////////////////////////////////// |   |          |         |                                      |   |   |   |
| 10           | IPUSER                               |   |          |         |                                      |   |   |   |
| 18           |                                      |   |          |         |                                      |   |   |   |
| 20           | //////////////////////////////////// |   |          |         |                                      |   |   |   |

**Parameter List Input Fields:****IPPATHID**

Contains the path ID of the path you want to sever.

**IPFLAGS1**

Contains options for the SEVER function.

**IPALL (X'80')**

Indicates that you want to sever all paths for this virtual machine.

**IPAPPC (X'08')**

Indicates the protocol to be used on this path. This bit must be set to 0.

**IPUSER**

Contains the user data that IUCV reflects across the path.

**Condition Codes and Return Codes****CONDITION CODES**

0 - Normal completion

1 - Nonzero value stored at IPRCODE.

**Parameter List Output Fields:****IPRCODE**

Contains the return code describing how this function completed.

**RETURN CODES in IPRCODE**

0 - X'00' - Normal return

1 - X'01' - Path ID specified is not an established path

30 - X'1E' - IPAPPC flag in IPFLAGS1 not 0.

**Note:** If you get a return code that is not documented here, it is an APPC/VM return code. An APPC/VM return code can result if the IPAPPC bit is set on during an IUCV CONNECT. For a description of the APPC/VM return code, refer to [“APPCVM SEVER” on page 509](#).

**Program Exceptions**

The program exceptions for IUCV SEVER are:

**Specification Exception**

The parameter list is not on a doubleword boundary.

**Operation Exception**

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

**Addressing Exception**

The parameter list address that you specified is outside the virtual machine's storage.

**Protection Exception**

The storage key of the specified parameter list address does not match the key of the user.

**Completion Conditions**

**Connection Severed External Interrupt:** To notify the other side of the path that you wish to terminate communication on a path, IUCV reflects an IUCV Connection Severed external interrupt.

The target virtual machine receives this external interrupt if it is enabled for IUCV interrupts in Control Register 0 and the PSW. The functions of SET MASK and SET CONTROL MASK also control the presentation of this type of interrupt.

**IPPATHID**

Contains the path ID of the path being severed.

**IPTYPE**

Indicates a Connection Severed external interrupt with a value of X'03'.

**IPUSER**

Contains the user data specified by the virtual machine that severed this path.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

## TEST COMPLETION Function

### Purpose

The TEST COMPLETION function determines whether you have a message completion pending for your virtual machine. If a message completion is pending, information about the message is returned in the parameter list. Since you now have the message completion information, there is no need for IUCV to reflect an IUCV Message Completion external interrupt and you will not receive one for this message.

Since IUCV normally informs you of a message completion by reflecting a Message Completion external interrupt, you should not use the TEST COMPLETION function unless you have disabled for this type of interrupt. The IUCV SET MASK function can be used to disable your virtual machine for Message Completion external interrupts.

When invoking the TEST COMPLETION function, you can completely identify the message by specifying the message ID, path ID, and source message class. You can also identify the message by either the path ID or the source message class, or both. If you do not specify any identifiers when invoking the TEST COMPLETION function, any available message completion satisfies the function.

This function has a different meaning in a virtual MP environment. For more information about a virtual MP environment, see [“Virtual MP Considerations for IUCV Applications”](#) on page 308.

### Parameters

#### Required Parameters:

##### TESTCMPL

Requests that CP perform the IUCV TEST COMPLETION function.

##### PRMLIST=

Specifies the *address* of the TEST COMPLETION parameter list. The IUCV instruction is generated to reference the *address* specified. The address of the parameter list must be on a doubleword boundary.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

##### MF=L

Lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

##### MSGID=

Specifies the message ID of the message. If the message ID is used to locate the message, the path ID and the source class must also be correctly specified in the parameter list.

## IUCV TEST COMPLETION

### **PATHID=**

Specifies the unique path identification number associated with a message.

### **SRCCLS=**

Specifies the source message class associated with a message.

### **Parameter List Format:**

| IPARML DSECT |           |   |          |         |                                      |                                      |   |   |
|--------------|-----------|---|----------|---------|--------------------------------------|--------------------------------------|---|---|

### **Parameter List Input Fields:**

#### **IPPATHID**

Contains the path ID for the message completion.

#### **IPFLAGS1**

Contains options for the TEST COMPLETION function.

#### **IPFGMID (X'04')**

Indicates that you have specified a message ID (IPMSGID) to identify the message completion.

#### **IPFGPID (X'02')**

Indicates that you have specified a path ID (IPPATHID) to identify the message completion.

#### **IPFGMCL (X'01')**

Indicates that you have specified a source message class (IPSRCCL) to identify the message completion.

#### **IPMSGID**

Contains the message ID for the message completion.

#### **IPSRCCLS**

Contains the source message class for the message completion.

## **Condition Codes and Return Codes**

### **CONDITION CODES**

- 0 - Normal completion
- 1 - Nonzero value stored at IPRCODE
- 2 - No message found
- 3 - Nonzero audit trail stored.

### **Parameter List Output Fields:**

#### **IPPATHID**

Contains the path ID on which the message was sent.

#### **IPFLAGS1**

Contains specific information about the message.

#### **IPRMDATA (X'80')**

Indicates that the 8-byte reply is in the parameter list.

#### **IPPRTY (X'20')**

Indicates that this is a priority message.

**IPMSGID**

Contains the message ID.

**IPAUDIT**

Contains information about possible asynchronous error conditions which may have affected the normal completion of this message. If this field is 0, the message has completed successfully.

The meanings of the bits in the audit trail are:

**IPADRPLE (X'800000')**

Reply too long for buffer

**IPADSNPX (X'400000')**

Protection exception on send buffer

**IPADSNAX (X'200000')**

Addressing exception on send buffer

**IPADANPX (X'100000')**

Protection exception on answer buffer

**IPADANAX (X'080000')**

Addressing exception on answer buffer

**IPADRJCT (X'040000')**

Message was rejected

**IPADPRMD (X'020000')**

Reply specified DATA=PRMMMSG, but this path cannot handle data in the parameter list.

**IPADPGNR (X'010000')**

Message purged on send or receive queue.

**IPADRCPX (X'008000')**

Protection exception on receive buffer

**IPADRCAX (X'004000')**

Addressing exception on receive buffer

**IPADRPPX (X'002000')**

Protection exception on reply buffer

**IPADRPAX (X'001000')**

Addressing exception on reply buffer

**IPADSVRD (X'000800')**

Path was severed

**IPADRLST (X'000400')**

Invalid RECEIVE or REPLY address list

**(X'000200')**

Reserved

**(X'000100')**

Reserved

**IPADBLEN (X'000080')**

Bad length in SEND buffer list

**IPADALEN (X'000040')**

Bad length in SEND answer list

**IPADBTOT (X'000020')**

Invalid total SEND buffer length

**IPADATOT (X'000010')**

Invalid total SEND answer length

**(X'000008')**

Reserved

## IUCV TEST COMPLETION

**(X'000004')**

Reserved

**(X'000002')**

Reserved

**(X'000001')**

Reserved.

### **IPRMMMSG1/IPRMMMSG2**

Contains the message when it is stored in the parameter list (indicated by IPRMDATA in IPFLAGS1). The label IPRMMMSG refers to the combined IPRMMMSG1 and IPRMMMSG2 fields.

### **IPSRCCLS**

Contains the source message class.

### **IPMSGTAG**

Contains the tag data of the message.

### **IPBFLN2F**

Contains one of the following values:

If the buffer is exactly the correct length, this field contains 0.

If the buffer is too long, this field contains the number of bytes unused in the buffer.

If the buffer is too short, this field contains a residual count (that is, the number of bytes remaining of the reply that do not fit into the buffer). The IPADRPLE bit is set in the audit trail on this condition.

### **IPPOLLFG**

Contains a flag returned by IUCV.

### **IPNOPOLL (X'80')**

Indicates that another iteration of this function will probably not find a reply waiting at this time.

### **IPRCODE**

Contains the return code describing how this function completed.

### **RETURN CODES in IPRCODE**

0 - X'00' - Normal return

1 - X'01' - Path ID specified is not an established path

8 - X'08' - Message ID found but message class or path ID invalid.

## **Program Exceptions**

The program exceptions for IUCV TEST COMPLETION are:

### **Specification Exception**

The parameter list is not on a doubleword boundary, or the message ID was specified without the path ID and the message class.

### **Operation Exception**

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

### **Addressing Exception**

The parameter list address that you specified is outside the virtual machine's storage.

### **Protection Exception**

The storage key of the specified parameter list address does not match the key of the user.

## TEST MESSAGE Function

### Purpose

The TEST MESSAGE function determines whether any IUCV Message Pending or IUCV Message Complete external interrupts are queued for your virtual machine.

This function, when used with the DESCRIBE and TEST COMPLETION functions, lets the virtual machine avoid the external interrupt handling associated with messages. In some applications, as when only one type of message is ever handled, the DESCRIBE may also be avoided and a RECEIVE issued directly.

When you receive message or message completions, IUCV informs you by reflecting a Message Pending or Message Complete external interrupt to your virtual machine. Therefore, unless you disable your virtual machine for Message Pending and Message Complete external interrupts, you should not use the TEST MESSAGE function.

If, when your virtual machine invokes the TEST MESSAGE function, it finds that there are no messages or message completions pending, your virtual machine enters a wait state. Your virtual machine remains enabled for all interrupts that were enabled when the TEST MESSAGE function was issued.

If, while your virtual machine is in a wait state, you receive an IUCV message or message completion, your virtual machine resumes execution by re-executing the TEST MESSAGE function (which returns a condition code).

This function has a different meaning in a virtual MP environment. For more information about a virtual MP environment, see [“Virtual MP Considerations for IUCV Applications”](#) on page 308.

### Condition Codes and Return Codes

The condition codes are:

- |   |                                             |
|---|---------------------------------------------|
| 1 | Message pending                             |
| 2 | Message completion pending                  |
| 3 | Both message and message completion pending |

### Program Exceptions

The program exceptions for IUCV TEST MESSAGE are:

#### Operation Exception

The external interrupt buffer has not been declared using the DECLARE BUFFER function, your virtual machine is not in supervisor state, or a previous RETRIEVE BUFFER function is outstanding and has not completed yet.

**IUCV TEST MESSAGE**

---

## Part 3. The Advanced Program-to-Program Communication/VM

This part contains the following chapters:

- [Chapter 6, “Overview of the APPC/VM Assembler Interface,” on page 387](#)
- [Chapter 7, “APPCVM Macro Functions,” on page 411](#)
- [Chapter 8, “IUCV Macro Functions for Use in APPC/VM,” on page 521](#)
- [Chapter 9, “Migrating Programs from IUCV to APPC/VM,” on page 567](#)
- [Chapter 10, “APPC Mapped with APPC/VM,” on page 571](#)

## Chapter 6. Overview of the APPC/VM Assembler Interface

In its simplest form, connectivity is the ability of one program to communicate with another program. In this document, we are concerned with communications between two application programs. Application programs are typically written to communicate with one another because a user needs access to some kind of data.

**System Network Architecture (SNA)** defines various sets of rules for data to be transmitted in a network. Application programs communicate with each other using a layer of SNA called **Advanced Program-to-Program Communication (APPC)**. APPC is also known as **LU 6.2**. z/VM implements the base set of APPC and several APPC option sets using **Advanced Program-to-Program Communication/VM (APPC/VM)**.

z/VM provides two programming interfaces to APPC/VM:

1. A low-level interface intended for programs written in assembler language. This low-level interface consists of CMS macros and CP macros. In this document we will discuss the APPC/VM macros that are part of the CP programming interface. The CMS macros that you can use with APPC/VM are documented in the *z/VM: CMS Macros and Functions Reference* and *z/VM: CMS Application Development Guide for Assembler*.
2. **Common Programming Interface (CPI) Communications**. This interface (also known as SAA communications interface) can be used with any programming language defined in the System Application Architecture (SAA). For z/VM, this interface can be used in CMS. This interface should be used for new application development.

**Note:** For more information about CPI Communications routines, see *Common Programming Interface Communications Reference* (<https://publibfp.dhe.ibm.com/epubs/pdf/c2643999.pdf>).

### Overview of APPC/VM Assembler Interface

The assembler programming interface for APPC/VM allows communications between application programs that are written in assembler language. The APPC/VM assembler interface implements the base set of APPC (SNA LU 6.2) verbs and several APPC option sets.

The APPC/VM assembler interface provides macros and parameter lists that applications can use to set up and control the communications environment within one z/VM system, and among z/VM systems in a TSAF or Communication Services (CS) collection. (For programs communicating outside a TSAF or CS collection to an SNA network, AVS translates APPC/VM protocol into APPC/VTAM, which is the VTAM® implementation of APPC.)

In addition, z/VM has implemented some IUCV functions for an APPC/VM environment. IUCV functions are not part of the APPC architecture and are unique to z/VM. **Note: The remainder of this document refers to the APPC/VM assembler programming interface as simply APPC/VM.**

### Basics of APPC/VM

The following sections describe some of the basics of APPC/VM communication: paths, states, and interrupts.

#### APPC/VM Paths

An APPC/VM path is a logical connection between one or more virtual machines. Information flows on APPC/VM paths. To establish an APPC/VM path between two virtual machines, at least one of the virtual machines must be authorized in the IUCV directory statement.

A path is created when the source virtual machine invokes the CONNECT function and the target virtual machine invokes the ACCEPT function. Once the path is created, communications can begin. Programs identify a path using the PATHID parameter of the pertinent APPC/VM function.

The target virtual machine can prevent the path from being established by invoking the SEVER function. Either virtual machine can destroy an established path with the SEVER function.

A single virtual machine can have up to 65,536 APPC/VM paths defined. Two virtual machines can have more than one path between them. Communication can occur over any and all paths at the same time.

## APPC/VM States

The APPC/VM interface is a half-duplex communications protocol. This means that only one of the communications partners can send data at any given time. Because of this, APPC/VM uses states to define what functions a program can and cannot issue at any given time.

A program is always in a single state for a particular conversation. When your program or your communications partner issues an APPC/VM function, the state of the conversation may change. If your virtual machine is communicating with different virtual machines through various paths, it may be in different states on different paths at the same time. A program participating in multiple conversations could have multiple states, too.

The basic states for APPC/VM assembler programs are:

### Reset

The state for each program before communications begin and after communications end.

### Connect

The state for a source program after a connection has been started but before it has completed, or the state for a target program after it has received a connection pending interrupt but before it has accepted.

### Send

The state in which a program is allowed to send data.

### Receive

The state in which a program is ready to receive data.

### Confirm

The state in which a program must respond to its communications partner.

### Sever

The state a program is in when its partner stops communications.

These APPC/VM states are based on the states that APPC defines, but there are two differences:

1. The Connect state is unique to APPC/VM
2. The Sever state is analogous to the APPC Deallocate state.

In addition, APPC/VM defines several other states for special programs involving coordinated resource recovery (CRR). Refer to [Table 72 on page 405](#) for details about these APPC/VM states.

## APPC/VM Interrupts

In APPC/VM, your program may receive notification of pending functions through external *interrupts*. Interrupts are caused by actions taken by the virtual machine on the other end of the local APPC/VM path. Interrupts indicate pending and completed functions. For example, your virtual machine receives an interrupt when another virtual machine sends you some kind of message that it wants you to receive.

At the start of your program, you must create a buffer to hold the interrupt information for any APPC/VM functions on any path. (You can create this buffer using the IUCV DCLBFR function.) This buffer is a 40-byte area called an external interrupt buffer. When your program is presented with an interrupt, information about the interrupt goes in this external interrupt buffer.

The possible APPC/VM interrupts you can get fall into two categories. The first type of interrupt signals that your communications partner has invoked some function, independent of your actions. These interrupts are:

- Connection pending
- Message pending
- Request-to-Send
- Sever.

The second type of interrupt signals the completion of a function that you initiated. These interrupts are:

- Connection complete
- Function complete.

The six basic types of APPC/VM interrupts are described in the following sections.

## Connection Pending External Interrupt

You get a connection pending interrupt when a virtual machine invokes an APPCVM CONNECT function to connect to your virtual machine. The interrupt is placed in a control buffer if the virtual machine wants to connect to a private resource; otherwise, the interrupt is presented to your virtual machine's application buffer.

Refer to the diagram in APPCVM CONNECT, [Connection Pending External Interrupt](#).

## Message Pending External Interrupt

You get a message pending interrupt when your communications partner issues an APPC/VM function for which you should issue an APPCVM RECEIVE. Your communications partner issuing any of the following APPCVM macro functions can cause a message pending interrupt:

- RECEIVE
- SENDCNF
- SENDDATA
- SENDERR.

You only get a message pending interrupt if you are in Receive state on the corresponding path.

Refer to the diagram in APPCVM SENDDATA, [Message Pending External Interrupt format](#).

## Request-to-Send External Interrupt

You get a request-to-send interrupt when your communications partner issues the APPCVM SENDREQ function to request to send data.

Refer to the diagram in APPCVM SENDREQ, [SENDREQ Interrupt](#).

## Sever External Interrupt

You get a sever interrupt when the program to which you are connected or trying to connect to invokes an APPCVM SEVER or IUCV SEVER, invokes an HNDIUCV CLR (or IUCV RTRVBFR), or abends. You could also get a sever interrupt when the virtual machine to which you are connected or trying to connect to resets its virtual machine or logs off.

**Note:** If you get a sever interrupt after you have issued an APPC/VM function to your partner, do not assume that your function has terminated.

Refer to the diagram in APPCVM SEVER, [SEVER External Interrupt format](#).

### Connection Complete External Interrupt

You get a connection complete interrupt when you issue the APPCVM CONNECT WAIT=NO function and the virtual machine on the other end of the local APPC/VM path accepts the connection.

When you get a connection complete interrupt, do not assume that the target program performed any action to cause your function to complete.

For a diagram of the connection complete external interrupt in APPCVM CONNECT, see [“Condition Codes and Return Codes”](#) on page 424.

### Function Complete External Interrupt

You get a function complete interrupt when the function that you issued completes. The completion of any of the following APPC/VM functions can cause a function complete interrupt:

- RECEIVE
- SENDCNF
- SENDDATA
- SENDERR
- SEVER.

The function complete interrupts are shown in the following sections:

- [APPCVM RECEIVE Output Parameter List](#) in APPCVM RECEIVE
- [AFFCVM SENDCNF Output Parameter List](#) in APPCVM SENDCNF
- [APPCVM SENDDATA Output Parameter List](#) in APPCVM SENDDATA
- [APPCVM SENDERR Output Parameter List](#) in APPCVM SENDERR
- [SEVER Output Parameter List format](#) in APPCVM SEVER

Whenever there are multiple APPC/VM interrupts queued for the virtual machine, control interrupts are always reflected to the virtual machine in first-in-first-out (FIFO) order before message interrupts. Message interrupts of the same subtype are reflected in first-in-first-out (FIFO), but message interrupts of different subtypes are reflected in the order shown in the previous list.

Interrupts are reflected to the virtual machine in this order regardless of the order in which the interrupts were queued for the virtual machine. There are many conditions which can cause more than one interrupt to be queued for a virtual machine, some of which are beyond the control of the application. For example, if the virtual machine disables for APPC/VM interrupts for a period of time or if the virtual machine is communicating with multiple partners, then often multiple APPC/VM interrupts will be on the virtual machine's queue. Also, the relative priorities and time slices given to the communicating virtual machines can affect the order in which APPC/VM interrupts are presented. For example, if virtual machine A sends a one-way message to virtual machine B, and B receives the message, a message complete interrupt (function complete interrupt for SENDDATA) is queued for A. If B then severs the APPC/VM path, then a sever interrupt is queued for A. If A is not dispatched, or doesn't enable for APPC/VM interrupts until after the sever interrupt is queued, then A would see the sever interrupt first. If A is dispatched and is enabled for APPC/VM interrupts before the sever interrupt is queued, then A would see the message complete interrupt first.

## Invoking APPC/VM Communication Functions

---

z/VM programs at each end of an APPC/VM path use APPC/VM functions to communicate with each other. Most APPC/VM communications functions are provided as parameters of the APPCVM macro.

To use the APPCVM or IUCV macro, issue the CMS GLOBAL command for the HCPGPI MACLIB before assembling your program.

The APPC/VM communications functions used with the APPCVM macro are:

| Function  | Description                                                                               | Page                                                           |
|-----------|-------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| CONNECT   | Establishes and reserves a path to communicate with another program.                      | <a href="#">“APPCVM CONNECT” on page 412</a>                   |
| QRYSTATE  | Determines the current state of a path.                                                   | <a href="#">“APPCVM QRYSTATE (Query State)” on page 447</a>    |
| RECEIVE   | Receives data and information sent to your program.                                       | <a href="#">“APPCVM RECEIVE” on page 451</a>                   |
| SENDCNF   | Sends a confirmation request to your communications partner.                              | <a href="#">“APPCVM SENDCNF (Send Confirm)” on page 465</a>    |
| SENDCNFD  | Sends a response to a confirmation request.                                               | <a href="#">“APPCVM SENDCNFD (Send Confirmed)” on page 471</a> |
| SENDDATA  | Sends data to your communications partner.                                                | <a href="#">“APPCVM SENDDATA” on page 475</a>                  |
| SENDERR   | Sends notice to your communications partner that your program has detected an error.      | <a href="#">“APPCVM SENDERR (Send Error)” on page 490</a>      |
| SENDREQ   | Requests permission to send data.                                                         | <a href="#">“APPCVM SENDREQ (Send Request)” on page 501</a>    |
| SETMODIFY | Sets the state to Defer_Receive or Defer_Seiver and sets the sync-point control modifier. | <a href="#">“APPCVM SETMODIFY (Set Modify)” on page 505</a>    |
| SEVER     | Ends communications with another program.                                                 | <a href="#">“APPCVM SEVER” on page 509</a>                     |

In addition, some APPC/VM functions are provided as parameters on the IUCV macro. The APPC/VM communications functions used with the IUCV macro are:

- IUCV ACCEPT
- IUCV QUERY
- IUCV SEVER.

The IUCV macro functions relate to both APPC/VM and IUCV paths. The IUCV functions are not defined by the SNA LU 6.2 (APPC architecture) verb interface, but they are a necessary complement for APPC programs executing in a z/VM processor. The IUCV macro functions that relate to APPC/VM are:

| Function  | Description                                                                         | Page                                                       |
|-----------|-------------------------------------------------------------------------------------|------------------------------------------------------------|
| ACCEPT    | Accepts a connection from another virtual machine or from your own virtual machine. | <a href="#">“IUCV ACCEPT” on page 524</a>                  |
| CONNECT   | Establishes a path to the Identify system service (*IDENT).                         | <a href="#">“IUCV CONNECT” on page 529</a>                 |
| DCLBFR*   | Defines an interrupt buffer to prepare for APPC/VM communications.                  | <a href="#">“IUCV DCLBFR (Declare Buffer)” on page 533</a> |
| DESCRIBE* | Gets a description of a pending APPC/VM or IUCV message.                            | <a href="#">“IUCV DESCRIBE” on page 538</a>                |

| Function  | Description                                                                                             | Page                                                           |
|-----------|---------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| I POLL*   | Checks for pending replies or incoming messages.                                                        | <a href="#">“IUCV I POLL (Interrupt Poll)” on page 540</a>     |
| QUERY     | Determines the maximum number of communications paths that can be established for your virtual machine. | <a href="#">“IUCV QUERY” on page 543</a>                       |
| RTRVBFR*  | Undefines the external interrupt buffer, ending communications.                                         | <a href="#">“IUCV RTRVBFR (Retrieve Buffer)” on page 548</a>   |
| SETCMASK* | Enables or disables external interrupts for certain APPC/VM and IUCV control functions.                 | <a href="#">“IUCV SETCMASK (Set Control Mask)” on page 550</a> |
| SETMASK*  | Enables or disables external interrupts for certain APPC/VM and IUCV functions.                         | <a href="#">“IUCV SETMASK” on page 553</a>                     |
| SEVER     | Terminates an APPC/VM or IUCV path or terminates a path established to the *IDENT system service.       | <a href="#">“IUCV SEVER” on page 556</a>                       |
| TESTCMPL* | Determines if any messages or functions have been completed.                                            | <a href="#">“IUCV TESTCMPL (Test Completion)” on page 562</a>  |
| TESTMSG*  | Allows programs to avoid using external interrupt handling.                                             | <a href="#">“IUCV TESTMSG (Test Message)” on page 566</a>      |

**Note:** Other IUCV macro functions can be used from APPC/VM, but are not recommended for use by APPC/VM programs running in CMS. For information about APPC/VM and IUCV macro functions that you can use in CMS, see the [z/VM: CMS Application Development Guide for Assembler](#).

\*These functions have different meanings in a virtual MP environment. For more information about a virtual MP environment, see [“Virtual MP Considerations for APPC/VM Applications” on page 398](#).

## Using Basic APPC/VM Functions

To write starter APPC/VM programs, you need to know the APPC/VM functions that do the basic steps of starting a conversation, communicating in a conversation, and ending a conversation.

### Starting a Conversation

To start a conversation, your user program must issue an APPCVM CONNECT with a resource ID. Depending on the type of connection, a user program also might supply a **connection parameter list extension**, which contains detailed information that is necessary to make a connection. (If the resource ID maps to an entry in a CMS communications directory file, the program generally does not have to build the extension itself, CMS does it.)

When your program issues an APPCVM CONNECT, your communications partner gets a connection pending interrupt. Your partner should examine the interrupt before accepting or rejecting the connection. The interrupt contains information such as the resource ID for which the connection is being made and the user ID of the requesting program.

In addition to the connection pending interrupt, your partner can also get other kinds of data before accepting the connection:

- *Allocate data*, which provides more details about the pending connection
- *Program Initialization Parameters (PIP data)*, which can serve many purposes. (See [Specifying a PIP Variable](#) for more information.)

After examining all this data, your communications partner can do either of the following in response to your connect request:

- Accept the connection if it wants to communicate with your program, making sure to specify the path ID that was on the connection pending interrupt.
- Accept the connection and then immediately sever the connection if it does not want to communicate with your program.

## Sending and Receiving Data on the Conversation

When you issue the command to connect to a target, and your communications partner accepts the connection:

- Your program is in Send state for the conversation.
- Your communications partner's program is in Receive state.

You can now send data, using APPCVM SENDDATA. Your program must set up data in buffers, and the data must be in APPC logical record format. Remember that you can only send data when your program is in Send state and receive data when your program is in the Receive state.

As you send data, your communications partner is notified through one or more message pending interrupts. Your partner can then receive the data using APPCVM RECEIVE.

## Ending a Conversation

When your program is finished communicating with your partner program, you should end the conversation by issuing APPCVM SEVER or IUCV SEVER.

### APPCVM SEVER

You can issue an APPCVM SEVER anytime after you have established a path with your partner (that is, you must first issue a CONNECT and your partner must issue an ACCEPT). At this point your partner will receive a sever interrupt that contains information about the path and any errors that may have occurred during the sever.

You can also include log data on an APPCVM SEVER. This data can be accepted by your partner and used for debugging and error recovery.

After you issue an APPCVM SEVER, your partner can examine the sever interrupt information and:

- Issue an APPCVM SEVER to sever their side of the path.
- If log data is available, issue an APPCVM RECEIVE to obtain that data before severing using IUCV SEVER.
- Issue an IUCV SEVER to sever their side of the path.

### IUCV SEVER

An IUCV SEVER can be issued at any time during a conversation. Usually your partner will receive a sever interrupt which contains information about the path and any errors that may have occurred during the sever.

After receiving an IUCV SEVER, your partner can issue an:

- APPCVM SEVER to sever their side of the path.
- IUCV SEVER to sever their side of the path.

In a CMS environment, you can also use the CMSIUCV macro. For more information on the CMSIUCV macro, see [z/VM: CMS Macros and Functions Reference](#).

## Managing a Resource

For a virtual machine to manage a local, global, or system resource, it must first be authorized to connect to the Identify System Service, \*IDENT. Your system administrator is the person who can authorize your virtual machine to manage a particular resource. To do this, the administrator must specify a special IUCV

\*IDENT statement in your virtual machine's directory entry. For more information on the IUCV directory control statement, see [z/VM: CP Planning and Administration](#).

Your virtual machine must connect to \*IDENT before using it to manage a resource or gateway. This connect should be done using an IUCV CONNECT. For more information on using IUCV CONNECT to connect to \*IDENT, see [“IUCV CONNECT”](#) on page 529.

If your virtual machine becomes a local, global, or system resource manager by establishing a connection to \*IDENT, APPC/VM lets other virtual machines connect to you. The connecting virtual machines must specify, on their connection request, the resource ID you identified through \*IDENT.

\*IDENT maintains a local system resource table. \*IDENT adds an entry to this table each time it accepts a virtual machine connection and deletes the entry when it severs the associated connection. A virtual machine manages a resource only while connected to \*IDENT. (For details on how \*IDENT works, refer to Chapter 16, [“Identify System Service \(\\*IDENT\),”](#) on page 729.)

## Revoking a Resource

To manage a resource, a program must identify the resource name by connecting to \*IDENT. The virtual machine for the program must have proper directory authorization to connect to \*IDENT. A program can also **revoke**—stop management of—a resource name.

A program can revoke a resource it manages by issuing an IUCV SEVER to sever its path to \*IDENT. \*IDENT then deletes the resource from the system resource table and severs its half of the path. Your program then gets an IUCV sever interrupt from \*IDENT. The SEVER does not affect existing APPC/VM paths to your virtual machine.

If another virtual machine connects to \*IDENT to manage the resource that you revoked, requests to connect to the resource go to that virtual machine.

**Note:** If a virtual machine tries to connect to a resource that you manage before your revoke completes, the path may be established.

A program can revoke a resource that *another* program manages by issuing an IUCV CONNECT to \*IDENT with the appropriate user data. The issuing program's virtual machine must have proper directory authorization to connect to \*IDENT and to do this kind of revoke. Your system administrator can authorize your program's virtual machine to revoke a particular resource.

For more information on using IUCV CONNECT to connect to \*IDENT, see [“IUCV CONNECT”](#) on page 529 and to [Chapter 16, “Identify System Service \(\\*IDENT\),”](#) on page 729.

You might have a case where two disjoint TSAF or CS collections merge, and the same resource name is identified (through connections to \*IDENT) by resource managers in both collections. If this happens, the TSAF virtual machine issues a revoke to one of the competing resource managers while ISFC issues revokes to both resource managers. \*IDENT severs the paths to the resource manager programs that own the revoked resources.

## Understanding APPC/VM Parameter Lists

---

**Note:** For more information on IUCV macro functions that can be used on APPC/VM paths, see [Chapter 8, “IUCV Macro Functions for Use in APPC/VM,”](#) on page 521.

Parameter lists for all APPC/VM functions are 40 bytes. Your program can specify a single 40-byte area in storage to use for all APPC/VM function parameter lists. The address of the 40-byte area must be a guest real address in the virtual machine's host-primary address space (guest=real).

The APPCVM and IUCV macros are both in the HCPGPI MACLIB, along with the IPARML DSECT. The APPCVM and IUCV macros use labels defined in IPARML DSECT to complete the parameter list. You need to provide a USING statement for the IPARML COPY file when you invoke the macro, and define proper storage for it.

To reference fields in parameter lists for APPCVM and IUCV functions, always use the name defined for that field in the IPARML DSECT, rather than using the displacement within IPARML DSECT. The parameter lists (IPARML DSECT mappings) are shown with each APPCVM and IUCV macro function.

All address fields in the APPCVM and IUCV parameter lists are 4-byte reserved fields.

## Setting for Optional Parameters

If you do not specify a parameter shown as *optional* when you invoke an APPCVM or IUCV macro function, the macro assumes that you have stored a value in the parameter list before invoking the APPCVM macro. **Therefore, you should set all fields and flag bits in the parameter list that you are not defining for a particular APPCVM or IUCV macro function to 0.** This helps ensure that if these fields are defined in the future, applications will continue to work.

**Note:** There are **no explicit default values** for the optional parameters on the IUCV and APPCVM macros. As such, if a parameter is not specified or is specified with a null value, the value of the field it represents will not be altered by the macro invocation. This allows the actual parameter list to be filled in on multiple macro invocations using the MF=L option. This also allows an application to build a parameter list once using the macro and use it multiple times without having to recode all of the macro parameters. However, please take note of any values that may be altered by function completion.

## Parameters Reserved for IBM Use Only

**You should set all fields and flag bits in the parameter list that are reserved for IBM use only to 0.** Otherwise, unpredictable results may occur. All areas denoted by a series of slashes (//////...) are reserved for IBM use.

## Reading the Parameter Lists

For your reference, the format of input and output parameter lists is shown in this chapter. Parameter lists for APPC/VM functions are 40 (X'28') bytes. These 40 bytes are shown in rows of 8 bytes for easier reading. The numeric values for rows and columns are shown in hexadecimal.

For example, look at the following example parameter list:

|    | 0                    | 1 | 2                    | 3     | 4 | 5                    | 6 | 7 |  |  |  |
|----|----------------------|---|----------------------|-------|---|----------------------|---|---|--|--|--|
| 0  | PARM1                |   | //////////////////// |       |   |                      |   |   |  |  |  |
| 8  | //////////////////// |   |                      |       |   |                      |   |   |  |  |  |
| 10 | //////////////////// |   |                      | PARM2 |   | //////////////////// |   |   |  |  |  |
| 18 | //////////////////// |   |                      |       |   |                      |   |   |  |  |  |
| 20 | //////////////////// |   |                      |       |   |                      |   |   |  |  |  |

PARM1 is in the first 2 bytes of the parameter list, and PARM2 is in byte 19. The slash characters (/) indicate bytes that are reserved for IBM use only and should contain X'00's.

## Formatting the Parameter List with MF=L

If you specify MF=L on a macro, the macro generates the instructions necessary to format the parameter list by using the keyword values provided on the macro. However, the macro does **not** generate any instructions to execute the specified function.

When using CMS support of APPC/VM, it is especially useful for you to use MF=L. For example, to request a connection in CMS, you can issue functions in this sequence:

1. Issue APPCVM CONNECT with MF=L and any other appropriate macro keywords to fully prepare the parameter list.
2. Then issue CMSIUCV CONNECT with any other appropriate macro keywords to invoke the connection request.

Step 1 formats the parameter list, and step 2 invokes the function using the already-formatted parameter list. You can use a similar sequence for these other functions in CMS:

## Condition Codes and Return Codes

- IUCV ACCEPT followed by CMSIUCV ACCEPT
- APPCVM SEVER followed by CMSIUCV SEVER
- IUCV SEVER followed by CMSIUCV SEVER.

If you do not specify MF=L on an APPCVM macro, the macro generates the instructions necessary to:

1. Format the parameter list as specified by parameter values on the macro.
2. Execute the APPC/VM function.

## Registers Altered by APPCVM and IUCV Macro Functions

If you specify MF=L on an APPCVM or IUCV macro function, the macro **may alter R0**. If you do not specify MF=L, **R0 is still altered** and for IUCV functions only **R1 may be altered**.

For more information on macro parameter lists, see [z/VM: CMS Macros and Functions Reference](#).

## Condition Codes and Return Codes

APPCVM macros generate four condition codes and four return codes. This section first gives a summary of the conditions under which each of the 4 return codes are generated followed by a description of each condition code and return codes that APPCVM macro functions generate. See the individual APPCVM macro details for the specific condition codes and return codes generated by each macro.

See Table 68 on page 396 for a summary of the conditions under which each of the 4 return code fields applies. In the figure, an X indicates that the field applies for the corresponding condition code.

Table 68. Applicable Codes Based on the Condition Code

|      | IPRCODE | IPAUDIT | IPCODE | IPWHATRC |
|------|---------|---------|--------|----------|
| CC=0 |         | X       | X      | X        |
| CC=1 | X       |         |        |          |
| CC=2 |         |         | X      | X        |
| CC=3 |         | X       |        |          |

**Note: For CC=0;** IPAUDIT, IPCODE, and IPWHATRC are meaningful in the **function complete interrupt**. (The interrupt signals the completion of the function that started with CC=0.)

**For CC=1, 2, or 3;** IPRCODE, IPAUDIT, IPCODE, and IPWHATRC are meaningful in the **output parameter list** for the function you issued.

## Condition Codes

The condition code (CC) is stored in the program status word (PSW). There are four possible values for condition codes: 0, 1, 2, and 3.

### CC=0

The function has started but has not yet completed. This condition code applies only when WAIT=NO (asynchronous processing). When the function does complete, a virtual machine gets a function complete interrupt.

**Note:** Throughout this section, function complete interrupt is meant to include the connection complete interrupt also.

### CC=1

An error occurred when the function was initiated. In this case, the error code is stored in the IPRCODE field of the output parameter list (see a description of IPRCODE below) and no processing occurred.

**CC=2**

The function has successfully completed with no errors.

**CC=3**

The function has completed, but an error was detected. In this case, the error code is stored in the IPAUDIT field of the output parameter list. (See a description of IPAUDIT below.) This condition code applies only when WAIT=YES (synchronous processing).

See [“Condition Codes and Return Codes for IUCV Macro Functions” on page 522](#) for completions of IUCV functions on APPC/VM paths.

## Return Codes

Four types of return code fields are possible in an APPC/VM environment. The various return codes are stored in either the output parameter list or the function complete interrupt.

Here are the four types of return code fields:

**IPRCODE**

reports error conditions that CP detects when the function is initiated. IPRCODE is a 1-byte field in the output parameter list. A value is placed into IPRCODE when CC=1. Note that IPRCODEs are often given as a result of issuing a function from the wrong state. (For more information about states, see [Table 71 on page 404](#).)

There is no corrective action for this type of error. You should generally sever the path when you get a nonzero value in this field.

**IPAUDIT**

reports error conditions that CP detects between the time that the function is initiated and the time that the function completes. These errors relate to data that is being sent between programs. IPAUDIT is a 4-byte field in the output parameter list and function complete interrupt. IPAUDIT is in the output parameter list (when WAIT=YES and CC=3) or in the function complete interrupt (when WAIT=NO and CC=0).

**IPWHATRC**

contains either a return code or what-received indication caused by your communications partner. IPWHATRC is a 1-byte field in the output parameter list and function complete interrupt.

When IPWHATRC is a what-received indication, IPRCODE contains 0 and serves no purpose. IPWHATRC represents a what-received indication when it contains one of the following:

**X'01'**

Data was received

**X'02'**

Your partner switched the conversation around

**X'04'**

Your partner is requesting confirmation

**X'05'**

Your partner is requesting confirmation that it can issue a SEVER

**X'06'**

Your partner has confirmed your request

**X'0B'**

Allocate data was received

**X'0C'**

Your partner is requesting confirmation that it can enter Receive state

**X'0D'**

Log data was received

**X'0E'**

PIP variable was received.

IPWHATRC represents a return code (with IPCODE) when it contains one of the following:

**X'03'**

Your partner issued SENDERR

**X'08'**

Your partner issued SEVER TYPE=NORMAL

**X'09'**

Your partner issued SEVER TYPE=ABEND.

**IPCODE**

contains the sever or error code caused by your communications partner. IPCODE is a 2-byte field in the output parameter list and function complete interrupt. The value of the IPWHATRC field determines what type of code is in IPCODE. If IPWHATRC is:

- X'09', IPCODE contains a sever code (meaning your partner issued a SEVER TYPE=ABEND). For more information on sever codes, see [“APPC/VM Sever, Error, and Sense Codes That You Can Get” on page 399.](#)
- X'03', IPCODE contains an error code (meaning your partner issued a SENDERR). For more information on error codes, see [“APPC/VM Sever, Error, and Sense Codes That You Can Get” on page 399.](#)

## Virtual MP Considerations for APPC/VM Applications

---

APPC/VM applications can be written to work in a virtual MP environment. The following list is intended to provide some guidance on using APPC/VM in a virtual MP environment.

- APPC/VM functions may be invoked by any virtual processor in the virtual configuration as long as one of the processors has issued an IUCV DECLARE BUFFER function.
- The IUCV DECLARE BUFFER function defines an interrupt buffer for the virtual processor that invokes it.
- In the virtual MP environment, APPC/VM interrupts are treated as "floating" interrupts. Any virtual processor that has one of the following conditions may receive an APPC/VM interrupt:
  - issued an IUCV DECLARE BUFFER
  - enabled to receive APPC/VM interrupts with the CR0 setting
  - enabled for APPC/VM interrupts with the SETMASK and SETCMASK functions
- The IUCV RETRIEVE BUFFER function will only retrieve the buffer for the currently running virtual processor. APPC/VM paths will not be SEVERed until the last virtual processor issues an IUCV RETRIEVE BUFFER.
- The IUCV SETMASK and SETCMASK functions will apply only to the virtual processor on which they are invoked. This will allow an application to force different types of APPC/VM interrupts to different virtual processors in the complex, if so desired.
- The following are associated with the virtual configuration:
  - APPC/VM directory specifications
  - APPC/VM paths
  - APPC/VM interrupts
  - APPC/VM messages.
- The following are associated with the virtual CPU:
  - the application buffer, the control interrupt buffer, and the interrupt buffer extension
  - interrupt enablement masks in the virtual PSW and virtual control register 0 (bit 30)
  - the interrupt enablement masks of SETMASK and SETCMASK
- The IUCV DESCRIBE, TEST COMPLETE, and IPOLL functions will complete on any processor in the virtual complex as long as one virtual processor has issued an IUCV DECLARE BUFFER (it does not have to be the virtual processor that issued the DESCRIBE, TEST COMPLETE, or IPOLL function).

- If multiple virtual processors in the complex issue the IUCV TEST MESSAGE function, it is unpredictable in which order the virtual processors will be taken out of their wait states.
  - All addresses specified with APPC/VM parameter lists are guest absolute addresses.
  - Without appropriate guest operating system support, it is difficult or impossible to use APPC/VM in a virtual MP environment. This support would allow your application to:
    - declare buffers on different processors
    - enable for APPC/VM interrupts on the needed processors
    - handle the interrupts and route them to the appropriate virtual processor.
- Note that CMS does not currently support APPC/VM virtual MP functions.

## APPC/VM Sever, Error, and Sense Codes That You Can Get

After issuing an APPCVM macro function, your program could get a special problem code returned in bytes 4 and 5 (the IPCODE field) of the output parameter list/function complete interrupt. This 2-byte code is a sever, error, or sense code, originating from your communications partner, intermediate communications server, or VM system.

Sever, error, and sense codes can be reported on completion of the following APPCVM macro functions: CONNECT, RECEIVE, SENDCNF, SENDDATA, or SENDERR.

### Currently-Defined APPC/VM Sever Codes

See [Table 69 on page 399](#) for a list of all the APPC/VM sever codes that your application program can get at the current time. Sever codes can come from your communications partner, from your VM system, or from an intermediate communications server. Note that these sever codes can come from VTAM® or other SNA network components. (The sever codes that are generated by VM are listed in [Table 70 on page 400](#) and are a subset of those listed in [Table 69 on page 399](#).)

The corresponding APPC error condition is given for each APPC/VM sever code; refer to the *SNA Transaction Programmer's Reference Manual for LU Type 6.2* for a description of each APPC error condition.

*Table 69. Possible APPC/VM Sever Codes*

| APPC/VM Sever Code        | APPC Error Condition            |
|---------------------------|---------------------------------|
|                           | ALLOCATION_ERROR                |
| X'0110'                   | ALLOCATION_FAILURE_NO_RETRY     |
| X'0111'                   | ALLOCATION_FAILURE_RETRY        |
| X'0112'                   | UNSUCCESSFUL                    |
| X'0120'                   | CONVERSATION_TYPE_MISMATCH      |
| X'0130'                   | SYNC_LEVEL_NOT_SUPPORTED_BY_PGM |
| X'0131'                   | SYNC_LEVEL_NOT_SUPPORTED_BY_LU  |
| X'0140'                   | TRANS_PGM_NOT_AVAIL_NO_RETRY    |
| X'0141'                   | TRANS_PGM_NOT_AVAIL_RETRY       |
| X'0142'                   | TPN_NOT_RECOGNIZED              |
| X'0150'                   | PIP_NOT_SPECIFIED_CORRECTLY     |
| X'0151'                   | PIP_NOT_ALLOWED                 |
| X'0160'                   | SECURITY_NOT_VALID              |
| X'0210'                   | DEALLOCATE_ABEND_PROG           |
| X'0220', X'0221', X'0222' | DEALLOCATE_ABEND_SVC            |

Table 69. Possible APPC/VM Sever Codes (continued)

| APPC/VM Sever Code | APPC Error Condition                                        |
|--------------------|-------------------------------------------------------------|
| X'0230'            | DEALLOCATE_ABEND_TIMER                                      |
| X'0301'            | PARAMETER_ERROR                                             |
| X'0302'            | Invalid LU name                                             |
|                    | Invalid mode name                                           |
| X'0610' (Note 1)   | RESOURCE_FAILURE_NO_RETRY or<br>ALLOCATION_FAILURE_NO_RETRY |
| X'0620' (Note 2)   | RESOURCE_FAILURE_RETRY or<br>ALLOCATION_FAILURE_RETRY       |

**Notes:**

1. X'0610' resulting from APPCVM CONNECT corresponds to ALLOCATION\_FAILURE\_NO\_RETRY; from all other functions, X'0610' corresponds to RESOURCE\_FAILURE\_NO\_RETRY.
2. X'0620' resulting from APPCVM CONNECT corresponds to ALLOCATION\_FAILURE\_RETRY; from all other functions, X'0620' corresponds to RESOURCE\_FAILURE\_RETRY.

## Sever Codes Generated by VM

Your program can get sever codes generated from the CP, CMS, TSAF, or AVS components on VM. See Table 70 on page 400 for a list of these sever codes and some possible causes for each sever code. See Table 69 on page 399 for the APPC error condition that corresponds to each of these APPC/VM sever codes.

Your program can also get sever codes from AVS that AVS is just passing along from VTAM or other SNA network component. See Table 69 on page 399 for a list of sever codes you can receive.

**Note:** It is important to note that the possible causes shown for each code may not be an exhaustive list.

| Table 70. Sever Codes Generated by VM |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Currently-Defined Error Codes

The following table summarizes the error codes that you can get in an APPC/VM program.

For each APPC/VM-defined error code shown in this section, the APPC error condition is given. For more information of each APPC error condition, see *SNA Transaction Programmer's Reference Manual for LU Type 6.2*.

| APPC/VM Code | APPC Error Condition |
|--------------|----------------------|
| X'0410'      | PROG_ERROR_NO_TRUNC  |
| X'0420'      | PROG_ERROR_TRUNC     |
| X'0430'      | PROG_ERROR_PURGING   |
| X'0510'      | SVC_ERROR_NO_TRUNC   |
| X'0520'      | SVC_ERROR_TRUNC      |
| X'0530'      | SVC_ERROR_PURGING    |

## Currently-Defined Sense Code

The following table shows the sense code that you can get in an APPC/VM program. Refer to the *SNA Transaction Programmer's Reference Manual for LU Type 6.2*, for a description of the APPC BACKOUT condition.

| APPC/VM Code | APPC Error Condition |
|--------------|----------------------|
| X'0824'      | BACKOUT              |

The *z/VM: CMS Application Development Guide for Assembler* contains programming information, scenarios, and sample programs that illustrate how to write APPC/VM programs using these APPCVM macro functions.

## State Table for APPC/VM Functions

The basic states for APPC/VM assembler programs are:

### Reset

The state for each program before communications begin and after communications end

### Connect

The state for a source program after a connection has been started but before it has completed, or the state for a target program after it has received a connection pending interrupt but before it has accepted.

### Send

The state in which a program is allowed to send data

### Receive

The state in which a program is ready to receive data

### Confirm

The state in which a program must respond to its communications partner

### Sever

The state a program is in when its partner stops communications.

These APPC/VM states are based on the states that APPC defines, but there are two differences:

- The Connect state is unique to APPC/VM
- The Sever state is analogous to the APPC Deallocate state.

The following table summarizes general APPC/VM functions that can be issued from the basic APPC/VM states.

*Table 71. APPC/VM States*

| <b>State</b> | <b>When the State Occurs</b>                                                                                                                                                                                                                                                                                                                                                                                                  | <b>Functions You Can Issue</b>                                                                                                                                                                                                                                                                                                                                   |

Table 71. APPC/VM States (continued)

| State | When the State Occurs                                                                                                                                                                                                                                                                                                        | Functions You Can Issue                                                     |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| Sever | <ul style="list-style-type: none"> <li>After a SEND or RECEIVE completes with an indication that your communications partner issued a SEVER.</li> <li>After your SENDCNF TYPE=SEVER is completed by your partner's SENDCNFD.</li> <li>After you issue SENDCNFD, in response to your partner's SENDCNF TYPE=SEVER.</li> </ul> | APPCVM SEVER TYPE=NORMAL<br>IUCV SEVER<br>APPCVM RECEIVE<br>APPCVM QRYSTATE |

In addition, APPC/VM defines several other states for special programs involved with coordinated resource recovery. The additional states for APPC/VM assembler programs are:

**Defer\_Receive**

The state a program is in after issuing SETMODIFY TYPE=RECEIVE.

**Defer\_Seuer**

The state a program is in after issuing SETMODIFY TYPE=SEVER.

**Prepare\_Receive**

The state a program is in when a RECEIVE or SENDDATA RECEIVE=YES function completes with IPWHATRC=IPPREPAR, an indication that the partner initiated a commit sync-point.

**Unsolicited\_Request\_Commit\_Received**

The state a program is in when a RECEIVE or SENDDATA RECEIVE=YES function completes with IPWHATRC=IPREQCOM, an indication that the partner initiated a commit sync-point.

**Backout\_Received**

The state a program is in when a function completes with IPWHATRC=IPBACK, an indication of a backout sync-point.

**Backout\_Required**

The state a program is in when CMS is backing out the CMS work unit.

The following table summarizes these states:

Table 72. APPC/VM States for Coordinated Resource Recovery

| State            | When the State Occurs                                                                                                                                                           | Functions You Can Issue                                                                                                              |

## Examples of Basic States

The following examples show one way that you can get into each of the APPC/VM basic states.

**Reset State:** After the path is established,

|                                                                                         |        |
|-----------------------------------------------------------------------------------------|--------|
| USER1:                                                                                  | USER2: |
| <ul style="list-style-type: none"> <li>issues APPCVM SEVER and receives CC=2</li> </ul> |        |

At this point, USER1 is in Reset state.

**Connect State:** After IUCV DCLBFR and an identification of a resource by USER2 has already been performed,

|                                                                                           |                                         |
|-------------------------------------------------------------------------------------------|-----------------------------------------|
| USER1:                                                                                    | USER2:                                  |
| <ul style="list-style-type: none"> <li>issues APPCVM CONNECT and receives CC=0</li> </ul> |                                         |
|                                                                                           | checks the connection pending interrupt |

At this point, USER1 and USER2 are in Connect state.

**Send State:** After IUCV DCLBFR and an identification of a resource by USER2 has already been performed,

|                                                                                           |                                                                                                                                    |
|-------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| USER1:                                                                                    | USER2:                                                                                                                             |
| <ul style="list-style-type: none"> <li>issues APPCVM CONNECT and receives CC=0</li> </ul> |                                                                                                                                    |
|                                                                                           | <ul style="list-style-type: none"> <li>checks the connection pending interrupt</li> <li>issues ACCEPT and receives CC=0</li> </ul> |

- checks the connection complete interrupt

At this point, USER1 is in Send state.

**Receive State:** After IUCV DCLBFR and an identification of a resource by USER2 has already been performed,

USER1:

- issues APPCVM CONNECT and receives CC=0

USER2:

- checks the connection pending interrupt
- issues ACCEPT and receives CC=0

- checks the connection complete interrupt

At this point, USER2 is in Receive state.

**Confirm State:** After a path is established with SYNCLVL=CONFIRM,

USER1:

- issues APPCVM SENDCNF and receive CC=0

USER2:

- checks the message pending interrupt
- issues RECEIVE and receives CC=2

At this point, USER2 is in Confirm state.

**Sever State:** After a path is established,

USER1:

- issues APPCVM SEVER and receives CC=2

USER2:

- checks the sever interrupt
- issues RECEIVE and receives CC=2

At this point, USER2 is in Sever state.

## State Table for Error Conditions

If you issue a function from the wrong state, you receive an IPRCODE. The IPRCODE tells you the error condition that CP detected when the function was initiated. The IPRCODE you receive depends on the function you issued and the state from which you issued it.

The following table lists the basic APPC/VM functions and the IUCV functions that you can use in APPC/VM. The numbers across the top of [Table 73 on page 408](#) correspond to the following states or conditions:

| Number | State or Condition |
|--------|--------------------|
| 1      | Reset              |

## State Table for APPC/VM Functions

- 2** Connect
- 3** Send
- 4** Receive
- 5** Confirm
- 6** Sever
- 7** Defer\_Receive
- 8** Defer\_Seuer
- 9** Prepare\_Received
- 10** (For IBM use only)
- 11** Unsolicited\_Request\_Commit\_Received
- 12** (For IBM use only)
- 13** Backout\_Received
- 14** Backout\_Required
- 15** (For IBM use only)
- 16** (For IBM use only)
- 17** Synchronization level is not SYNCPT.

The following matrix shows which APPC/VM functions can be invoked from each defined state. The number in the box indicates the IPRCODE (in decimal) given when a function is issued from a particular state. An X in the box indicates that no IPRCODE is issued because of the function issued from that particular state. If a number and an X appear in a box then the IPRCODE is conditional.

## Chapter 7. APPCVM Macro Functions

This chapter describes in detail the following APPCVM macro functions:

- CONNECT
- QRYSTATE (Query State)
- RECEIVE
- SENDCNF (Send Confirm)
- SENDCNFD (Send Confirmed)
- SENDDATA
- SENDERR (Send Error)
- SENDREQ (Send Request)
- SETMODIFY
- SEVER.

If you are unfamiliar with reading syntax diagrams, see [“Syntax, Message, and Response Conventions”](#) on page xxxv.

---

### Using the Online HELP Facility for APPCVM Functions

You can receive online information about the APPCVM macro functions by using the z/VM HELP Facility. For example, to display a menu of the APPCVM macro functions, enter:

```
help appcvm menu
```

To display information about a specific APPCVM macro function (CONNECT in this example), enter:

```
help appcvm connect
```

For more information about using the HELP Facility, see [z/VM: CMS User's Guide](#). To display the main HELP task panel, enter:

```
help
```

For more information about the HELP command, see [z/VM: CMS Commands and Utilities Reference](#) or enter:

```
help cms help
```

## APPCVM CONNECT

### Purpose

Use the **CONNECT** function to establish a communication path with a program residing in either your own virtual machine, another virtual machine in your TSAF or CS collection, or in an SNA network.

**Note:** If an external security manager is installed on your system, you may not be authorized to use this function. For additional information, contact your security administrator.

## Parameters

### Required Parameter:

#### PRMLIST=

Lets you specify the address of the APPC/VM parameter list. The address must be a guest real address; that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

#### *label*

Is the relocatable label of the parameter list.

#### *(reg)*

Is the register number that contains the address of the parameter list.

### Optional Parameters:

#### MF=L

Generates the instructions necessary to initialize the APPC/VM parameter list as specified, but does not invoke the APPCVM CONNECT.

#### CONTROL=

Lets you specify whether a control path is being established. Control paths allow interrupt information for your half of the path to be placed in the control buffer.

#### YES

Sends APPC/VM interrupt information on this path to the control buffer.

**Note: Do not specify CONTROL=YES in application programs running in CMS; CMS uses control paths.**

#### NO

Sends APPC/VM interrupt information on this path to the application buffer.

#### RESID=

Lets you specify a 1- to 8-character resource identifier. Your program will be connected to the program that manages the resource. If the resource ID you specify is less than eight bytes, left-justify the value in this field and pad the right with blanks.

#### *label*

Is the relocatable label of the storage area that contains the resource ID.

#### *(reg)*

Is the register number that contains the address of the storage area. This storage area contains the resource ID.

The RESID value you specify here either specifies the target transaction program name (TPN), or it is resolved into a transaction program name and additional allocation data using a CMS communication directory file. When CMS resolves the TPN, CMS replaces the RESID value specified in IPRESID with the first 8 bytes of the TPN.

#### Notes:

1. The RESID (or the RESID resolved by CMS) must match the TPN. If the TPN is longer than 8 bytes, then just the first 8 bytes must match. If the TPN is less than 8 bytes, then the TPN is padded to the right with blanks for the compare.
2. The RESID value (or resolved TPN) should be the same as the resource manager program name required by the CMS interface to assembler APPC/VM (the NAME parameter on the HNDIUCV and CMSIUCV macros).
3. RESIDs beginning with a period (.). The . character must be reserved for recovery servers.

#### SYNCLVL=

Lets you specify the synchronization level for the path being established.

**NONE**

Does not let either communication partner request confirmation (issue SENDCNF or SENDCNFD) on the path this connection is establishing.

**CONFIRM**

Lets either communication partner request confirmation (issue SENDCNF or SENDCNFD) on the path this connection is establishing.

**SYNCPT**

Specifies that this path can have SYNCPT synchronization level.

**Notes:**

1. SYNCPT also allows either communication partner to issue confirmation functions (SEDCNF, SENDCNFD).
2. CP rejects connections attempted with SYNCLVL=SYNCPT if the resource manager is located in a TSAF or CS collection.
3. CMS does not allow SYNCLVL=SYNCPT specified on control paths.

**WAIT=**

Lets you specify when control is returned to your virtual machine.

**YES**

Returns control to your virtual machine after the CONNECT completes.

**NO**

Returns control to your virtual machine as soon as the CONNECT request is initiated. When the CONNECT completes, you are notified by a connection complete interrupt. You can issue any APPC/VM function on any path, except the path that you are trying to establish with the CONNECT; the only function that you can issue on the path you are trying to establish is IUCV SEVER.

**BUFFER=**

Lets you specify the starting address of the connection parameter list extension. This extension either contains actual allocate data (VM area, FMH5, and VM-defined variable-length section) or information that CP uses to build the allocate data. This buffer address must be a *guest* real address (real to the virtual machine).

***label***

Is the relocatable label of the storage area that contains the connection parameter list extension.

***(reg)***

Is the register number that contains the address of the storage area. This storage area contains the connection parameter list extension.

If you wish to invoke a connection using communication directory resolution (COMDIR=YES on CMSIUCV CONNECT), you do not need to specify this BUFFER address. However, if you want communication directory resolution without invoking a connection (CMSIUCV RESOLVE), you must specify this BUFFER address.

**BUFLEN=**

Is a 4-byte field that specifies the length of the area containing the connection parameter list extension.

***label***

Is the relocatable label of the storage area that contains the length.

***(reg)***

Is the register number that contains the length of the storage area.

If you specify FMH5=NO, you are passing CP information it needs to build the allocate data needed by your communication partner. The value you specify for BUFLEN depends on how you want the connection parameter list extension created.

1. If you are explicitly creating the extension, the valid lengths for BUFLEN are 0, 16, 32, 56, 120, 128, or 160 bytes. If you supply fewer bytes than any of these values, the remaining bytes are

considered to be omitted. When SYNCLVL=SYNCPT and FMH5=NO, or when you use PIP data, BUFLLEN must be 160.

2. If you wish to invoke a connection using CMS communication directory resolution (COMDIR=YES on CMSIUCV CONNECT), you do not need to specify BUFLLEN.
3. If you want communication directory resolution without invoking a connection (CMSIUCV RESOLVE), BUFLLEN must be set to at least 120 bytes.

If you specify FMH5=YES (allowed only for communication servers), this means you are directly passing the allocate data needed by your communication partner. The allocate data consists of a VM area, an FMH5, and a VM-defined variable-length section. In addition, if a communication server is passing a PIP variable, it needs to include the length of the VM communication server area (8-bytes) in the BUFLLEN total. As a result, BUFLLEN can vary from 43 to 911 bytes for a communication server.

See [Considerations for Communications Servers](#) for more details.

#### **TYPE=**

lets you specify the conversation type being established by the invoker.

##### **BASIC**

indicates that a basic conversation is being allocated.

##### **MAPPED**

Indicates that a mapped conversation is being allocated.

**Note:** It is the programmer's responsibility to format and interpret the data according to the connection type specified here. Refer to [“APPCVM SENDDATA” on page 475](#).

#### **RETURN=**

lets you specify whether the SNA communication server should wait for a session to become available or should return immediately if no suitable session is available. This operand applies only to connections outside of a TSAF collection.

##### **ALLOCD**

indicates that an SNA session should be allocated for the conversation before control is returned to the invoker.

##### **IMMED**

indicates that an SNA session should be allocated for the conversation only if a suitable session is immediately available.

#### **LOGDATA=**

lets you specify whether your connecting program receives log data on the path being established.

##### **YES**

Indicates that the connecting program receives log data.

##### **NO**

Indicates that the connecting program does not receive log data. In this case, CP does not log the data for the program.

#### **Communication Server Parameters:**

##### **ALTID=**

is the 8-byte user ID of the virtual machine that made the original connection for which the communication server is establishing the path. If the user ID that you specify is less than eight bytes, left-justify the value in this field and pad the right with blanks.

##### ***label***

Is the relocatable label of the storage area that contains the user ID.

##### ***(reg)***

Is the register number that contains the address of the storage area. This storage area contains the user ID.

**Note:** Only virtual machines authorized as communication servers can specify ALTID. (Refer to [Considerations for Communications Servers](#).)

**FMH5=**

indicates whether your program's connection parameter list extension (specified by the BUFFER=keyword) contains actual allocate data or information that CP uses to build the allocate data. Actual allocate data consists of a VM area, an FMH5 (Function Management Header Type 5) area, and a VM-defined variable-length section.

**NO**

indicates that information in the connection parameter list extension is being supplied so that CP can build the allocate data for you.

You should specify FMH5=NO if you want to invoke the connection using the CMS communication directory (COMDIR=YES on the CMSIUCV CONNECT), or if you just want communication directory resolution without invoking a connection (CMSIUCV RESOLVE). In these two cases, CMS fills in the extension from the information in the communication directory file.

If your program is explicitly supplying the connection extension so that CP can build the allocate data, refer to [CONNECT Input Parameter List Extension](#) for a description on how you must set up this extension.

**YES**

indicates that your program is a communication server, and it is supplying allocate data (a VM area, an FMH5, and a VM-defined variable-length section) and possibly a VM communication server area in the connection parameter list extension. See [Considerations for Communications Servers](#) for more information.

**Note:** If you specify FMH5=YES, CMS communication directory resolution is disabled on any subsequent CMSIUCV CONNECT or CMSIUCV RESOLVE functions.

**Input Parameter List:** The APPCVM CONNECT parameter list has the input format shown in the following figure when establishing APPC paths:

Figure 22. APPCVM CONNECT Input Parameter List

**IPFLAGS1**

may contain one or more of the following input bit flags:

**IPAPPC (X'08')**

APPC protocol is used on the path.

**IPCNTL (X'04')**

a control path is being established.

**X'80'**

this value is reserved for IBM use only.

**IPFLAGS2**

may contain one or more of the following input bit flags:

**IPWAIT (X'80')**

the connecting program specified WAIT=YES (meaning a synchronous connection).

**IPLVLCF (X'40')**

a synchronization level of CONFIRM is permitted.

**Note:** If this bit is on, IPSYNCPPT must be off.

**IPCOMSRV (X'20')**

This connection is being made for another user. This flag is set when the ALTID keyword is specified. See [Considerations for Communications Servers](#).

**IPMAPPED (X'10')**

A mapped conversation is being created.

**IPFMH5 (X'08')**

A connection parameter list extension contains the VM area, the FMH5 area, and a VM-defined variable-length section.

**IPLOGDOK (X'04')**

The connecting program specified LOGDATA=YES.

**IPIMMED (X'02')**

The connecting program specified RETURN=IMMED.

**IPSYNCPT (X'01')**

SYNCLVL=SYNCPT is specified for the conversation.

**Note:**

1. A synchronization level of CONFIRM is also permitted on this conversation.
2. If this bit is on, IPLVLCF must be off.

**IPVMID**

is the user ID that this connection is made for. Only communication servers can supply this parameter. This field is set from the user ID value specified with the ALTID parameter. See [Considerations for Communications Servers](#).

**IPRESID**

is the name of the 1- to 8-character resource identifier. Your program is connected to the program that manages the resource. If IPRESID is less than eight bytes, left-justify the value in this field and pad the right with blanks.

IPRESID either specifies the target transaction program name (TPN), or it is resolved into a transaction program name and additional allocation data using a CMS communication directory file. When CMS resolves the TPN, CMS replaces the IPRESID value specified in IPRESID with the first 8 bytes of the TPN.

**Notes:**

1. The IPRESID (or the IPRESID resolved by CMS) must match the TPN. If the TPN is longer than 8 bytes, then just the first 8 bytes must match. If the TPN is less than 8 bytes, then the TPN is padded to the right with blanks for the compare.
2. IPRESID (or resolved TPN) should be the same as the resource manager program name required by the CMS interface to assembler APPC/VM (the NAME parameter on the HNDIUCV and CMSIUCV macros).

**IPBFADR2**

is the address of the connection parameter list extension.

**IPBFLN2F**

is the length of the connection parameter list extension.

For a communication server (where FMH5=YES), this must include the allocate data length and, if applicable, the length of the VM communication server area. (See [Considerations for Communications Servers](#).)

**Input Parameter List Extension:** If your program specifies FMH5=NO on APPCVM CONNECT, it wants CP to build the allocate data (the VM area, the FMH5 area, and the VM-defined variable-length section) that your communication partner needs. In this case, your program can supply CP with the connection parameter list extension data shown in this section.

**Does Your Program Need to Make This Extension?:**

Your program **does not** have to actually build a connection parameter extension as shown in this section if any of the following are true:

- 1. Your program is an intermediate communication server that specifies FMH5=YES on the connection. (Refer to [Considerations for Communications Servers](#).)
- 2. Your program does not specify a PIP variable and requests a connection using CMS communication directory resolution (COMDIR=YES on CMSIUCV CONNECT) to resolve the RESID on APPCVM CONNECT. In this case, CMS provides an extension for you; your program's APPCVM CONNECT does not have to specify BUFFER or BUFLen.
- 3. Your program just requests to resolve RESID using the CMS communication directory, without invoking a connection (CMSIUCV RESOLVE). In this case, CMS fills in the extension for you; your program's APPCVM CONNECT must specify a BUFFER and a BUFLen of at least 120 bytes.

If your program is building its own connection parameter list extension, it should include a USING statement for the IPARMLX COPY file and define proper storage for this file. (The IPARMLX COPY file is contained in the HCPGPI MACLIB.) IPARMLX contains labels that your program can refer to in the connection parameter list extension.

Certain fields of the connection parameter list extension can be omitted. There are two ways you can indicate this, you can specify a:

- Field as binary zeros.
- Connection parameter list extension length (BUFLen), which is less than the displacement of that field into the extension. For example, if you specify a BUFLen of 0, all fields are considered to be omitted. If you specify a BUFLen of 16, the first 16 bytes of the extension are used, and the fields in the remaining bytes are considered to be omitted. Note that the length must still be a valid lengths for the BUFLen parameter. See the description of BUFLen.

The format of the connection parameter list extension is shown in the following figure.

Figure 23. Connection Parameter List Extension

**IPXMODE**

contains the **mode name**. This is an 8-byte field, left-justified and padded with blanks as necessary.

When the target LU name, IPXTRGLU or IPXLKLU, is omitted (a connection within a TSAF or CS collection), the mode name identifies the type of communication server being used:

- VMINT or binary zeros (the default) identifies an interactive communication server.
- VMBAT identifies a batch-oriented communication server. A path with a mode name of VMBAT gives messages or files a lower priority than messages or files over VMINT or regular TSAF virtual machine session paths.

If an outbound connection through AVS is being requested and the LU name qualifier (gateway name) is specified in the connection parameter list extension, the mode name can be any mode name that is valid for the locally known LU name specified in IPXLKLU. Information on mode name is in *SNA Transaction Programmer's Reference Manual for LU Type 6.2*.

## IPXLKLU

contains the **locally known LU name**. The locally known LU name is a 16-byte field that is made up of these two pieces:

- IPXLQUAL—an 8-byte **LU name qualifier**
- IPXTRGLU—an 8-byte **target LU name**.

Both these 8-byte fields are left-justified and padded with blanks as necessary.

The meaning of the target LU name depends on the LU name qualifier and the type of connection:

- *Connection to a local, system, or global resource:* If the LU name qualifier is \*IDENT, the resource manager program (IPRESID) has already identified itself to the TSAF or CS collection as a local, global, or system resource using the Identify system service (\*IDENT). The connection is routed to the local, global, or system resource manager program. If the LU name qualifier is omitted, then it is assumed to be \*IDENT. The target LU name must be omitted if the LU name qualifier is \*IDENT or is omitted.
- *Connection to a private resource:* If the LU name qualifier is \*USERID, then the target LU name is the user ID of the private server virtual machine. The connection is routed to the private resource manager program (IPRESID), which is located in the virtual machine named in the target LU name field.

**Note:** Private resource connections to recovery servers (IPRESID is X'06F2', or whose first character is a period .) are treated differently.

- *Connection to a specific system:* If the LU name qualifier is a system gateway name of a system in the TSAF or CS collection, then the connection is routed to this specific system. If the target LU name is binary zeros, then the target system routes the connection to either the system or global resource manager that identified the resource specified in the IPRESID field. If the target LU name is not binary zeros, then the target system routes the connection to the private resource manager whose user ID is the target LU name. The connection is only completed if the resource manager resides on the specified system.
- *Connection to a resource in the SNA network:* The LU name qualifier is a gateway name. The target LU name is the name of an LU in the SNA network, and resource name (IPRESID) is the name of a transaction program at the remote LU. If the gateway name has already been identified to the Identify system service (\*IDENT), then the connection is routed to the specified gateway, and the target LU name is presented to the AVS virtual machine that defined the gateway. The gateway uses the target LU name to allocate the conversation for the invoker of the connect.

The connection is rejected if the LU name qualifier is one of the following:

- A gateway name, and that gateway is not owned by a virtual machine
- \*IDENT, and the resource is not owned by a virtual machine.

For a summary of the connections, given a LU name qualifier and target LU name, see [Table 74 on page 420](#).

Table 74. Summary of Locally Known LU Names

| Locally Known LU Name |                |               |                                                                                                                 |
|-----------------------|----------------|---------------|-----------------------------------------------------------------------------------------------------------------|
| LU Name Qualifier     | Target LU Name | IPRESID Value | Connection Made To:                                                                                             |
| *IDENT                | Omitted        | X             | Local, global, or system resource X                                                                             |
| *USERID               | <i>userid</i>  | Y             | Private resource Y                                                                                              |
| G                     | L              | Z             | Transaction program Z residing at LU L accessed through gateway G                                               |
| SYSGATE               | Omitted        | X             | A global or system resource X on the system in the TSAF or CS collection that owns the system gateway, SYSGATE. |
| SYSGATE               | <i>userid</i>  | Y             | A private resource Y on the system in the TSAF or CS collection that owns the system gateway, SYSGATE.          |

**IPXSTYPE**

indicates the **access security type** of the connection.

**IPXSSAME (X'00')**

SECURITY(SAME) is specified.

The target of the connection receives a connection pending interrupt with the source user ID in the IPV MID field. The source user ID is one of the following:

- The logon user ID of the virtual machine issuing the CONNECT
- An alternate user ID specified by a virtual machine issuing DIAGNOSE code X'D4'
- The user ID specified on the ALTID keyword (from intermediate servers)

If the target LU is a TSAF collection, the source user ID is sent to the target program in the connection pending interrupt and the already verified flag set in the FMH5. If the target LU is in the SNA network, the source user ID is sent to the target LU with the already verified flag set in the FMH5. If the target LU does not support the already verified option, the local LU downgrades the security information to the equivalent of SECURITY(NONE).

**IPXSNONE (X'01')**

SECURITY(NONE) is specified.

The target of the connection receives a connection pending interrupt with binary zeros in the IPV MID field and an FMH5 with no security fields.

1. If the LU name qualifier is \*IDENT, the connection is rejected, unless the resource specified that it would receive connections with SECURITY(NONE) when it connected to \*IDENT.
2. If the LU name qualifier is \*USERID, the connection is made to the private resource manager, who may or may not reject the connection depending on the CMS authorization list (in the \$SERVER\$ NAMES file) for that private resource.
3. If the LU name qualifier is not \*IDENT or \*USERID (meaning a connection to a program in the SNA network), the connection is routed to the specified gateway to be sent to the remote LU.

**Note:** The following two paragraphs apply to IPXSPGM, IPXSPGLU, and IPXSPGU.

If the LU name qualifier is \*IDENT or \*USERID, the security fields are validated in the TSAF or CS collection. If the access user ID and password are valid, the access user ID (not the user ID of the virtual machine issuing the CONNECT) is specified as the user ID in the IPV MID field of the connection pending interrupt and in the FMH5. The virtual machine issuing the CONNECT must have directory authorization to connect to the target virtual machine; however, when the

connection is to a private resource and the user ID of the target private server is the same as the access user ID, no authorization is needed.

If the LU name qualifier is not \*IDENT or \*USERID, the remote LU validates fields in the security area. If the remote LU is a TSAF or CS collection, the collection validates the access user ID and password, the target program gets an FMH5 containing the user ID and the already verified flag set.

#### **IPXSPGM (X'02')**

SECURITY(PGM) is specified; the access user ID and password are both supplied in this extension. (The user ID is in field IPXSUSER; the password is in IPXSPSWD.)

#### **IPXSPGLU (X'03')**

SECURITY(PGM) is specified; and the access user ID and password are taken from the invoker's APPCPASS directory statement.

The APPCPASS directory statement used must have a locally known LU name that matches the locally known LU name supplied in the connection parameter list extension (field IPXLKLU). If there are multiple APPCPASS directory statements in the invoker's directory entry with matching LU names, the user ID and password in the first match are used.

#### **IPXSPGUS (X'04')**

SECURITY(PGM) is specified; the access user ID is supplied in field IPXSUSER of this extension, and the access password is taken from the invoker's APPCPASS directory statement.

The APPCPASS directory statement used must have a locally known LU name that matches the locally known LU name supplied in field IPXLKLU and a user ID that matches the user ID supplied in field IPXSUSER. If there are multiple APPCPASS directory statements in the invoker's directory entry with a matching locally known LU name and access user ID, then the password in the first match is used.

**Note:** This lets a single user have multiple user IDs at a given LU, each with a different password.

#### **IPXTPNL**

is the **length of the transaction program name** (which is contained in field IPXTPN). The length can be 0 to 64 bytes.

#### **IPXFLAG**

may contain the following flag:

#### **IPXPBUFL (X'40')**

specifies that the PIP address field (IPXPADR) contains the address of a list of buffer addresses and lengths for the PIP variable. (Refer to [Specifying a PIP Variable](#) for more information.)

#### **IPXLUWL**

is the length (in bytes) of the logical-unit-of-work identifier fields defined in the IPXLUW field. Values 0 and 10 through 26 are valid. CMS fills in this field for APPC/VM programs that use SYNCLVL=SYNCPT paths.

#### **IPXSUSER**

is the **access security user ID**.

This area is valid only when IPXSTYPE is IPXSPGM, IPXSPGLU, or IPXSPGUS (indicating a security type of PGM).

#### **IPXSPSWD**

is the **access security password**.

This area is valid only when IPXSTYPE is IPXSPGM, IPXSPGLU, or IPXSPGUS (indicating a security type of PGM).

**Note:** The target virtual machine never receives the password. When the password is supplied, CP verifies the password and sends the verified user ID to the resource manager program. If the password being verified by CP is LBYONLY then the password validation, and subsequently the CONNECT, will fail. Refer to the USER or IDENTITY directory statement in [z/VM: CP Planning and Administration](#) for more information about the LBYONLY operand.

**IPXTPN**

is the **transaction program name** (TPN). This must be a 64-byte field. (IPXTPNL describes the actual length of this name.)

If the TPN length (IPXTPNL) is 0 or omitted, CP places:

- 8 into the transaction program name length field (CPEFTPNL) of the FMH5
- The RESID value from the APPCVM CONNECT into the transaction program name field (CPEFTPN) of the FMH5.

Any value specified in IPXTPN is not used.

If the length is not 0, CP places:

- The value from IPXTPNL into the transaction program name length field (CPEFTPNL) of the FMH5
- The value from IPXTPN into the transaction program name field (CPEFTPN) of the FMH5. Even though CP places IPXTPN into the FMH5, the RESID value on APPCVM CONNECT still determines the target resource.

If IPXTPNL is less than 64 bytes, the user must still supply the full 64-byte transaction program name area. The value of IPXTPNL must equal the value of IPRESID. See [“IPRESID” on page 417](#) for details.

For SYNCLVL=SYNCPT conversations, only the first 24 bytes of the TPN length register the path to the sync-point manager.

**IPXALTID**

is an alternate user ID that is supplied to the target virtual machine. To specify a nonzero value in this field, a virtual machine must be authorized in the CP directory for DIAGNOSE code X'D4'.

**IPXLUW**

is the *logical-unit-of-work identifier*. This is a 26-byte field. (IPXLUWL describes the actual length.) CMS fills in this field for APPC/VM programs in CMS for SYNCLVL=SYNCPT conversations only.

**IPXPLEN**

is the length, in binary, of the number of bytes for the *entire* PIP variable (PIP data and all header information). Valid values are 0, 4, or any value from 8 to 32,767.

**IPXPADR**

specifies either the address of a PIP variable buffer, or the address of a list that contains addresses and lengths of multiple PIP variable buffers.

**Usage Notes**

**Specifying a PIP Variable:** Your program can supply a PIP variable that the target program can receive before accepting your connection. When specifying a PIP variable, your program must supply the following information in the APPCVM CONNECT parameter list extension:

- The length of the PIP variable (field IPXPLEN)
- The address of the PIP variable (field IPXPADR)
- An indication of whether you are specifying the PIP variable with a single buffer using one address and one length, or specifying multiple buffers using a list of addresses and lengths (flag IPXPBUFL in field IPXFLAG).

When you specify a single buffer using one address and one length:

- IPXPADR specifies the address.
- IPXPLEN specifies the length.
- The flag IPXPBUFL in the field IPXFLAG must be turned off.

When you specify multiple buffers with a list of addresses and lengths,

- IPXPADR specifies the address of the list.

- IPXPLEN specifies the sum of the lengths of the buffers in the list.
- The flag IPXPBUFL in the field IPXFLAG must be turned on.

You must follow these conventions when you use address lists:

- The list must begin on a doubleword boundary.
- Each list entry must be two fullwords:
  - The first fullword is the address of that portion of the list.
  - The second fullword is the length of that portion of the list.

When you use an address list, the addresses and lengths in the address list are updated during APPC/VM processing. Do not alter them during processing or assume that they are unchanged when APPC/VM processing is complete. Also, APPC/VM assumes that there is another entry in the list until the sum of the lengths of the entries processed is equal to the total length specified (by IPXPLEN).

**Note:** The data in a PIP variable buffer must not be reused until the connection is completed by the partner's IUCV ACCEPT or rejected by the partner's IUCV or APPCVM SEVER. This is because the data in a PIP variable buffer (specified on APPCVM CONNECT) does not move to the receive area (specified on APPCVM RECEIVE) until APPCVM RECEIVE PIP=YES is issued by the target.

The PIP variable you are sending in buffers must be coded into a PIP general data stream (GDS) variable. A PIP GDS variable has the format shown in [Figure 24 on page 423](#) as defined by SNA LU 6.2:

*Figure 24. Format of the PIP Variable*

#### **CPEIPLN**

the total length in binary, of the PIP variable (including this length field). CPEIPLN should be equal to the IPXPLEN field specified in the connection parameter list extension.

#### **CPEIPID**

the GDS identifier for the PIP variable, X'12F5'.

#### **CPEIPSU**

zero or more PIP subfields, each of which has the format shown in [Figure 25 on page 423](#).

*Figure 25. Format of a PIP Subfield*

#### **CPEIPSL**

is the length, in binary, of the PIP subfield (including this length field).

#### **CPEIPSI**

is the GDS identifier for a PIP subfield, X'12E2'.

#### **CPEIPSD**

is the actual PIP data.

**Considerations for single system image (SSI):** When APPCVM CONNECT is used from within an SSI cluster to connect to a private resource, the initial search for the associated userid is performed across the SSI cluster before extending the search across the ISFC Collection.

Examples

**Example of Specifying a PIP Variable:** A simple example of specifying a PIP variable would be if you wanted to send the letter Z to a program with which you are trying to connect. To do this, you could specify the PIP variable as:

```
X'000912F5000512E2E9'
```

- The X'0009' gives the length of the entire PIP variable. This corresponds to the CPEIPLN field in [Figure 24 on page 423](#).
- The X'12F5' is the GDS identifier for the PIP variable. This corresponds to the CPEIPID field in [Figure 24 on page 423](#). If you are sending PIP variable, CPEIPID must always have a value of X'12F5'.
- The X'0005' is the number of bytes in the PIP subfield. This corresponds to CPEIPSL field in [Figure 25 on page 423](#).
- The X'12E2' is the GDS identifier for the PIP subfield. This corresponds to the CPEIPSI field in [Figure 25 on page 423](#).

If you are sending PIP variables with subfields, each subfield must specify a length in the first 2 bytes and the value X'12E2' in the next 2 bytes.

- The X'E9' (Z) is the actual PIP data that we want to send.

The format of this PIP variable would look like what is shown in the following figure.

Figure 26. Example Format for a PIP Variable

For more information about the PIP variable, see *SNA Format and Protocol Reference Manual: Architectural Logic for LU Type 6.2*.

Condition Codes and Return Codes

CC=0

the CONNECT started successfully, but has not completed. IPPATHID is placed in the output parameter list, identifying the path being started by this connection. When the function does complete and your virtual machine is properly enabled for interrupts, you get a connection complete or Sever interrupt. Both the connection complete and the Sever interrupt have the same format as the APPCVM CONNECT output parameter list (see CC=2).

**Note:** When you specify WAIT=YES, CC=0 is not possible.

CC=1

an error occurred before the CONNECT was initiated. The output parameter list is the same as the input shown in [CONNECT Input Parameter List](#), except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                                                                                                                                                      |
|----------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'0A'    | 10           | The buffer length for the PIP variable is negative.                                                                                                                         |
| X'0B'    | 11           | CP could not find the resource or gateway, or, the resource or gateway is not available for connections, and no TSAF virtual machine is currently operating on your system. |

| Hex Code | Decimal Code | Why the Error Occurred                                                                                                                                                                                                                                                                                                                                              |
|----------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'0C'    | 12           | Your communication partner has not invoked the HNDIUCV SET (or IUCV DCLBFR) function.                                                                                                                                                                                                                                                                               |
| X'0D'    | 13           | Your virtual machine already has the maximum number of connections.                                                                                                                                                                                                                                                                                                 |
| X'0E'    | 14           | Your communication partner already has the maximum number of connections.                                                                                                                                                                                                                                                                                           |
| X'0F'    | 15           | <ul style="list-style-type: none"> <li>Your virtual machine is not authorized to connect to the resource, or</li> <li>The request was from a communication server and security label checking is enabled on the system, or</li> <li>A problem was detected in internal CP control structures. In this case, the error is accompanied by a CP soft abend.</li> </ul> |
| X'1A'    | 26           | The buffer list for the PIP variable is not on a doubleword boundary.                                                                                                                                                                                                                                                                                               |
| X'1D'    | 29           | You are not authorized to act for another user.                                                                                                                                                                                                                                                                                                                     |
| X'27'    | 39           | Your program specified an invalid connection parameter list extension length.                                                                                                                                                                                                                                                                                       |
| X'28'    | 40           | Your program specified an invalid locally known LU name.                                                                                                                                                                                                                                                                                                            |
| X'29'    | 41           | Your program specified an invalid mode name.                                                                                                                                                                                                                                                                                                                        |
| X'2F'    | 47           | Your program specified invalid security fields in the FMH5.                                                                                                                                                                                                                                                                                                         |
| X'31'    | 49           | Your communication partner does not allow connections with SECURITY(NONE).                                                                                                                                                                                                                                                                                          |
| X'32'    | 50           | Your program specified invalid allocation data. Or, a communication server did not include the length of the VM communication server area in the allocate data length. Refer to <a href="#">Considerations for Communications Servers</a> for more information.                                                                                                     |
| X'34'    | 52           | There is no APPCPASS directory statement.                                                                                                                                                                                                                                                                                                                           |
| X'35'    | 53           | Your program specified an invalid transaction program name (TPN) length.                                                                                                                                                                                                                                                                                            |
| X'36'    | 54           | Your program specified an invalid transaction program name (TPN).                                                                                                                                                                                                                                                                                                   |
| X'38'    | 56           | WAIT=YES was specified on a function issued to this same virtual machine.                                                                                                                                                                                                                                                                                           |
| X'39'    | 57           | Your program specified an invalid length for the PIP variable. Valid values are 0, 4, or any value from 8 to 32,767.                                                                                                                                                                                                                                                |

| Hex Code | Decimal Code | Why the Error Occurred                                                                                                                                                                                                                                                                                  |
|----------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'3A'    | 58           | Your program specified an invalid length for the VM communication server area. Valid values are 0 and 8.                                                                                                                                                                                                |
| X'3D'    | 61           | Your virtual machine is not authorized to specify an alternate user ID.                                                                                                                                                                                                                                 |
| X'3F'    | 63           | Your program specified an invalid logical-unit-of-work identifier length. Valid values are 0 and 10 to 26.                                                                                                                                                                                              |
| X'40'    | 64           | Your program specified an invalid fully-qualified LU network name in the logical-unit-of-work identifier.                                                                                                                                                                                               |
| X'41'    | 65           | Your program specified SYNCLVL=SYNCPT, but the logical-unit-of-work identifier length field is zeros.                                                                                                                                                                                                   |
| X'43'    | 67           | Both SYNCLVL=CONFIRM and SYNCLVL=SYNCPT were specified in IPFLAGS2 in the APPCVM CONNECT input parameter list.                                                                                                                                                                                          |
| X'56'    | 86           | A control buffer must be declared to issue APPCVM CONNECT with SYNCLVL=SYNCPT.                                                                                                                                                                                                                          |
| X'59'    | 89           | For your SYNCLVL=SYNCPT connection, CP could not find the resource, or the resource is not available for connections on the local system. Therefore, your SYNCLVL=SYNCPT would have to be routed through a TSAF virtual machine or ISFC, but TSAF and ISFC do not support SYNCLVL=SYNCPT conversations. |
| X'5C'    | 92           | A paging or storage error was detected.                                                                                                                                                                                                                                                                 |

**CC=2 or****CC=3**

the connect completed. (See [CONNECT Completion](#) for more information.) When CC=2, the connect completed with no errors; when CC=3, there is some error information in the IPAUDIT field.

**Note:** When WAIT=NO, CC=2 or 3 is not possible.

The output parameter list when CC=2 or 3 is shown in [Figure 27 on page 426](#).

Figure 27. APPCVM CONNECT Output Parameter List (Connection Complete Interrupt)

**IPPATHID**

contains the path ID on which the connection was completed or severed.

**IPFLAGS1**

contains one of the following bit flags:

**IPCNTL (X'04')**

a connection complete is on a control path. This flag is not set if the external interrupt was caused by a SEVER (IPTYPE=X'83').

**IPREMOTE (X'02')**

the connection was accepted by a communication server.

**IPTYPE**

contains one of the following codes:

**IPTYPCCA (X'82')**

the connection complete interrupt code, indicating your partner or an intermediate communication server accepted the connection.

**IPTYPSVA (X'83')**

the sever interrupt code, indicating your partner or an intermediate communication server rejected the connection with the SEVER function.

**IPCODE**

contains the sever code from the partner's SEVER. IPCODE is only valid when the external interrupt was caused by a SEVER (IPTYPE=X'83'). See [“APPC/VM Sever, Error, and Sense Codes That You Can Get”](#) on page 399.

**IPWHATRC**

contains the following what-received code:

**IPSABEND (X'09')**

your partner issued SEVER TYPE=ABEND.

IPWHATRC is only valid when the external interrupt was caused by a SEVER (IPTYPE=X'83').

**IPAUDIT**

has four fields that may contain error information caused by a PIP data problem.

**Notes:** In the following descriptions:

- *PIP area* refers to either a PIP buffer specified by IPXPADR or a PIP buffer that is part of a buffer list.
- *Receive area* refers to either a receive buffer specified directly on APPCVM RECEIVE, BUFFER= or a receive buffer that is part of a buffer list.

**IPAUDIT1 (first byte of IPAUDIT)**

may contain one of the following bit flags:

**IPADSNPX (X'40')**

a protection exception occurred on your PIP area.

**IPADSNAX (X'20')**

an addressing exception occurred on your PIP area.

**IPAUDIT2 (second byte of IPAUDIT)**

may contain one of the following bit flags:

**IPADRCPX (X'80')**

a protection exception occurred on your communication partner's receive area for the PIP variable.

**IPADRCAX (X'40')**

an addressing exception occurred on your communication partner's receive area for the PIP variable.

**IPADRLST (X'04')**

your communication partner specified an invalid receive buffer list.

**IPAUDIT3 (third byte of IPAUDIT)**

may contain the following bit flag:

**IPADBLEN (X'80')**

an invalid length is in your PIP variable buffer list.

**IPADBTOT (X'20')**

your total PIP data buffer length (CPEPIPLN) is invalid.

**IPASYRC (fourth byte of IPAUDIT)**

may contain one of the following error codes (for which an appropriate IPRCODE was given to your communication partner):

| Hex Code | Decimal Code | Meaning                                                                                                                                                              |
|----------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'3B'    | 59           | An invalid general data stream ID was specified within the PIP variable.                                                                                             |
| X'3C'    | 60           | An invalid length was specified for a PIP subfield, or the total length in bytes 0 through 1 of the PIP variable is not the sum of the lengths of the PIP subfields. |
| X'5B'    | 91           | A paging or storage error occurred on your PIP area.                                                                                                                 |
| X'5C'    | 92           | A paging or storage error occurred on your communication partner's receive area for the PIP variable.                                                                |

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

**IPSTATE**

contains the current state for this path, which has one of the following values:

**IPSENDST (X'03')**

the path is in the Send state.

**IPBKREQ (X'0E')**

the path is in the Backout\_Required state.

IPSTATE is not valid when the connection completes with a sever interrupt (IPTYPE=X'83').

**Program Exceptions**

The program exceptions for CONNECT are:

| Type          | Description                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address or connection extension address is outside of the virtual machine.                                                                        |
| Operation     | Either an external interrupt buffer has not been declared, or the invoking virtual machine is not in the supervisor state.                                           |
| Protection    | The storage key of the parameter list address does not match the key of the user. This exception also occurs if the connection extension address is fetch-protected. |
| Specification | The parameter list is not on a doubleword boundary.                                                                                                                  |

**Note:** APPC/VM does not reflect addressing exceptions or protection exceptions on PIP variable buffers, because your partner cannot have a predefined receive area for the PIP variable. Instead, the errors are reported to your program in the corresponding IPAUDIT flags in the connection complete data.

## State Checks and State Changes

There are no state checks for APPCVM CONNECT.

Your virtual machine path is in one of the following states:

- The Connect state for either of the following situations:
  - After you issue the CONNECT, but before your communication partner or an intermediate communication server accepts the connection (CC=0).
  - If your communication partner or an intermediate communication server issues a SEVER when you issue the CONNECT, you get a sever interrupt and no path is established. You remain in the Connect state, and you must issue IUCV SEVER to delete your side of the path.
- The Send state after you receive the connection complete indication.

## Completion Conditions

Connection complete data can be in different forms, depending on whether you specify WAIT=YES or WAIT=NO on the APPCVM CONNECT.

If you specify WAIT=YES, and your communication partner or intermediate communication server accepts the connection, you get a connection complete indication (with CC=2 or CC=3). If it severs the connection, you get a sever indication in the connection complete data.

The connection complete data goes to the parameter list that you specified on the APPCVM CONNECT macro. The format of the connection complete data is the same as the output parameter list described under CC=2 in [Figure 27 on page 426](#).

If you specify WAIT=NO, and your communication partner accepts the connection, you get a connection complete interrupt. If your partner severs the connection, you get a sever interrupt.

When you specify WAIT=NO and your virtual machine is enabled for external interrupts, the connection complete data goes to your external interrupt buffer.

The format of the connection complete interrupt data is the same as described under CC=2 in [Figure 27 on page 426](#). All subsequent interrupts for the established path are presented in the same buffer as the connection complete interrupt.

**Note:** The connection complete interrupt indicates only that your CONNECT has completed and that you are now in the Send state on the path. A connection complete interrupt does not necessarily indicate that the actual target of your CONNECT has issued an ACCEPT for the connection, or even that the target of the CONNECT has been invoked. For example, if your connection goes through AVS, AVS accepts the conversation when it communicates with VTAM.

**Connection Complete Extended Data:** When an APPC/VM connection complete interrupt is reflected to a virtual machine, the Connection Complete Extended Data (CCED) is reflected in the interrupt buffer extension, if it exists. The CCED DSECT and CCED COPY files are located in the HCPGPI macro library. Note that when running in CMS the interrupt buffer extension is defined by the virtual machine, not by the application.

A program running in CMS can obtain connection complete extended data in two ways:

- After CMSIUCV CONNECT completes with return code 0 (signifying CC=0 from APPCVM CONNECT), and while the user exit (interrupt handler) is being driven for the connection complete interrupt, Register 3 points to the CCED.
- When CMSIUCV CONNECT completes with return code 2 or 3 (signifying CC=2 or CC=3 from APPCVM CONNECT), the connection complete extended data is in the address specified on the CMSIUCV CONNECT BUFFER parameter.

A program running in GCS can obtain connection complete extended data when IUCVCOM CONNECT completes with return code 0 (signifying CC=0 from APPCVM CONNECT), and while the user exit (interrupt handler) is being driven for the connection complete interrupt, Register 3 points to the CCED.

The virtual machine has no way of getting any CCED data that does not fit in the interrupt buffer extension.

#### Notes:

1. CCED data is returned for all synchronization levels, but it is most useful for SYNCLVL=SYNCPT conversations.
2. You still get CCED data, even if a PIP data problem caused an IPAUDIT error.

The following shows the format of the connection complete extended data.

#### CCED DSECT

| 0  | 1                                    | 2        | 3        | 4        | 5                                    | 6 | 7 |
|----|--------------------------------------|----------|----------|----------|--------------------------------------|---|---|
| 0  | CCEDTOTL                             |          | CCEDFIXL |          | //////////////////////////////////// |   |   |
| 8  | CCEDSIIL                             | CCEDCVCL | CCEDLFQL | CCEDRFQL | //////////////////////////////////// |   |   |
| 10 | CCEDSII                              |          |          |          |                                      |   |   |
| 18 | CCEDCVC                              |          |          |          |                                      |   |   |
| 20 | CCEDLFQN                             |          |          |          |                                      |   |   |
| 30 | CCEDRFQN                             |          |          |          |                                      |   |   |
| 40 | //////////////////////////////////// |          |          |          |                                      |   |   |
| 48 | CCEDUSER                             |          |          |          |                                      |   |   |

Figure 28. Connection Complete Extended Data

#### CCEDTOTL

contains the total length of the CCED.

#### CCEDFIXL

contains the length of the fixed length fields of the CCED (CCEDSIIL through CCEDUSER).

#### CCEDSIIL

contains the length of the session instance identifier (field CCEDSII). Valid values for the length are 0 and 2 through 8. If the session instance identifier is not known because neither the issuer of CONNECT or ACCEPT specified it, this length field is 0, and CCEDSII is undefined.

#### CCEDCVCL

contains the length of the conversation correlator (field CCEDCVC). Valid values for the length are 0 through 8. If the conversation correlator is not known because the issuer of CONNECT did not specify it and CP could not generate it, this length field is zero, and CCEDCVC is undefined.

**Note:** CP does not generate a conversation correlator if the CONNECT was specified with FMH5=YES. This means that if the length of the conversation correlator specified in the FMH5 is zero, the corresponding length in field CCEDCVCL is zero. CCEDCVCL is nonzero in all other cases.

#### CCEDLFQL

contains the length of the local network fully qualified LU name (field CCEDLFQN). Valid values for the length are 0 through 17. If the local fully qualified LU name is not known because neither the issuer of CONNECT or ACCEPT specified it, this length field is 0, and CCEDLFQN is undefined. (This happens when the target program is on the same system as the source program and AVS is not used.)

#### CCEDRFQL

contains the length of the remote network fully qualified LU name (CCEDRFQN). Valid values for the length are 0 through 17. If the remote fully qualified LU name is not known because neither the issuer of CONNECT or ACCEPT specified it, this length field is zero, and CCEDRFQN is undefined. (This happens when the target program is on the same system as the source program and AVS is not used.)

**Note:** The following applies to all fields that have a corresponding length field in the CCED. If the actual length of the field is less than the maximum length, the data is left-justified within the field and padded on the right with blank characters (X'40'):

#### **CCEDSII**

contains the session instance identifier.

If the length CCEDSIIL is zero, this field is undefined and contains binary zeros. This is the case if neither the virtual machine which issued the CONNECT nor the ACCEPT is the SNA communication server.

#### **CCEDCVC**

contains the conversation correlator.

If the length CCEDCVCL is zero, the conversation correlator is undefined and contains binary zeros.

#### **CCEDLFQN**

contains the local network fully qualified LU name.

If the length CCEDLFQL is zero, this field is undefined and contains binary zeros. This is the case if neither the virtual machine which issued the CONNECT nor the ACCEPT is the SNA communication server.

#### **CCEDRFQN**

contains the remote network fully qualified LU name.

If the length CCEDRFQL is zero, this field is undefined and contains binary zeros. This is the case if neither the virtual machine which issued the CONNECT nor the ACCEPT is the SNA communication server.

#### **CCEDUSER**

is the access user ID provided for this conversation.

Because the source application does not always specify this user ID, this field allows the source application to know what access security user ID was used when establishing this connection. The value of this field depends on the SECURITY level specified by the invoker of CONNECT.

- When SECURITY NONE was specified, CCEDUSER contains binary zeros. This is the same value that is passed to the target program, assuming that the target program is on a VM system. SECURITY NONE might be presented to the target program differently on non-VM systems. However, the target program will be able to determine that SECURITY NONE was specified.
- When SECURITY PGM was specified, CCEDUSER contains the user ID specified by the invoker. This is the same value passed to the target program.
- When SECURITY SAME was specified, then CCEDUSER generally contains the logon user ID of the invoker. However, there are two exceptions to this:
  1. If the CONNECT was issued by a communication server on behalf of another user (IPCOMSRV is on), CCEDUSER contains the user ID specified on the ALTID parameter of CONNECT.
  2. If the CONNECT was not issued by a communication server on behalf of another user (IPCOMSRV is off), but the invoker has an alternate user ID defined using DIAGNOSE code X'D4', CCEDUSER contains this alternate user ID.

This is the same value that is passed to the target program if the target program is within a TSAF collection. If the target program is on a VM system outside of the source TSAF collection, this user ID may be mapped to another user ID on the target system.

## **What Happens to Your VM Communication Partner**

This section describes the information presented to your partner program after your program issues APPCVM CONNECT. It includes information on:

- Connection pending interrupt
- Connection pending extended data (allocate data).

**Connection Pending Interrupt:** When you invoke a CONNECT, your communication partner gets a connection pending external interrupt (assuming it is enabled for interrupts). If you are connecting to a private resource, the connection pending interrupt data goes to the private resource manager's virtual machine control buffer; for all connections to local, global, or system resources, the connection pending external interrupt data always goes to your communication partner's application buffer.

The connection pending external interrupt format is shown in the following figure.

Figure 29. Connection Pending External Interrupt

### IPPATHID

contains the path ID on which a connection is pending.

### IPFLAGS1

may contain the following bit flag:

#### IPREMOTE (X'02')

the connection is through ISFC, the TSAF virtual machine, AVS virtual machine, or another communication server that specified a connection using ALTID.

### IPTYPE

contains the interrupt type for a connection pending (IPTYPPCA, X'81').

### IPPIPLEN

contains the number of bytes (in binary) for the PIP variable. If a PIP variable was not specified on the APPCVM CONNECT, this field is set to zero. If IPPIPLEN is greater than zero, your partner can receive a PIP variable in addition to the allocate data.

Your partner can obtain a PIP variable using APPCVM RECEIVE PIP=YES before accepting the connection with IUCV ACCEPT. See “APPCVM RECEIVE” on page 451 for information about receiving PIP variables. Programs running on CMS and using CMS support for communication do not need to issue a receive to get a PIP variable. CMS receives the PIP variable and places its address in register 4.

### IPFLAGS2

may contain one or more of the following bit flags:

#### IPINVOKE (X'80')

the IPRESID specified is a private resource. The private resource manager program should be invoked if it is not currently active and if the connecting program is authorized in the \$SERVER\$ NAMES file.

#### Notes:

1. CMS examines this flag, and when necessary, invokes the appropriate application. Applications not running in the CMS environment can provide this program invocation function if desired.
2. This flag is set when the incoming connection has an LU name qualifier (gateway name) of \*USERID. However, do not assume that the connecting application specified \*USERID as the gateway name; the SNA communication server (AVS) could have transformed the gateway name originally specified by the connecting application.

#### IPVLVLCF (X'40')

confirmation requests (SEND CNF and SEND CNFD functions) are permitted on this path.

#### IPMAAPPED (X'10')

a mapped conversation is being established.

**IPIMMED (X'02')**

the connecting program specified RETURN=IMMED.

**IPSYNCPT (X'01')**

the conversation was established with SYNCLVL=SYNCPT.

**IPVMID**

contains the source user ID of the virtual machine that wants to connect which may be one of the following:

- The user ID specified with the ALTID parameter of APPCVM CONNECT
- An alternate user ID set by a DIAGNOSE code X'D4'
- The logon user ID of the virtual machine issuing the APPCVM CONNECT
- The access security user ID when a security type of PGM was specified on the APPCVM CONNECT.

The field may be zero, which indicates that the identity of the connecting virtual machine is unknown. This is an 8-byte field, left-justified and padded with blanks as necessary.

**IPRESID**

for a noncommunication server, this field contains the name of the resource that is the target of the connection (the transaction program name, or TPN).

For a communication server (including ISFC, and the TSAF and AVS virtual machines), this field contains one of the following:

- The name of the target resource, if the connection is to a VM local, global, or system resource. (The LU name qualifier on the connection was \*IDENT.)
- The value \*USERID, if the connection is to a VM private resource. (The LU name qualifier on the connection was \*USERID.)
- The value \*GATEWAY, if the connection is outbound to a resource in the SNA network. (The LU name qualifier on the connection was the name of an established gateway.)

**IPBFLN2F**

contains the length of pending allocate data. Refer to [Connection Pending Extended Data](#) for a further explanation of pending allocate data.

**Note:** This allocate data consists of the VM area, the FMH5, and the VM-defined variable-length section only. The length of the PIP variable is contained in the IPPIPLEN field of this interrupt.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

**Connection Pending Extended Data (Allocate Data):** When your partner is presented with a connection pending interrupt, it is also presented with connection pending extended data (CPED), if the interrupt buffer extension exists. The CPED is referred to as allocate data, which consists of three parts:

- VM architected area
- Attach FMH5 (Function Management Header Type 5)
- VM-defined variable-length section.

The allocate data is created from information in the entire connection parameter list, including the connection parameter list extension.

The CPED (allocate data) currently has a maximum of 919 bytes<sup>3</sup>: 164 bytes maximum length for the VM area, 255 bytes maximum length for the FMH5, and 500 bytes maximum length (NGROUPS\_MAX \* 4) for the VM-defined variable-length section.

Your partner can obtain the allocate data in two ways:

1. Use APPCVM RECEIVE to receive the data into buffers. If some of the allocate data does not fit in the interrupt buffer extension, the virtual machine must still receive all the allocate data (as indicated by the IPBFLN2F field in the connection pending interrupt), not just the portion of allocate data that fits in the interrupt buffer extension.
2. When CMS (or GCS) drives the user exit with the connection pending interrupt, Register 3 contains the address of the connection pending extended data.

Once a program accepts the connection, the allocate data is purged by CP. If the target of your connection wants to use the allocate data, it must do so before accepting the connection—once the connection is accepted, CP purges allocate data.

The three pieces of allocation data are described in the following sections. Diagrams of these areas are shown in [Figure 30 on page 435](#) and in [Figure 31 on page 438](#).

**CPED Part One-VM Area:**

---

<sup>3</sup> There are two exceptions to this:

- When the TSAF virtual machine is handling a connection to a private resource, the VM area is preceded with an 8-byte node ID. Or when a communications server is making a connection with PIP data on behalf of another virtual machine, the FMH5 is followed by the 8-byte VM communications area. As a result, the maximum CPED length is 927.
- When the TSAF virtual machine is handling a connection to a private resource with PIP data, the maximum CPED length will be 935.

Figure 30. Connection Pending Extended Data, Part One: VM Area

#### CPEVTOTL

is the total length of the VM architected area, including this length field. CPEVTOTL can have one of the following values: 32, 64, 120, 148, or 164.

#### CPEVFIXL

is the length of the **fixed length fields** area (the total length of the fields CPEVSESL through CPEVVARL).

#### CPEVSRVL

contains zeros. ([Handling PIP Variables](#) has further information.)

#### CPEVSESL

is the length of the session instance identifier (field CPEVSESS). Valid lengths are 2 to 8.

#### CPEVLLUL

is the length of the local fully-qualified LU name (field CPEVLLUN). Valid lengths are 1 to 17.

#### CPEVRLUL

is the length of the remote fully-qualified LU name (field CPEVRLUN). Valid lengths are 1 to 17.

#### CPEVMODE

is the mode name.

#### CPEVSESS

is the session instance identifier. If the connection is being made by a noncommunication server, this field contains binary zeros. Refer to *VTAM Programming for LU 6.2* for more information about the session instance identifier.

#### CPEVLKL

is the locally known LU name used by the connecting program as its target. This consists of two 8-byte fields:

**CPEVLUQ**

the LU name qualifier (gateway, name) used on the initial connection.

**CPEVTLU**

the LU name of the target of the connection.

See [Table 74 on page 420](#) for the LU name qualifiers and target LU names.

**CPEVPLKL**

is the locally known LU name that the target of the initial connect could use to connect back to the source's LU. (Note that to connect back to the source LU, a program also needs to specify a TPN and also needs to specify \*USERID,userid. See [Table 74 on page 420](#).)

This consists of two 8-byte fields:

**CPEVPLUQ**

the LU name qualifier (gateway) that the program uses to connect back to the source's LU.

**CPEVPTLU**

the LU name of the original source connecting program.

See [Table 74 on page 420](#) for the LU name qualifiers and target LU names.

**CPEVLLUN**

is the local fully-qualified LU name. If the connection was made by a noncommunication server, this field contains binary zeros.

**CPEVRLUN**

is the remote fully-qualified LU name. If the connection was made by a noncommunication server, this field contains binary zeros.

See *SNA Format and Protocol Reference Manual: Architectural Logic for LU Type 6.2* for details on the local and remote fully-qualified LU names.

**CPEVALT**

is an alternate user ID the target virtual machine uses. The user ID must be left-justified and padded on the right with blanks as necessary.

This alternate user ID is *assigned* to the target virtual machine when that machine accepts the connection, and it is unassigned when that machine severs the connection. Connection pending interrupts are not presented to a virtual machine that has an alternate user ID assigned; such interrupts are deferred until the alternate user ID has been unassigned. No user ID is assigned if this field contains all zeros.

**CPEVCIT**

contains the virtual configuration identification token (VCIT) of the virtual machine requesting the connection, if that virtual machine is located in the same system as you are. If the partner virtual machine is on a different system, then this field contains binary zeros.

VCITs are used as an alternative to a user ID as a way of identifying a virtual machine for certain operations, such as the PERMIT function of the CP ADRSPACE macro.

**CPEVIDFL**

contains access control information. Valid values are:

**1... ....**

POSIX user ID (UID) and group ID (GID) information has been filled in.

**.1... ....**

Reserved

**..1. ....**

Reserved

**...1 ....**

Reserved

**.... 1...**

Reserved

.... **.1..**

Reserved

.... **..1.**

Reserved

.... **...1**

Reserved

**If bit zero is on,**

the access control information (effective and real UIDs, effective and real GIDs, and supplementary GIDs) has been supplied.

**All other bits**

are reserved.

**CPEVEUID**

contains one of the following:

- the effective UID of the process that issued the CONNECT
- the database UID value associated with the userid determined by the rules governing access security and based on the access security type specified.

Refer to [Additional Considerations for POSIX Security Values](#) for details.

**CPEVEGID**

contains one of the following:

- the effective GID of the process that issued the CONNECT
- the database GID value associated with the userid determined by the rules governing access security and based on the access security type specified.

Refer to [Additional Considerations for POSIX Security Values](#) for details.

**CPEVRUID**

contains one of the following:

- the real UID of the process that issued the CONNECT
- the database UID value associated with the userid determined by the rules governing access security and based on the access security type specified.

Refer to [Additional Considerations for POSIX Security Values](#) for details.

**CPEVRGID**

contains one of the following:

- the real GID of the process that issued the CONNECT
- the database GID value associated with the userid determined by the rules governing access security and based on the access security type specified.

Refer to [Additional Considerations for POSIX Security Values](#) for details.

**CPEVIDLN**

contains the length of the supplementary GID area, CPESGIDV.

**CPEVVARL**

contains the length of the VM-defined variable-length section of the CPED.

**CPEVCBPL**

contains the connect-back partner LU name. This is the LU name that should be used (rather than CPEVPLKL) by the target of the initial connect to connect back to the source's LU. (Note that to connect back to the source LU, a program also needs to specify a TPN. See [Table 74 on page 420](#).) CPEVCBPL consists of two 8-byte fields:

**CPEVCBLQ**

The LU name qualifier (gateway) that the program uses to connect back to the source's LU.

CPEVCBTL

The LU name of the original source connecting program.

See [Table 74 on page 420](#) for the LU name qualifiers and target LU names.

**CPED Part Two—FMH5:** APPC (LU Type 6.2) uses an FMH5 to carry a request for a conversation to be established between two transaction programs. This header identifies the transaction program that is the target of a connection and that is invoked. An FMH5 is variable length.

It is possible for your program to receive FMH5 information from the SNA network. This FMH5 may be different from the FMH5 generated by VM. For more information on what you can expect from the SNA network, see *SNA Format and Protocol Reference Manual: Architectural Logic for LU Type 6.2* for more information on the FMH5.)

In APPC/VM, you are concerned with a certain type of FMH5—an Attach FMH5. Throughout the rest of this document, we refer to the Attach FMH5 as simply FMH5.

If CP creates the FMH5, it specifies the values shown below. Fields CPEFLEN through CPEFTPN are created for any connection; fields CPEFASIL and the security area are created only for connections with SECURITY(SAME) or SECURITY(PGM).

Figure 31. Connection Pending Extended Data, Part Two: FMH5

CPEFLEN

is the total length, in hexadecimal, of the Attach FMH5 (including this length byte).

CPEFTYPE

is the type code for FMH5, X'05'.

CPEFCODE

is the command code for APPC Attach, X'02FF'.

CPEFFLG1

may contain one or more of the following flags:

CPEFSECI (X'80')

indicates that access security user ID is already verified.

CPEFPIP (X'08')

indicates a PIP (program initialization parameter) variable is present.

CPEFPRML

is the total length of the **fixed length parameters** field, currently three bytes.

**Note:** Programs should be sensitive to the fact that this length could change.

CPEFCONT

contains the conversation type.

CPEFBASC (X'D0')

indicates a basic conversation

**CPEFMAPC (X'D1')**

indicates a mapped conversation

**CPEFFLG2**

contains one of the following flags:

**CPEFSYNO (X'00')**

indicates that no confirmation requests can be issued (SYNCLVL=NONE).

**CPEFSYCF (X'40')**

indicates that confirmation requests can be issued (SYNCLVL=CONFIRM).

**CPEFSYSP (X'80')**

indicates that requests for confirmation, taking a synchronization point, or making a backout can be issued (SYNCLVL=SYNCPT).

**CPEFTPNL**

is the length of the transaction program name.

**CPEFTPN**

is the transaction program name, which is a variable length.

**Note:** For connections inbound from an SNA network, CPEFTPN can be from 1 to 64 bytes in length. However, in the case where CPEFTPN is greater than 8, CP uses only the first 8 bytes.

For SYNCLVL=SYNCPT conversions, only the first 24 bytes of the TPN length register the path to the sync-point manager.

**CPEFASIL**

is the length of the security area (CPEFSEC). CP only creates this for SECURITY(SAME) and SECURITY(PGM).

**CPEFSSEC**

is a variable-length area that contains one or two subfields of security information, depending on the security level and the destination:

- For a SECURITY(SAME) connection, there will be one subfield—for a user ID.
- For a SECURITY(PGM) connection, there will be two subfields—one for a user ID and one for a password.

The format of a security subfield is shown in the following figure.

CPED DSECT

Figure 32. Security Subfield in an Attach FMH5 for VM

The items in a security subfield are as follows:

**CPEFSUBL**

is the length of CPEFSUBT (one byte) plus the length of CPEFDATA.

**CPEFSUBT**

is a flag indicating the contents of CPEFDATA:

**CPEFPROF (X'00')**

if CPEFDATA contains a profile

**Note:** For connections inbound from an SNA network CPEFSUBT can contain a profile flag (CPEFPROF).

**CPEFPASS (X'01')**

if CPEFDATA contains a password

**CPEFUSER (X'02')**

if CPEFDATA contains a user ID.

**CPEFDATA**

contains either a user ID or a password, depending on the value for CPEFSUBT. For VM, this user ID or password can be from one to eight bytes in length.

**Note:** For connections inbound from an SNA network, CPEFDATA can be from one to ten bytes in length. However, the 9th and 10th byte, if present, must be blank.

**CPEFLUWL**

is the length of the LUWID, not including this length byte. The actual LUWID is composed of the following parts:

**CPEFFQNL**

is the length of the fully qualified LU name, not including this length byte.

**CPEFFQN**

is the name of the network fully qualified LU name. This is a variable length.

**CPEFLUIN**

is the instance number of the LUWID.

**CPEFLUSN**

is the sequence number of the LUWID.

**CPEFCORL**

is the length of the sender's conversation correlator.

**CPEFCORT**

is the conversation correlator of the sender's transaction. This has a variable length.

**CPED Part Three—VM-Defined Variable-Length Section:** Immediately following the FHM5 is an optional part of the allocate area, the VM-defined variable-length section. The length of this section is defined in field CPEVVARL in the VM area, and is zero if this section does not exist.

The VM-defined variable-length section contains the supplementary GID area, a part of the POSIX access control information. The length of the supplementary GID area is also defined in the VM area (CPEVIDLN).

Figure 33. Connection Pending Extended Data, Part Three: VM-Defined Variable-Length Section

**Examples of Allocate Data for a Connection to a VM Private Resource:** The following three scenarios show examples of portions of allocate data for a connection to a private resource within a TSAF collection. Assume that the extension information is provided either directly by the program or through a CMS communication directory file.

1. Assume that a source program runs in a virtual machine whose user ID is USER1. The program issues a connection with the following information specified in the parameter list and extension:
  - A resource ID (TPN) of PAYROLL
  - Mode name omitted
  - SYNCLVL=CONFIRM
  - MAPPED=NO
  - SECURITY(NONE).

The VM architected area and FMH5 is in the following format (assume that PAYROLL is managed by USER2):

| Hexadecimal code    | Explanation                                |
|---------------------|--------------------------------------------|
|                     | <i>The VM architected area begins here</i> |
| X'0040003800000000' | Lengths                                    |
| X'0000000000000000' | Reserved                                   |

| Hexadecimal code      | Explanation                                                                           |
|-----------------------|---------------------------------------------------------------------------------------|
| X'0000000000000000'   | Mode name omitted                                                                     |
| X'0000000000000000'   | Reserved                                                                              |
|                       | Locally known LU name:<br>(from source program's point of view)                       |
| X'5CE4E2C5D9C9C440'   | LU name qualifier, *USERID                                                            |
| X'E4E2C5D9F2404040'   | Target LU name, USER2                                                                 |
|                       | Partner program's locally known LU name:<br>(from priv. res. manager's point of view) |
| X'5CE4E2C5D9C9C440'   | Partner's LU name qualifier, *USERID                                                  |
| X'E4E2C5D9F1404040'   | Partner's target LU name, USER1                                                       |
|                       | <i>FMH5 starts here</i>                                                               |
| X'120502FF0003D00040' | First 9 bytes                                                                         |
| X'08D7C1E8D9D6D3D340' | Transaction program named PAYROLL                                                     |

2. In the previous example, if the source program specifies SECURITY(SAME) instead of SECURITY(NONE), then the FMH5 is in the following format:

| Hexadecimal code      | Explanation                       |
|-----------------------|-----------------------------------|
|                       | <i>FMH5 starts here</i>           |
| X'1A0502FF8003D00040' | Already verified flag is set      |
| X'08D7C1E8D9D6D3D340' | Transaction program named PAYROLL |
| X'07'                 | Length of security area           |
| X'0602E4E2C5D9F1'     | User ID, USER1                    |

3. If the source program specifies SECURITY(PGM) with an access user ID of USER3 and an access password of PASS3 instead of SECURITY(NONE), then the FMH5 is in the following format. Note that CP places only the access user ID into the FMH5 before the FMH5 is sent to the private resource manager program. (The target LU verifies the password, and in this case the target LU is the same as the source LU.)

| Hexadecimal code      | Explanation                       |
|-----------------------|-----------------------------------|
|                       | <i>FMH5 starts here</i>           |
| X'1A0502FF8003D00040' | Already verified flag is set      |
| X'08D7C1E8D9D6D3D340' | Transaction program named PAYROLL |
| X'07'                 | Length of security area           |
| X'0602E4E2C5D9F3'     | Access user ID, USER3             |

## Considerations for Communication Servers

A communication server is an intermediate program (a *middleman*) that makes connections on behalf of another program. Communication servers must be authorized in the CP directory with the OPTION COMSRV statement.

When a communication server makes a connection on behalf of another user, it specifies FMH5=YES on its APPCVM CONNECT. This means that its connection parameter list extension contains allocate data. CP does not create this FMH5 and does not verify the format or contents of the supplied FMH5; CP simply passes it on to your partner.

CP can receive any valid FMH5 information from the SNA network and it may be different from the FMH5 generated from VM. For example, even though VM never generates the CPEFPROF flag in the CPEFSUBT security subfield, it may receive an FMH5 from the SNA network that does use this flag.

For more information on valid FMH5 information, see *SNA Format and Protocol Reference Manual: Architectural Logic for LU Type 6.2*.

The VM area being created by a communication server must be in the same format as part one of the CPED data (see [Connection Pending Extended Data](#)). However, a communication server creating a VM area must note special considerations for several VM area fields:

#### **CPEVSRVL**

when a communication server is making a connection with PIP data on behalf of another virtual machine, it must supply a value of 8 in this field. The value 8 is the length of the VM communication server area which points to the PIP variable (see note). Refer to [Handling PIP Variables](#) for more information.

**Note:** When a communication server specifies the length of the connection parameter list extension (BUFLN=) and a PIP variable is present, the maximum length of the extension is 915 bytes. Refer to note “3” on [page 415](#) for the BUFLN= parameter when FMH5=YES is specified.

#### **CPEVALT**

is an alternate user ID that the target virtual machine uses. The user ID must be left-justified and padded on the right with blanks as necessary.

This alternate user ID is *assigned* to the target virtual machine when that machine accepts the connection, and it is *unassigned* when the connection is severed. Connection pending interrupts that contain an alternate user ID are not presented to a virtual machine that already has an alternate user ID assigned; such interrupts are deferred until the alternate user ID is unassigned. (However, these types of connection pending interrupts are presented if the virtual machine is a communication server.) No user ID is assigned if this field contains all zeros.

To specify this field, a virtual machine must be authorized in the CP directory for DIAGNOSE code X'D4'. Note that this defaults to class B privilege. However, using VM's user class modification, a virtual machine can be authorized to specify this alternate user ID without being given other class B privileges. For more information about modifying user classes, see [z/VM: CP Planning and Administration](#).

#### **CPEVIDFL**

is a 1-byte field consisting of access control information. For valid values, see the description of “CPEVIDFL” on [page 436](#).

#### **CPEVEUID**

contains one of the following:

- the effective UID of the process that issued the CONNECT
- the database UID value associated with the userid determined by the rules governing access security and based on the access security type specified.

Refer to [Additional Considerations for POSIX Security Values](#) for details.

#### **CPEVEGID**

contains one of the following:

- the effective GID of the process that issued the CONNECT
- the database GID value associated with the userid determined by the rules governing access security and based on the access security type specified.

Refer to [Additional Considerations for POSIX Security Values](#) for details.

#### **CPEVRUID**

contains one of the following:

- the real UID of the process that issued the CONNECT

- the database UID value associated with the userid determined by the rules governing access security and based on the access security type specified.

Refer to [Additional Considerations for POSIX Security Values](#) for details.

#### **CPEVRGID**

contains one of the following:

- the real GID of the process that issued the CONNECT
- the database GID value associated with the userid determined by the rules governing access security and based on the access security type specified.

Refer to [Additional Considerations for POSIX Security Values](#) for details.

#### **CPEVIDLN**

contains the length of the supplementary GID area, CPESGIDV.

#### **CPESGIDS (in the VM-defined variable-length section)**

contains the list of supplementary GIDs, a list of 4-byte GIDs immediately following each other.

Refer to [Connection Pending Extended Data](#) for a complete description of the FMH5, and also *SNA Format and Protocol Reference Manual: Architectural Logic for LU Type 6.2*.

**Note:** If you specify FMH5=YES, CMS communication directory resolution is disabled on any subsequent CMSIUCV CONNECT or CMSIUCV RESOLVE functions.

When a communication server is establishing a connection for another virtual machine, the communication server should use the ALTID keyword on APPCVM CONNECT. This parameter specifies the user ID of the virtual machine that made the original connection and is the virtual machine for which the connection is being made.

The communication server should use the user ID sent in the IPVMMID field of the connection pending interrupt for accounting and problem determination. The value of the user ID sent in the IPVMMID field of the connection pending interrupt depends on whether the connection is inbound from the SNA network or outbound to the SNA network.

If the connection is inbound from the SNA network to a TSAF collection and the SECURITY value is:

- NONE, then IPVMMID in the connection pending interrupt is set to binary zeros.
- SAME, then IPVMMID in the connection pending interrupt is set to the source user ID.
- PGM, then IPVMMID is set to the verified access user ID from the security field of the FMH5.

If the connection is outbound from a TSAF or CS collection to the SNA network, the IPVMMID field in the connection pending interrupt contains a source user ID. The source user ID is one of the following:

- The user ID specified with the ALTID parameter of APPCVM CONNECT
- An alternate user ID set by a DIAGNOSE code X'D4'
- The logon user ID of the virtual machine issuing the APPCVM CONNECT.

**Note:** The TSAF virtual machine gets an 8-byte node ID preceding the VM area, the FMH5, and the VM-defined variable-length section when it is handling a private resource connection.

**Additional Considerations for POSIX Security Values:** The VM area and the supplementary GID area together contain a set of fields known collectively as the POSIX access control information. These fields are:

- CPEVIDFL
- CPEVEUID
- CPEVEGID
- CPEVRUID
- CPEVRGID
- CPEVIDLN

- CPEVSGIDS

If the communications server knows the appropriate values to fill in for these fields, it should do so and ensure that bit zero of flag CPEVIDFL is one. If the communications server does not fill in these fields, it must ensure that bit zero of flag CPEVIDFL is zero. CP will then fill in the information.

How the VM systems are connected together and the level of each of the systems involved makes a difference in determining the source of the security data that is provided to the server.

- A server that resides on the same system as the requestor is provided with the POSIX security values for the currently-active process.
- A server accessible via ISFC (the system is a member of a CS collection) where all systems involved in the route from the requestor to the server are at least at the VM/ESA Version 2 Release 1.0 level is provided with the POSIX security values for the currently-active process. If there is a system with CP at a level prior to VM/ESA Version 2 Release 1.0 in the route, the POSIX security values are provided for the currently-active process, but the supplementary GIDs are stripped off.
- A server accessible via TSAF where all systems involved in the route from the requestor to the server are at least at the VM/ESA Version 2 Release 1.0 level and systems at prior levels have the appropriate APAR installed (see the Conversion Notebook for details) is provided with the POSIX security values for the currently-active process.
- A server accessible via AVS is provided with the database POSIX security values
- In each of the previous cases, if there is no currently-active process, the user's database POSIX security values are provided.

**Examples of Allocate Data for an Outbound Connection:** The following three scenarios show examples of portions of allocate data that the SNA communication server (AVS) gets for an outbound connection. Assume that the extension information is provided either by the source program or through a CMS communication directory file.

1. If a source program, running in a virtual machine whose user ID is USER1, issues a connection with the following information specified in the parameter list and extension:
  - A mode name of FAST
  - An LU name qualifier GATE1
  - A target LU name of ENDICOTT
  - A resource ID of PAYROLL
  - SYNCLVL=CONFIRM
  - MAPPED=NO
  - SECURITY(NONE).

The SNA communication server gets a VM area, an FMH5, and a VM-defined variable-length section in this format:

| Hexadecimal code    | Explanation                                                         |
|---------------------|---------------------------------------------------------------------|
|                     | <i>VM architected area starts here</i>                              |
| X'0040003800000000' | Lengths                                                             |
| X'0000000000000000' | Reserved                                                            |
| X'C6C1E2E340404040' | Mode name, FAST                                                     |
| X'0000000000000000' | Reserved                                                            |
|                     | Locally known LU name:<br>(from the source program's point of view) |
| X'C7C1E3C5F0404040' | LU name qualifier, GATE1                                            |
| X'C5D5C4C9C3D6E3E3' | Target LU name, ENDICOTT                                            |

| Hexadecimal code      | Explanation                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------|
|                       | Partner program's locally known LU name:<br>(from the communication server's point of view) |
| X'5CE4E2C5D9C9C440'   | Partner's LU name qualifier, *USERID                                                        |
| X'E4E2C5D9F1404040'   | Partner's target LU name, USER1<br><i>FMH5 starts here</i>                                  |
| X'120502FF0003D00040' | First 9 bytes                                                                               |
| X'08D7C1E8D9D6D3D340' | Transaction program named PAYROLL                                                           |

2. In the previous example, if the source program specifies SECURITY(SAME) instead of SECURITY(NONE), then the communication server gets an FMH5 in this format:

| Hexadecimal code      | Explanation                       |
|-----------------------|-----------------------------------|
|                       | <i>FMH5 starts here</i>           |
| X'1A0502FF8003D00040' | Already verified flag is set      |
| X'08D7C1E8D9D6D3D340' | Transaction program named PAYROLL |
| X'07'                 | Length of security area           |
| X'0602E4E2C5D9F1'     | User ID, USER1                    |

3. If the source program specifies SECURITY(PGM) with an access user ID of USER3 and an access password of PASS3 instead of SECURITY(NONE), then the communication server gets an FMH5 in the format following format. Note that in this case, CP places the access user ID **and** the access password in the FMH5 before the FMH5 is sent to the communication server. (The target LU verifies the password, and in this case the target LU is not the same as the source LU.)

| Hexadecimal code      | Explanation                       |
|-----------------------|-----------------------------------|
|                       | <i>FMH5 starts here</i>           |
| X'210502FF0003D00040' | First 9 bytes                     |
| X'08D7C1E8D9D6D3D340' | Transaction program named PAYROLL |
| X'0E'                 | Length of security area           |
| X'0602E4E2C5D9F3'     | Access user ID, USER3             |
| X'0601D7C1E2E2F3'     | Access password, PASS3            |

**Handling PIP Variables:** Communication servers typically make connections on behalf of other users. They receive a connection pending interrupt, receive the allocate data, and pass on the allocate data using APPCVM CONNECT, FMH5=YES. The allocate data, consisting of a VM area and FMH5, is already contained in the parameter list extension.

Communication servers handle PIP variables a little differently. If the IPPIPLEN field in the connection pending interrupt is greater than 0, indicating PIP data is present, the communication server must do the following:

1. Receive the PIP variable using APPCVM RECEIVE PIP=YES.

**Note:** If the communication server program is running in CMS, CMS issues the APPCVM RECEIVE PIP=YES. In CMS, when a user exit is driven for a connection pending interrupt, register 4 (R4) points to the PIP variable if it is nonzero. The communication server can thus access the PIP variable before accepting the conversation.

2. Set up the PIP variable using a single buffer or multiple buffers.
3. Create a **VM communication server area** that passes the PIP variable to the final target.

- 4. Specify a value of 8 in field CPEVSRVL of the VM area to denote the length of the VM communication server area.
- 5. Include the length of the VM communication server area (eight bytes) when specifying the BUFLLEN parameter on APPCVM CONNECT.

The VM communication server area must follow the VM-defined variable-length section, and it has the format shown in the following figure.

Figure 34. VM Communication Server Area

**CPECOMFL**

is a byte that contains the following flag:

**CPECOMBL (X'40')**

specifies that CPECOMPA contains the address of a list of multiple buffer addresses and lengths for the PIP variable.

**CPECOMPL**

is the **total** number of bytes (in binary) for the PIP variable. Valid values are 0, 4, or any value from 8 to 32,767. (CPECOMPL should be equal to the IPPILEN field specified in the connection pending interrupt.)

**/////**

is reserved and set to zeros.

**CPECOMPA**

specifies either the address of a single data buffer, or the address of a list that contains multiple buffer addresses and lengths for the PIP variable.

If the VM communication server area is created, a communication server must add the area's length to the allocate data length (the BUFLLEN parameter or IPBFLN2F field) when it issues the APPCVM CONNECT, FMH5=YES. If the communication server does not append the length, IPRCODE 50 results.

When the virtual machine that is the target of the APPCVM CONNECT receives the allocate data (using APPCVM RECEIVE), the VM communication server area is not presented. As a result, the CPEVSRVL field in the VM area contains binary zeros, and the allocate data length in the connection pending interrupt reflects only the lengths of the VM area, the FMH5, and the VM-defined variable-length section.

**Considerations when using an External Security Manager with security label checking:** An APPCVM CONNECT from a communication server will fail with a condition code of 1 (cc=1) and a return code of 15 (IPRCODE=X'0F') if security label checking is enabled on the system.

## APPCVM QRYSTATE (Query State)

### Purpose

The QRYSTATE function gets the current state of any APPC/VM path on the issuing virtual machine.

**Note:** This is issued only by the CMS Protected Conversation Adapter (PCA).

### Parameters

Required Parameters:

#### PRMLIST=

specifies the address of the APPC/VM parameter list. The address must be a guest real address (real to the virtual machine), and the parameter list must be on a doubleword boundary.

##### *label*

is the relocatable label of the parameter list.

##### *(reg)*

is the register number that contains the address of the parameter list.

Optional Parameters:

#### MF=L

generates the instructions necessary to initialize the APPC/VM parameter list as specified, but does not invoke the APPCVM QRYSTATE.

#### PATHID=

specifies the path ID on which the state is to be queried.

##### *label*

is the relocatable label of a halfword that contains the path ID.

##### *(reg)*

is the register number that contains the path ID in the low-order halfword.

**Input Parameter List:** The APPCVM QRYSTATE parameter list has the following input format:

APPCVM QRYSTATE (Query State)

Figure 35. APPCVM QRYSTATE Input Parameter List

The parameters are:

**IPPATHID**  
contains the path ID on which the state is to be queried.

**IPFLAGS1**  
contains the following input bit flag:

**IPAPPC (X'08')**  
This is an APPC function.

**IPSIPCD**  
this value should always be set.

**X'00'**  
this value is reserved for IBM use only.

**X'01'**  
this value is reserved for IBM use only.

**X'02'**  
this value is reserved for IBM use only.

Condition Codes and Return Codes

| CC=0         | CC=1 | CC=2 | CC=3         |
|--------------|------|------|--------------|
| Not Possible | X    | X    | Not Possible |

QRYSTATE always completes immediately.

**CC=1**  
An error occurred before the QRYSTATE was initiated. The output parameter list is the same as the input shown in [QRYSTATE Input Parameter List](#), except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Meaning                                       |
|----------|--------------|-----------------------------------------------|
| X'01'    | 1            | The specified path ID is not yet established. |
| X'1E'    | 30           | This is a non-APPC path.                      |

**CC=2**  
QRYSTATE completed (also see [SENDREQ Completion](#)). The output parameter list when CC=2 is:

| IPARML DSECT |                                      |   |          |                                      |         |          |          |  |  |  |  |
|--------------|--------------------------------------|---|----------|--------------------------------------|---------|----------|----------|--|--|--|--|

Figure 36. APPCVM QRYSTATE Output Parameter List

The parameters are:

**IPPATHID**

contains the path ID on which QRYSTATE completed.

**IPFLAGS1**

may contain the following output bit flag:

**IPLRECL (X'10')**

A logical record is in progress.

**IPSIPFG**

is reserved for IBM use only.

**X'00'**

this value is reserved for IBM use only.

**X'01'**

this value is reserved for IBM use only.

**IPSTATE**

contains the current state for this path, which may have one of the following values:

**IPENDING (X'00')**

A function is pending on the path. When the function completes, the state change will occur.

**IPRESET (X'01')**

The path is in the Reset state.

**IPCONNCT (X'02')**

The path is in the Connect state.

**IPSENDST (X'03')**

The path is in the Send state.

**IPRECVST (X'04')**

The path is in the Receive state.

**IPCONFRM (X'05')**

The path is in the Confirm state.

**IPSEVER (X'06')**

The path is in the Sever state.

**IPDEFRCV (X'07')**

The path is in the Defer\_Receive state.

**IPDEFSVR (X'08')**

The path is in the Defer\_Sever state.

**IPPREPARE (X'09')**

The path is in the Prepare\_Received state.

**X'0A'**

this value is reserved for IBM use only.

**IPURQCMT (X'0B')**

The path is in the Unsolicited\_Request\_Commit\_Received state.

**IPBKOUT (X'0D')**

The path is in the Backout\_Received state.

**IPBKREQ (X'0E')**

The path is in the Backout\_Required state.

**IPSPCMOD**

is reserved for IBM use only.

**X'03'**

this value is reserved for IBM use only.

**X'04'**

this value is reserved for IBM use only.

**X'06'**

this value is reserved for IBM use only.

**IPSYCLVL**

indicates the synchronization level for the path.

**IPSYCNON (X'00')**

SYNCLVL=NONE.

**IPSYCCNF (X'01')**

SYNCLVL=CONFIRM.

**IPSYCSP (X'02')**

SYNCLVL=SYNCPT.

**Program Exceptions**

The program exceptions for QRYSTATE are:

| Type          | Description                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address is outside of the virtual machine.                                                                 |
| Operation     | Either an application interrupt buffer has not been declared, or the invoking virtual machine is not in the supervisor state. |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                             |
| Specification | The parameter list is not on a doubleword boundary.                                                                           |

**State Checks and State Changes**

There are no state changes associated with the QRYSTATE function.

## APPCVM RECEIVE

### Purpose

Use the `RECEIVE` function to receive data that is sent to your program.

In addition to receiving regular application data (sent by `APPCVM SENDDATA`), you can receive these special types of data:

- Log data, sent from your communication partner so that you can diagnose an error indication.
- Allocate data, sent from your communication partner to describe its connection request to you. You can receive this before accepting a connection.
- A program initialization parameter (PIP) variable. You can receive this before accepting a connection.

Refer to [Message Pending External Interrupt](#) for format and a description of the message pending interrupt.

When you issue `RECEIVE` and no message is currently pending on the path, the receive area that you specify is allocated for future messages on the path.

### Parameters

**Required Parameter:**

**PRMLIST=**

lets you specify the address of the APPC/VM parameter list. The address must be a guest real address, that is, the address is within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

***label***

is the relocatable label of the parameter list.

***(reg)***

is the register number that contains the address of the parameter list.

**Optional Parameters:****MF=L**

generates the instructions necessary to initialize the APPC/VM parameter list as specified, but does not invoke the APPCVM RECEIVE function.

**PATHID=**

lets you identify the path on which to receive data.

***label***

is the relocatable label of a halfword that contains the path ID.

***(reg)***

is the register number that contains the path ID in the low-order halfword.

**BUFLIST=**

specifies the type of buffer address that the BUFFER parameter refers to. (See [Specifying Buffers on RECEIVE.](#))

**YES**

refers to a list of addresses.

**NO**

refers to a single address.

**BUFFER=**

specifies the addresses of the areas into which CP places the data received. If BUFLIST=YES, this BUFFER address is the start of a list of addresses of discontinuous buffers. (See [Specifying Buffers on RECEIVE.](#))

***label***

is the relocatable label in storage where CP places the data received.

***(reg)***

is the register number that contains the address in storage where CP places the data received. This storage area is where CP places the message.

**BUFLN=**

specifies the total length of the area(s) into which APPC/VM places the data. (See [Specifying Buffers on RECEIVE.](#))

***label***

is the relocatable label of the fullword that contains the length.

***(reg)***

is the register number that contains the length.

**WAIT=**

lets you specify when control is returned to your virtual machine.

**YES**

returns control to your virtual machine after the RECEIVE completes.

**NO**

returns control to your virtual machine when you initiate the RECEIVE. If the RECEIVE does not complete immediately, you are notified with a function complete interrupt when it does complete.

**PIP=**

lets you specify whether or not the APPCVM RECEIVE is for a PIP variable.

**YES**

specifies that this APPCVM RECEIVE is for the PIP variable. PIP=YES can only be specified from the Connect state.

You can determine the total length of the PIP variable from the IPPIPLEN field in the connection pending interrupt. If you receive only part of the PIP variable or have not yet received any portion of the PIP variable, and then either accept or sever the connection, any remaining portion of the PIP variable gets purged.

You can receive the PIP variable before any allocate data is received, after all the allocate data is received, or after only a portion of the allocate data is received.

**NO**

specifies that this APPCVM RECEIVE is not for the PIP variable.

**Input Parameter List:** The APPCVM RECEIVE parameter list has the input format shown in the following figure.

Figure 37. APPCVM RECEIVE Input Parameter List

**IPPATHID**

contains the path ID over which you receive data.

**IPFLAGS1**

contains one of the following input bit flags:

**IPBUFLST (X'40')**

a buffer list was specified.

**IPAPPC (X'08')**

an APPC function was issued.

**IPFLAGS2**

contains the following input bit flag:

**IPWAIT (X'80')**

a synchronous return is desired (WAIT=YES was specified). IPWAIT is ignored if IPPIP is on.

**IPPIP (X'20')**

this program is receiving the PIP variable (PIP=YES was specified).

**IPBFADR1**

contains the address of the area where APPC/VM stores the received data or the address of the list. See the following section, [Specifying Buffers on RECEIVE](#).

**IPBFLN1F**

contains receive area length that IPBFADR1 specifies. See [Specifying Buffers on RECEIVE](#).

**Usage Notes**

**Specifying Buffers on RECEIVE:** You can use the buffer support with APPCVM RECEIVE to receive normal application data, log data, allocate data, and PIP variables. You can receive data by specifying a single buffer using one address and one length, or by specifying multiple buffers using a list of addresses and lengths.

When you specify a single buffer using one address and one length:

- BUFFER specifies the address.
- BUFLLEN specifies the length.
- BUFLIST must be equal to NO.

When you specify multiple buffers with a list of addresses and lengths:

- BUFFER specifies the address of the list.
- BUFLLEN specifies the sum of the lengths of the buffers in the list.
- BUFLIST must be equal to YES.

When specifying address lists (BUFLIST=YES), note the following:

1. The list must begin on a doubleword boundary.
2. Each list entry must be two fullwords:
  - The first fullword is the address of that portion of the list.
  - The second fullword is the length of that portion of the list.
3. The addresses and lengths in the address list are updated during APPC/VM processing. Do not alter them during processing or assume that they are unchanged when APPC/VM processing is complete.
4. APPC/VM assumes that there is another entry in the list until the sum of the lengths of the entries processed is equal to the total length specified by BUFLLEN.

**Note:** Do not code a receiving program so that the length of the receive buffer is based on the length of your communication partner's send buffer.

When a program on the local system sends data, the length in the message pending interrupt is the actual length of the data sent. However, when a program on a remote system sends data, intermediate communication servers (like the TSAF virtual machine) could break up a single data stream into multiple data streams, or combine numerous data streams. As a result, the length shown in your message pending interrupt is the length of the data sent by the intermediate communication server, *not* the length of the data sent by the source program. For example, your communication partner could send a data stream of 0 length followed by a data stream of 100 bytes. However, your program, the target, might get only one data stream message with a length of 100 bytes.

When participating in a basic conversation, your program should examine the 2-byte logical record length (LL) field to determine how much data your communication partner has sent on a logical record. See [Setting Up the Data To Send](#) for more information on logical records.

## Condition Codes and Return Codes

### CC=0

The RECEIVE started successfully, but has not yet completed. If your virtual machine is enabled for function complete interrupts, one is presented to your virtual machine when RECEIVE completes. The interrupt format is the same as the RECEIVE output parameter list (see CC=2 or CC=3). When you get the function complete interrupt, check the IPAUDIT field for error information.

When control is returned to your virtual machine with CC=0, the parameter list may have been altered.

**Note:** CC=0 is not possible when WAIT=YES or PIP=YES.

### CC=1

An error occurred before the RECEIVE was initiated. The parameter list format is the same as the input shown in [RECEIVE Input Parameter List](#), except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'01'    | 1            | You specified a path ID that is not yet established.                                                                                                                                                                                                                                                                                                                                                                           |
| X'03'    | 3            | A function is pending on this path.                                                                                                                                                                                                                                                                                                                                                                                            |
| X'06'    | 6            | <p>A storage protection exception occurred on one of your partner's buffers that was used for one of the following:</p> <ul style="list-style-type: none"> <li>• Application data (from APPCVM SENDDATA)</li> <li>• The PIP variable (from APPCVM CONNECT)</li> <li>• Log data (from APPCVM SENDERR or APPCVM SEVER)</li> </ul> <p>This applies only when your RECEIVE was issued after a message was pending on the path.</p> |
| X'07'    | 7            | <p>An addressing exception occurred on one of your partner's buffers that was used for one of the following:</p> <ul style="list-style-type: none"> <li>• Application data (from APPCVM SENDDATA)</li> <li>• The PIP variable (from APPCVM CONNECT)</li> <li>• Log data (from APPCVM SENDERR or APPCVM SEVER)</li> </ul> <p>This applies only when your RECEIVE was issued after a message was pending on the path.</p>        |
| X'0A'    | 10           | Your receive buffer length is negative.                                                                                                                                                                                                                                                                                                                                                                                        |
| X'14'    | 20           | The PIP variable cannot be received because the originator has severed the path.                                                                                                                                                                                                                                                                                                                                               |
| X'16'    | 22           | Your communication partner's send buffer list or PIP variable buffer list is invalid.                                                                                                                                                                                                                                                                                                                                          |
| X'17'    | 23           | A length specified in your receive buffer list is negative.                                                                                                                                                                                                                                                                                                                                                                    |
| X'18'    | 24           | The total length specified (BUFLEN) is not the total of the receive buffer lengths in your list.                                                                                                                                                                                                                                                                                                                               |
| X'1A'    | 26           | The receive buffer list address is not on a doubleword boundary.                                                                                                                                                                                                                                                                                                                                                               |
| X'1E'    | 30           | You specified an APPC/VM function on a non-APPC path.                                                                                                                                                                                                                                                                                                                                                                          |

| X'24'    | 36           | RECEIVE is an invalid function from the Sever state when the receive is not for log data.                                                                                                                                                                                                                                                                                                                                      |
| X'2B'    | 43           | There is an invalid logical record length in your communication partner's data stream.                                                                                                                                                                                                                                                                                                                                         |
| X'2C'    | 44           | Before issuing RECEIVE, you started—but did not finish—sending a logical record.                                                                                                                                                                                                                                                                                                                                               |
| X'2D'    | 45           | Your communication partner started—but did not finish—sending a logical record and tried to change to the Receive state.                                                                                                                                                                                                                                                                                                       |
| X'38'    | 56           | WAIT=YES was specified on a function issued to this same virtual machine.                                                                                                                                                                                                                                                                                                                                                      |

| Hex Code | Decimal Code | Why the Error Occurred                                                                                                                                                    |
|----------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'3B'    | 59           | Your partner specified an invalid GDS ID within the PIP variable.                                                                                                         |
| X'3C'    | 60           | Your partner specified an invalid length for a PIP subfield, or the total length in bytes 0 and 1 of the PIP variable is not the sum of the lengths of the PIP subfields. |
| X'44'    | 68           | RECEIVE is invalid from the Reset state.                                                                                                                                  |
| X'45'    | 69           | RECEIVE is invalid from the Defer_Receive state.                                                                                                                          |
| X'46'    | 70           | RECEIVE is invalid from the Defer_Sever state.                                                                                                                            |
| X'47'    | 71           | RECEIVE is invalid from the Prepare_Received state.                                                                                                                       |
| X'49'    | 73           | RECEIVE is invalid from the Unsolicited_Request_Commit_Received state.                                                                                                    |
| X'4B'    | 75           | RECEIVE is invalid from the Backout_Received state.                                                                                                                       |
| X'4C'    | 76           | RECEIVE is invalid from the Backout_Required state.                                                                                                                       |
| X'5B'    | 91           | A paging or storage error was detected in your communication partner's SEND data area                                                                                     |
| X'5C'    | 92           | A paging or storage error was detected in the RECEIVE data area                                                                                                           |

These return codes can only occur if a message is pending for the specified path at the time you issued the RECEIVE: X'06', X'07', X'16', X'17', X'18', X'2B', and X'2D'.

If no message is pending for the specified path at the time you issued the RECEIVE, CP reports the above error conditions (X'06', X'07', X'16', X'17', X'18', X'2B', and X'2D') to you in the corresponding IPAUDIT flags of your RECEIVE output parameter list, when your RECEIVE completes.

#### Notes:

1. Whenever CC=1, fields in the parameter list may have been altered.
2. For return codes X'16', X'17', X'18', X'2B', X'2D', X'3B', and X'3C' some data may have been received, but the amount is unpredictable.

#### CC=2 or CC=3

The RECEIVE is complete. (Also see [RECEIVE Completion](#).) When CC=2, the function completed with no errors; when CC=3, there is error information in IPAUDIT.

**Note:** CC=3 is not possible when WAIT=NO or PIP=YES.

The output parameter list when CC=2 or CC=3 is shown in the following figure.

| IPARML DSECT |                                  |          |        |                                  |          |          |       |
|--------------|----------------------------------|----------|--------|----------------------------------|----------|----------|-------|
| 0            | 1                                | 2        | 3      | 4                                | 5        | 6        | 7     |
| 0            | IPPATHID                         | IPFLAGS1 | IPTYPE | IPCODE                           | IPWHATRC | IPSENDOP |       |
| 8            | IPAUDIT                          |          |        | //////////////////////////////// |          |          |       |

Figure 38. APPCVM RECEIVE Output Parameter List (Function Complete Interrupt)

#### IPPATHID

contains the path ID on which the function is complete.

**IPFLAGS1**

may contain one or more of the following bit flags:

**IPFLUSH (X'40')**

for a non-sync-point conversation, your partner issued SENDDATA FLUSH=YES. In this case, this flag can only be seen by a communication server.

For a sync-point conversation, this flag is set under two conditions:

- Your partner issued SENDDATA FLUSH=YES BUFLLEN=0 from the Send state. In this case, you must be a communication server to see this flag.
- Your partner issued a SENDDATA FLUSH=YES from the Defer\_Receive state. In this case, you see this flag even if you are not a communication server.

**X'20'**

This value is reserved for IBM use only.

**IPTYPE**

contains the function complete interrupt code (IPTYPFCA, X'87').

**IPCODE**

contains the error, sever, or sense code from the partner's SENDERR, SEVER, or attempt to initiate a backout sync-point. IPCODE is only valid when IPWHATRC=IPERROR, IPSABEND, or X'14'. See [“APPC/VM Sever, Error, and Sense Codes That You Can Get”](#) on page 399.

**IPWHATRC**

contains the what-received code:

**IPDATA (X'01')**

only data was received, with no other indications.

**IPSEND (X'02')**

Your partner has switched the conversation around (using RECEIVE, SENDDATA RECEIVE=YES, or SENDDATA FLUSH=YES from the Defer\_Receive state) and you are now in the Send state.

**IPERROR (X'03')**

Your partner issued SENDERR.

**IPCNFRM (X'04')**

Your partner issued SENDCNF TYPE=NORMAL.

**IPCNFSEV (X'05')**

Your partner issued SENDCNF TYPE=SEVER.

**IPSNORM (X'08')**

Your partner issued a SEVER TYPE=NORMAL.

**IPSABEND (X'09')**

Your partner issued a SEVER TYPE=ABEND.

**IPALLOCD (X'0B')**

The allocate data was received.

**IPSNDCNF (X'0C')**

Your partner issued SENDCNF TYPE=PREPRECV.

**IPLGDATA (X'0D')**

The log data was received.

**IPPIPDAT (X'0E')**

The PIP variable has been received.

**IPPREPAR (X'0F')**

The function was completed with an indication that your partner initiated a CRR commit sync-point. You should commit the CMS work unit of which this conversation is a part.

**IPREQCOM (X'10')**

The function was completed with an indication that your partner initiated a CRR commit sync-point. You should commit the CMS work unit of which this conversation is a part.

**IPBACK (X'14')**

The function was completed with an indication that your partner initiated a CRR backout sync-point. You should back out the CMS work unit of which this conversation is a part.

**X'16'**

This value is reserved for IBM use only.

**Notes:**

1. Data may have been received for any IPWHATRC value.
2. You get IPDATA in IPWHATRC until you receive all the data that your partner (or intermediate communication server) sent with or before a nondata function. For example, IPWHATRC would be IPDATA if:
  - a. Your partner (or intermediate communication server) issued SENDDATA RECEIVE=YES with a data length of 200 bytes, and
  - b. You did a RECEIVE for 199 bytes.

When you issue a RECEIVE for the 200th byte, then IPWHATRC would become IPSEND.

**IPSENDOP**

contains the SEND option code:

**IPRECV (X'0A')**

The function being completed is a RECEIVE.

**IPAUDIT**

has four fields that may contain error information.

**Note:** In the following descriptions,

- **Receive area** refers to either a receive buffer specified directly on an APPCVM RECEIVE, BUFFER= or a receive buffer that is part of a buffer list.
- **Send area** refers to a buffer specified for the PIP variable (on APPCVM CONNECT), a buffer specified directly on an APPCVM SENDDATA, BUFFER=, or a buffer that is part of a buffer list.

**IPAUDIT1 (first byte of IPAUDIT)**

may contain one of the following bit flags:

**IPADANPX (X'10')**

A protection exception occurred on your receive area. This only applies if your RECEIVE was issued before a message was pending on the path. (It does not apply when receiving log data.)

**IPADANAX (X'08')**

An addressing exception occurred on your receive area. This only applies if your RECEIVE was issued before a message was pending on the path. (It does not apply when receiving log data.)

**IPAUDIT2 (second byte of IPAUDIT)**

May contain one of the following bit flags:

**IPADRPX (X'20')**

A protection exception occurred on your communication partner's send area. This only applies if your RECEIVE was issued before a message was pending on the path. (It does not apply when log data is being sent.)

**IPADRPAX (X'10')**

An addressing exception occurred on your communication partner's send area. This only applies if your RECEIVE was issued before a message was pending on the path. (It does not apply when log data is being sent.)

**IPADRLST (X'04')**

Your communication partner had an invalid SEND list.

**IPAUDIT3 (third byte of IPAUDIT)**

May contain one of the following bit flags:

**IPADALEN (X'40')**

A bad length is in your RECEIVE buffer list.

**IPADATOT (X'10')**

Your RECEIVE buffer length is invalid.

**IPADTINV (X'08')**

Your communication partner's data stream has an invalid logical record length.

**IPADTTRN (X'02')**

Your communication partner started, but did not finish, sending a logical record and tried to change to the Receive state.

**IPASYRC (fourth byte of IPAUDIT)**

May contain one of the following error codes (for which and appropriate IPRCODE was given to your communication partner):

| Hex Code | Decimal Code | Meaning                                                                               |
|----------|--------------|---------------------------------------------------------------------------------------|
| X'5B'    | 91           | A paging or storage error was detected in your communication partner's SEND data area |
| X'5C'    | 92           | A paging or storage error was detected in the RECEIVE data area.                      |

**Note:** IPAUDIT X'5D' and X'5E' are possible on a RECEIVE when the partner issues a RECEIVE prior to the SENDDATA (RECEIVE ahead).

**IPBFLN1F**

contains the length of pending log data for you to receive. This field is only meaningful when IPWHATRC is equal to IPSABEND or IPERROR.

**IPBFLN2F**

contains one of the following depending on the value of IPWHATRC:

- If IPWHATRC is equal to IPDATA, IPBFLN2F contains the number of bytes that were sent but did not fit into your defined RECEIVE area. This length is the byte length of your communication partner's (or communication server's) application data, allocation data, log data, or PIP variable, minus the length that you already received.

For example, your communication partner or communication server issues SENDDATA with a data length of 100, and you issue RECEIVE with a buffer length of 40, then IPBFLN2F would contain 60.

- If IPWHATRC is not equal to IPDATA, then IPBFLN2F contains the number of unused bytes remaining in your RECEIVE area.

For example, your communication partner or communication server issues SENDDATA RECEIVE=YES with a data length of 150, and you issue RECEIVE with a buffer length of 200, then IPWHATRC would contain IPSEND and IPBFLN2F would contain 50.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

**IPSTATE**

Contains the current state for this path, which may be any of the following values:

**IPCONNCT (X'02')**

The path is in the Connect state.

**IPSENDST (X'03')**

The path is in the Send state.

**IPRECVST (X'04')**

The path is in the Receive state.

**IPCONFRM (X'05')**

The path is in the Confirm state.

**IPSEVER (X'06')**

The path is in the Sever state.

**IPREPRE (X'09')**

The path is in the Prepare\_Received state.

**IPURQCMT (X'0B')**

The path is in the Unsolicited\_Request\_Commit\_Received state.

**IPBKOUT (X'0D')**

The path is in the Backout\_Received state.

**IPBKREQ (X'0E')**

The path is in the Backout\_Required state.

**IPWHTRC2**

further qualifies the IPWHATRC=IPPREPAR and IPWHATRC=IPREQCOM.

**IPTPSEND (X'03')**

Your partner requests to be in the Send state upon the successful completion of the commit sync-point.

**IPTPRECV (X'04')**

Your partner requests to be in the Receive state upon the successful completion of the commit sync-point.

**IPTPSEVR (X'06')**

Your partner requests to be in the Sever state upon the successful completion of the commit sync-point.

## Program Exceptions

The program exceptions for RECEIVE are:

| Type       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Addressing | <p>The parameter list address is outside of the virtual machine. An addressing exception also occurs for any of the following:</p> <ul style="list-style-type: none"> <li>• An invalid buffer address in the RECEIVE parameter list</li> <li>• An invalid buffer list address in the RECEIVE parameter list</li> <li>• An invalid buffer address in the RECEIVE buffer list.</li> </ul> <p>This only applies if the RECEIVE is issued after a message is pending on the path. (This includes messages for application data, the PIP variable, and log data.)</p> |
| Operation  | <p>Either an external interrupt buffer is not declared, or the invoking virtual machine is not in the supervisor state.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protection    | <p>The storage key of the parameter list address does not match the key of the user. A protection exception also occurs for any of the following:</p> <ul style="list-style-type: none"> <li>• The buffer address in the parameter list is protected.</li> <li>• The buffer list address in the parameter list is protected.</li> <li>• A buffer address in the buffer list is protected.</li> </ul> <p>This only applies if the RECEIVE is issued after a message is pending on the path. (This includes messages for application data, the PIP variable, and log data.)</p> |
| Specification | The parameter list is not on a doubleword boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## State Checks and State Changes

A state check results when APPCVM RECEIVE is issued from an improper state (you receive an IPRCODE when you issue a function from the improper state). You get a state check (IPRCODE=X'20') if you issue an APPCVM RECEIVE from the Connect state under the following conditions:

- After you have received all the allocate data
- After you have received all the PIP variable (when PIP=YES)
- When no PIP variable was sent (when PIP=YES)
- You issue an APPCVM RECEIVE PIP=YES after a previous APPCVM RECEIVE PIP=YES was invalid.

You get a state check (IPRCODE=X'2B' or X'2C') if you issue APPCVM RECEIVE PIP=YES from the Receive or the Send state. You also get a state check (IPRCODE=X'2C') if you start, but do not finish, sending a logical record on this path. See the list of APPCVM RECEIVE return codes for all state check conditions.

No state change occurs when CC=1. State changes can occur when either of the following happens:

- The function completes, and control is returned to the virtual machine (CC=2 or 3).
- The function complete interrupt is accepted by your virtual machine (or you use IUCV TESTCMPL to discover that the function completed).

The state change depends on the IPWHATRC value you got in the output parameter list:

| IPWHATRC Value | New State                   | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IPDATA         | Receive or Connect or Sever | <p>Depends on your state when you invoke RECEIVE:</p> <ul style="list-style-type: none"> <li>• If you are <b>not</b> in the Connect state or the Sever state, you enter the Receive state. The RECEIVE completed without you receiving any nondata indications. Your communication partner sent data to complete the RECEIVE, or the receive length was 0.</li> <li>• If you are in the Connect state, you remain in the Connect state. An IPDATA indication means there is still some allocation data or a portion of PIP variable left for you to receive.</li> <li>• If you are in the Sever state, you remain in the Sever state. An IPDATA indication means that there is still some log data left for you to receive.</li> </ul> |

| IPWHATRC Value | New State                           | Cause                                                                                                                                                                                                                                                                           |
|----------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IPSEND         | Send                                | Your communication partner issued RECEIVE or SENDDATA RECEIVE=YES to complete the RECEIVE.<br><br>Otherwise, your communication partner issued SENDDATA FLUSH=YES, BUFLLEN=0 from the Defer_Receive state.                                                                      |
| IPERROR        | Receive                             | Your communication partner issued a SENDERR to complete the RECEIVE.                                                                                                                                                                                                            |
| IPCNFRM        | Confirm                             | Your communication partner issued a SENDCNF TYPE=NORMAL to complete the RECEIVE.                                                                                                                                                                                                |
| IPSNDCNF       | Confirm                             | The partner is requesting confirmation that it can enter the Receive state. Your communication partner issued a SENDCNF TYPE=PREPRECV from the Send state to complete the RECEIVE.<br><br>Your communication partner issued SENDCNF TYPE=PREPRECV from the Defer_Receive state. |
| IPCNFSEV       | Confirm                             | Your communication partner issued a SENDCNF TYPE=SEVER to complete the RECEIVE.                                                                                                                                                                                                 |
| IPSNORM        | Sever                               | Your communication partner issued a SEVER TYPE=NORMAL to complete the RECEIVE.                                                                                                                                                                                                  |
| IPSABEND       | Sever                               | Your communication partner issued a SEVER TYPE=ABEND to complete the RECEIVE.                                                                                                                                                                                                   |
| IPALLOCD       | Connect                             | You completed the RECEIVE of the allocate data.                                                                                                                                                                                                                                 |
| IPPIPDAT       | Connect                             | You completed the RECEIVE of the PIP variable.                                                                                                                                                                                                                                  |
| IPLGDATA       | Receive or Sever                    | You completed the RECEIVE of the log data. If you were in the Receive state, you remain in the Receive state; if you were in the Sever state, you remain in the Sever state.                                                                                                    |
| IPPREPAR       | Prepare_Received                    | Your communications partner initiated a commit sync-point to complete the RECEIVE.                                                                                                                                                                                              |
| IPREQCOM       | Unsolicited_Request_Commit_Received | Your communications partner initiated a commit sync-point to complete the RECEIVE.                                                                                                                                                                                              |
| IPBACK         | Backout_Received                    | Your communications partner initiated a backout sync-point to complete the RECEIVE.                                                                                                                                                                                             |
| X'16'          |                                     | This state is reserved for IBM use only.                                                                                                                                                                                                                                        |

## Completion Conditions

You cannot issue another RECEIVE, SEND, or SEVER TYPE=NORMAL on the same path until your outstanding RECEIVE completes. (In this case, SEND refers to the set of APPC/VM send functions: SENDCNF, SENDCNFD, SENDDATA, SENDERR, and SENDREQ.) Your RECEIVE completes immediately when it is issued for the following:

- A pending message that has no data
- A pending message that has enough data to fill your receive area.

If the amount of pending data is not enough to fill your receive area, your program's RECEIVE waits until either it gets more data or gets a nondata indication from your partner.

Your RECEIVE also completes when your receive area is larger than the data in the pending message, but you get an indication (in IPWHATRC) that:

- Your communication partner issued RECEIVE, SENDCNF, SENDDATA RECEIVE=YES, SENDERR, or SEVER.
- You have received all allocate data, PIP variables, or log data.

When your receive area has a 0 length and you are in:

- The Receive state, the RECEIVE completes immediately
- The Send state, the RECEIVE completes when your communication partner or an intermediate communication server receives notice that it is in the Send state.

Note the following:

- When the RECEIVE is for allocate data, you get IPDATA in IPWHATRC if you only partially receive allocate data. When you receive all the allocate data, you get IPALLOCD in IPWHATRC.
- When the RECEIVE is for a PIP variable, you get IPDATA in IPWHATRC if you only partially receive the PIP variable. When you receive the entire PIP variable, you get IPPIPDAT in IPWHATRC.
- When the RECEIVE is for log data, you get IPDATA in IPWHATRC if you only partially receive log data. When you receive all the log data, you get IPLGDATA in IPWHATRC.
- Your RECEIVE always completes immediately if your receive area is larger than pending allocate data, PIP variable, or log data.
- Except when receiving allocation data or PIP data, if your communication partner severs, your RECEIVE completes immediately. The IPWHATRC value in your output parameter list indicates the sever, and you are presented with a sever interrupt.

## What Happens to Your VM Communication Partner

If an intermediate communication server (like TSAF, ISFC, or AVS) handles communication between you and your partner, the information in this section also describes what happens to the intermediate server when you issue RECEIVE.

After you issue APPCVM RECEIVE, your communication partner may get a function complete interrupt, a message pending interrupt, or no indication at all.

Your partner gets a function complete interrupt for the following conditions, your partner:

- Has a SENDDATA RECEIVE=NO or SENDDATA RECEIVE=YES with a 0 answer length outstanding on its half of the path, and you have received all the data sent.
- Issued SENDERR without sending log data.
- Issued SENDERR with log data, and you have received all the log data.
- Issued APPCVM SEVER TYPE=ABEND with log data, and you have received all the log data.

If your communication partner has a SENDCNF or SENDDATA RECEIVE=YES outstanding on its half of the path, your partner does not get any notification of your actions on that path until you respond.

Your communication partner does not get an indication that you have received allocate data or PIP variable.

**Note:** Your communication partner should not reuse the data buffers for the PIP variable until the connection request has completed.

Your partner gets a message pending interrupt if your partner:

- Has no function outstanding on its half of the path
- Is in the Receive state on its half of the path
- Is enabled for message pending interrupts.

## APPCVM RECEIVE

See [Message Pending External Interrupt](#).

**SEVER**

requests a confirmation that would let you issue a SEVER.

**Note:** For a SYNCLVL=SYNCPT conversation, this parameter can only be specified by an authorized communication server.

**PREPRECV**

also requests a normal confirmation, but if this confirmation is successful, your program switches to the Receive state.

**Optional Parameters:**

**MF=L**

generates the instructions necessary to initialize the APPC/VM parameter list as specified, but does not invoke the APPCVM SENDCNF.

**PATHID=**

lets you identify the path on which to send the confirmation request.

**label**

is the relocatable label of a halfword that contains the path ID.

**(reg)**

is the register number that contains the path ID in the low-order halfword.

**WAIT=**

specifies when control is returned to your virtual machine.

**YES**

returns control to your virtual machine when the SENDCNF is complete.

**NO**

returns control to your virtual machine as soon as the SENDCNF request is initiated. When the SENDCNF completes, you are notified with a function complete interrupt.

**Input Parameter List:** The APPCVM SENDCNF parameter list has the input format shown in the following figure.

Figure 39. APPCVM SENDCNF Input Parameter List

**IPPATHID**

contains the path ID on which the confirmation request is sent.

**IPFLAGS1**

contains the following input bit flag:

**IPAPPCSN (X'02')**

indicates an APPC SEND function was issued.

**IPFLAGS2**

may contain one or more of the following input bit flags:

**IPWAIT (X'80')**

a synchronous return was requested.

**IPCOMSRV (X'20')**

SENDCNF was issued by a communication server.

**Note:** This bit must be set on by an authorized communication server if SENDCNF TYPE=SEVER is issued on a SYNCLVL=SYNCPT conversation.

### IPSENDOP

contains one of the following SEND option codes:

#### IPCNFRM (X'04')

You are requesting normal confirmation from your communication partner.

#### IPCNFSEV (X'05')

You are requesting confirmation from your communication partner that you can issue a SEVER.

#### IPPREPRC (X'0C')

You are requesting confirmation from your communication partner that you can enter the Receive state.

## Condition Codes and Return Codes

| CC=0 | CC=1 | CC=2 | CC=3         |
|------|------|------|--------------|
| X    | X    | X    | Not Possible |

### CC=0

SENDCNF started successfully, but has not yet completed. When it completes, CP presents your virtual machine with a function complete interrupt. The function complete interrupt buffer has the same format as the SENDCNF output parameter list (see CC=2, below).

**Note:** When WAIT=YES, CC=0 is not possible.

### CC=1

An error occurred. The output parameter list is the same as the input shown in [SENDCNF Input Parameter List](#), except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                                                              |
|----------|--------------|-------------------------------------------------------------------------------------|
| X'01'    | 1            | You specified a path ID that is not yet established.                                |
| X'03'    | 3            | A function is pending on this path.                                                 |
| X'1D'    | 29           | You are not authorized as a communication server.                                   |
| X'1E'    | 30           | You specified an APPC/VM function on a non-APPC path.                               |
| X'20'    | 32           | SENDCNF is an invalid function from the Connect state.                              |
| X'22'    | 34           | SENDCNF is an invalid function from the Receive state.                              |
| X'23'    | 35           | SENDCNF is an invalid function from the Confirm state.                              |
| X'24'    | 36           | SENDCNF is an invalid function from the Sever state.                                |
| X'25'    | 37           | The connection was established with SYNCLVL=NONE.                                   |
| X'26'    | 38           | The IPSENDOP field contains an invalid value.                                       |
| X'2C'    | 44           | Before invoking SENDCNF, you started, but did not finish, sending a logical record. |
| X'38'    | 56           | WAIT=YES was specified on a function issued to this same virtual machine.           |
| X'44'    | 68           | SENDCNF is invalid from the Reset state.                                            |
| X'45'    | 69           | SENDCNF TYPE=NORMAL or TYPE=SEVER is invalid from the Defer_Receive state.          |

| Hex Code | Decimal Code | Why the Error Occurred                                                                              |
|----------|--------------|-----------------------------------------------------------------------------------------------------|
| X'46'    | 70           | SENDCNF TYPE=NORMAL/SEVER is invalid from the Defer_Sever state.                                    |
| X'47'    | 71           | SENDCNF is invalid from the Prepare_Received state.                                                 |
| X'49'    | 73           | SENDCNF is invalid from the Unsolicited_Request_Commit_Received state.                              |
| X'4B'    | 75           | SENDCNF is invalid from the Backout_Received state.                                                 |
| X'4C'    | 76           | SENDCNF is invalid from the Backout_Required state.                                                 |
| X'4F'    | 79           | SENDCNF TYPE=SEVER is invalid on a SYNCLVL=SYNCPT conversation when the IPCOMSRV bit is not set on. |

**CC=2**

SENDCNF completed (see [SENDCNF Completion](#)), with no errors.

The output parameter list when CC=2 is shown in the following figure.

Figure 40. APPCVM SENDCNF Output Parameter List (Function Complete Interrupt)

**IPPATHID**

contains the path ID on which the function is complete.

**IPTYPE**

contains the function complete interrupt code (IPTYPFCA, X'87').

**IPCODE**

contains the error code from the partner's SENDERR or sever code from the partner's SEVER. IPCODE is only valid when IPWHATRC=IPERROR or IPSABEND. See [“APPC/VM Sever, Error, and Sense Codes That You Can Get” on page 399](#).

**IPWHATRC**

contains one of the following what-received codes:

**IPCOMP (X'00')**

Your partner's SENDCNFD completed the function.

**IPERROR (X'03')**

Your partner issued SENDERR.

**IPSABEND (X'09')**

Your partner issued a SEVER TYPE=ABEND.

**IPBACK (X'14')**

Your partner initiated a backout sync-point.

**IPSENDOP**

contains one of the following SEND option codes:

**IPCNFRM (X'04')**

The SENDCNF TYPE=NORMAL is being completed.

**IPCNFSEV (X'05')**

The SENDCNF TYPE=SEVER is being completed.

**IPPREPRC (X'0C')**

The SENDCNF TYPE=PREPRECV is being completed.

**IPBFLN1F**

contains the length of pending log data for you to receive. This field is meaningful only when IPWHATRC is equal to IPSABEND or IPERROR.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

**IPSTATE**

contains one of the following values that show the current state for this path:

**IPSENDST (X'03')**

The path is in the Send state.

**IPRECVST (X'04')**

The path is in the Receive state.

**IPSEVER (X'06')**

The path is in the Sever state.

**IPBKOUT (X'0D')**

The path is in the Backout\_Received state.

**IPBKREQ (X'0E')**

The path is in the Backout\_Required state.

## Program Exceptions

The program exceptions for SENDCNF are:

| Type          | Description                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address is outside of the virtual machine.                                                        |
| Operation     | Either an external interrupt buffer is not declared, or the invoking virtual machine is not in the supervisor state. |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                    |
| Specification | The parameter list is not on a doubleword boundary.                                                                  |

## State Checks and State Changes

A state check results when your virtual machine issues APPCVM SENDCNF and it is not in the Send state on this path. A state check also occurs (IPRCODE=X'2C') if you started—but did not finish—sending a logical record on this path. (See the list of APPCVM SENDCNF return codes for all state check conditions.)

No state change occurs when CC=1. State changes can occur when the function completes, and one of the following occurs:

- You regain control (CC=2).
- You accept the function complete interrupt (CC=0), or you use TESTCMPL to discover that the function was completed.

The state change depends on the IPWHATRC value:

| <b>IPWHATRC Value</b> | <b>New State</b> | <b>Cause</b>                                                                                                                       |
|-----------------------|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| IPCOMP                | Send             | The SENDCNF TYPE=NORMAL was completed by the communication partner issuing a SENDCNFD.                                             |
| IPCOMP                | Sever            | The SENDCNF TYPE=SEVER was completed by the communication partner issuing a SENDCNFD.                                              |
| IPCOMP                | Receive          | The SENDCNF TYPE=PREPRECV, issued from Send or Defer_Receive state, was completed by the communication partner issuing a SENDCNFD. |
| IPERROR               | Receive          | The SENDCNF was completed by the communication partner issuing a SENDERR.                                                          |
| IPSABEND              | Sever            | The SENDCNF was completed by the communication partner issuing a SEVER TYPE=ABEND.                                                 |
| IPBACK                | Backout_Received | Your communication partner initiated a backout sync-point.                                                                         |

**Note:** When you issue SENDCNF, you have no way of telling if the SENDERR or SEVER indication received is in response to your confirmation request or if it was issued before your SENDCNF.

### Completion Conditions

After issuing a SENDCNF, you cannot issue another SEND, RECEIVE, or SEVER TYPE=NORMAL on that path until the outstanding SENDCNF is complete. (SEND generally refers to the APPC/VM send functions: SENDCNF, SENDCNFD, SENDDATA, SENDERR, and SENDREQ.) SENDCNF is complete when the communication partner responds with a SENDCNFD, SENDERR, or SEVER.

### What Happens to Your VM Communication Partner

Your communication partner's outstanding function may complete, or your partner may get a message pending interrupt.

If your partner has a RECEIVE, SENDDATA RECEIVE=YES, or SENDERR outstanding on its half of the path, your partner's outstanding function is completed.

Your partner gets a message pending interrupt, if your partner:

- Has no function outstanding on its half of the path
- Is in the Receive state on its half of the path
- Is enabled for message pending interrupts.

See [Message Pending External Interrupt](#).

## APPCVM SENDCNFD (Send Confirmed)

### Purpose

Use the SENDCNFD (Send Confirmed) function to send a confirmation response from your program to another program. You should issue this as a positive response to your partner sending a SENDCNF (or to confirm your partner's backout sync-point). (For a negative response, invoke SENDERR; see “[APPCVM SENDERR \(Send Error\)](#)” on page 490.)

### Parameters

#### Required Parameter:

##### PRMLIST=

specifies the address of the APPC/VM parameter list. The address must be a guest real address, that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

##### *label*

is the relocatable label of the parameter list.

##### (*reg*)

is the register number that contains the address of the parameter list.

#### Optional Parameters:

##### MF=L

generates the instructions necessary to initialize the APPC/VM parameter list as specified, but does not invoke the APPCVM SENDCNFD.

##### PATHID=

identifies the path on which to send the confirmation.

##### *label*

is the relocatable label of a halfword that contains the path ID.

##### (*reg*)

is the register number that contains the path ID in the low-order halfword.

**Input Parameter List:** The APPCVM SENDCNFD parameter list has the input format shown in the following figure.

APPCVM SENDCNFD (Send Confirmed)

Figure 41. APPCVM SENDCNFD Input Parameter List

**IPPATHID**

contains the path ID on which the confirmation is sent.

**IPFLAGS1**

contains the following input bit flag:

**IPAPPCSN (X'02')**

The APPC SEND function was issued.

**IPFLAGS2**

Contains the following input bit flag:

**IPCOMSRV (X'20')**

The SENDCNFD was issued from a communication server.

**Note:** The flag must be set by an authorized communication server. Virtual machines that are not communication servers, should not set this flag.

**IPSENDOP**

contains the SEND option code:

**IPCNFRMD (X'06')**

your communication partner is sending confirmation as requested.

**Condition Codes and Return Codes**

|              |             |             |              |
|--------------|-------------|-------------|--------------|
| <b>CC=0</b>  | <b>CC=1</b> | <b>CC=2</b> | <b>CC=3</b>  |
| Not Possible | X           | X           | Not Possible |

SENDCNFD always completes immediately.

**CC=1**

An error occurred. The parameter list format is the same as the input shown in the [SENDCNFD Input Parameter List](#), except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                                  |
|----------|--------------|---------------------------------------------------------|
| X'01'    | 1            | You specified a path ID that is not yet established.    |
| X'1E'    | 30           | You specified an APPC/VM function on a non-APPC path.   |
| X'20'    | 32           | SENDCNFD is an invalid function from the Connect state. |
| X'21'    | 33           | SENDCNFD is an invalid function from the Send state.    |
| X'22'    | 34           | SENDCNFD is an invalid function from the Receive state. |
| X'24'    | 36           | SENDCNFD is an invalid function from the Sever state.   |
| X'26'    | 38           | The IPSENDOP field contains an invalid value.           |

| Hex Code | Decimal Code | Why the Error Occurred                                                  |
|----------|--------------|-------------------------------------------------------------------------|
| X'44'    | 68           | SENDCNFD is invalid from the Reset state.                               |
| X'45'    | 69           | SENDCNFD is invalid from the Defer_Receive state.                       |
| X'46'    | 70           | SENDCNFD is invalid from the Defer_Seiver state.                        |
| X'47'    | 71           | SENDCNFD is invalid from the Prepare_Received state.                    |
| X'49'    | 73           | SENDCNFD is invalid from the Unsolicited_Request_Commit_Received state. |
| X'4C'    | 76           | SENDCNFD is invalid from the Backout_Required state.                    |

**CC=2**

SENDCNFD completed (see [SENDCNFD Completion](#)).

The output parameter list when CC=2 is shown in the following figure.

Figure 42. APPCVM SENDCNFD Output Parameter List (Function Complete Interrupt)

**IPPATHID**

contains the path ID on which the function is complete.

**IPTYPE**

contains the function complete interrupt code (IPTYPFCA, X'87').

**IPWHATRC**

contains one of the following what-received codes:

**IPCOMP (X'00')**

SENDCNFD completed in response to a SENDCNF TYPE=NORMAL.

**IPSNORM (X'08')**

SENDCNFD completed in response to a SENDCNF TYPE=SEVER.

**IPSNDCNF (X'0C')**

SENDCNFD completed in response to a SENDCNF TYPE=PREPREC.V.

**IPCNFBK (X'15')**

SENDCNFD completed in response to your partner's backout sync-point.

**IPSENDOP**

contains the SEND option code:

**IPCNFRMD (X'06')**

the SENDCNFD is being completed.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV

DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

**IPSTATE**

contains one of the following values for the state of this path:

**IPSENDST (X'03')**

The path is in the Send state.

**IPRECVST (X'04')**

The path is in the Receive state.

**IPSEVER (X'06')**

The path is in the Sever state.

**Program Exceptions**

The program exceptions for SENDCNFD are:

| Type          | Description                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address is outside of the virtual machine.                                                        |
| Operation     | Either an external interrupt buffer is not declared, or the invoking virtual machine is not in the supervisor state. |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                    |
| Specification | The parameter list is not on a doubleword boundary.                                                                  |

**State Checks and State Changes**

A state check results when your virtual machine issues APPCVM SENDCNFD and it is not in the Confirm state or the Backout\_Received state on this path. (You receive an IPRCODE if you issue a function from the wrong state.) See the list of APPCVM SENDCNFD return codes for all state check conditions.

No state change occurs when CC=1. State changes do occur when the function completes; that is, when control is returned to the virtual machine (CC=2). The state change depends on the value of IPWHATRC:

| IPWHATRC Value | New State          | Cause                                                                         |
|----------------|--------------------|-------------------------------------------------------------------------------|
| IPCOMP         | Receive            | The SENDCNFD was in response to SENDCNF TYPE=NORMAL.                          |
| IPSNORM        | Sever              | The SENDCNFD was in response to SENDCNF TYPE=SEVER.                           |
| IPSNDCNF       | Send               | The SENDCNFD was in response to SENDCNF TYPE=PREPRECV.                        |
| IPCNFBK        | <i>saved_state</i> | The SENDCNFD was issued from the BACKOUT_Received state to confirm a backout. |

**Completion Conditions**

Because the SENDCNFD function completes immediately, you can issue another function on the same path as soon as your virtual machine regains control.

**What Happens to Your VM Communication Partner**

You can only issue SENDCNFD in response to a SENDCNF for SYNCLVL=CONFIRM or SYNCLVL=SYNCPT conversations. SENDCNFD always causes the completion of the SENDCNF. For SYNCLVL=SYNCPT conversations, SENDCNFD can also be issued in response to your partner's backout sync-point. If your communication partner issued SENDCNF with WAIT=NO, and your partner is enabled for function complete interrupts, then your partner gets a function complete interrupt.

## APPCVM SENDDATA

### Purpose

Use the `SENDATA` function to send data from your program to your communication partner. You can also use this function to switch the conversation state from the Send state to the Receive state and to define an answer area for your partner's `SENDATA`.

### Parameters

#### Required Parameters:

**PRMLIST=**

specifies the address of the APPC/VM parameter list. The address must be a guest real address, that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

***label***

is the relocatable label of the parameter list.

**(reg)**

is the register number that contains the address of the parameter list.

**RECEIVE=**

specifies whether to switch from Send to Receive state and define an answer area to get data back from your communication partner.

**YES**

switches the conversation state and defines an answer area.

**Note:** If you specify RECEIVE=YES, FLUSH=YES is invalid for this SENDDATA.

**NO**

keeps your program in the Send state and does not define an answer area.

**Optional Parameters:****MF=L**

generates the instructions necessary to initialize the APPC/VM parameter list as specified, but does not invoke the APPCVM SENDDATA.

**PATHID=**

specifies the path ID on which you send the data.

***label***

is the relocatable label of a halfword that contains the path ID.

**(reg)**

is the register number that contains the path ID in the low-order halfword.

**BUFLIST=**

specifies whether the BUFFER parameter refers to a single buffer address or an address for a list of buffers. (For more information, see [Specifying Buffers on SENDDATA](#).)

**YES**

specifies that BUFFER refers to a list of addresses.

**NO**

specifies that BUFFER refers to a single address.

**BUFFER=**

specifies the areas in storage where CP gets the data to send. (See [Specifying Buffers on SENDDATA](#).)

***label***

is the relocatable label for this storage area.

**(reg)**

is the register number that contains the address of this storage area.

**BUFLEN=**

specifies the total length, in bytes, of the data to be sent. See [Specifying Buffers on SENDDATA](#).

Note that this length is not related to the length of a logical record, because the data does not have to be sent in complete logical records. See [Setting Up the Data To Send](#).

***label***

is the relocatable label of the fullword that contains the length.

**(reg)**

is the register number that contains the length.

**ANSLIST=**

specifies whether the ANSBUF parameter refers to a single buffer address or an address for a list of buffers. (See [Specifying Buffers on SENDDATA.](#))

**YES**

specifies that ANSBUF refers to a list of addresses.

**NO**

specifies that ANSBUF refers to a single address.

**ANSBUF=**

specifies the areas in storage where CP places data that is sent by your communication partner. (See [Specifying Buffers on SENDDATA.](#))

**label**

is the relocatable label for this storage area.

**(reg)**

is the register number that contains the address of this storage area.

**ANSLEN=**

specifies the total length of the data (in bytes) sent by your communication partner. (See [Specifying Buffers on SENDDATA.](#))

**label**

is the relocatable label of the fullword that contains the length.

**(reg)**

is the register number that contains the length.

**WAIT=**

specifies when control is returned to your virtual machine.

**YES**

returns control to your virtual machine when the SENDDATA is complete.

**NO**

returns control to your virtual machine when the SENDDATA request is initiated.

After you issue a SENDDATA with WAIT=NO, do not assume that the data is moved out of the buffer until you receive a function complete indication.

**FLUSH=**

specifies whether your local LU should flush its send buffer.

**YES**

causes your local LU to flush its send buffer when SENDDATA is complete.

**Note:** FLUSH=YES is invalid if you also specify RECEIVE=YES on this SENDDATA.

**NO**

does not cause your local LU to flush its send buffer when SENDDATA is complete.

**Input Parameter List:** The APPCVM SENDDATA parameter list has the input format shown in the following figure.

| IPARML DSECT |                                  |   |          |   |                                  |   |          |          |
|--------------|----------------------------------|---|----------|---|----------------------------------|---|----------|----------|
|              | 0                                | 1 | 2        | 3 | 4                                | 5 | 6        | 7        |
| 0            | IPPATHID                         |   | IPFLAGS1 |   | //////////////////////////////// |   | IPFLAGS2 | IPSENDOP |
| 8            | //////////////////////////////// |   |          |   | IPBFADR1                         |   |          |          |
| 10           | IPBFLN1F                         |   |          |   | //////////////////////////////// |   |          |          |
| 18           | //////////////////////////////// |   |          |   | IPBFADR2                         |   |          |          |
| 20           | IPBFLN2F                         |   |          |   | //////////////////////////////// |   |          |          |

Figure 43. APPCVM SENDDATA Input Parameter List

**IPPATHID**

contains the path ID over which you send the data.

**IPFLAGS1**

contains one of the following input bit flags:

**IPBUFLST (X'40')**

BUFLIST was specified.

**IPANSLST (X'08')**

ANSLIST was specified.

**IPAPPCSN (X'02')**

The APPC SEND function was issued.

**X'80'**

this value is reserved for IBM use only.

**IPFLAGS2**

contains one of the following input bit flags:

**IPWAIT (X'80')**

A synchronous return is desired.

**IPNOFLSH (X'40')**

FLUSH=NO is specified. This flag is ignored unless IPSENDOP=IPDATA is set.

**IPSENDOP**

contains one of the following SEND option codes:

**IPDATA (X'01')**

You are sending data.

**IPSNDRCV (X'02')**

You are sending the data. The conversation is to be turned around, and an answer area is defined by IPBFADR2 and IPBFLN2F.

**IPBFADR1**

contains the address from which CP gets the data to send. This address is either the address of a buffer or the address of a list of buffer addresses. (See [Specifying Buffers on SENDDATA](#).)

**IPBFLN1F**

contains the total length of the data being sent. This length is not related to the length of a logical record; it is used only to determine the length of the data to be moved by this SENDDATA. (See [Specifying Buffers on SENDDATA](#).)

**IPBFADR2**

contains the address where CP places the answer data from your communication partner. This address is either the address of a buffer or the address of a list of buffer addresses. IPBFADR2 is only valid when IPSENDOP=IPSNDRCV. (See [Specifying Buffers on SENDDATA](#).)

**IPBFLN2F**

contains the total length of the answer data received from your communication partner. IPBFADR2 is only valid when IPSENDOP=IPSNDRCV. (See [Specifying Buffers on SENDDATA](#).)

**Usage Notes**

**Setting Up the Data To Send:** Using APPCVM SENDDATA, data is sent from a source program to a target program in buffers. APPC defines a **logical record** so that applications can communicate without depending on each other's buffering priorities and the priorities of any intermediate communication servers.

A logical record consists of a 2-byte logical record length field (LL) followed by a data field as shown in the following figure.

Figure 44. APPC Logical Record Format

The LL field, in its low-order 15 bits, contains the **total** length of the logical record. A discussion of the high-order bit of the LL field follows later in this section. This total logical record length includes the 2-bytes for the LL field, plus the length of the data field; as a result, the total logical record length must always be at least 2 bytes. If the data field has a length of 0, the logical record contains only the 2-byte length field.

The data field in a single logical record can range from 0 to 32,765 bytes long. If your program sends more than 32,765 bytes of data, it must break up the data into multiple logical records.

APPC defines two kinds of conversations, basic conversations and mapped conversations.

**Basic Conversations:** For *basic conversations*, application programs send data directly in the APPC-defined logical record format. They need to include a 2-byte length field (LL) followed by the data field, as described above. For basic conversations, the LUs do not examine the high-order bit of the LL field. The following logical record length values are invalid, because the total length must be at least 2 and the high-order bit is ignored: X'0000', X'0001', X'8000', and X'8001'.

The length of the data that a program actually sends on a single APPCVM SENDDATA is independent of the logical record length. The data actually sent by a program on one SENDDATA could consist of one or more complete logical records, the beginning of a record, the middle of a record, or the end of a record. For example, you can specify any of the following combinations:

- One or more complete records, followed by the beginning of a record
- The end of a record, followed by one or more complete records
- The end of a record, followed by one or more complete records, followed by the beginning of a record
- The end of a record, followed by the beginning of a record.

**Note:** However, you only specify the 2-byte logical record length (LL) once per logical record—even if that logical record spans more than one SENDDATA.

**Mapped Conversations:** A program using the APPC/VM assembler language API and attempting to conduct a mapped conversation with its partner must be aware that CP does not encode or decode mapped conversation data streams; rather, it is the responsibility of the APPC/VM assembler application.

**Note:** CPI Communication (also known as SAA communications interface) performs the data stream encoding and decoding functions for the applications it serves. If you use CPI communication, you do not have to encode or decode mapped conversation data streams.

An APPC/VM assembler application allocates a mapped conversation by specifying TYPE=MAPPED on the APPCVM CONNECT macro (this results in the IPMAPIED bit in the IPFLAGS2 field of the CONNECT parameter list being set). A receiving APPC/VM assembler application can determine whether an inbound conversation is mapped by checking the IPMAPIED bit of the IPFLAGS2 field in the connection pending interrupt buffer.

A technique called *general data stream* organizes the data flowing on an APPC mapped conversation. (In fact, GDS formats organize not only APPC mapped conversations, but other line flows in SNA as well.) For more information on GDS formats, and on how GDS formats to organize APPC mapped conversations, see *Systems Network Architecture: Formats*, GA27-3136.

**Specifying Buffers on SENDDATA:** With APPCVM SENDDATA, you can specify a single buffer using one address and one length, or multiple buffers using a list of addresses and lengths.

When you specify a single buffer using one address and one length:

- BUFFER (or ANSBUF) specifies the address
- BUFLen (or ANSLen) specifies the length
- BUFLIST (or ANSLIST) must be equal to NO.

When you specify multiple buffers with a list of addresses and lengths:

- BUFFER (or ANSBUF) specifies the address of the list
- BUFLen (or ANSLen) specifies the sum of the lengths of the buffers in the list
- BUFLIST (or ANSLIST) must be equal to YES.

You must follow these conventions when you use address lists (BUFLIST=YES or ANSLIST=YES):

- The list must begin on a doubleword boundary.
- Each list entry must be two fullwords:
  - The first is the address of that portion of the list.
  - The second is the length of that portion of the list.

When you use an address list, the addresses and lengths in the address list are updated during APPC/VM processing. Do not alter them during processing or assume that they are unchanged when APPC/VM processing is complete. Also, APPC/VM assumes that there is another entry in the list until the sum of the lengths of the entries processed is equal to the total length specified (by BUFLLEN or ANSLLEN).

Each application involved in the communication must determine the amount of data sent in each data stream. You can choose buffer sizes based on whatever is important to your application, such as the size of free storage buffers or efficient storage utilization.

**Note:** Even if you are responsible for both ends of the communication, do not code a receiving program so that the length of the receive buffer is based on the length of the send buffer.

When a program on the local system sends data, the length in the message pending interrupt is the actual length of the data sent. However, when a program on a remote system sends data, intermediate communication servers (like the TSAF virtual machine) could break up a single data stream into multiple data streams, or combine numerous data streams; as a result, the length shown in the target's message pending interrupt is the length of the data sent by the intermediate communication server, **not** the length of the data sent by the source program. For example, you could send a data stream of 0 length followed by a data stream of 100 bytes. However, the target program might get only one data stream message with the length of 100 bytes.

For basic conversations, your communication partner should examine the 2-byte logical record length field to determine how much data you sent on a logical record.

## Condition Codes and Return Codes

### CC=0

The SENDDATA started successfully, but has not yet completed. If your virtual machine is enabled for function complete interrupts, one is presented to your virtual machine when SENDDATA completes. The interrupt format is the same as the SENDDATA output parameter list (see CC=2, 3). When you get the function complete interrupt, check the IPAUDIT field for error information.

When control is returned to your virtual machine with CC=0, the parameter list may have been altered.

**Note:** CC=0 is not possible when WAIT=YES.

### CC=1

An error occurred before the SENDDATA was initiated. The output parameter list is the same as the input shown in [SENDATA Input Parameter List](#), except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                                                                                     |
|----------|--------------|------------------------------------------------------------------------------------------------------------|
| X'01'    | 1            | You specified a path ID that is not yet established.                                                       |
| X'03'    | 3            | A function is pending on this path.                                                                        |
| X'06'    | 6            | A protection exception occurred on your communication partner's <b>predefined</b> answer or receive area.  |
| X'07'    | 7            | An addressing exception occurred on your communication partner's <b>predefined</b> answer or receive area. |

| Hex Code | Decimal Code | Why the Error Occurred                                                                                                        |
|----------|--------------|-------------------------------------------------------------------------------------------------------------------------------|
| X'0A'    | 10           | Your send buffer length (BUFLEN) or answer buffer length (ANSLEN) is negative.                                                |
| X'16'    | 22           | Your communication partner's predefined answer list or receive list is invalid.                                               |
| X'17'    | 23           | A length specified in your send buffer list is negative.                                                                      |
| X'18'    | 24           | The total length that you specified (BUFLEN) is not the total of the lengths in your send buffer list.                        |
| X'1A'    | 26           | The send buffer list does not begin on a doubleword boundary.                                                                 |
| X'1B'    | 27           | The answer buffer list does not begin on a doubleword boundary.                                                               |
| X'1E'    | 30           | You specified an APPC/VM function on a non-APPC path.                                                                         |
| X'20'    | 32           | SENDATA is an invalid function from the Connect state.                                                                        |
| X'22'    | 34           | SENDATA is an invalid function from the Receive state.                                                                        |
| X'23'    | 35           | SENDATA is an invalid function from the Confirm state.                                                                        |
| X'24'    | 36           | SENDATA is an invalid function from the Sever state.                                                                          |
| X'26'    | 38           | There was an invalid value in IPSENDOP field.                                                                                 |
| X'2A'    | 42           | There is an invalid logical record length in your data stream.                                                                |
| X'2C'    | 44           | You started, but did not finish, sending a logical record. (This can only occur if you specified RECEIVE=YES on the SENDATA.) |
| X'38'    | 56           | WAIT=YES was specified on a function issued to this same virtual machine.                                                     |
| X'44'    | 68           | SENDATA is invalid from the Reset state.                                                                                      |
| X'45'    | 69           | SENDATA FLUSH=NO or SENDATA FLUSH=YES, BUFLEN > 0 is invalid from the Defer_Receive state.                                    |
| X'46'    | 70           | SENDATA is invalid from the Defer_Sever state.                                                                                |
| X'47'    | 71           | SENDATA is invalid from the Prepare_Received state.                                                                           |
| X'49'    | 73           | SENDATA is invalid from the Unsolicited_Request_Commit_Received state.                                                        |
| X'4B'    | 75           | SENDATA is invalid from the Backout_Received state.                                                                           |
| X'4C'    | 76           | SENDATA is invalid from the Backout_Required state.                                                                           |
| X'5B'    | 91           | A paging or storage error was detected in the SEND data area.                                                                 |
| X'5C'    | 92           | A paging or storage error was detected in the RECEIVE data area.                                                              |
| X'5D'    | 93           | A paging or storage error was detected in the ANSWER data area.                                                               |
| X'5E'    | 94           | A paging or storage error was detected in the REPLY data area.                                                                |

The following return codes can only occur if your communication partner defined an answer area or receive area before you issued the SENDATA:

X'06', X'07', X'16', X'17', X'18', X'2A', and X'2C'.

If your communication partner did not define an answer area or receive area before you issued the SENDATA, CP reports the above error conditions (X'06', X'07', X'16', X'17', X'18', X'2A', and X'2C') to you in the IPAUDIT flags of your SENDATA output parameter list, when your partner's RECEIVE completes.

Your partner learns of the error through one of the following:

- A protection exception from CP
- An addressing exception from CP

- A return code on the RECEIVE
- The IPAUDIT flags of the RECEIVE output parameter list, when the RECEIVE completes.

For the following return codes, data may be copied to your communication partner's virtual machine before the error is detected (the amount of data copied in this case is unpredictable):

X'16', X'17', X'18', X'2A', and X'2C'

Note that for CC=1, other fields in the parameter list might have been altered.

#### CC=2 or

#### CC=3

The SENDDATA completed. (Also see [SENDDATA Completion](#).) When CC=2, then the function completed with no errors; when CC=3, there is some error information in IPAUDIT.

**Note:** When WAIT=NO, CC=3 is not possible.

The output parameter list when CC=2 or 3 is shown in the following figure.

| IPARML DSECT |                                      |          |        |                                      |          |          |       |
|--------------|--------------------------------------|----------|--------|--------------------------------------|----------|----------|-------|
| 0            | 1                                    | 2        | 3      | 4                                    | 5        | 6        | 7     |
| 0            | IPPATHID                             | IPFLAGS1 | IPTYPE | IPCODE                               | IPWHATRC | IPSENDOR |       |
| 8            | IPAUDIT                              |          |        | //////////////////////////////////// |          |          |       |

| 20           | IPBFLN2F                             |          |        | IPPOLLFG                             | IPSTATE  | IPWHTRC2 | ///// |

Figure 45. APPCVM SENDDATA Output Parameter List (Function Complete Interrupt)

#### IPPATHID

contains the path ID on which the function is complete.

#### IPFLAGS1

may contain the following output bit flag:

##### X'20'

This value is reserved for IBM use only.

#### IPTYPE

contains the function complete interrupt code (IPTYPFCA, X'87').

#### IPCODE

contains the error or sever code from the partner's SENDERR or SEVER. IPCODE is only valid when IPWHATRC=IPERROR or IPSABEND. See [“APPC/VM Sever, Error, and Sense Codes That You Can Get”](#) on page 399.

#### IPWHATRC

contains the what-received code. For RECEIVE=YES or RECEIVE=NO:

##### IPCOMP (X'00')

Either of the following has occurred:

- The SENDDATA RECEIVE=NO completed normally.
- The SENDDATA RECEIVE=YES or NO completed with an error on your SEND buffer or on your partner's answer or RECEIVE buffer. See the IPAUDIT description.

##### IPERROR (X'03')

Your partner issued SENDERR.

##### IPSABEND (X'09')

Your partner issued a SEVER TYPE=ABEND.

##### IPBACK (X'14')

The function was completed with an indication that your partner initiated a CRR backout sync-point. You should back out the CMS work unit of which this conversation is a part.

For RECEIVE=YES only:

**IPDATA (X'01')**

Only data was received.

**IPSEND (X'02')**

Your partner switched the conversation around, and you are now in the Send state.

**IPCNFRM (X'04')**

Your partner is requesting confirmation.

**IPCNFSEV (X'05')**

Your partner is requesting confirmation that it can issue a SEVER.

**IPSNORM (X'08')**

Your partner issued a SEVER TYPE=NORMAL.

**IPSNDCNF (X'0C')**

Your partner is requesting confirmation that it can enter the Receive state.

**IPPREPAR (X'0F')**

The function was completed with an indication that your partner initiated a CRR commit sync-point. You should commit the CMS work unit of which this conversation is a part. (This is not possible when RECEIVE=NO.)

**IPREQCOM (X'10')**

The function was completed with a SENDRQCM indication. (This is not possible when RECEIVE=NO.)

**Notes:**

1. When SENDDATA RECEIVE=YES is specified, data might have been received for any IPWHATRC value.
2. You do not get a nondata indication in IPWHATRC until you do a SENDDATA RECEIVE=YES for all the data that your partner (or intermediate communication server) sent with or before the nondata function. For example, if both of the following were true:
  - a. You did a SENDDATA RECEIVE=YES with a 199-byte answer area
  - b. Your partner (or intermediate communication server) issued SENDDATA RECEIVE=YES with a data length of 200 bytes.

IPWHATRC would be IPDATA. When you issue a RECEIVE for the 200th byte, IPWHATRC would become IPSEND.

**IPSENDOP**

Contains one of the following SEND option codes:

**IPDATA (X'01')**

Your SENDDATA RECEIVE=NO is completing.

**IPSNDRCV (X'02')**

Your SENDDATA RECEIVE=YES is completing.

**IPAUDIT**

Has four fields that may contain error information.

**Note:** In the following descriptions,

- **Send area** refers to either a send buffer specified directly on an APPCVM SENDDATA, BUFFER= or a send buffer that is part of a buffer list.
- **Answer area** refers to either an answer buffer specified directly on an APPCVM SENDDATA, ANSBUF= or an answer buffer that is part of a buffer list.
- **Receive area** refers to either a receive buffer specified directly on an APPCVM RECEIVE, BUFFER= or a receive buffer that is part of a buffer list.

(See [Specifying Buffers on SENDDATA](#) for more information.)

**IPAUDIT1 (first byte of IPAUDIT)**

May contain one of the following bit flags:

**IPADSNPX (X'40')**

A protection exception occurred on your send area. This only applies if your partner did not have a receive area defined when your data was sent.

**IPADSNAX (X'20')**

An addressing exception occurred on your send area. This only applies if your partner did not have a receive area defined when your data was sent.

**IPADANPX (X'10')**

A protection exception occurred on your answer area.

**IPADANAX (X'08')**

An addressing exception occurred on your answer area.

**IPAUDIT2 (second byte of IPAUDIT)**

May contain one of the following bit flags:

**IPADRCPX (X'80')**

A protection exception occurred on your communication partner's receive area (if your partner did not have the receive area defined when your data was sent), or your communication partner's answer area.

**IPADRCAX (X'40')**

An addressing exception occurred on your communication partner's receive area (if your partner did not have the receive area defined when your data was sent), or your communication partner's answer area.

**IPADRPPX (X'20')**

A protection exception occurred on your communication partner's send area.

**IPADRPAX (X'10')**

An addressing exception occurred on your communication partner's send area.

**IPADRLST (X'04')**

Your communication partner had an invalid send, answer, or receive buffer list.

**IPAUDIT3 (third byte of IPAUDIT)**

May contain one of the following bit flags:

**IPADBLEN (X'80')**

A bad length is in your send buffer list.

**IPADALEN (X'40')**

A bad length is in your answer buffer list.

**IPADBTOT (X'20')**

Your total send buffer length is invalid.

**IPADATOT (X'10')**

Your total answer buffer length is invalid.

**IPADTINV (X'08')**

There is an invalid logical record length in your communication partner's data stream.

**IPADIINV (X'04')**

There is an invalid logical record length in your data stream.

**IPADTTRN (X'02')**

Your communication partner started, but did not finish, sending a logical record and tried to change to the Receive state.

**IPADITRN (X'01')**

You started, but did not finish, sending a logical record and you tried to change to the Receive state.

**IPASYRC (fourth byte of IPAUDIT)**

May contain one of the following error codes (for which an appropriate IPRCODE was given to your communication partner):

| Hex Code | Decimal Code | Meaning                                                          |
|----------|--------------|------------------------------------------------------------------|
| X'5B'    | 91           | A paging or storage error was detected in the SEND data area     |
| X'5C'    | 92           | A paging or storage error was detected in the RECEIVE data area. |
| X'5D'    | 93           | A paging or storage error was detected in the ANSWER data area.  |
| X'5E'    | 94           | A paging or storage error was detected in the REPLY data area.   |

**Note:** IPRCODEs X'5D' and X'5E' are possible on a SENDDATA when the partner issues a RECEIVE prior to the SENDDATA (RECEIVE ahead).

**IPBFLN1F**

Contains the length of pending log data for you to receive. This field is only meaningful when IPWHATRC is equal to IPSABEND or IPERROR.

**IPBFLN2F**

Contains one of the following depending on the value of IPWHATRC. If IPWHATRC is:

- Equal to IPDATA, IPBFLN2F contains the number of bytes that were sent by your communication partner, but did not fit into the defined answer area. This length is not the length of the APPC data stream being sent, rather, it is the length of the data that has arrived and is ready to receive.
- Not equal to IPDATA, IPBFLN2F contains the number of bytes left in your defined answer area.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

**IPSTATE**

Contains the current state for this path, which may be any of the following values:

**IPSENDST (X'03')**

The path is in the Send state.

**IPRECVST (X'04')**

The path is in the Receive state.

**IPCONFRM (X'05')**

The path is in the Confirm state.

**IPSEVER (X'06')**

The path is in the Sever state.

**IPREPRE (X'09')**

The path is in the Prepare\_Received state.

**IPURQCM (X'0B')**

The path is in the Unsolicited\_Request\_Commit\_Received state.

**IPBKOUT (X'0D')**

The path is in the Backout\_Received state.

**IPBKREQ (X'0E')**

The path is in the Backout\_Required state.

**IPWHTRC2**

Further qualifies the IPWHATRC=IPPREPAR and IPWHATRC=IPREQCOM:

**IPTSEND (X'03')**

Your partner requests to be in the Send state upon the successful completion of the commit sync-point.

**IPTPRECV (X'04')**

Your partner requests to be in the Receive state upon the successful completion of the commit sync-point.

**IPTPSEVR (X'06')**

Your partner requests to be in the Sever state upon the successful completion of the commit sync-point.

**Program Exceptions**

The program exceptions for SENDDATA are:

| Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Addressing    | <p>The parameter list address is outside of the virtual machine. An addressing exception also occurs for any of the following:</p> <ul style="list-style-type: none"> <li>• An invalid buffer address in SENDDATA's parameter list</li> <li>• An invalid buffer list address in SENDDATA's parameter list</li> <li>• An invalid buffer address in SENDDATA's buffer list.</li> </ul> <p>This only applies if your partner had a receive area defined when you sent the data. (Answer areas are always predefined.)</p>                    |
| Operation     | <p>Either an external interrupt buffer was not declared, or the invoking virtual machine is not in the supervisor state.</p>                                                                                                                                                                                                                                                                                                                                                                                                              |
| Protection    | <p>The storage key of the parameter list address does not match the key of the user. A protection exception also occurs for any of the following:</p> <ul style="list-style-type: none"> <li>• An invalid buffer address in SENDDATA's parameter list</li> <li>• An invalid buffer list address in SENDDATA's parameter list</li> <li>• An invalid buffer address in SENDDATA's buffer list.</li> </ul> <p>This only applies if your partner had a receive area defined when you sent the data. (Answer areas are always predefined.)</p> |
| Specification | <p>The parameter list is not on a doubleword boundary.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**State Checks and State Changes**

A state check results when your virtual machine issues APPCVM SENDDATA and it is not in the Send state for this path. (You also receive an IPRCODE since you issued a function from an improper state.) A state check also occurs (IPRCODE=X'2C') if you started, but did not finish, sending a logical record on this path at the completion of the send portion of your SENDDATA RECEIVE=YES. See the list of APPCVM SENDDATA return codes for all state check conditions.

When you issue SENDDATA RECEIVE=YES, your communication partner receives notice of this as if you had issued the following sequence of functions:

1. SENDDATA RECEIVE=NO
2. RECEIVE.

When the receive part of the SENDDATA RECEIVE=YES begins, you should have completed sending any outstanding logical records. For example, the following sequence would cause an error:

1. You issue SENDDATA RECEIVE=YES BUFLLEN=999 to send a logical record with a logical record length of 1000 bytes.
2. Your partner does a RECEIVE of the 999 bytes.
3. The receive portion of your SENDDATA RECEIVE begins.

In this situation, the error is caused because you did not send all 1000 bytes; therefore, you did not complete sending the outstanding logical record.

No state change occurs when CC=1. State changes occur when:

- The function completes; that is, control returns to the virtual machine (CC=2 or 3).
- The function complete interrupt is accepted by the virtual machine (CC=0) or you complete the function using TESTCMPL.

The state change depends on the IPWHATRC value:

| IPWHATRC Value | New State               | Cause                                                                                                                                                                                                                                                                                                                         |
|----------------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IPCOMP         | No state change occurs. | Either of the following could be the cause: <ul style="list-style-type: none"> <li>• The SENDDATA RECEIVE=NO has completed normally.</li> <li>• The SENDDATA RECEIVE=YES or NO completed with an error on your SEND buffer or on your partner's answer or RECEIVE buffer.</li> </ul>                                          |
| IPCOMP         | Receive                 | The SENDDATA FLUSH=YES is issued from the Defer_Receive state.                                                                                                                                                                                                                                                                |
| IPDATA         | Receive                 | Either of the following could be the cause: <ul style="list-style-type: none"> <li>• The SENDDATA RECEIVE=YES with a nonzero length answer area was completed by your partner sending data.</li> <li>• The SENDDATA RECEIVE=YES with a 0 length answer area was completed by your partner receiving the data sent.</li> </ul> |
| IPSEND         | Send                    | The SENDDATA RECEIVE=YES was completed by the communication partner issuing a RECEIVE or SENDDATA RECEIVE=YES.                                                                                                                                                                                                                |
| IPERROR        | Receive                 | The SENDDATA was completed by the communication partner issuing a SENDERR.                                                                                                                                                                                                                                                    |
| IPCNFRM        | Confirm                 | The SENDDATA RECEIVE=YES was completed by the communication partner issuing a SENDCNF TYPE=NORMAL.                                                                                                                                                                                                                            |
| IPCNFSEV       | Confirm                 | The SENDDATA RECEIVE=YES was completed by the communication partner issuing a SENDCNF TYPE=SEVER.                                                                                                                                                                                                                             |
| IPSNDCNF       | Confirm                 | The SENDDATA RECEIVE=YES was completed by the communication partner issuing a SENDCNF TYPE=PREPRECV.                                                                                                                                                                                                                          |
| IPSNORM        | Sever                   | The SENDDATA RECEIVE=YES was completed by the communication partner issuing a SEVER TYPE=NORMAL.                                                                                                                                                                                                                              |
| IPSABEND       | Sever                   | The SENDDATA was completed by the communication partner issuing a SEVER TYPE=ABEND.                                                                                                                                                                                                                                           |

| IPWHATRC Value | New State                           | Cause                                                                              |
|----------------|-------------------------------------|------------------------------------------------------------------------------------|
| IPPREPAR       | Prepare_Received                    | Your communication partner initiated a commit sync-point to complete the SENDDATA. |
| IPREQCOM       | Unsolicited_Request_Commit_Received | Your communication partner initiated a commit sync-point to complete the SENDDATA. |
| IPBACK         | Backout_Received                    | Your communication partner issued a SENDBACK to complete the SENDATA.              |

## Completion Conditions

After issuing a SENDDATA, you cannot issue another SEND (see note), RECEIVE, or SEVER TYPE=NORMAL on that path until the outstanding SENDDATA is complete.

**Note:** SEND generally refers to all of the APPC/VM send functions: SENDCNF, SENDCNFD, SENDDATA, SENDERR, and SENDREQ.

When the SENDDATA completes for a communication program depends on the value you give to the RECEIVE parameter of SENDDATA:

- When RECEIVE=NO, your SENDDATA is complete when all of the data is copied out of your SEND buffer, or when your communication partner issues a SENDERR or a SEVER.
- Your SENDDATA completes immediately when RECEIVE=NO, FLUSH=NO, and you specify a 0-length send buffer.
- When RECEIVE=NO, FLUSH=YES, and you specify a 0-length send buffer (this is called a **pure flush**), your SENDDATA completes immediately, unless your partner is notified of the flush. (See IPFLUSH (X'40') in the IPFLAGS1 Return Code for “APPCVM RECEIVE” on page 451 for more information.)
- When RECEIVE=YES and you specify a 0 answer area, your SENDDATA is complete when all of the data is copied out of your SEND buffer.
- When RECEIVE=YES and you specify a nonzero answer area, then the SENDDATA is complete when all of the data is copied out of your SEND buffer and your communication partner:
  - Sends messages to your virtual machine to completely fill the answer area specified on your virtual machine's SENDDATA
  - Issues RECEIVE, SENDCNF, SENDDATA RECEIVE=YES, SENDERR, or SEVER.

Remember, when you specify SENDDATA RECEIVE=YES with a nonzero answer area length, you get one function complete interrupt when your communication partner or an intermediate communication server issues a function. But, when you specify SENDDATA RECEIVE=NO followed by a RECEIVE, you receive two function complete interrupts. The first interrupt is a result of the data being copied out of your SEND buffer; the second interrupt is when your RECEIVE is completed.

## What Happens to Your VM Communication Partner

**Note:** If an intermediate communication server (like TSAF, ISFC, or AVS) handles communication between you and your partner, the information in this section also describes what happens to the intermediate server when you issue SENDDATA.

When you issue an APPCVM SENDDATA, your communication partner's outstanding function may complete, or your partner may get a message pending interrupt:

- If your partner has a SENDERR outstanding on its half of the path, your partner's function completes.
- If your partner has a SENDDATA RECEIVE=YES or RECEIVE outstanding on its half of the path and you issued SENDDATA RECEIVE=YES or RECEIVE, then your partner's function completes.

- If your partner has a SENDDATA RECEIVE=YES outstanding on its half of the path and you issued SENDDATA RECEIVE=NO, your partner's function completes only when you send enough data to fill your partner's predefined receive area.
- Your partner gets a message pending interrupt if it:
  - Has no function outstanding on its half of the path
  - Is in the Receive state on its half of the path
  - Is enabled for message pending interrupts.

**Message Pending External Interrupt:** Your program can get a message pending interrupt when your communication partner issues APPCVM SENDDATA, RECEIVE, SENDCNF, SENDERR, or initiates a commit or backout sync-point.

The APPC/VM message pending external interrupt has the format shown in the following figure.

Figure 46. Message Pending External Interrupt

#### IPPATHID

contains the path ID on which a message is pending.

#### IPTYPE

contains the interrupt type for a message pending (IPTYPMPA, X'89').

#### IPBFLN1F

contains the length of the pending message. This length is the length of the data that has arrived and is ready to receive.

When the data is sent by a virtual machine on your system, IPBFLN1F specifies the entire length of the data sent. When the data is sent by a virtual machine on a remote system, IPBFLN1F specifies only the length of the data sent by the communication server (typically TSAF or AVS).

#### IPPOLLFG

Contains a flag returned by IUCV.

#### IPNOPOLL (X'80')

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

Your program gets a message pending interrupt for a path only when its half of the path is in the Receive state. If your program is not in the Receive state on that path, the message pending interrupt is kept pending until your half of the path enters the Receive state; then you get the message pending interrupt. When you receive the message, check the condition code or the IPWHATRC field to find what to do next. See [“APPCVM RECEIVE” on page 451](#) for more information.

## APPCVM SENDERR (Send Error)

### Purpose

Use the **SENDERR** function to notify your communication partner that an error has occurred and causes a break in a typical send/receive sequence. You can also issue **SENDERR** as a negative response to a confirmation request (**SENDCNF**). After issuing **SENDERR**, your program can send error information to your communication partner using **SENDDATA**.

Your program can optionally specify log data directly on the **SENDERR** call.

### Parameters

#### Required Parameter:

##### **PRMLIST=**

specifies the address of the APPC/VM parameter list. The address must be a guest real address, that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

***label***

is the relocatable label of the parameter list.

***(reg)***

is the register number that contains the address of the parameter list.

**Optional Parameters:****MF=L**

generates the instructions necessary to initialize the APPC/VM parameter list as specified, but does not invoke the APPCVM SENDERR.

**PATHID=**

specifies the path ID of the path on which you send the error notice.

***label***

is the relocatable label of a halfword that contains the path ID.

***(reg)***

is the register number that contains the path ID in the low-order halfword.

**WAIT=**

specifies when control is returned to your virtual machine.

**YES**

returns control to your virtual machine when the SENDERR is complete.

**NO**

returns control to your virtual machine as soon as you issue the SENDERR request. When the SENDERR completes, you are notified with a function complete interrupt.

**TYPE=**

describes the level of error that CP reports to your communication partner. CP generates the appropriate error code to correspond to this value. TYPE is invalid if CODE is specified.

**PROG**

indicates that a user application program error is being reported. The error code will be one of the following: X'0410', X'0420', or X'0430'.

**SVC**

indicates that an LU services error is being reported. For example, this error type is used by the programs providing mapped conversation support to report errors. (CP does not check to ensure that SENDERR TYPE=SVC is issued on a mapped conversation.) The error code sent will be one of the following: X'0510', X'0520', or X'0530'.

See [Error Codes that CP and Communication Servers Can Issue](#) for the APPC meanings of these error codes.

**CODE=**

specifies a 2-byte error code that a communication server sends to your communication partner. CODE is invalid if TYPE is specified.

***label***

is a relocatable label in the storage area that contains the error code.

***(reg)***

is the register number that contains the error code in the low-order halfword.

Only communication servers (authorized by OPTION COMSRV in their directory entries) can specify CODE. Communication servers should use the APPC/VM-defined error codes; they should not define error codes for their own use. See [Error Codes that CP and Communication Servers Can Issue](#).

If your program is not a communication server, it should just issue the APPCVM SENDERR function without an error code; CP generates the appropriate error code based on the states of the programs.

**BUFLIST=**

specifies the type of buffer address to which the BUFFER parameter refers.

## APPCVM SENDERR (Send Error)

### YES

refers to a list of addresses.

### NO

refers to a single address.

### BUFFER=

specifies the address of the areas from which CP takes the log data.

#### *label*

is the relocatable label in storage where CP gets the log data to send.

#### *(reg)*

is the register number that contains the address of the storage area. This storage area is where CP gets the log data to send.

### BUFLEN=

specifies the length of the areas from which APPC/VM takes the log data to be sent. The minimum length is eight bytes; the maximum length is 600 bytes. This length is not related to the length of a logical record.

#### *label*

is the relocatable label of the fullword that contains the length.

#### *(reg)*

is the register number that contains the length.

### DIRECT=

specifies the state (SEND or RECEIVE) your program was in when you detected the error. Specifying the state ensures that the partner gets the correct error code.

DIRECT is ignored unless this is the first function issued after receiving both data and a SEND indication on the last function to complete. DIRECT is invalid if CODE is specified.

### SEND

indicates that the error was detected while the program was preparing to send data. The error code issued for this case indicates that the logical record was not truncated.

### RECEIVE

indicates that the error was detected while the program was receiving the data. The error code issued for this case indicates that the remaining data was purged.

**Input Parameter List:** The APPCVM SENDERR parameter list has the input format shown in the following figure.

| IPARML DSECT |                                      |   |          |       |          |   |          |          |  |  |  |
|--------------|--------------------------------------|---|----------|-------|----------|---|----------|----------|--|--|--|
| 0            | 1                                    | 2 | 3        | 4     | 5        | 6 | 7        |          |  |  |  |
| 0            | IPPATHID                             |   | IPFLAGS1 | ///// | IPCODE   |   | IPFLAGS2 | IPSENDOP |  |  |  |
| 8            | //////////////////////////////////// |   |          |       | IPBFADR1 |   |          |          |  |  |  |
| 10           | IPBFLN1F                             |   |          |       |          |   |          |          |  |  |  |
| 18           | //////////////////////////////////// |   |          |       |          |   |          |          |  |  |  |
| 20           | //////////////////////////////////// |   |          |       |          |   |          |          |  |  |  |

Figure 47. APPCVM SENDERR Input Parameter List

### IPPATHID

contains the path ID over which to send the SENDERR.

### IPFLAGS1

contains one of the following input bit flags:

#### **IPBUFLST (X'40')**

You specified the buffer list option.

#### **IPAPPCSN (X'02')**

The APPC SEND function was issued.

**IPCODE**

contains the error code you are sending on the APPCVM SENDERR. IPCODE is only valid when IPCOMSRV is set. Refer to [Error Codes that CP and Communication Servers Can Issue](#).

**IPFLAGS2**

contains one of the following input bit flags:

**IPWAIT (X'80')**

You specified a synchronous return.

**IPCHGDIR (X'40')**

You specified DIRECT=RECEIVE.

**IPCOMSRV (X'20')**

The SENDERR is being issued for another user. Only an authorized communication server (OPTION COMSRV in the directory entry) can specify IPCOMSRV. When you do specify IPCOMSRV, CP does not generate a SENDERR code, but, instead, uses the one that you provide. It is your responsibility to ensure that the code is appropriate.

**IPTPSVC (X'10')**

You specified an LU services error.

**IPSENDOP**

contains the SEND option code:

**IPERROR (X'03')**

indicates the SENDERR.

**IPBFADR1**

contains the address of the area from which APPC/VM takes one of the following:

- The log data
- The address of a list of buffer addresses.

See [Specifying Log Data](#).

**IPBFLN1F**

contains the length of the log data being sent. If IPBFLN1F is 0, then no log data is being sent. Otherwise, log data is being sent.

**Usage Notes**

**Specifying Log Data:** An application program can choose to set up log data and send that log data using buffers specified on APPCVM SENDERR. Log data conveys error information to an LU, where it is added to the system error log. This error information can be used in debugging and error recovery.

When using APPCVM SENDERR to send log data to your communication partner, you use buffers. You can specify a single buffer using one address and one length or specify multiple buffers using a list of addresses and lengths.

When you specify a single buffer using one address and one length,

- BUFFER specifies the address
- BUFLN specifies the length
- BUFLIST must be equal to NO.

When you specify multiple buffers with a list of addresses and lengths,

- BUFFER specifies the address of the list
- BUFLN specifies the sum of the lengths of the buffers in the list
- BUFLIST must be equal to YES.

When specifying address lists (BUFLIST=YES), note the following:

- The list must begin on a doubleword boundary.

**APPCVM SENDERR (Send Error)**

- Each list entry must be two fullwords; the first is the address of that portion of the list, and the second is the length.
- The addresses and lengths in the address list are updated during APPC/VM processing. Do not alter them during processing or assume that they are unchanged when APPC/VM processing is complete.
- APPC/VM assumes that there is another entry in the list until the sum of the lengths of the entries processed is equal to the total length specified by BUFLLEN.

The log data you are sending in buffers must be coded into an error log general data stream (GDS) variable. An error log GDS variable has the format as defined by SNA LU 6.2 and shown in the following figure.

Figure 48. Error Log GDS Variable Format

- GDS1**  
contains the length, in binary, of the error log GDS variable, including this length field. This must be in the range from 8 to 600 bytes.
- GDS2**  
contains a GDS identifier for an error log variable, X'12E1'.
- GDS3**  
contains the length, in binary, of the product set ID (GDS4) including this length field.  
**Note:** The length field is always present; a value of 2 indicates no product set ID subvector follows.
- GDS4**  
contains the product set ID subvector. This subvector, which is variable length, uniquely identifies the product.
- GDS5**  
contains the length, in binary, of the log data including this length field.  
**Note:** The length field is always present; a value of 2 indicates no log data follows.
- GDS6**  
contains the log data.

For more information about the error log GDS variable and product set ID, see *SNA Format and Protocol Reference Manual: Architectural Logic for LU Type 6.2*.

**Error Codes That CP and Communication Servers Can Issue:** See [Table 75 on page 494](#) for the codes that CP or a communication server can issue on an APPCVM SENDERR.

This table also shows the APPC error condition associated with each error code. For more information on what these APPC conditions mean and when to use these error codes, see *SNA Format and Protocol Reference Manual: Architectural Logic for LU Type 6.2*.

**Note:** A communication server within a TSAF collection can specify only codes X'0410', X'0420', and X'0430'.

Table 75. APPC/VM-Defined SENDERR Codes

| APPC/VM Code | APPC Error Condition |
|--------------|----------------------|
| X'0410'      | PROG_ERROR_NO_TRUNC  |

Table 75. APPC/VM-Defined SENDERR Codes (continued)

| APPC/VM Code | APPC Error Condition |
|--------------|----------------------|
| X'0420'      | PROG_ERROR_TRUNC     |
| X'0430'      | PROG_ERROR_PURGING   |
| X'0510'      | SVC_ERROR_NO_TRUNC   |
| X'0520'      | SVC_ERROR_TRUNC      |
| X'0530'      | SVC_ERROR_PURGING    |

If your program is not a communication server, it should just issue the APPCVM SENDERR function without an error code; CP generates the appropriate error code based on the states of the programs.

**Sever Codes That You May Receive in Response to a SENDERR:** If the SENDERR was completed by the communication partner issuing a SEVER, a sever code is returned. The sever code you get when your SENDERR completes depends on the state you are in when you issue SENDERR. If you are in the:

- Send state, you may get any valid sever code.
- Receive state, you may get either sever code X'0610' or X'0620'. You would receive notice of any other sever condition on a subsequent APPC/VM function on which an error can be reported.

In addition, you get an indication of SEVER TYPE=NORMAL (IPWHATRC=IPSNORM) when your SENDERR completes, if your communication partner issued SEVER TYPE=NORMAL.

You also get an indication of SEVER TYPE=NORMAL when your SENDERR completes, if your partner issued SEVER TYPE=ABEND with any of the sever codes X'210', X'220', X'230'. In this case, you will not see the sever code.

- Confirm state, you may get either sever code X'0610' or X'0620'. You would receive notice of any other sever condition on a subsequent APPC/VM function on which an error can be reported.

## Condition Codes and Return Codes

| CC=0 | CC=1 | CC=2 | CC=3 |
|------|------|------|------|
| X    | X    | X    | X    |

### CC=0

SENDERR started successfully, but has not yet completed. When the function completes, a function complete interrupt is presented to your virtual machine. The function complete interrupt has the same format as the SENDERR output parameter list (see CC=2, 3). When you get the function complete interrupt, check the IPAUDIT field for error information.

**Note:** When you specify WAIT=YES, CC=0 is not possible.

### CC=1

An error occurred. The output parameter list is the same as the input shown in [SENDERR Input Parameter List](#), except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                               |
|----------|--------------|------------------------------------------------------|
| X'01'    | 1            | You specified a path ID that is not yet established. |
| X'03'    | 3            | A function is pending on this path.                  |
| X'0A'    | 10           | Your buffer length is negative.                      |

| Hex Code | Decimal Code | Why the Error Occurred                                                                        |
|----------|--------------|-----------------------------------------------------------------------------------------------|
| X'17'    | 23           | A length specified in your SEND buffer list is negative.                                      |
| X'18'    | 24           | The total length that you specified is not the total of the lengths in your SEND buffer list. |
| X'1A'    | 26           | The buffer list address is not on a doubleword boundary.                                      |
| X'1D'    | 29           | You are not authorized to act for another user.                                               |
| X'1E'    | 30           | You specified an APPC/VM function on a non-APPC path.                                         |
| X'20'    | 32           | SENDERR is an invalid function from the Connect state.                                        |
| X'24'    | 36           | SENDERR is an invalid function from the Sever state.                                          |
| X'26'    | 38           | There is an invalid value in IPSENDOP field.                                                  |
| X'33'    | 51           | You must receive pending log data before issuing SENDERR.                                     |
| X'37'    | 55           | Your buffer length is either less than eight or greater than 600.                             |
| X'38'    | 56           | WAIT=YES was specified on a function issued to this same virtual machine.                     |
| X'44'    | 68           | SENDERR is invalid from the Reset state.                                                      |
| X'45'    | 69           | SENDERR is invalid from the Defer_Receive state.                                              |
| X'46'    | 70           | SENDERR is invalid from the Defer_Sever state.                                                |
| X'4B'    | 75           | SENDERR is valid from the Backout_Received state only when issued by a communication server.  |
| X'4C'    | 76           | SENDERR is invalid from the Backout_Required state.                                           |

**CC=2 or****CC=3**

SENDERR completed (also see [SENDERR Completion](#)). When CC=2, the function completed with no errors; when CC=3, there is error information in IPAUDIT.

**Note:** When you specify WAIT=NO, CC=3 is not possible.

The output parameter list when CC=2 or 3 is shown in the following figure.

| IPARML DSECT |                                      |   |       |        |                                      |         |                                  |          |
|--------------|--------------------------------------|---|-------|--------|--------------------------------------|---------|----------------------------------|----------|
| 0            | 1                                    | 2 | 3     | 4      | 5                                    | 6       | 7                                |          |
| 0            | IPPATHID                             |   | ///// | IPTYPE | IPCODE                               |         | IPWHATRC                         | IPSENDOP |

| 10           | IPBFLN1F                             |   |       |        | //////////////////////////////////// |         |                                  |          |
| 18           | //////////////////////////////////// |   |       |        |                                      |         |                                  |          |
| 20           | //////////////////////////////////// |   |       |        | IPPOLLFG                             | IPSTATE | //////////////////////////////// |          |

Figure 49. APPCVM SENDERR Output Parameter List (Function Complete Interrupt)

**IPPATHID**

contains the path ID on which the function is complete.

**IPTYPE**

contains the function complete interrupt code (IPTYPFCA, X'87').

**IPCODE**

contains the error or sever code from the partner's SENDERR or SEVER. IPCODE is only valid when IPWHATRC=IPERROR or IPSABEND. See [Sever Codes That You May Receive in Response to a SENDERR](#). Also see [“APPC/VM Sever, Error, and Sense Codes That You Can Get”](#) on page 399 for a complete list of the error and sever codes.

**IPWHATRC**

contains the what-received code:

**IPCOMP (X'00')**

SENDERR completed with nothing received.

**IPERROR (X'03')**

Your partner issued SENDERR.

**IPSNORM (X'08')**

Your partner issued a SEVER TYPE=NORMAL, or SEVER TYPE=ABEND with sever codes X'0210', X'0220', or X'0230'.

**IPSABEND (X'09')**

Your partner issued a SEVER TYPE=ABEND with sever codes other than X'0210', X'0220', or X'0230'.

**IPBACK (X'14')**

The function completed with an indication that your partner initiated a CRR backout sync-point. You should back out the CMS work unit of which this conversation is a part.

**IPSENDOP**

contains the SEND option code:

**IPERROR (X'03')**

Means that the SENDERR is being completed.

**IPAUDIT**

has four fields that may contain error information.

**Note:** In the following descriptions:

- *Send area* refers to either a send buffer specified directly on an APPCVM SENDERR, BUFFER= or a send buffer that is part of a buffer list. These buffers are used for sending log data.
- *Receive area* refers to either a receive buffer specified directly on your partner's APPCVM RECEIVE, BUFFER= or a receive buffer that is part of a buffer list. These buffers are used for receiving log data.

(See [Specifying Log Data](#) for more information on specifying buffers and buffer lists for log data.)

**IPAUDIT1 (first byte of IPAUDIT)**

may contain one of the following bit flags:

**IPADSNPX (X'40')**

A protection exception occurred on your send area.

**IPADSNAX (X'20')**

An addressing exception occurred on your send area.

**IPAUDIT2 (second byte of IPAUDIT)**

may contain one of the following bit flags:

**IPADRCPX (X'80')**

A protection exception occurred on your communication partner's receive area for log data.

**IPADRCAX (X'40')**

An addressing exception occurred on your communication partner's receive area for log data.

**IPADRLST (X'04')**

Your communication partner had an invalid receive buffer list.

**IPAUDIT3 (third byte of IPAUDIT)**

may contain one of the following bit flags:

**IPADBLN (X'80')**

A bad length is in your send buffer list.

**IPADBTOT (X'20')**

Your total send buffer length is invalid.

**IPADIINV (X'04')**

There is an invalid logical record length in your data stream.

**IPASYRC (fourth byte of IPAUDIT)**

Reserved.

**IPBFLN1F**

contains the length of pending log data for you to receive. This field is only meaningful when IPWHATRC is equal to IPSABEND or IPERROR.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

**IPSTATE**

Contains the current state for this path, which may be one of the following values:

**IPSENDST (X'03')**

The path is in the Send state.

**IPRECVST (X'04')**

The path is in the Receive state.

**IPSEVER (X'06')**

The path is in the Sever state.

**IPBKOUT (X'0D')**

The path is in the Backout\_Received state.

**IPBKREQ (X'0E')**

The path is in the Backout\_Required state.

**Program Exceptions**

The program exceptions for SENDERR are:

| Type          | Description                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address is outside of the virtual machine.                                                         |
| Operation     | Either an external interrupt buffer was not declared, or the invoking virtual machine is not in the supervisor state. |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                     |
| Specification | The parameter list is not on a doubleword boundary.                                                                   |

## State Checks and State Changes

A state check results when APPCVM SENDERR is issued from an improper state. (You also receive an IPRCODE when you issue a function from the wrong state.) See the list of APPCVM SENDERR return codes for all state check conditions.

No state change occurs when CC=1. State changes occur when:

- The function completes, that is, when control is returned to the virtual machine (CC=2 or CC=3).
- The function complete interrupt is accepted by the virtual machine or you use TESTCMPL to discover that the function was completed.

The state change depends on the IPWHATRC value in the output parameter list:

| IPWHATRC Value | State            | Cause                                                                                                                                                  |
|----------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| IPCOMP         | Send             | The SENDERR has completed.                                                                                                                             |
| IPERROR        | Receive          | The SENDERR was completed by the communication partner issuing a SENDERR from the Receive state.                                                       |
| IPSNORM        | Sever            | The SENDERR was completed by the communication partner issuing a SEVER TYPE=NORMAL, or SEVER TYPE=ABEND with sever codes X'0210', X'0220', or X'0230'. |
| IPSABEND       | Sever            | The SENDERR was completed by the communication partner issuing a SEVER TYPE=ABEND with sever codes other than X'0210', X'0220', or X'0230'.            |
| IPBACK         | Backout_Received | The SENDERR was completed by the communication partner initiating a backout sync-point. Your program must respond with a SENDCNFD.                     |

## Completion Conditions

After you issue a SENDERR, you cannot issue another SEND (see note), RECEIVE, or SEVER TYPE=NORMAL on that path until the outstanding SENDERR is complete. SENDERR is complete when your communication partner or an intermediate communication server gets notified of the SENDERR by an IPERROR indication in IPWHATRC (in the function complete interrupt).

**Note:** In this case, SEND refers to the set of APPC/VM send functions: SENDCNF, SENDCNFD, SENDDATA, SENDERR, and SENDREQ.

APPC/VM notifies your communication partner of the SENDERR when your partner's SENDDATA, SENDCNF, SENDERR, or RECEIVE completes. SENDERR causes your partner's outstanding functions to complete. If none of these functions are outstanding when the SENDERR is issued, the SENDERR indication will not be presented to the communications partner until the next function is issued.

If your communication partner is in the Receive state and sends a SENDERR before it receives your SENDERR notice, your partner's SENDERR is invoked over yours. In this case, your partner would enter the Send state, and you would be switched to the Receive state.

If your communication partner specified that it is willing to receive log data (LOGDATA=YES on either APPCVM CONNECT or IUCV ACCEPT, whichever is applicable) your SENDERR completes when all of the log data is copied out of your buffer. If your partner specified that it would not receive log data (LOGDATA=NO on either APPCVM CONNECT or IUCV ACCEPT, whichever is applicable), the log data is considered to be copied out of your buffer and the SENDERR completes.

When SENDERR completes, CP resets your logical record count to zero, as well as your communication partner's; that is, your next SENDDATA would be a new logical record.

## **What Happens to Your VM Communication Partner**

Your communication partner's outstanding function may complete, or your partner may get a message pending interrupt.

If your partner has a RECEIVE, SENDDATA, SENDCNF, or SENDERR outstanding on its half of the path, your partner's function is completed.

Your partner gets a message pending interrupt, if your partner:

- Has no function outstanding on its half of the path
- Is in the Receive state on its half of the path
- Is enabled for message pending interrupts.

See [Message Pending External Interrupt](#).

If you do not specify CODE=, the SENDERR code (IPCODE) that your communication partner gets depends on the state of the conversation and whether a logical record is being truncated.

For communication server programs, the code that your communication partner gets depends on the code specified on the CODE parameter of APPCVM SENDERR.

## APPCVM SENDREQ (Send Request)

### Purpose

Use the SENDREQ (Send Request) function to signal your communication partner that you would like to send data. The communication partner can ignore your request.

### Parameters

#### Required Parameter:

##### PRMLIST=

specifies the address of the APPC/VM parameter list. The address must be a guest real address, that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

##### *label*

is the relocatable label of the parameter list.

##### (*reg*)

is the register number that contains the address of the parameter list.

#### Optional Parameters:

##### MF=L

generates the instructions necessary to initialize the APPC/VM parameter list as specified, but does not invoke the APPCVM SENDREQ.

##### PATHID=

specifies the path ID on which to send the request.

##### *label*

is the relocatable label of a halfword that contains the path ID.

##### (*reg*)

is the register number that contains the path ID in the low-order halfword.

**Input Parameter List:** The APPCVM SENDREQ parameter list has the input format shown in the following figure.

APPCVM SENDREQ (Send Request)

Figure 50. APPCVM SENDREQ Input Parameter List

- IPPATHID**  
contains the path ID on which the request to send is sent.
- IPFLAGS1**  
contains the following input bit flag:
- IPAPPCSN (X'02')**  
The APPC SEND function is issued.
- IPSENDOP**  
contains the SEND option code:
- IPREQSND (X'07')**  
indicates the request to send.

Condition Codes and Return Codes

|              |      |      |              |
|--------------|------|------|--------------|
| CC=0         | CC=1 | CC=2 | CC=3         |
| Not possible | X    | X    | Not possible |

SENDREQ always completes immediately.

**CC=1**  
An error occurred. The output parameter list is the same as the input shown in [SENDREQ Input Parameter List](#), except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                                    |
|----------|--------------|-----------------------------------------------------------|
| X'01'    | 1            | You specified a path ID that is not yet established.      |
| X'1E'    | 30           | You specified an APPC/VM function on a non-APPC path.     |
| X'20'    | 32           | SENDREQ is an invalid function from the Connect state.    |
| X'24'    | 36           | SENDREQ is an invalid function from the Sever state.      |
| X'26'    | 38           | There is an invalid value in the IPSENDOP field.          |
| X'33'    | 51           | You must receive pending log data before issuing SENDREQ. |
| X'44'    | 68           | SENDREQ is invalid from the Reset state.                  |
| X'45'    | 69           | SENDREQ is invalid from the Defer_Receive state.          |
| X'46'    | 70           | SENDREQ is invalid from the Defer_Sever state.            |
| X'4B'    | 75           | SENDREQ is invalid from the Backout_Received state.       |
| X'4C'    | 76           | SENDREQ is invalid from the Backout_Required state.       |

**CC=2**

SENDREQ completed (also see [SENDREQ Completion](#)). The output parameter list when CC=2 is shown in the following figure.

Figure 51. APPCVM SENDREQ Output Parameter List

**IPPATHID**

contains the path ID on which the function is complete.

**IPTYPE**

contains the function complete interrupt code (IPTYPFCA, X'87').

**IPSENDOP**

contains the SEND option code:

**IPREQSND (X'07')**

The SENDREQ is being completed.

**IPSTATE**

contains one of the following values for the path's state:

**IPSENDST (X'03')**

The path is in the Send state.

**IPRECVST (X'04')**

The path is in the Receive state.

**IPCONFIRM (X'05')**

The path is in the Confirm state.

## Program Exceptions

The program exceptions for SENDREQ are:

| Type          | Description                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address is outside of the virtual machine.                                                              |
| Operation     | Either an external interrupt buffer has not been declared, or the invoking virtual machine is not in the supervisor state. |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                          |
| Specification | The parameter list is not on a doubleword boundary.                                                                        |

## State Checks and State Changes

A state check results when APPCVM SENDREQ is issued from an improper state. (You also receive an IPRCODE when you issue a function from an improper state.) See the list of APPCVM SENDREQ return codes for all state check conditions.

No state change occurs.

## Completion Conditions

Because the SENDREQ function completes immediately, you can issue another SEND (see note) or RECEIVE on the path when your virtual machine regains control.

**Note:** In this case, SEND refers to the set of APPC/VM send functions: SENDCNF, SENDCNFD, SENDDATA, SENDERR, and SENDREQ.

You can issue more than one SENDREQ. Your communication partner does not get additional SENDREQs until it receives an indication of any preceding SENDREQs. Those SENDREQs, sent before previous SENDREQs have been indicated to your partner, are lost. CP does not notify you when your communication partner actually gets the SENDREQ interrupt. You also do not receive an error message if you issue another SENDREQ before your partner receives notification of previous SENDREQs.

You can issue SENDREQ even when another function is pending on the path. If the pending function is a SENDCNF TYPE=SEVER, then your partner may not be informed of your SENDREQ.

If you issue a SEVER before your communication partner learns of your SENDREQ, your communication partner may not be informed of your SENDREQ.

## What Happens to Your VM Communication Partner

If your communication partner is enabled for SENDREQ interrupts, it gets the SENDREQ interrupt shown in the following figure.

Figure 52. SENDREQ (Request-to-Send) Interrupt

### IPPATHID

is the path ID on which you get the SENDREQ notice.

### IPTYPE

is the interrupt type for a SENDREQ notification (IPTYPSRA, X'88').

### IPPOLLFG

Contains a flag returned by IUCV.

### IPNOPOLL (X'80')

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

CP does not queue more than one SENDREQ interrupt on a single path for the communication partner at one time. Thus, the number of SENDREQ interrupts reflected to your communication partner may be less than the number of SENDREQs issued.

You cannot receive SENDREQ indicators with the RECEIVE function. They are only presented as an interrupt or with the DESCRIBE function.

If your connection to your VM partner is routed over a VTAM link, then the partner may not receive a SENDREQ interrupt for the conversation until it performs some other APPC/VM operation on the conversation. For more information, see [Chapter 10, "APPC Mapped with APPC/VM,"](#) on page 571.

## APPCVM SETMODFY (Set Modify)

### Purpose

The SETMODFY function sets the state to Defer\_Receive or Defer\_Sever state, and sets the sync-point control modifier to Receive or Sever. The sync-point control modifier specifies the state to occur after a subsequent sync-point completes.

**Note:** If SETMODFY is not issued, a program is in the Send state when the sync-point completes.

### Parameters

#### Required Parameters:

##### PRMLIST=

specifies the address of the APPC/VM parameter list. The address must be a guest real address, that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

##### *label*

is the relocatable label of the parameter list.

##### *(reg)*

is the register number that contains the address of the parameter list.

#### Optional Parameters:

##### TYPE=

specifies the sync-point control modifier, which indicates the state that a program wishes to be in at the end of the sync-point sequence:

##### RECEIVE

the program is in the Receive state when the sync-point sequence completes.

##### SEVER

the program is in the Sever state when the sync-point sequence completes.

##### MF=L

generates the instructions necessary to initialize the APPC/VM parameter list as specified, but does not invoke the APPCVM SETMODFY.

**PATHID=**  
specifies the path ID on which the sync-point control modifier is being specified.

**label**  
is the relocatable label of a halfword that contains the path ID.

**(reg)**  
is the register number that contains the path ID in the low-order halfword.

**Input Parameter List:** The APPCVM SETMODFY parameter list has the input format shown in the following figure.

Figure 53. APPCVM SETMODFY Input Parameter List

**IPPATHID**  
contains the path ID on which the sync-point control modifier is being specified.

**IPFLAGS1**  
contains the following input bit flag:

**IPAPPC (X'08')**  
specifies that this is an APPC function.

**IPSNDOF2**  
contains one of the following SEND option codes:

**IPTPRECV (X'04')**  
a Receive state was requested when the sync-point sequence completes.

**IPTPSEVR (X'06')**  
a Sever state was requested when the sync-point sequence completes.

Condition Codes and Return Codes

|              |      |      |              |
|--------------|------|------|--------------|
| CC=0         | CC=1 | CC=2 | CC=3         |
| Not possible | X    | X    | Not possible |

SETMODFY always completes immediately.

**CC=1**  
An error occurred before the SETMODFY was initiated. The output parameter list is the same as the input shown in [SETMODFY Input Parameter List](#), except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                        |
|----------|--------------|-----------------------------------------------|
| X'01'    | 1            | The specified path ID is not yet established. |
| X'03'    | 3            | A function is pending on this path.           |
| X'1E'    | 30           | This is a non-APPC path.                      |

| Hex Code | Decimal Code | Why the Error Occurred                                                                     |
|----------|--------------|--------------------------------------------------------------------------------------------|
| X'20'    | 32           | SETMODFY is invalid from the Connect state.                                                |
| X'22'    | 34           | SETMODFY is invalid from the Receive state.                                                |
| X'23'    | 35           | SETMODFY is invalid from the Confirm state.                                                |
| X'24'    | 36           | SETMODFY is invalid from the Sever state.                                                  |
| X'25'    | 37           | The connection was established with SYNCLVL=NONE or CONFIRM.                               |
| X'2C'    | 44           | Before invoking SETMODFY, the program started but did not finish sending a logical record. |
| X'44'    | 68           | SETMODFY is invalid from the Reset state.                                                  |
| X'45'    | 69           | SETMODFY is invalid from the Defer_Receive state.                                          |
| X'46'    | 70           | SETMODFY is invalid from the Defer_Sever state.                                            |
| X'47'    | 71           | SETMODFY is invalid from the Prepare_Received state.                                       |
| X'49'    | 73           | SETMODFY is invalid from the Unsolicited_Request_Commit_Received state.                    |
| X'4B'    | 75           | SETMODFY is invalid from the Backout_Received state.                                       |
| X'4C'    | 76           | SETMODFY is invalid from the Backout_Required state.                                       |
| X'4E'    | 78           | IPSNDOP2 contains an invalid value.                                                        |

**CC=2**

SETMODFY completed with no error caused by the invoker. The output parameter list when CC=2 is shown in the following figure.

Figure 54. APPCVM SETMODFY Output Parameter List

**IPPATHID**

contains the path ID on which SETMODFY completed.

**IPSTATE**

contains the current state for this path, which may have one of the following values:

**IPDEFRCV (X'07')**

The path is in the Defer\_Receive state.

**IPDEFSEV (X'08')**

The path is in the Defer\_Sever state.

**Program Exceptions**

The program exceptions for SETMODFY are:

| Type       | Description                                                   |
|------------|---------------------------------------------------------------|
| Addressing | The parameter list address is outside of the virtual machine. |

| Type          | Description                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------|
| Operation     | Either an external interrupt buffer has not been declared, or the invoking virtual machine is not in supervisor state. |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                      |
| Specification | The parameter list is not on a doubleword boundary.                                                                    |

### **State Checks and State Changes**

A state check occurs (see the IPRCODEs) if the path is not in the Send state.

The state change depends on the value of the TYPE= parameter:

- When TYPE=RECEIVE, the state changes to the Defer\_Receive state.
- When TYPE=SEVER, the state changes to the Defer\_Seiver state.

### **Completion Conditions**

The SETMODFY function always completes immediately. This allows the program to issue another function on the same path as soon as the virtual machine regains control.

### **What Happens to Your VM Communication Partner**

The communication partner is not affected by the SETMODFY function.

## APPCVM SEVER

### Purpose

Use the SEVER function to break a communication path with another virtual machine or your own virtual machine. After severing the connection with the other virtual machine, you cannot send or receive any other messages on that connection. Remember that your communication partner cannot receive any of the data that has not yet been copied out of your storage. However, your partner can receive log data that you send with APPCVM SEVER.

### Parameters

#### Required Parameters:

##### PRMLIST=

specifies the address of the APPC/VM parameter list. The address must be a guest real address, that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

##### *label*

is the relocatable label of the parameter list.

**(reg)**

is the register number that contains the address of the parameter list.

**TYPE=**

indicates the type of SEVER performed.

**NORMAL**

severs the path normally. You can only do this if you are in the Send state (see note) and not in the middle of sending a logical record, or if you are in the Sever state.

**Note:** For a SYNCLVL=SYNCPT conversation, only communication servers can issue TYPE=NORMAL from the Send state.

**ABEND**

severs the path abnormally. APPC/VM invokes SEVER TYPE=ABEND from the Send, Receive, or Confirm state, even if there is a function that still has not completed on the specified path.

TYPE=NORMAL is not valid if BUFLIST, BUFFER, and BUFLLEN are specified.

**Optional Parameters:****CODE=**

specifies a 2-byte sever code. CODE is only valid when you specify TYPE=ABEND. IBM defines all the codes; applications may not define error or sever codes for their own use.

**label**

is the relocatable label of the 2-byte sever code.

**(reg)**

is the register number that contains the sever code.

When CP issues a SEVER, or your communication partner issues an IUCV SEVER or RTRVBFR, CP determines the sever code to reflect. See [What Happens to Your VM Communications Partner](#) for more information on what this sever code could be. Also see [Sever Codes That You Can Issue](#) for information on what you can issue.

**MF=L**

generates the instructions necessary to initialize the APPC/VM parameter list as specified, but does not invoke the APPCVM SEVER.

**PATHID=**

specifies the path ID that is severed.

**label**

is the relocatable label of a halfword that contains the path ID.

**(reg)**

is the register number that contains the path ID in the low-order halfword.

**WAIT=**

lets you specify when control is returned to your virtual machine.

**YES**

returns control to your virtual machine when the SEVER is complete.

**NO**

returns control to your virtual machine when the SEVER is initiated.

**BUFLIST=**

specifies the type of buffer address to which the BUFFER parameter refers.

**YES**

refers to a list of addresses.

**NO**

refers to a single address.

This parameter is not valid if TYPE=NORMAL.

**BUFFER=**

specifies the address of the areas from which CP takes the log data.

**label**

is the relocatable label in storage where CP gets the log data to send.

**(reg)**

is the register number that contains the address of the storage area. This storage area is where CP gets the log data to send.

This parameter is not valid if TYPE=NORMAL.

**BUFLEN=**

specifies the length of the areas from which APPC/VM takes the log data to be sent. The minimum length is eight bytes; the maximum length is 600 bytes. This length is not related to the length of a logical record.

**label**

is the relocatable label of the fullword that contains the length.

**(reg)**

is the register number that contains the length.

This parameter is not valid if TYPE=NORMAL.

**KEEP=**

indicates whether the path ID may be reassigned by CP for another conversation immediately after the APPCVM SEVER.

**YES**

indicates that the path ID is not to be freed for reuse by CP for another conversation.

**Note:** This value is invalid when TYPE=NORMAL.

**NO**

indicates that the path ID is to be freed for reuse by CP for another conversation.

**Input Parameter List:** The APPCVM SEVER parameter list has the input format shown in the following figure.

| IPARML DSECT |                                      |   |          |       |                                      |   |                   |
|--------------|--------------------------------------|---|----------|-------|--------------------------------------|---|-------------------|
| 0            | 1                                    | 2 | 3        | 4     | 5                                    | 6 | 7                 |
| 0            | IPPATHID                             |   | IPFLAGS1 | ///// | IPCODE                               |   | IPFLAGS2 IPSENDOP |
| 8            | //////////////////////////////////// |   |          |       | IPBFADR1                             |   |                   |
| 10           | IPBFLN1F                             |   |          |       | //////////////////////////////////// |   |                   |
| 18           | //////////////////////////////////// |   |          |       |                                      |   |                   |
| 20           | //////////////////////////////////// |   |          |       |                                      |   |                   |

Figure 55. APPCVM SEVER Input Parameter List

**IPPATHID**

contains the path ID being severed.

**IPFLAGS1**

contains one of the following input bit flags:

**IPBUFLIST (X'40')**

You specified the buffer list option. This flag is ignored unless IPSENDOP=IPSABEND.

**IPAPPC (X'08')**

The APPC SEVER function was issued.

**IPKEEP (X'10')**

indicates that the path ID is not to be freed for reuse after the APPCVM SEVER completes.

**Note:** This flag is ignored unless IPSENDOP=IPSABEND.

**IPCODE**

contains the sever code. IPCODE is only valid when IPSENDOP=IPSABEND. See [Sever Codes That You Can Issue](#).

**IPFLAGS2**

contains one of the following input bit flags:

**IPWAIT (X'80')**

You specified the wait option. This flag is ignored unless LOGDATA was specified.

**IPCOMSRV (X'20')**

Means that the SEVER is on behalf of another user. Only an authorized user (OPTION COMSRV in directory) can specify IPCOMSRV.

**IPSENDOP**

contains one of the following SEND option codes:

**IPSNORM (X'08')**

You requested that the path be severed normally.

**IPSABEND (X'09')**

You requested that the path be severed abnormally.

**IPBFADR1**

contains the address of the area from which APPC/VM takes the log data or the address of the address list or the length list. This parameter is ignored unless IPSENDOP=IPSABEND.

**IPBFLN1F**

contains the length of the log data being sent. If IPBFLN1F is 0, then no log data is being sent. Otherwise, log data is being sent. This parameter is ignored unless IPSENDOP=IPSABEND.

**Usage Notes**

**Specifying Log Data:** An application program can choose to set up log data and to send that log data using buffers specified on APPCVM SEVER. Log data conveys error information to an LU, where it is added to the system error log. This error information can be used in debugging and error recovery.

When using APPCVM SEVER to send log data to your communication partner, you use buffers. You can specify a single buffer using one address and one length or specify multiple buffers using a list of addresses and lengths.

When you specify a single buffer using one address and one length:

- BUFFER specifies the address
- BUFLN specifies the length
- BUFLIST must be equal to NO.

When you specify multiple buffers with a list of addresses and lengths:

- BUFFER specifies the address of the list
- BUFLN specifies the sum of the lengths of the buffers in the list
- BUFLIST must be equal to YES.

When specifying address lists (BUFLIST=YES), note the following:

1. The list must begin on a doubleword boundary.
2. Each list entry must be two fullwords; the first is the address of that portion of the list, and the second is the length.
3. The addresses and lengths in the address list are updated during APPC/VM processing. Do not alter them during processing or assume that they are unchanged when APPC/VM processing is complete.
4. APPC/VM assumes that there is another entry in the list until the sum of the lengths of the entries processed is equal to the total length specified by BUFLN.

**Note:** Log data is ignored on an incomplete path.

The log data you are sending in buffers must be coded into an error log general data stream (GDS) variable. An error log GDS variable has the following format, defined by SNA LU 6.2:

Figure 56. Error Log GDS Variable Format

#### GDS1

contains the length, in binary, of the error log GDS variable, including this length field. This must be in the range from 8 to 600 bytes.

#### GDS2

contains a GDS identifier for an error log variable, X'12E1'.

#### GDS3

contains the length, in binary, of the product set ID (GDS4) including this length field.

**Note:** The length field is always present; a value of 2 indicates no product set ID subvector follows.

#### GDS4

contains the product set ID subvector. This subvector, which is variable length, uniquely identifies the product.

#### GDS5

contains the length, in binary, of the log data including this length field.

**Note:** The length field is always present; a value of 2 indicates no log data follows.

#### GDS6

contains the log data.

For more information about the error log GDS Variable and product set ID, see *SNA Format and Protocol Reference Manual: Architectural Logic for LU Type 6.2*.

**Sever Codes That You Can Issue:** You can specify a sever code using the CODE= parameter on an APPCVM SEVER with TYPE=ABEND. The point at which you can specify a sever code depends on the state of your path. (However, you can issue an IUCV SEVER function on any APPC path at any time.)

The table below shows the APPC error condition associated with each sever code. Refer to *SNA Format and Protocol Reference Manual: Architectural Logic for LU Type 6.2* for an explanation of what these APPC conditions mean and when to use these sever codes.

- If you are in the Connect state, you can only issue IUCV SEVER, which has no associated sever codes.
- After you ACCEPT the connection, and before you issue any other function on the path, you can issue APPCVM SEVER with any of the following APPC/VM sever codes:

| APPC/VM Code | APPC Error Condition            |
|--------------|---------------------------------|
| X'0120'      | CONVERSATION_TYPE_MISMATCH      |
| X'0130'      | SYNC_LEVEL_NOT_SUPPORTED_BY_PGM |
| X'0140'      | TRANS_PGM_NOT_AVAIL_NO_RETRY    |
| X'0141'      | TRANS_PGM_NOT_AVAIL_RETRY       |
| X'0142'      | TPN_NOT_RECOGNIZED              |
| X'0150'      | PIP_NOT_SPECIFIED_CORRECTLY     |

| APPC/VM Code | APPC Error Condition   |
|--------------|------------------------|
| X'0151'      | PIP_NOT_ALLOWED        |
| X'0160'      | SECURITY_NOT_VALID     |
| X'0210'      | DEALLOCATE_ABEND_PROG  |
| X'0220'      | DEALLOCATE_ABEND_SVC   |
| X'0230'      | DEALLOCATE_ABEND_TIMER |

- After the path is established (that is, CONNECT or ACCEPT is complete) you can issue APPCVM SEVER with the sever codes shown as follows:

| APPC/VM Code | APPC Error Condition   |
|--------------|------------------------|
| X'0210'      | DEALLOCATE_ABEND_PROG  |
| X'0220'      | DEALLOCATE_ABEND_SVC   |
| X'0230'      | DEALLOCATE_ABEND_TIMER |

- Communication servers can sever with any defined SEVER code. See page [“Currently-Defined APPC/VM Sever Codes”](#) on page 399 for all currently-defined sever codes. The communication server is responsible for using only valid sever codes based on the conversation state according to the APPC architecture.

The sever type and code presented to your partner may not always be the sever type and code that you specified. For example, if your partner issues a SENDERR from the Receive state, a sever code of DEALLOCATE\_ABEND\_PROG is presented to your partner as DEALLOCATE\_NORMAL in the completion data of your partner's SENDERR. See [“APPCVM SENDERR \(Send Error\)”](#) on page 490 for more information.

## Condition Codes and Return Codes

| CC=0 | CC=1 | CC=2 | CC=3 |
|------|------|------|------|
| X    | X    | X    | X    |

### CC=0

The APPCVM SEVER started successfully, but has not yet completed. If your virtual machine is enabled for function complete interrupts, one is presented to your virtual machine when SEVER completes. When you get the function complete interrupt, check the IPAUDIT field for error information. The function complete interrupt has the same format as the SEVER output parameter list (see CC=2, 3).

When control is returned to your virtual machine with CC=0, the parameter list may have been altered.

**Note:** CC=0 is not possible when WAIT=YES.

### CC=1

An error occurred. The parameter list format is the same as the input shown in [SEVER Input Parameter List](#), except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                               |
|----------|--------------|------------------------------------------------------|
| X'01'    | 01           | You specified a path ID that is not yet established. |
| X'03'    | 03           | A function is pending on this path.                  |
| X'0A'    | 10           | Your buffer length is negative.                      |

| Hex Code | Decimal Code | Why the Error Occurred                                                                                                                                                                                                                                                                            |
|----------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'17'    | 23           | A length specified in your SEND buffer list is negative.                                                                                                                                                                                                                                          |
| X'18'    | 24           | The total length that you specified is not the total of the lengths in your SEND buffer list.                                                                                                                                                                                                     |
| X'1A'    | 26           | The buffer list address is not on a doubleword boundary.                                                                                                                                                                                                                                          |
| X'1D'    | 29           | You are not authorized to act for another user.                                                                                                                                                                                                                                                   |
| X'1E'    | 30           | You specified an APPC/VM function on a non-APPC path.                                                                                                                                                                                                                                             |
| X'20'    | 32           | APPCVM SEVER is an invalid function from the Connect state.                                                                                                                                                                                                                                       |
| X'22'    | 34           | APPCVM SEVER TYPE=NORMAL is an invalid function from the Receive state.                                                                                                                                                                                                                           |
| X'23'    | 35           | APPCVM SEVER TYPE=NORMAL is an invalid function from the Confirm state.                                                                                                                                                                                                                           |
| X'24'    | 36           | APPCVM SEVER TYPE=ABEND is an invalid function from the Sever state.                                                                                                                                                                                                                              |
| X'26'    | 38           | There is an invalid value in the IPSENDOP field.                                                                                                                                                                                                                                                  |
| X'2C'    | 44           | Before invoking APPCVM SEVER TYPE=NORMAL, you started but did not finish, sending a logical record.                                                                                                                                                                                               |
| X'2E'    | 46           | You specified an invalid sever code.                                                                                                                                                                                                                                                              |
| X'37'    | 55           | Your buffer length is either less than 8 or greater than 600.                                                                                                                                                                                                                                     |
| X'38'    | 56           | WAIT=YES was specified on a function issued to this same virtual machine.                                                                                                                                                                                                                         |
| X'44'    | 68           | APPCVM SEVER is an invalid function from the Reset state.                                                                                                                                                                                                                                         |
| X'45'    | 69           | APPCVM SEVER TYPE=NORMAL is invalid from the Defer_Receive state.                                                                                                                                                                                                                                 |
| X'46'    | 70           | APPCVM SEVER TYPE=NORMAL is invalid from the Defer_Sever state.                                                                                                                                                                                                                                   |
| X'47'    | 71           | APPCVM SEVER TYPE=NORMAL is invalid from the Prepare_Received state.                                                                                                                                                                                                                              |
| X'49'    | 73           | APPCVM SEVER TYPE=NORMAL is invalid from the Unsolicited_Request_Commit_Received state.                                                                                                                                                                                                           |
| X'4B'    | 75           | APPCVM SEVER TYPE=NORMAL is invalid from the Backout_Received state.                                                                                                                                                                                                                              |
| X'4C'    | 76           | APPCVM SEVER TYPE=NORMAL is invalid from the Backout_Required state.                                                                                                                                                                                                                              |
| X'4F'    | 79           | APPCVM SEVER TYPE=NORMAL is invalid on a SYNCLVL=SYNCPT conversation when issued by: <ul style="list-style-type: none"> <li>• A communication server from a state other than the Sever or the Send state</li> <li>• A noncommunication server from a state other than the Sever state.</li> </ul> |
| X'57'    | 87           | An APPCVM SEVER with KEEP=YES is invalid after a previous APPCVM SEVER that specified log data.                                                                                                                                                                                                   |

**CC=2 or CC=3**

The SEVER completed (also see [SEVER Completion](#)). When CC=2, the function completed with no errors; when CC=3, there is error information in IPAUDIT.

**Note:** When you specify WAIT=NO, CC=3 is not possible.

The output parameter list when CC=2 or CC=3 is as shown in the following figure.

| IPARML DSECT |                                      |   |          |        |                  |          |                                  |

Figure 57. APPCVM SEVER Output Parameter List (Function Complete Interrupt)

## IPPATHID

contains the path ID on which the function is complete.

## IPFLAGS1

may contain one or more of the following output bit flags:

### X'20'

This value is reserved for IBM use only.

### X'02'

This value is reserved for IBM use only.

### X'01'

This value is reserved for IBM use only.

## IPTYPE

Contains the function complete interrupt code (IPTYPFCA, X'87').

## IPWHATRC

Contains the what-received code.

### IPCOMP (X'00')

SEVER completed normally.

## IPSENDOP

contains one of the following SEND option codes:

### IPSNORM (X'08')

SEVER TYPE=NORMAL has completed.

### IPSABEND (X'09')

SEVER TYPE=ABEND has completed.

## IPAUDIT

has three fields that may contain error information.

**Note:** In the following descriptions:

- *Send area* refers to either a send buffer specified directly on an APPCVM SEVER, BUFFER= or a send buffer that is part of a buffer list. This area is used for sending log data.
- *Receive area* refers to either a receive buffer specified directly on an APPCVM RECEIVE, BUFFER= or a receive buffer that is part of a buffer list. This area is used for receiving log data.

(See [Specifying Log Data](#) for more information on specifying buffers and buffer lists.)

### IPAUDIT1 (first byte of IPAUDIT)

may contain one of the following bit flags:

#### IPADSNPX (X'40')

A protection exception occurred on your send area for log data.

#### IPADSNAX (X'20')

An addressing exception occurred on your send area for log data.

### IPAUDIT2 (second byte of IPAUDIT)

may contain one of the following bit flags:

**IPADRCPX (X'80')**

A protection exception occurred on your communication partner's receive area for log data.

**IPADRCAX (X'40')**

An addressing exception occurred on your communication partner's receive area for log data.

**IPADRLST (X'04')**

Your communication partner had an invalid receive buffer list.

**IPAUDIT3 (third byte of IPAUDIT)**

may contain one of the following bit flags:

**IPADBLEN (X'80')**

A bad length is in your send buffer list.

**IPADBTOT (X'20')**

Your total send buffer length is invalid.

**IPADIINV (X'04')**

There is an invalid logical record length in your data stream.

**IPASYRC (fourth byte of IPAUDIT)**

Reserved.

Even when an error is reported in the IPAUDIT field, the path is severed.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

**IPSTATE**

contains the current state for this path.

**IPRESET (X'01')**

Indicates that the path is in the Reset state.

**IPSENDST (X'03')**

Indicates that the path is in the Send state.

**IPRECVST (X'04')**

Indicates that the path is in the Receive state.

## Program Exceptions

The program exceptions for SEVER are:

| Type          | Description                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address is outside of the virtual machine.                                                         |
| Operation     | Either an external interrupt buffer was not declared, or the invoking virtual machine is not in the supervisor state. |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                     |
| Specification | The parameter list is not on a doubleword boundary.                                                                   |

## State Checks and State Changes

A state check occurs (IPRCODE=X'44') if the path is in the Reset state. (When you issue a function from an improper state, you receive an IPRCODE.) Other state checks depend on whether TYPE=NORMAL or TYPE=ABEND. See the list of APPCVM SEVER return codes for all state check conditions.

When your virtual machine regains control after successfully completing the SEVER (CC=2 or CC=3), you enter the Reset state. However, if APPCVM SEVER TYPE=ABEND was issued by a noncommunication server while a sync-point was in progress, the state changes to the *saved\_state* value (either the Send or the Receive state).

The state of a path on a SYNCLVL=SYNCPT conversation is **saved** when the conversation is initialized and when each SYNCPT completes. This is so the conversation can back out to the saved state when a backout occurs.

No state change occurs when CC=1.

## Completion Conditions

After APPCVM SEVER completes, you cannot issue any other functions on that path. The timing of an APPCVM SEVER completion depends on whether log data was specified.

If you do not specify log data on the APPCVM SEVER, it always completes immediately. If you **do** specify log data, the APPCVM SEVER function completes when all of the log data is copied out of your buffer. An APPCVM SEVER with log data also completes when your partner issues a SEVER.

If your communication partner specified that it does not accept log data, the log data is automatically considered copied out of your buffer. If log data is specified and control is returned to your virtual machine with CC=0, this indicates that the function started successfully. The only functions that can be issued on the path are:

- IUCV SEVER, KEEP=NO
- APPCVM SEVER, KEEP=NO, TYPE=ABEND, with no log data.

If you issue either of these two functions after issuing an APPCVM SEVER with log data, your communication partner cannot receive any log data that has not yet been copied out of your storage.

You cannot issue APPCVM SEVER TYPE=NORMAL if there is another function outstanding on the path. You can, however, issue APPCVM SEVER TYPE=ABEND without log data if there is an outstanding function on a path. (However, if the pending function is a syncpoint function, IPCODEs of X'210', X'220', and X'230' may not be specified.) In this case, CP may not present the outstanding function to your communication partner. For example, if you issue the following sequence of functions, your communication partner is notified of the SEVER, but not the SENDERR:

1. SENDERR
2. SEVER TYPE=ABEND (before your partner receives the SENDERR).

Also, in the following example sequence of functions, your communication partner cannot receive more than the amount of data specified in the RECEIVE.

1. You issue a SENDDATA BUFLen=200.
2. Your communication partner issues a RECEIVE BUFLen=100.
3. You issue a SEVER TYPE=ABEND.

CP notifies your communication partner of the APPCVM SEVER with a sever interrupt. In addition, CP notifies your partner the next time your partner issues a function on which CP can report the APPCVM SEVER.

If KEEP=YES is not specified for APPCVM SEVER, the path ID is no longer valid when the SEVER completes. If another function is then issued for that path ID, the function completes with CC=1 and an IPRCODE of X'01' (specified path ID not established).

## What Happens to Your VM Communication Partner

Any time after you and your partner have established a path (after the CONNECT/ACCEPT sequence is complete), you can issue an APPCVM SEVER with TYPE=NORMAL or TYPE=ABEND.

**Note:** Before a path is established, you cannot issue an APPCVM SEVER, only an IUCV SEVER, unless your program is a communication server. Refer to “IUCV SEVER” on page 556.

When you issue an APPCVM SEVER, your partner gets a sever interrupt (assuming it is enabled for sever interrupts). In addition, if your partner has a RECEIVE, SENDDATA, SENDCNF, or SENDERR outstanding on its half of the path, the function completes. Otherwise, if your partner issues one of those four functions after you have issued the APPCVM SEVER, their function completes immediately with indication of IPWHATRC=IPSNORM or IPWHATRC=IPSABEND.

A sever interrupt does not change your partner's path to the Sever state (the partner could have been in the Sever state already). Your partner only enters the Sever state after it issues a function that completes with IPWHATRC=IPSNORM or IPWHATRC=IPSABEND.

When you issue an APPCVM SEVER with log data, the way your partner receives it depends on what state it was in when it got the Sever interrupt:

- If your partner was already in the Sever state when it got the Sever interrupt, it must next issue an APPCVM RECEIVE to get the log data.
- If your partner was not in the Sever state when it got the Sever interrupt, it finds out about the log data when it issues a function that completes with IPWHATRC=IPSABEND. It must then issue an APPCVM RECEIVE to get the log data.

If your connection to your VM partner is routed over a VTAM link, then the partner may not receive a SEVER interrupt for the conversation until it performs some other APPC/VM operation on the conversation. For more information, see Chapter 10, “APPC Mapped with APPC/VM,” on page 571.

**SEVER External Interrupt:** A SEVER external interrupt on an APPC/VM path can result from an APPCVM SEVER or an IUCV SEVER. In either case, it has the format shown in the following figure.

Figure 58. SEVER External Interrupt

### IPPATHID

contains the path ID being severed.

### IPTYPE

contains the interrupt type for SEVER (IPTYPSVA, X'83').

### IPCODE

contains the sever code from the partner's SEVER. See “APPC/VM Sever, Error, and Sense Codes That You Can Get” on page 399 for a description of the sever codes.

### IPWHATRC

contains the what-received code:

#### IPSNORM (X'08')

Your partner issued a SEVER TYPE=NORMAL.

#### IPSABEND (X'09')

Your partner issued SEVER TYPE=ABEND.

**IPBFLN1F**

contains the length of the pending log data.

For an IUCV SEVER, CP ignores the user data field, issues an APPCVM SEVER TYPE=ABEND to your communication partner, and then reflects a sever code. For an explanation of possible sever codes, see [What Happens to Your VM Communications Partner](#).

---

## Chapter 8. IUCV Macro Functions for Use in APPC/VM

This chapter describes, in detail, each IUCV macro function that can be used in APPC/VM. These are:

- IUCV ACCEPT
- IUCV CONNECT
- IUCV DCLBFR (Declare Buffer)
- IUCV IPOLL (Interrupt Poll)
- IUCV QUERY
- IUCV RTRVBFR (Retrieve Buffer)
- IUCV SETCMASK (Set Control Mask)
- IUCV SETMASK
- IUCV SEVER
- IUCV TESTCMPL (Test Completion)
- IUCV TESTMSG (Test Message)

If you are unfamiliar with reading syntax diagrams, see [“Syntax, Message, and Response Conventions” on page xxxv](#).

The set of IUCV macro functions that can be used with APPC/VM is split into two sections. Those that:

- Can be used in CMS without special considerations
- Should be avoided in CMS.

---

### Shared Functions That Can Be Used in CMS

The following table summarizes each IUCV macro function that can be used in CMS, then points to the section that describes each function in detail.

| Function | Description                                                                                           | Page                                       |
|----------|-------------------------------------------------------------------------------------------------------|--------------------------------------------|
| ACCEPT   | Accepts the connection from a requesting program to complete a path.                                  | <a href="#">“IUCV ACCEPT” on page 524</a>  |
| CONNECT  | Establishes and reserves a path for resource manager programs to communicate with *IDENT.             | <a href="#">“IUCV CONNECT” on page 529</a> |
| QUERY    | Gets information about the external interrupt buffer and finds out how many paths can be established. | <a href="#">“IUCV QUERY” on page 543</a>   |
| SEVER    | Ends communications with another program when APPCVM SEVER is not appropriate.                        | <a href="#">“IUCV SEVER” on page 556</a>   |

For information on CMS in a virtual MP environment, see [“Virtual MP Considerations for APPC/VM Applications” on page 398](#).

---

### Shared Functions That Should Be Avoided in CMS

Other functions are also shared for both APPC/VM and IUCV. These shared functions should not be used in a CMS environment because they could affect other programs in the same virtual machine; however, they can be used safely in a non-CMS environment.

Each of these functions is briefly described in the following list, then described in detail in the remainder of this chapter.

The following table summarizes each IUCV macro function that should be avoided in a CMS environment, then points to the section that describes each function in detail.

| Function | Description                                                                                                                                                                                                                                                                                                                                         | Page                                                           |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| DCLBFR   | Declares an interrupt buffer. (This buffer can be used for both APPC/VM and IUCV interrupts.)                                                                                                                                                                                                                                                       | <a href="#">“IUCV DCLBFR (Declare Buffer)” on page 533</a>     |
| DESCRIBE | Gives the following information: <ul style="list-style-type: none"> <li>• The next message pending on non-APPC paths</li> <li>• The next message pending on an APPC path that is in the Receive state</li> <li>• A SENDREQ on an APPC path.</li> </ul>                                                                                              | <a href="#">“IUCV DESCRIBE” on page 538</a>                    |
| I POLL   | Determines if any messages or replies are pending.                                                                                                                                                                                                                                                                                                  | <a href="#">“IUCV I POLL (Interrupt Poll)” on page 540</a>     |
| RTRVBFR  | Releases an interrupt buffer. (This buffer can be used for both APPC/VM and IUCV interrupts.)                                                                                                                                                                                                                                                       | <a href="#">“IUCV RTRVBFR (Retrieve Buffer)” on page 548</a>   |
| SETMASK  | Disables and enables APPC and non-APPC interrupts.                                                                                                                                                                                                                                                                                                  | <a href="#">“IUCV SETCMASK (Set Control Mask)” on page 550</a> |
| SETCMASK | Disables and enables APPC and non-APPC control interrupts.                                                                                                                                                                                                                                                                                          | <a href="#">“IUCV SETMASK” on page 553</a>                     |
| TESTCMPL | Determines the next APPC or non-APPC function that has completed.                                                                                                                                                                                                                                                                                   | <a href="#">“IUCV TESTCMPL (Test Completion)” on page 562</a>  |
| TESTMSG  | Waits for the following: <ul style="list-style-type: none"> <li>• A message pending or message complete interrupt on non-APPC paths</li> <li>• A message pending interrupt on an APPC path that is in the Receive state</li> <li>• A request-to-send interrupt on an APPC path</li> <li>• A function complete interrupt on an APPC path.</li> </ul> | <a href="#">“IUCV TESTMSG (Test Message)” on page 566</a>      |

For more information on how to use the IUCV macro functions when writing programs, see [z/VM: CMS Macros and Functions Reference](#).

## Condition Codes and Return Codes for IUCV Macro Functions

This section summarizes the condition codes and return codes that IUCV macro functions generate. See the individual IUCV function details for specific condition code and return code information.

## Condition Codes

The condition code (CC) is stored in the program status word (PSW). There are four possible values for condition codes: 0, 1, 2, and 3. Here is the general meaning for each CC value:

| Code        | Meaning                                                                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CC=0</b> | The function successfully completed with no errors.                                                                                                                                           |
| <b>CC=1</b> | An error occurred when the function was initiated. In this case, the error code is stored in the IPRCODE field of the output parameter list. (See a description of IPRCODE below.)            |
| <b>CC=2</b> | The function completed immediately with no errors. In most cases, the requested function was not performed. However, for IUCV ACCEPT on an APPC path, CC=2 indicates a successful completion. |
| <b>CC=3</b> | The function completed, but an error was detected.                                                                                                                                            |

**Note:** CC values for the IUCV TESTMSG have different meanings than shown here.

## Return Codes

Return codes are stored in IPRCODE, 1-byte field in the output parameter list. IPRCODE reports error conditions that CP detects when the function is initiated. A nonzero value is placed into IPRCODE when CC=1. There is no corrective action for this type of error. You should sever the path when you get a nonzero value in this field.

**Note:** In addition, the IUCV TESTCMPL output parameter list may define a field called IPAUDIT. IPAUDIT reports error conditions that CP detects between the time that the function is initiated and the time it completes. Like IPRCODE, there is no corrective action for this type of error. You should sever the path when you get a nonzero IPAUDIT.

## Using the Online HELP Facility for IUCV Macro Functions

---

You can receive online information about the IUCV macro functions (used with APPC/VM) by using the z/VM HELP Facility. For example, to display a menu of the IUCV macro functions, enter:

```
help iucv menu
```

To display information about a specific IUCV macro function (ACCEPT in this example), enter:

```
help iucv accept
```

For more information about using the HELP Facility, see [z/VM: CMS User's Guide](#). To display the main HELP Task Menu, enter:

```
help
```

For more information about the HELP command, see [z/VM: CMS Commands and Utilities Reference](#) or enter:

```
help cms help
```

## IUCV ACCEPT

### Purpose

Use the ACCEPT function of the IUCV macro to accept a connection from another virtual machine or from your own virtual machine. You should use ACCEPT only after your virtual machine gets a connection pending external interrupt.

**Note:** The ACCEPT function is not part of the APPC architecture and is unique to VM.

In a CMS environment, you should use IUCV ACCEPT to set up an ACCEPT parameter list, then call CMSIUCV ACCEPT to invoke the function. For more information, see [z/VM: CMS Application Development Guide for Assembler](#).

### Parameters

#### Required Parameter

##### PRMLIST=

specifies the address of the IUCV ACCEPT parameter list. The address must be a guest real address, that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

##### label

is the relocatable label of the parameter list.

##### (reg)

is the register number that contains the address of the parameter list.

## Optional Parameters

### MF=L

generates the instructions necessary to initialize the IUCV parameter list as specified, but does not invoke the IUCV ACCEPT.

### PATHID=

identifies the path on which to accept the connection. If you specify the path ID, it must be the same value presented in the connection pending interrupt; if you do not specify the path ID, it defaults to the value contained in the first two-bytes of your parameter list.

#### *label*

is the relocatable label of a halfword that contains the path ID.

#### *(reg)*

is the register number that contains the path ID in the low-order halfword.

### LOGDATA=

indicates whether the accepting program is willing to receive log data on the path being established.

#### YES

indicates that the accepting program receives log data.

#### NO

indicates that the accepting program does not receive log data. CP discards any log data sent to this program.

## Communication Server Parameters

### COMSRV=

indicates whether the connection is being accepted for another user.

#### YES

indicates that the connection is being accepted for another virtual machine. Only communication server virtual machines (OPTION COMSRV specified in the directory) can specify this parameter.

#### NO

indicates that the connection is not being accepted for another virtual machine.

### BUFFER=

specifies the address of the connection complete extended data. (See [Connection Complete Extended Data](#) for more information.) Only communication servers can specify this parameter. If a noncommunication server specifies this parameter, it is ignored. There is not an error indication, and CP builds the extended data.

#### *label*

is the relocatable label of connection complete extended data address.

#### *(reg)*

is the register number that contains the address of the connection complete extended data.

### BUFLEN=

specifies the length of the connection complete extended data. (See [Connection Complete Extended Data](#) for more information.) Only communication servers can specify this parameter. If a noncommunication server specifies this parameter, it is ignored and there is no error indication.

#### *label*

is the relocatable label of the fullword storage location containing the length.

#### *(reg)*

is the register number that contains the length. If BUFLEN is 0, BUFFER and BUFLEN are considered not specified; if BUFLEN is nonzero, length must be 80 (X'50') bytes, the current length of the connection complete extended data.

### CONTROL=

lets you specify whether a control path is being established. Control paths allow interrupt information for your half of the path to be placed in the control buffer.

## IUCV ACCEPT

### YES

sends the APPC/VM interrupt information on this path to the control buffer.

**Note:** Do not specify CONTROL=YES in application programs running in CMS; CMS uses control paths.

### NO

sends APPC/VM interrupt information on this path the to application buffer.

**Input Parameter List:** The IUCV ACCEPT parameter list has the input format shown in the following figure when accepting a connection on an APPC path:

| IPARML DSECT |                                      |   |          |                                      |   |          |      |
|--------------|--------------------------------------|---|----------|--------------------------------------|---|----------|------|
| 0            | 1                                    | 2 | 3        | 4                                    | 5 | 6        | 7    |
| 0            | IPPATHID                             |   | IPFLAGS1 | //////////////////////////////////// |   | IPFLAGS2 | //// |
| 8            | //////////////////////////////////// |   |          | IPBFADR1                             |   |          |      |
| 10           | IPBFLN1F                             |   |          | //////////////////////////////////// |   |          |      |
| 18           | //////////////////////////////////// |   |          |                                      |   |          |      |
| 20           | //////////////////////////////////// |   |          |                                      |   |          |      |

Figure 59. IUCV ACCEPT Input Parameter List

### IPPATHID

is the path ID on which to accept the connection.

### IPFLAGS1

contains the following input bit flag:

#### IPCNTRL (X'04')

a control path is being established.

#### X'80'

this value is reserved for IBM use only.

### IPFLAGS2

contains one of the following input bit flags:

#### IPCOMSRV (X'20')

the connection is being accepted for another user.

#### IPLOGDOK (X'04')

the accepting program is specifying LOGDATA=YES.

### IPBFADR1

specifies the address of the connection complete extended data.

### IPBFLN1F

specifies the length of the connection complete extended data.

## Usage Notes

**Considerations for SNA Communication Servers:** An SNA communication server can use the BUFFER and BUFLen parameters to send connection-complete extended data to the source (connecting) program. The connection-complete extended data, which is sent to the source program along with connection-complete data, contains the session ID, the conversation correlator, the local and remote network fully qualified LU names, and the access user ID. CP passes the connection-complete extended data information unchanged from the SNA communication server to the source program.

It is the communication server's responsibility to ensure that the conversation correlator provided matches the conversation correlator received in the FMH5.

If an I/O error is encountered while reading in the connection-complete extended data from BUFFER, CP builds the connection-complete extended data from the allocate data as it would for an ACCEPT by a noncommunication server.

## Condition Codes and Return Codes

| CC=0         | CC=1 | CC=2 | CC=3         |
|--------------|------|------|--------------|
| Not Possible | X    | X    | Not Possible |

### CC=1

an error occurred. The output parameter list is the same as the ACCEPT input parameter list, except one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                                                                                                                                                                                                                                                                                         |
|----------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'01'    | 1            | IUCV ACCEPT cannot be issued on an APPC path until the connection pending interrupt is presented. You specified a path ID that is not yet established, or you tried issuing IUCV ACCEPT before getting a connection pending interrupt. You can also get this code if you issue a second IUCV ACCEPT on a path. |
| X'0A'    | 10           | Invalid length for the connection complete extended data buffer                                                                                                                                                                                                                                                |
| X'14'    | 20           | Connection cannot be completed—originator has severed the path.<br><br><b>Note:</b> If your path gets severed, you must still issue IUCV SEVER to clean up your side of the path.                                                                                                                              |
| X'1D'    | 29           | You are not authorized to act for another user.                                                                                                                                                                                                                                                                |
| X'44'    | 68           | IUCV ACCEPT is invalid from the Reset state.                                                                                                                                                                                                                                                                   |
| X'56'    | 86           | You must have a control buffer declared to accept a SYNCLVL=SYNCPT connection.                                                                                                                                                                                                                                 |

### CC=2

ACCEPT is complete. The format of the output parameter list is as shown in the following figure.

Figure 60. IUCV ACCEPT Output Parameter List

#### IPPATHID

is the path ID on which the connection was accepted.

#### IPSTATE

contains the current state for this path, which may have one of the following values:

##### IPRECVST (X'04')

the path is in the Receive state.

##### IPBKREQ (X'0E')

the path is in the Backout\_Required state.

## Program Exceptions

The program exceptions for ACCEPT are:

| Type          | Description                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address is outside of the virtual machine, the CCED buffer is outside the virtual machine, or the CCED buffer address is 0. |
| Operation     | Either an external interrupt buffer has not declared, or the invoking virtual machine is not in the supervisor state.                          |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                                              |
| Specification | The parameter list is not on a doubleword boundary.                                                                                            |

## State Checks and State Changes

If the ACCEPT completes successfully, your virtual machine enters the Receive state.

If the connection cannot be completed because the path was severed (IPRCODE 20), your virtual machine remains in the Connect state.

When IUCV ACCEPT completes for a conversation established with SYNCLVL=SYNCPT, the current state (Receive) is saved as the initial state value.

## Completion Conditions

Because you can issue ACCEPT only when there is a connection pending, the ACCEPT function completes immediately. If you have not yet received the allocation data pending for this path, that data is purged when ACCEPT completes.

If the connection is for a private resource, the connection pending interrupt is presented in the control buffer; after the ACCEPT is issued, all subsequent interrupts are placed in the application buffer.

When IUCV ACCEPT is issued before the PIP variable has been completely received, CP purges any remaining data for the PIP variable that has not been received.

## What Happens to Your VM Communication Partner

When you issue the ACCEPT function, the receiver of the connection-complete indication depends on the system your communication partner (the virtual machine that issued the original CONNECT) is on. If it is:

- The same system, your partner gets the indication.
- A different system, the intermediate communication server (for example, TSAF or AVS) gets it.

The ACCEPT function can be issued by an intermediate communication server that is not the target of the CONNECT. In this case, accepting a connection does not necessarily mean that the APPC/VM path has been completed between two communicating programs. See [“APPCVM CONNECT” on page 412](#) for more details on the connection-complete indication.

# IUCV CONNECT

## Purpose

Use the CONNECT function of the IUCV macro to establish a path to the Identify system service (\*IDENT). A program in a virtual machine with proper directory authorization can manage or revoke a resource by establishing a path to \*IDENT.

Although the CONNECT may complete successfully, you are not able to use the path until you receive a connection-complete external interrupt (meaning that \*IDENT has accepted your connection) for this path.

If you get an connection-severed external interrupt for this path (meaning that \*IDENT has severed your connection), you may not use the path. For more information on \*IDENT, see [Chapter 16, “Identify System Service \(\\*IDENT\),” on page 729.](#)

### Notes:

1. The IUCV CONNECT function has more options when being used in an IUCV environment. However, only the IUCV CONNECT parameters shown here should be used when connecting to \*IDENT.
2. If an external security manager is installed on your system, you may not be authorized to use this function. For additional information, contact your security administrator.

## Parameters

### Required Parameter:

#### PRMLIST=

specifies the address of the IUCV parameter list. The IUCV instruction is generated to reference the address specified.

**label**

is the relocatable label of the parameter list.

**(reg)**

is the register number that contains the address of the parameter list.

### Optional Parameters:

#### MF=L

lets you build an IUCV CONNECT parameter list without initializing any registers or invoking the connection. After using MF=L, you can use CMSIUCV CONNECT to actually issue the connect request to \*IDENT. (For more information, see [z/VM: CMS Application Development Guide for Assembler.](#))

**USERDTA=**

specifies the data area containing the 16 bytes of user data that you are supplying to \*IDENT. The user data is presented to \*IDENT as part of the connection pending external interrupt.

**label**

is the relocatable label of the user data.

**(reg)**

is the register number that contains the address of the user data.

On this IUCV CONNECT, the user data field must have the format shown in the following figure.

Figure 61. User Data Field for CONNECT

**Name**

contains the name of the resource or gateway that you are managing or revoking. The first byte of this name must be alphanumeric; IBM reserves names beginning with the remaining characters for its own use. In addition, this resource/gateway name cannot be blanks (X'40's), nulls (X'00's), ANY, ALLOW, or SYSTEM.

**Fcode**

is the function code. FCODE=1 indicates a request to identify (manage) a resource or gateway. FCODE=2 indicates a request to revoke a resource or gateway.

**Flag**

is a flag byte.

For **manage** requests (FCODE=1):

**Bit 0 on**

The resource is accessible from outside the local system:

- If bit 0 is on and bit 2 is off, this is a global resource, unique in the TSAF or CS collection, and accessible throughout the TSAF or CS collection and by AVS.
- If bit 0 is on and bit 2 is on, this is a system resource, accessible throughout the TSAF or CS collection through the system gateway and by AVS.

This bit must be on for a gateway.

**Bit 0 off**

The resource is accessible only from the local system (a local resource).

**Bit 1 on**

The resource manager program accepts connections with SECURITY(NONE).

**Bit 1 off**

The resource manager program does not accept connections with SECURITY(NONE).

**Bit 2 on**

The resource is a system resource. If this bit is on, bit 0 must also be on.

**Bit 2 off**

This resource is not a system resource.

For **revoke** requests (FCODE=2):

**Bit 0 on**

CP revokes the global or system resource or gateway, known to the TSAF or CS collection. It must also be on for revoking a system resource (see bit 2).

**Bit 0 off**

CP revokes the local resource, known only to the local system.

**Bit 2 on**

This resource is a system resource. If this bit is on, bit 0 must also be on.

**Bit 2 off**

This resource is not a system resource.

**Ntype**

indicates the type for name. If Ntype is 0 indicates a resource ID; if Ntype is 1 indicates a gateway name.

**USERID=**

specifies \*IDENT, the 8-character user ID for the Identify system service.

**Input Parameter List:** The IUCV CONNECT parameter list has the input format shown in the following figure.

Figure 62. IUCV CONNECT Input Parameter List

**IPFLAGS1**

contains all zeros.

**IPMSGLIM**

contains all zeros.

**IPVMID**

contains \*IDENT, the user ID of the system service to which you want to establish this path.

**IPUSER**

contains the user data that is reflected to the \*IDENT system service.

## Condition Codes and Return Codes

| CC=0 | CC=1 | CC=2         | CC=3         |
|------|------|--------------|--------------|
| X    | X    | Not Possible | Not Possible |

**CC=0**

the IUCV CONNECT completed successfully. The output parameter field, IPPATHID, identifies the path ID that IUCV assigns this new path.

**CC=1**

the IUCV CONNECT encountered an error, and stored one of the following return codes in IPRCODE (byte 3) of the output parameter list:

| Hex Code | Decimal Code | Why the Error Occurred                                              |
|----------|--------------|---------------------------------------------------------------------|
| X'00'    | 0            | Normal return                                                       |
| X'0D'    | 13           | Your virtual machine already has the maximum number of connections. |
| X'0F'    | 15           | Your virtual machine is not authorized to connect to *IDENT.        |

| <b>Hex Code</b> | <b>Decimal Code</b> | <b>Why the Error Occurred</b>                               |
|-----------------|---------------------|-------------------------------------------------------------|
| X'10'           | 16                  | Your program specified an invalid IUCV system service name. |

## **Program Exceptions**

The program exceptions for IUCV CONNECT are:

| <b>Type</b>   | <b>Description</b>                                                                                                      |
|---------------|-------------------------------------------------------------------------------------------------------------------------|
| Specification | The parameter list is not on a doubleword boundary.                                                                     |
| Operation     | Either an application interrupt buffer is not declared, or the invoking virtual machine is not in the supervisor state. |
| Addressing    | The parameter list address that you specified is outside the virtual machine's storage.                                 |
| Protection    | The storage key of the specified parameter list address does not match the key of the user.                             |

## IUCV DCLBFR (Declare Buffer)

### Purpose

Use the DCLBFR (Declare Buffer) function before you use any other APPC/VM functions (except IUCV QUERY) to set the address of a buffer that APPC/VM and IUCV can use to store external interrupt data. After you receive an external interrupt, this buffer contains information about the message, reply, or control function that caused the interrupt.

When you issue DCLBFR, the virtual machine is enabled for all types of APPC/VM and IUCV external interrupts. Use the SETMASK and the SETCMASK functions to change these initial settings.

In addition, programs using control paths can set up an interrupt buffer extension.

**Note:** The IUCV interrupt mask in control register 0 is not affected by DCLBFR. See [“IUCV SETMASK”](#) on page 553 for more details. If your program is running in a CMS environment, you can use HNDIUCV SET to do the same job as DCLBFR.

Note that CMS does not currently support IUCV or APPC/VM virtual MP functions.

### Parameters

#### Required Parameters:

##### PRMLIST=

specifies the address of the IUCV DCLBFR parameter list. The address must be a guest real address, that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

##### *label*

is the relocatable label of the parameter list.

##### *(reg)*

is the register number that contains the address of the parameter list.

#### Optional Parameters:

### MF=L

expands the IUCV macro to generate the instructions necessary to initialize the parameter list as specified, but not to invoke the DCLBFR function.

### BUFFER=

identifies the external interrupt buffer. When an external interrupt is sent to the virtual machine, APPC/VM stores information about the message or the control interrupt in this buffer.

#### *label*

is the relocatable label of the storage area used as the external interrupt buffer.

#### *(reg)*

is the register number that contains the address of the storage area used as the external interrupt buffer.

**Note:** You can reduce the overhead involved in reflecting APPC/VM external interrupts to the virtual machine if the buffer you declare is entirely within one page. You can further reduce overhead if the buffer is entirely within page 0 of the virtual machine.

### CONTROL=

lets you declare an application buffer or a control buffer.

#### **YES**

declares a control buffer.

#### **NO**

declares an application buffer.

User applications running CMS and GCS should not use a control buffer and control paths. CMS and GCS declare control buffers during their initialization process. CMS and GCS do not allow applications that use the control buffer to establish paths.

However, applications **not** running in CMS or GCS can use control and application buffers. If you declare a control buffer with DCLBFR, you can establish control paths with CONNECT CONTROL=YES. When you specify CONTROL=YES, only you view the path as a control path. Your communications partner views it as an application path.

When an interrupt for a control path is presented to your virtual machine, it goes to the control buffer. When an interrupt for an application path comes in, it goes to the application buffer, and the path ID is stored in the control buffer. The rest of the control buffer contains zeros.

When a private resource manager connection pending interrupt is presented to a virtual machine, the interrupt is presented in the control buffer. If the conversation is accepted with CONTROL=YES, then all subsequent interrupts for the conversation are placed in the control buffer. If the conversation is accepted with CONTROL=NO, then all subsequent interrupts for the conversation are placed in the application buffer. For more information, see [“IUCV ACCEPT” on page 524](#).

### Restricted Parameters:

#### EXTBUF=

specifies the address of the interrupt buffer extension. This parameter should not be used by applications running in CMS or GCS. (See [Interrupt Buffer Extension](#).)

#### *label*

is the relocatable label in storage that contains the interrupt buffer extension.

#### *(reg)*

is the register number that contains the address of the interrupt buffer extension.

**Note:** EXTBUF is not valid when CONTROL=NO.

#### EXTLEN=

specifies the length of the interrupt buffer extension. This length must have a value from 0 to 4096 (inclusive). This parameter should not be used by applications running in CMS or GCS. (See [Interrupt Buffer Extension](#).)

You can use the IUCV QUERY function to determine the maximum length of data that can be returned in the external interrupt buffer.

**label**

Is the relocatable label of the fullword storage location containing the length.

**(reg)**

Is the register number that contains the length.

**Note:** EXTLEN is not valid when CONTROL=NO.

**Input Parameter List:** The IUCV DCLBFR parameter list has the input format shown in the following figure.

Figure 63. IUCV DCLBFR Input Parameter List

**IPFLAGS1**

may contain the following input bit flag:

**IPCNTL (X'04')**

a control buffer is being established.

**IPBFADR1**

identifies the area where information about an APPC/VM or IUCV external interrupt is stored.

**IPBFADR2**

specifies the address of the interrupt buffer extension.

**IPBFLN2F**

specifies the length of the interrupt buffer extension.

**Interrupt Buffer Extension:** When an interrupt for which extended information is defined (that is, connection pending and connection complete interrupts on APPC/VM paths.) is reflected to the virtual machine, the extended information is placed in the interrupt buffer extension declared by the virtual machine. When a function (for which extended information is defined) completes with CC=2 instead of a completion interrupt, the extended information is still placed in the interrupt buffer extension (declared by the virtual machine), even though the other information is placed in the parameter list.

**Note:** If an I/O error is encountered while paging in the user's interrupt buffer extension, the extended information is not valid.

To ensure that you get all of the extended information, declare your extended interrupt buffer using the maximum allowable size. Use the IUCV QUERY,PRMLIST= function to determine the maximum size of the buffer. (See [“IUCV QUERY”](#) on page 543 for more information.)

If the length of the interrupt buffer extension is greater than the length of the extended information, the remaining area is undefined and may be set to zero by CP or may contain data left over from a previous interrupt. All extended interrupt data that can be variable in length contains length fields so that the application can determine what data is valid. The data is valid only until the next IUCV or APPC/VM interrupt is reflected to the virtual machine regardless of whether the next interrupt has extended data defined.

The interrupt buffer extension should not be used directly by applications running in CMS or GCS. CMS and GCS should use the interrupt buffer extension to obtain information necessary for coordinated resource recovery, such as the conversation correlator, session ID, and the network fully qualified logical unit (LU) names.

**Note:** Issuing IUCV RTRVBFR has no effect on an interrupt buffer extension.

## Condition Codes and Return Codes

| CC=0 | CC=1 | CC=2         | CC=3 |
|------|------|--------------|------|
| X    | X    | Not Possible | X    |

### CC=0

DCLBFR completed with no errors. The output parameter list is the same as the input shown in the [DCLBFR Input Parameter List](#).

### CC=1

an error occurred before the DCLBFR was initiated. The output parameter list is the same as the input shown in the [DCLBFR Input Parameter List](#), except that the return code is stored in IPRCODE (byte 3) You can get the following return codes:

| Hex Code | Decimal Code | Why the Error Occurred                                                                                                                                                                                                                   |
|----------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X'0A'    | 10           | Invalid length for the interrupt buffer extension.                                                                                                                                                                                       |
| X'13'    | 19           | Depends on the value for the CONTROL parameter: <ul style="list-style-type: none"> <li>• If CONTROL=YES, a control buffer has already been defined.</li> <li>• If CONTROL=NO, an application buffer has already been defined.</li> </ul> |
| X'3E'    | 62           | Two of the following buffers overlap: <ul style="list-style-type: none"> <li>• Control buffer</li> <li>• External interrupt buffer</li> <li>• Interrupt buffer extension.</li> </ul>                                                     |
| X'5C'    | 92           | A paging or storage error was detected.                                                                                                                                                                                                  |

### CC=3

IUCV found errors while reading your directory.

## Program Exceptions

The program exceptions for DCLBFR are:

| Type          | Description                                                                                                                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address or specified buffer address is outside the virtual machine or at virtual address zero; or, the interrupt buffer extension is outside the virtual machine storage or at virtual address zero. |
| Operation     | The invoking virtual machine is not in the supervisor state.                                                                                                                                                            |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                                                                                                                       |
| Specification | The parameter list is not on a doubleword boundary.                                                                                                                                                                     |

## State Checks and State Changes

DCLBFR does not act on any one path and does not cause any state changes.

**Completion Conditions**

The DCLBFR function completes immediately.

## IUCV DESCRIBE

### Purpose

Use the DESCRIBE function to get the following:

- A description of a pending APPC/VM or IUCV message without receiving it
- A request-to-send indication.

DESCRIBE returns information about a message only once—the next time you invoke DESCRIBE, you get a description of the next *undescribed* message. You can issue a RECEIVE on a message after you have described it. However, it is not necessary to describe a message before receiving it.

Note that CMS does not currently support IUCV or APPC/VM virtual MP functions.

### Parameters

#### Required Parameter:

##### PRMLIST=

specifies the address of the IUCV DESCRIBE parameter list. The address must be a guest real address, that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

##### *label*

is the relocatable label of the parameter list.

##### *(reg)*

is the register number that contains the address of the parameter list.

### Usage Notes

1. For APPC/VM messages, the message is only described if the corresponding path is in the Receive state. APPC/VM presents request-to-send indications regardless of the state of the corresponding path.
2. DESCRIBE does not describe messages that are pending on control paths.
3. If there is a function outstanding on a path, APPC/VM may report the message on the completion of that function (instead of on DESCRIBE).
4. CP considers a message described if you do one of the following:
  - Completely or partially receive a message
  - Get a message pending interrupt
  - Get a request-to-send interrupt.

### Condition Codes and Return Codes

| CC=0 | CC=1         | CC=2 | CC=3         |
|------|--------------|------|--------------|
| X    | Not Possible | X    | Not Possible |

**CC=0**

DESCRIBE completed with no errors. The output parameter list of an APPC/VM message is shown in the following figure.

Figure 64. IUCV DESCRIBE Output Parameter List

**IPPATHID**

contains the path ID on which the message is pending.

**IPTYPE**

contains the interrupt type for a message pending (IPTYPMPA, X'89') or request-to-send (IPTYPSRA, X'88').

**IPBFLN1F**

contains the length of the message that is pending. This length has no relationship to the length of the APPC data stream being sent; it is only the length of the data that has arrived and is ready to be received. If the interrupt type is not X'89', this has no meaning.

**IPPOLLFG**

contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that another iteration of this function will probably not find a message waiting at this time.

**CC=2**

IUCV did not find any APPC/VM or IUCV *undescribed* messages.

## Program Exceptions

The program exceptions for DESCRIBE are:

| Type          | Description                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address is outside of the virtual machine.                                                           |
| Operation     | Either an application interrupt buffer is not declared, or the invoking virtual machine is not in the supervisor state. |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                       |
| Specification | The parameter list is not on a doubleword boundary.                                                                     |

## State Checks and State Changes

No state changes occur.

## Completion Conditions

The DESCRIBE function completes immediately with CC=0 or CC=2.

## IUCV IPOLL (Interrupt Poll)

### Purpose

Use the IPOLL (Interrupt Poll) function of the IUCV macro to determine if you have any replies or incoming messages pending. If IUCV finds any replies or incoming messages pending, it returns the information about them in the buffer provided. The maximum number of pending interrupts that can be retrieved on a single request is the number of IUCV external interrupt buffers that can fit on one 4K page.

### Notes:

1. Unless you disable your virtual machine for IUCV message-complete and message-pending interrupts, you should not use the IPOLL function. When the virtual machine is enabled for these interrupts, IUCV automatically informs you of message completion or arrival of an incoming message by reflecting an external interrupt to your virtual machine.
2. No external interrupt occurs for a reply represented by a message-complete returned by IPOLL.
3. No external interrupt occurs for a message represented by a message-pending returned by IPOLL. It is your responsibility to use the RECEIVE or REJECT function to process a message obtained using IPOLL.

Note that CMS does not currently support IUCV or APPC/VM virtual MP functions.

### Parameters

#### Required Parameters:

##### PRMLIST=

identifies to IUCV the address of your parameter list. The address of the parameter list must be a guest real address (an address that is real to your virtual machine), and it must be on a doubleword boundary.

##### label

is the relocatable label of the parameter list.

##### (reg)

is the register number that contains the address of the parameter list.

#### Optional Parameters:

**MF=L**

lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction.

**BUFFER=**

specifies the address of the IPOLL buffer for interrupt data.

***label***

is the relocatable label of the buffer.

**(reg)**

is the register number that contains the address of the buffer.

**BUFLEN=**

specifies the length of the IPOLL buffer for interrupt data. This length must be at least the size of an IUCV interrupt buffer and not more than 4096 bytes, and the buffer may not cross a 4K page boundary. The length need not be an exact multiple of the length of an IPARML.

***label***

is the relocatable label of the halfword storage location containing the length.

**(reg)**

is the register number that contains the length of the buffer.

**Input Parameter List:** The IUCV IPOLL parameter list has the input format shown in the following figure.

Figure 65. IUCV IPOLL Output Parameter List

**IPBFADR1**

contains the address of the input buffer.

**IPBFLN1F**

contains the length of the input buffer. For output data returned by the IPOLL function, it contains the length of the output data returned by the IPOLL function. This value will always be a multiple of the length of an IUCV external interrupt buffer (IPARML).

**Output Buffer Format** When the condition code is zero, the buffer contains one or more interrupt data areas for replies or messages. See the [Message Complete External Interrupt](#), the [Message Pending External Interrupt](#), the [Message Pending External Interrupt, SENDREQ Interrupt](#), and [APPCVM RECEIVE Output Parameter List](#). The remainder of the buffer not occupied by the external interrupt data remains unchanged.

If no more replies or messages are pending for the invoker, the last interrupt placed in the output buffer will have the IPNOPOLL flag set.

If IPOLL is issued in an APPC/VM environment you may receive interrupt information both for IUCV and APPC/VM paths.

**Condition Codes and Return Codes**

| CC=0 | CC=1 | CC=2 | CC=3         |
|------|------|------|--------------|
| X    | X    | X    | Not possible |

### CC=0

IUCV returned one or more messages and/or replies

### CC=1

An error occurred. The output parameter list is the same as the IPOLL input parameter list, except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                  |
|----------|--------------|-----------------------------------------|
| X'5C'    | 92           | A paging or storage error was detected. |

### CC=2

IUCV did not find any replies or messages

## Program Exceptions

The program exceptions for IPOLL are:

| Type          | Description                                                                                                                                                                                                                                                                 |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Addressing    | Your parameter list address or buffer address is invalid; the address you specified is outside of your virtual machine's storage.                                                                                                                                           |
| Operation     | IUCV is inactive; you have not used the DCLBFR function to declare an external interrupt buffer.                                                                                                                                                                            |
| Specification | <ul style="list-style-type: none"><li>• You did not define your parameter list on a doubleword boundary.</li><li>• You specified a buffer length less than the size of an IUCV interrupt buffer.</li><li>• You specified a buffer which spans a 4K page boundary.</li></ul> |

## IUCV QUERY

### Purpose

Use the QUERY function to obtain information about the IUCV environment in your virtual machine. An application program can use the QUERY function to determine the maximum number of communication paths that can be established for your virtual machine. The value is returned in register 1.

In addition, CMS and GCS can use IUCV QUERY during initialization to determine the following:

1. The size of the external interrupt buffer. This value is returned in register 0.
2. The maximum length of data that can be returned in the external interrupt buffer extension, if you specify the PRMLIST=parameter. This value is returned in the output parameter list.
3. The maximum length Input Parameter List Extension (IPARMLX) that will be accepted on an APPC/VM connect. This value is only available if the PRMLIST=parameter was specified. This value is returned in the output parameter list.

An application program can use IUCV QUERY to obtain information about a specific connection.

**Note:** The IUCV QUERY function:

- Causes no state changes
- Completes immediately
- Does not involve a communication partner.

### Parameters

#### Optional Parameter:

##### MF=L

generates the instructions necessary to initialize the IUCV parameter list as specified, but does not invoke the IUCV QUERY function.

##### QRYTYPE=

specifies the IUCV QUERY subtype. The value must represent one of the codes defined for IPQTYPE. The input QRYTYPE refines the IUCV QUERY request as follows:

##### BUFFERS

CP returns the length of the APPC/VM parameter/buffer extensions.

**CONNECT**

CP returns information about the connection on a specified PATHID.

**PRMLIST=**

specifies the address of the IUCV QUERY parameter list. The address must be a guest real address; the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary. The PRMLIST is optional. If it is omitted, the IUCV QUERY will only return information through the Output Registers. (This is the basic IUCV QUERY format.) If PRMLIST is specified without QRYTYPE, the IUCV QUERY will return extended buffer length information. (This is equivalent to QRYTYPE=BUFFERS.)

**label**

is the relocatable label of the parameter list.

**(reg)**

is the register number that contains the address of the parameter list.

**PATHID=**

specifies the IUCV path ID to be interrogated by this operation. The specified path ID is assigned to the field IPPATHID in the Input Parameter List.

**label**

is the relocatable label of a halfword that contains the path ID.

**(reg)**

is the register number that contains the path ID in the low-order halfword.

**Input Parameter List:** IUCV QUERY may be issued without a parameter list. When PRMLIST is specified, the parameter list passed to the IUCV instruction has the format shown in [Figure 66 on page 544](#):

Figure 66. IUCV QUERY Input Parameter List

The parameters are as follows:

**IPPATHID**

contains the path ID to be interrogated for path-specific information. This field is set from the PATHID parameter, and is only relevant when IPQTYPE=IPQCONN.

**IPQTYPE**

IPQTYPE contains one of the following codes which represent the specified QRYTYPE:

**IPQBFLN (X'00')**

Return general information about the parameter and interrupt extension lengths for the APPC/VM interface. This is set as the default value for IPQTYPE when IUCV QUERY is specified with a PRMLIST value.

**IPQCONN (X'01')**

Return information about the connection that exists on a specific path (the one specified in IPPATHID).

**Note:** All other fields in the input parameter list are reserved for IBM use, and should be initialized to zero by the invoker. A nonzero value in one of these fields is not reported as an error, but may cause undesirable results at some point in the future.

## Condition Codes and Return Codes

| CC=0 | CC=1 | CC=2 | CC=3 |
|------|------|------|------|
| X    | X    | X    | X    |

**Note:** QUERY always completes immediately.

### CC=0

QUERY completed with no errors. The requested information is returned through the output parameter list. The format of the output parameter list is determined by the input IPQTYPE field value.

**Output Parameter List:** When IPQTYPE=IPQBFLN (Query Buffer Lengths) the IUCV QUERY output parameter list has the output format shown in [Figure 67 on page 545](#):

Figure 67. IUCV QUERY Output Parameter List (QRYTYPE=BUFFERS)

### IPQTYPE

Contains the input QRYTYPE value

### IPIXMLN

Contains the length (in bytes) of the maximum valid APPC/VM connect input parameter list extension (IPARMLX)

### IPBFLN2F

Contains the maximum length (in bytes) of data that can be reflected in the interrupt buffer extension

When IPQTYPE=IPQCONN (Query Connection) the IUCV QUERY output parameter list has the output format shown in [Figure 68 on page 545](#) :

Figure 68. IUCV QUERY Output Parameter List (QRYTYPE=CONNECT)

### IPPATHID

Contains the original input value (the specified path ID)

### IPQCODE

Contains one of the following codes:

#### IPQCNOT (0)

The specified PATHID is NOT connected at all.

#### IPQCNPD (1)

The specified PATHID is Connection Pending.

**IPQCNCTD (2)**

The specified PATHID is Connected.

**IPQCNSEV (3)**

The specified PATHID is Severed.

**IPQFLAGS**

These flags provide additional information about an IUCV path. Note that some characteristics (such as IPQAPPC) can be established for any valid path. Other characteristics (like IPQCMSRV) can only be established if IPQCODE=IPQCNCTD (indicating that the path is already connected). IPQFLAGS may contain a combination of the following flags:

**IPQAPPC (X'80')**

The path specified on input represents an APPC/VM connection (instead of an IUCV connection).

**IPQCMSRV (X'40')**

The specified path is connected to a Virtual Machine operating as a Communication Server. This normally means the path is being extended to a remote partner.

**IPQISFC (X'20')**

The specified path is connected to CP ISFC (Inter-System Facility for Communication) services. This normally means the path is being extended to a remote partner.

**IPQCPSVC (X'10')**

The specified path is connected to a CP System Service (for example, \*IDENT). None of the CP System Services would extend a connection beyond the local system.

**IPQTYPE**

Contains the input QRYTYPE value.

**CC=1**

QUERY did not complete. The output parameter list is the same as the QUERY input parameter list, except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                                                                                                                     |
|----------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| X'01'    | 1            | You specified a path ID that does not exist.                                                                                               |
| X'11'    | 17           | The input IPQTYPE is not one of the supported QUERY subfunctions (refer to <a href="#">“Parameters”</a> on page 543 for more information). |

**CC=2**

QUERY did not complete. The user ID of the invoking virtual machine was not found in the CP directory, or the QUERY function was initiated while an IUCV RTRVBFR was in progress. The output parameter list is the same as the QUERY input parameter list.

**CC=3**

QUERY did not complete. CP encountered an error while trying to read the CP user directory entry for the invoking virtual machine. The output parameter list is the same as the QUERY input parameter list.

**Program Exceptions**

The program exceptions for QUERY are:

| Type          | Description                                                        |
|---------------|--------------------------------------------------------------------|
| Operation     | The invoking virtual machine is not in the supervisor state.       |
| Specification | The parameter list is not doubleword aligned.                      |
| Addressing    | The parameter list is outside the virtual machine storage.         |
| Protection    | The parameter list storage area key does not match the user's key. |

**Output Registers:** When the IUCV QUERY code is executed, the following information is returned in the invoker's general purpose registers R0 and R1:

**R0**

The size (in bytes) of the external interrupt buffer for IUCV

**R1**

The maximum number of communication paths that can be established for your virtual machine

**Usage Notes**

1. IUCV QUERY does not require an IUCV interrupt buffer. So it can be issued before the IUCV DCLBFR (Declare Buffer) function.
2. IUCV QUERY completes immediately and does not cause a state change for any APPC/VM conversation.
3. An IUCV application can use a simple IUCV QUERY function (with no PRMLIST) to determine how much storage to allocate for interrupt buffers and path information. An APPC/VM application can use IUCV QUERY with QRYTYPE=BUFFERS to determine how much storage to allocate for the Input Parameter List Extension and the Interrupt Buffer Extension.
4. An IUCV or APPC/VM application can use IUCV QUERY with QRYTYPE=CONNECT to obtain information about a specific connection. For example, if the output IPQCODE=IPQCNCTD and either IPQCMSRV or IPQISFC is ON, it would be reasonable to assume that the specified PATHID is extended to a remote partner.

## IUCV RTRVBFR (Retrieve Buffer)

### Purpose

Use the RTRVBFR (Retrieve Buffer) function to do the following:

- Stop all IUCV and APPC/VM outstanding messages
- Sever all IUCV and APPC/VM communication paths
- End IUCV and APPC/VM communications.

When issued by a virtual machine, RTRVBFR causes all paths except control paths to be severed. For example, if a program using CMSIUCV support issues HNDIUCV CLR, CMS issues RTRVBFR and all paths are severed **except control paths**.

When issued by CP, the RETRIEVE BUFFER function severs **all** paths.

**Note:** Be aware that CP issues RTRVBFR for the following commands:

- SYSTEM RESET
- IPL, which issues SYSTEM RESET
- LOGOFF.

This severs **all** paths, including control paths.

Note that CMS does not currently support IUCV or APPC/VM virtual MP functions.

### Condition Codes and Return Codes

| CC=0 | CC=1         | CC=2         | CC=3         |
|------|--------------|--------------|--------------|
| X    | Not Possible | Not Possible | Not Possible |

#### CC=0

normal completion.

### Program Exceptions

The program exception for RTRVBFR is:

| Type      | Description                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------|
| Operation | Either an application interrupt buffer is not declared, or the invoking virtual machine is not in the supervisor state. |

### State Checks and State Changes

RTRVBFR does not act on any one path; therefore, no state checks occur. When RTRVBFR is done executing, all paths for your virtual machine are destroyed (put in the Reset state) except your control paths, which do not change states.

## Completion Conditions

The RTRVBFR function completes immediately.

## What Happens to Your VM Communication Partner

When you invoke RTRVBFR, all your noncontrol APPC/VM and IUCV communication paths are severed. APPC/VM informs your communication partners as if you issued a SEVER TYPE=ABEND. See [What Happens to Your VM Communications Partner](#) for a description of possible sever codes.

## IUCV SETCMASK (Set Control Mask)

### Purpose

Use the SETCMASK (Set Control Mask) function to enable or disable external interrupts for the following APPC/VM and IUCV control functions:

- Connection pending
- Connection complete
- Path severed
- Path quiesced (non-APPC only)
- Path resumed (non-APPC only).

You cannot use the SETCMASK function to disable interrupts on control paths.

To use this function, you must enable your virtual machine for external interrupts by setting the following bits to 1:

- Bit 7 in the virtual PSW
- Submask bit 30 in the control register 0.

You must also enable external interrupts with the SETMASK function. Otherwise, APPC/VM ignores the SETCMASK settings.

Note that CMS does not currently support IUCV or APPC/VM virtual MP functions.

### Parameters

#### Required Parameters:

##### PRMLIST=

specifies the address of the IUCV SETCMASK parameter list. The address must be a guest real address, that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

##### label

is the relocatable label of the parameter list.

##### (reg)

is the register number that contains the address of the parameter list.

#### Optional Parameters:

**MF=L**

expands the IUCV macro to generate the instructions necessary to initialize the parameter list as specified, but not to invoke the SETCMASK function.

**MASK=**

specifies the mask byte to determine for which, if any, of the APPC/VM and IUCV external interrupts a virtual machine is enabled for.

***label***

is the relocatable label of a byte containing the mask.

***(reg)***

is the register number that contains the mask in its low-order byte.

**Input Parameter List:** The IUCV SETCMASK parameter list has the input format shown in the following figure.

Figure 69. IUCV SETCMASK Input Parameter List

**IPCMASK**

specifies the mask byte to determine for which of the control interrupts your virtual machine is enabled for.

When a bit is turned off, the virtual machine is disabled for that interrupt. For example, if IPCMASK contains X'C0', this means that your virtual machine is enabled for connection pending and connection complete interrupts, but disabled for all other interrupts.

**IPCLPC (X'80')**

you are enabled for connection pending interrupts. This is type X'81' for APPC and type X'01' for non-APPC.

**IPCLCC (X'40')**

you are enabled for connection complete interrupts. This is type X'82' for APPC and type X'02' for non-APPC.

**IPCLPS (X'20')**

you are enabled for sever interrupts. This is type X'83' for APPC and type X'03' for non-APPC.

**IPCLPQ (X'10')**

you are enabled for path-quiesced interrupts. This is type X'04'; it applies to non-APPC only.

**IPCLPR (X'08')**

you are enabled for path-resumed interrupts. This is type X'05'; it applies to non-APPC only.

**Condition Codes and Return Codes**

| CC=0 | CC=1         | CC=2         | CC=3         |
|------|--------------|--------------|--------------|
| X    | Not Possible | Not Possible | Not Possible |

**CC=0**

normal completion.

## **Program Exceptions**

The program exceptions for SETCMASK are:

| <b>Type</b>   | <b>Description</b>                                                                                                      |
|---------------|-------------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address is outside of the virtual machine.                                                           |
| Operation     | Either an application interrupt buffer is not declared, or the invoking virtual machine is not in the supervisor state. |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                       |
| Specification | The parameter list is not on a doubleword boundary.                                                                     |

## **State Checks and State Changes**

There are no states associated with the SETCMASK function.

## **Completion Conditions**

The SETCMASK function completes immediately.

## IUCV SETMASK

### Purpose

Use the SETMASK (Set Mask) function to enable or disable external interrupts for the following APPC/VM and IUCV functions:

- Message-pending interrupts
- SENDREQ (request-to-send) interrupts
- Function-complete interrupts
- APPC/VM and IUCV control interrupts.

You cannot use the SETMASK function to disable interrupts on control paths.

To use this function, you must enable your virtual machine for external interrupts by setting the following bits to 1:

- Bit 7 in the virtual PSW
- Submask bit 30 in control register 0.

The IUCV SETMASK function specifies a byte of selective masks. This lets you mask APPC/VM and IUCV external interrupts selectively.

Note that CMS does not currently support IUCV or APPC/VM virtual MP functions.

### Parameters

#### Required Parameter:

##### PRMLIST=

specifies the address of the IUCV SETMASK parameter list. The address must be a guest real address, that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

##### *label*

is the relocatable label of the parameter list.

##### *(reg)*

is the register number that contains the address of the parameter list.

#### Optional Parameters:

IUCV SETMASK

MF=L

expands the IUCV macro to generate the instructions necessary to initialize the parameter list as specified, but not to invoke the SETMASK function.

MASK=

lets you specify the mask byte to determine which, if any, of the APPC/VM and IUCV external interrupts a virtual machine is enabled for.

*label*

is the relocatable label of a byte containing the mask.

(reg)

is the register number that contains the mask in its low-order byte.

**Input Parameter List:** The IUCV SETMASK parameter list has the input format shown in the following figure.

Figure 70. IUCV SETMASK Input Parameter List

IPMASK

specifies the mask byte to determine which types of interrupts a virtual machine is enabled for.

When a bit is turned off, the virtual machine is disabled for that interrupt. For example, if IPMASK contains X'C0', the virtual machine is enabled for IUCV and APPC message interrupts and APPC SENDREQ interrupts, but disabled for all other interrupts.

IPSNDN (X'80')

you are enabled for nonpriority message interrupts (type X'09', for non-APPC) and message-pending interrupts (type X'89', for APPC).

IPSNDP (X'40')

you are enabled for priority message interrupts (type X'08', for non-APPC) and SENDREQ interrupts (type X'88', for APPC).

IPRPYN (X'20')

you are enabled for nonpriority reply interrupts (type X'07', for non-APPC) and function-complete interrupts (type X'87', for APPC).

IPRPYP (X'10')

you are enabled for priority reply interrupts (type X'06', for non-APPC only).

IPCTRL (X'08')

you are enabled for control interrupts (non-APPC and APPC).

Condition Codes and Return Codes

| CC=0 | CC=1         | CC=2         | CC=3         |
|------|--------------|--------------|--------------|
| X    | Not possible | Not possible | Not possible |

CC=0

normal completion.

## Program Exceptions

The program exceptions for SETMASK are:

| Type          | Description                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address is outside of the virtual machine.                                                           |
| Operation     | Either an application interrupt buffer is not declared, or the invoking virtual machine is not in the supervisor state. |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                       |
| Specification | The parameter list is not on a doubleword boundary.                                                                     |

## State Checks and State Changes

No states are associated with the SETMASK function.

## Completion Conditions

The SETMASK function completes immediately.

## IUCV SEVER

### Purpose

Use the SEVER function of the IUCV macro for the following reasons:

- To revoke ownership of a resource that you manage by ending an established path with the Identify system service (\*IDENT)
- To terminate your side of the path when a connecting program severs its path or logs off
- When your program wants to terminate a path that could be either an IUCV (non-APPC) path or an APPC path.

### Parameters

#### Required Parameter:

##### PRMLIST=

specifies the address of the IUCV SEVER parameter list. The IUCV instruction is generated to reference the address specified.

##### *label*

Is the relocatable label of the parameter list.

##### *(reg)*

Is the register number that contains the address of the parameter list.

**Optional Parameters:** If you do not specify these parameters, the macro assumes that you have stored the desired values into the parameter list before invoking the IUCV macro.

##### MF=L

lets you build an IUCV parameter list without initializing any registers or executing the IUCV instruction. Using this format, you can then use CMSIUCV SEVER to actually issue the sever. For more information on using CMSIUCV SEVER, see [z/VM: CMS Macros and Functions Reference](#).

##### ALL=

specifies whether all paths for this virtual machine are to be severed. When ALL is specified by a virtual machine, all paths **except control paths** are severed.

**YES**

indicates that all of your paths are to be severed.

**NO**

indicates that you do not want all of your paths severed, only the one specified by PATHID.

**KEEP=**

indicates whether the path ID may be reassigned by CP for another conversation immediately after the IUCV SEVER. This applies only to APPC/VM paths.

**YES**

indicates that the path ID is not to be freed for reuse by CP for another conversation.

**Note:** This value is invalid when ALL=YES.

**NO**

indicates that the path ID is to be freed for reuse by CP for another conversation.

**PATHID=**

specifies the path ID to be severed.

**label**

is the relocatable label of a halfword that contains the path ID.

**(reg)**

is the register number that contains the path ID in the low-order halfword.

**USERDTA=**

specifies the data area containing the 16 bytes of user data that IUCV is to reflect across the path. The user data is reflected as part of the IUCV connection-severed external interrupt. USERDTA is ignored on APPC/VM paths.

**label**

is the relocatable label of the user data.

**(reg)**

is the register number that contains the address of the user data.

**Input Parameter List:** The IUCV SEVER parameter list has the input format shown in the following figure.

Figure 71. IUCV SEVER Input Parameter List

**IPPATHID**

contains the path ID of the path you want to sever.

**IPFLAGS1**

contains options for the SEVER function.

**IPAPPC (X'08')**

indicates the protocol to be used on this path. This bit must be set to 0.

**IPKEEP (X'10')**

indicates that the path ID is not to be freed for reuse after the IUCV SEVER completes.

**Note:** This flag is ignored on a non-APPC/VM path, or if the IPALL flag is set on.

**IPALL (X'80')**

indicates that you want to sever all paths for this virtual machine.

**IPUSER**

contains the user data that IUCV reflects across the path.

**Condition Codes and Return Codes**

| CC=0 | CC=1 | CC=2         | CC=3         |
|------|------|--------------|--------------|
| X    | X    | Not possible | Not possible |

**CC=0**

The SEVER completed normally. The output parameter list is shown in the following figure.

Figure 72. IUCV SEVER Output Parameter List (Sever Complete Interrupt)

**IPPATHID**

contains the path ID of the path you want to sever.

**Note:** IPPATHID is undefined when ALL=YES.

**IPFLAGS1**

may contain one or more of the following output bit flags:

**Note:** IPFLAGS1 is undefined when ALL=YES.

**X'20'**

reserved for IBM use only.

**X'02'**

reserved for IBM use only.

**X'01'**

reserved for IBM use only.

**IPUSER**

contains the user data that IUCV reflected across the path. IPUSER is ignored on APPC/VM paths.

**IPPOLLFG**

Contains a flag returned by IUCV.

**IPNOPOLL (X'80')**

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

**IPSTATE**

contains the current state of the path:

**IPRESET (X'01')**

the path is in Reset state.

**IPSENDST (X'03')**

the path is in Send state.

**IPRECVST (X'04')**

the path is in Receive state.

**Note:** IPSTATE is undefined when ALL=YES and for non-APPC paths.

**CC=1**

An error occurred. The output parameter list is the same as the SEVER input parameter list, except that one of the following return codes is stored in IPRCODE (byte 3):

| Hex Code | Decimal Code | Why the Error Occurred                                                                                  |
|----------|--------------|---------------------------------------------------------------------------------------------------------|
| X'01'    | 1            | You specified a path ID that does not exist.                                                            |
| X'1E'    | 30           | The IPAPPC flag in IPFLAGS1 is not 0.                                                                   |
| X'44'    | 68           | IUCV SEVER with KEEP=YES is an invalid function from the Reset state.                                   |
| X'57'    | 87           | IUCV SEVER with KEEP=YES is invalid when a previous APPCVM SEVER was issued with log data on this path. |

**Program Exceptions**

The program exceptions for SEVER are:

| Type          | Description                                                                                                               |
|---------------|---------------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address that you specified is outside the virtual machine's storage.                                   |
| Operation     | Either an application interrupt buffer has not been declared, or the invoking virtual machine is not in supervisor state. |
| Protection    | The storage key of the specified parameter list address does not match the key of the user.                               |
| Specification | The parameter list is not on a doubleword boundary.                                                                       |

**State Checks and State Changes**

A state check occurs (IPRCODE=X'44') if KEEP=YES is specified for an APPC/VM path that is in Reset state.

When IUCV SEVER completes (CC=0), the state changes to Reset.

**Completion Conditions**

IUCV SEVER always completes immediately. When IUCV SEVER with KEEP=YES specified completes, the path ID is still valid, and IUCV SEVER (without KEEP=YES) may be issued from RESET state to free the path ID for reuse.

If KEEP=YES is not specified for IUCV SEVER, the path ID is no longer valid when the SEVER completes. If another function is then issued for that path ID, the function will complete with CC=1 and IPRCODE=X'01' (specified path ID not established).

**What Happens to Your VM Communication Partner**

Your communications partner may be affected different ways, depending on the sequence of functions that you issue. Any of the following conditions can occur when you issue:

## IUCV SEVER

- CONNECT, and then issue IUCV SEVER before your partner gets the connection pending interrupt. In this case, your partner does not get a connection pending interrupt or a sever interrupt.
- CONNECT, and then issue IUCV SEVER after your partner gets the connection pending interrupt, but before your partner issues ACCEPT. In this case, your partner gets a sever interrupt (assuming it is enabled for sever interrupts).
- An IUCV SEVER after receiving a connection pending interrupt, instead of issuing an ACCEPT. If your partner issued:
  - CONNECT with WAIT=NO, your partner gets a sever interrupt (assuming it is enabled for sever interrupts).
  - CONNECT with WAIT=YES, your partner's CONNECT completes with a sever indication.

If IUCV SEVER is issued on an APPC/VM path established with SYNCLVL=CONFIRM or SYNCLVL=NONE, CP reflects the SEVER to the partner as an APPCVM SEVER TYPE=ABEND with a sever code X'0610' (RESOURCE\_FAILURE\_NO\_RETRY).

Note the following when IUCV SEVER is issued on an APPC/VM path established with APPCVM CONNECT, SYNCLVL=SYNCPT. If you issue IUCV SEVER:

- Immediately after issuing IUCV ACCEPT, CP reflects the SEVER to the partner as an APPCVM SEVER TYPE=ABEND with a sever code X'0610' (RESOURCE\_FAILURE\_NO\_RETRY).
- From Connect state or Reset state, CP reflects the SEVER to the partner as an APPCVM SEVER TYPE=ABEND with a sever code X'0610' (RESOURCE\_FAILURE\_NO\_RETRY).
- After the path is established, CP reflects the SEVER to the partner as an APPCVM SEVER TYPE=ABEND with sever code X'0220' (DEALLOCATE\_ABEND\_SVC).

Because IUCV SEVER may be issued twice on the path, once with KEEP=YES then again with KEEP=NO, the second SEVER is not reflected to the communication partner.

**IUCV SEVER External Interrupt:** When IUCV SEVER is issued on an IUCV path (for \*IDENT connection), the sever interrupt that your communications partner gets has the format shown in the following figure.

Figure 73. IUCV SEVER External Interrupt

### IPPATHID

contains the path ID being severed.

### IPTYPE

contains the interrupt type for IUCV SEVER (IPTYPESVC, X'03').

### IPUSER

contains the user data specified by the program that severed this path.

If the sever interrupt came from \*IDENT, byte 10 of this IPUSER field contains a reason code. See [“\\*IDENT Sever Reason Codes” on page 734](#).

### IPPOLLFG

Contains a flag returned by IUCV.

### IPNOPOLL (X'80')

Indicates that an IPOLL function would not be productive for the user.

**Note:** When an IPNOPOLL flag is set in an interrupt, this indicates that a brief check by CP of the user's pending replies and messages reveals that an IPOLL request at this time may not be productive. If a user enables for a reply interrupt or for a message interrupt, or issues an IUCV DESCRIBE, an IUCV TESTCMPL, or an IUCV IPOLL function immediately, the user may still see a reply or message even though IPNOPOLL was set on the previous function's completion.

When IUCV SEVER is issued on an APPC/VM path, CP ignores the user data field and issues an APPCVM SEVER TYPE=ABEND to your communications partner. Your partner then gets an APPC/VM SEVER interrupt. Refer to [SEVER External Interrupt](#) for information on the sever interrupt.

## IUCV TESTCMPL (Test Completion)

### Purpose

Use the TESTCMPL (Test Completion) function to determine if any messages or functions have been completed. You can identify a specific path when you invoke this function. If you do not specify a path, the next function on the queue of completed functions (if such a function exists) is displayed. TESTCMPL does not present functions completed on control paths.

Note that CMS does not currently support IUCV or APPC/VM virtual MP functions.

### Parameters

#### Required Parameter:

##### PRMLIST=

specifies the address of the IUCV TESTCMPL parameter list. The address must be a guest real address, that is, the address must be within the virtual machine's real address space (guest=real). Also, the parameter list must be on a doubleword boundary.

##### *label*

is the relocatable label of the parameter list.

##### *(reg)*

is the register number that contains the address of the parameter list.

#### Optional Parameters:

##### MF=L

expands the IUCV macro to generate the instructions necessary to initialize the parameter list as specified, but not to invoke the TESTCMPL function.

##### PATHID=

identifies the path ID to do the test completion.

##### *label*

is the relocatable label of a halfword that contains the path ID.

##### *(reg)*

is the register number that contains the path ID in the low-order halfword.

**Input Parameter List:** The IUCV TESTCMPL parameter list has the format shown in the following figure.

| IPARML DSECT |                                      |   |          |                                      |   |   |   |
|--------------|--------------------------------------|---|----------|--------------------------------------|---|---|---|
| 0            | 1                                    | 2 | 3        | 4                                    | 5 | 6 | 7 |
| 0            | IPPATHID                             |   | IPFLAGS1 | //////////////////////////////////// |   |   |   |
| 8            | //////////////////////////////////// |   |          |                                      |   |   |   |
| 10           | //////////////////////////////////// |   |          |                                      |   |   |   |
| 18           | //////////////////////////////////// |   |          |                                      |   |   |   |
| 20           | //////////////////////////////////// |   |          |                                      |   |   |   |

Figure 74. IUCV TESTCMPL Input Parameter List

**IPPATHID**

contains the path ID on which you want to complete the function. This parameter is only valid when the IPFGPID flag is set.

**IPFLAGS1**

contains the following input bit flag:

**IPFGPID (X'02')**

You specified a path ID.

**Condition Codes and Return Codes**

| CC=0 | CC=1 | CC=2 | CC=3 |
|------|------|------|------|
| X    | X    | X    | X    |

**CC=0**

indicates normal completion. The output parameter list is shown in the following figure.

| IPARML DSECT |                                      |   |          |        |                                      |         |                   |
|--------------|--------------------------------------|---|----------|--------|--------------------------------------|---------|-------------------|
| 0            | 1                                    | 2 | 3        | 4      | 5                                    | 6       | 7                 |
| 0            | IPPATHID                             |   | IPFLAGS1 | IPTYPE | IPCODE                               |         | IPWHATRC IPSENDOP |
| 8            | IPAUDIT                              |   |          |        | //////////////////////////////////// |         |                   |
| 10           | IPBFLN1F                             |   |          |        | //////////////////////////////////// |         |                   |
| 18           | //////////////////////////////////// |   |          |        |                                      |         |                   |
| 20           | IPBFLN2F                             |   |          |        | IPPOLLFG                             | IPSTATE | IPWHTRC2 IPSNDOP2 |

Figure 75. IUCV TESTCMPL Output Parameter List

**Note:** Only the contents of the IPSENDOP and IPBFLN1F fields are described here. The contents of the other fields in this parameter list depend on what function has completed. The function that has completed is indicated in IPSENDOP. Refer to the CC=2 description under the specific function being completed.

**IPSENDOP**

contains one of the following SEND option codes:

**IPDATA (X'01')**

SENDDATA RECEIVE=NO is being completed.

**IPSNDRCV (X'02')**

SENDDATA RECEIVE=YES is being completed.

**IPERROR (X'03')**

SENDERR is being completed.

**IPCNFRM (X'04')**

SEND CNF TYPE=NORMAL is being completed.

**IPCNFSEV (X'05')**

SEND CNF TYPE=SEVER is being completed.

**IPSABEND (X'09')**

SEVER TYPE=ABEND is being completed.

**IPRECV (X'0A')**

RECEIVE is being completed.

**IPPREPRC (X'0C')**

SEND CNF TYPE=PREPRECV is being completed.

**X'0F'**

reserved for IBM use only.

**X'10'**

reserved for IBM use only.

**X'11'**

reserved for IBM use only.

**X'14'**

is reserved for IBM use only.

**X'16'**

reserved for IBM use only.

**IPBFLN1F**

contains the length of pending log data for you to receive. This field is only meaningful when IPWHATRC is equal to IPSABEND or IPERROR.

**CC=1**

means an error occurred. The parameter list format is the same as the input shown in the TESTCMPL input parameter list except that the following return code is stored in IPRCODE:

| Hex Code | Decimal Code | Why the Error Occurred                               |
|----------|--------------|------------------------------------------------------|
| X'01'    | 1            | You specified a path ID that is not yet established. |

**CC=2**

no APPC/VM function completes, or IUCV message completes were found.

**CC=3**

a nonzero IPAUDIT value was stored.

**Program Exceptions**

The program exceptions for the IUCV TESTCMPL are:

| Type          | Description                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------|
| Addressing    | The parameter list address is outside of the virtual machine.                                                           |
| Operation     | Either an application interrupt buffer is not declared, or the invoking virtual machine is not in the supervisor state. |
| Protection    | The storage key of the parameter list address does not match the key of the user.                                       |
| Specification | The parameter list is not on a doubleword boundary.                                                                     |

**State Checks and State Changes**

TESTCMPL sets the state of the path on which the function is being completed. The state that is set depends on which function is being completed; refer to the individual function description for details.

**Completion Conditions**

The TESTCMPL function completes immediately.

## IUCV TESTMSG (Test Message)

### Purpose

Use the TESTMSG (Test Message) function to avoid using external interrupt handling. When you invoke the TESTMSG function, your virtual machine enters the WAIT state if none of the following are pending:

- SENDREQ interrupts (APPC/VM)
- Function-complete interrupts (APPC/VM)
- Message-pending interrupts (IUCV and APPC/VM)
- Message-complete interrupts (IUCV).

If any of these interrupts are pending while your virtual machine is in the WAIT state, the virtual machine reexecutes the TESTMSG function. TESTMSG then returns a condition code. TESTMSG ignores APPC/VM message pending interrupts unless the path corresponding to the message pending is in the Receive state. TESTMSG does not receive or describe the interrupt. You must use RECEIVE, DESCRIBE, or TESTCMPL, or enable for interrupts to clear the interrupt.

Note that CMS does not currently support IUCV or APPC/VM virtual MP functions.

### Condition Codes and Return Codes

| CC=0         | CC=1 | CC=2 | CC=3 |
|--------------|------|------|------|
| Not possible | X    | X    | X    |

#### CC=1

means a message or SENDREQ indication is pending.

#### CC=2

means a message completion or function completion is pending.

#### CC=3

means one or more conditions causing a condition code 1 and one or more conditions causing a condition code 2 are pending.

### Program Exceptions

The program exception for TESTMSG is:

| Type      | Description                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------|
| Operation | Either an application interrupt buffer is not declared, or the invoking virtual machine is not in the supervisor state. |

### State Checks and State Changes

No states are associated with the TESTMSG function.

### Completion Conditions

The TESTMSG function completes when control is returned to your virtual machine.

## Chapter 9. Migrating Programs from IUCV to APPC/VM

The Inter-User Communications Vehicle (IUCV) provides a way for program-to-program communications within one z/VM system. A program using IUCV can communicate with itself, with a CP system service, or with another program on the same system. IUCV is not part of the APPC (SNA LU 6.2) architecture. Chapter 8, “[IUCV Macro Functions for Use in APPC/VM,](#)” on page 521 has more details on IUCV.

APPC/VM, which is z/VM's implementation of APPC (SNA LU 6.2) protocol, includes some IUCV support. However, because IUCV is not part of the APPC architecture, it is important to know the differences between APPC/VM and IUCV.

To start, APPC/VM depends on a half-duplex protocol, while IUCV communication uses a full-duplex protocol. In support of half duplex protocol, APPC/VM defines and enforces states on each path.

In addition, in APPC/VM the high-order bit of the IPTYPE field is set to designate APPC/VM from IUCV interrupts. (The IPTYPE field is part of an interrupt.)

APPC/VM and IUCV each provide a set of communication functions. This chapter outlines the differences and similarities between APPC/VM functions and IUCV functions.

### APPC/VM and IUCV Functions That Work Differently

The following functions are supported in both APPC/VM and IUCV, but work differently. For more information about the APPC/VM function discussed in this section, see Chapter 7, “[APPCVM Macro Functions,](#)” on page 411. For more information about the IUCV functions discussed in this section, see Chapter 8, “[IUCV Macro Functions for Use in APPC/VM,](#)” on page 521.

#### • CONNECT

The RESID on the APPCVM CONNECT defines the target of the connection. The target could be on the same z/VM system, a different system within the same TSAF collection, or in an SNA network. For IUCV CONNECT, the USERID defines the target. The target must be on the same z/VM system.<sup>4</sup>

Other APPC/VM differences are:

- APPCVM CONNECT does not have a message limit parameter, whereas IUCV CONNECT does. This is because the message limit is always one on APPC/VM paths.
- APPCVM CONNECT does not have a user data field.
- APPCVM CONNECT has a WAIT=YES option.
- You cannot use APPCVM CONNECT to connect to a CP system service.
- A connection parameter list extension is defined for APPCVM CONNECT that lets you specify additional information needed to complete the connect.

Note that resource manager programs in APPC/VM must use IUCV CONNECT to connect to the Identify system service. This function is described in “[IUCV CONNECT](#)” on page 529.

#### • RECEIVE

APPC/VM differences are:

- You must provide a path ID on APPCVM RECEIVE.

<sup>4</sup> This chapter focuses on the migration of traditional, single-system IUCV communication. In general, migration from a distributed IUCV environment would have the same considerations. However, the target of a CONNECT does not need to be on the same z/VM system with distributed IUCV. Distributed IUCV might also be considered as an alternative to migrating to APPC. Refer to “[IUCV in a Distributed Environment](#)” on page 309 for more information.

- You can issue APPCVM RECEIVE before data arrives on a path.
- APPCVM RECEIVE has a WAIT=YES option.
- APPCVM RECEIVE has a PIP=YES option.
- **SEND** (for APPC/VM, **SENDDATA**)  
APPCVM SENDDATA and IUCV SEND differences are:
  - APPCVM SENDDATA does not have a parameter list data option.
  - APPCVM SENDDATA does not have a priority message option.
  - APPCVM SENDDATA does not have any special message identifiers (a message class or a message tag).
  - APPCVM SENDDATA has a WAIT=YES option.
  - APPCVM SENDDATA has a RECEIVE=YES option that lets you define an answer area. IUCV SEND has a TYPE=2WAY option that lets you define an answer area.

The APPC/VM user responds to a SENDDATA RECEIVE=YES with a SENDDATA. The length of the response does not depend on the size of the answer area. The IUCV user, on the other hand, responds to a SEND TYPE=2WAY with a REPLY. The length of the response cannot be bigger than the size of the answer area.

- With APPC/VM, the data sent is in logical record format. With IUCV, the data can be in any format.

- **SEVER**

APPC/VM differences are:

- APPCVM SEVER does not have a user data field.
- APPCVM SEVER has a WAIT=YES option.
- There are two APPCVM SEVER types, TYPE=NORMAL and TYPE=ABEND. There is only one IUCV SEVER type.
- APPCVM SEVER has a function complete interrupt for log data.

Resource manager programs must use IUCV SEVER to:

- Sever a connection to the Identify system service
- Sever an APPC/VM connection before a path is established.

For more information about IUCV SEVER, refer to on page [“IUCV SEVER” on page 556](#).

## IUCV Functions Not Supported on APPC/VM Paths

---

The following IUCV functions are not supported on APPC/VM paths:

- **PURGE**

- **QUIESCE** and **RESUME**

(However, because the message limit on APPC/VM paths is one, an application can quiesce a path by not receiving a message pending on that path.)

- **REJECT**

(However, APPCVM SENDERR is similar to IUCV REJECT.)

- **REPLY**

(However, APPCVM SENDDATA can be used in place of IUCV REPLY. Refer to [“APPCVM SENDDATA” on page 475](#) for more information.)

## APPC/VM Functions Not Supported on IUCV Paths

---

The following APPC/VM functions are not supported on IUCV paths:

- **QRYSTATE**

(IUCV does not have any equivalent functions.)

- **SENDCNF** and **SENDCNFD**

(IUCV does not have any equivalent functions.)

- **SENDERR**

(However, IUCV REJECT is similar to APPCVM SENDERR.)

- **SENDREQ**

(However, APPCVM SENDREQ is similar to an IUCV priority 1WAY parameter data SEND, when that SEND is used as a signal and does not contain any data.)

- **SETMODFY**

(IUCV does not have any equivalent functions.)

## Shared APPC/VM and IUCV Functions

---

Several functions are shared for both APPC/VM and IUCV. This section describes these functions as they relate to an APPC/VM environment. Chapter 8, “IUCV Macro Functions for Use in APPC/VM,” on page 521 describes the IUCV versions of these functions unrelated to APPC/VM. Parameters other than those described in this document are available, but have no meaning on APPC/VM paths and are ignored.

### Shared Functions That Can Be Used in CMS

The following two functions are documented in Chapter 7, “APPCVM Macro Functions,” on page 411 and can be safely used in a CMS environment:

- **ACCEPT**

When ACCEPT is issued to establish an APPC path,

- ACCEPT does not have a message limit parameter, whereas non-APPC ACCEPT does. This is because the message limit is always one on APPC/VM paths.
- ACCEPT does not have a user data field.

- **QUERY**

QUERY gives you the following information about a virtual machine:

- The size of the external interrupt buffer
- The maximum number of communication paths that can be established for the virtual machine.
- The maximum length of the interrupt buffer extension used in CMS and GCS.

### Shared Functions That Should Be Avoided in CMS

Other functions are also shared for both APPC/VM and IUCV. These shared functions should not be used in a CMS environment because they could affect other programs in the same virtual machine; however, they can be used safely in a non-CMS environment.

Each of these functions is briefly described in the following list, then described in detail in Chapter 8, “IUCV Macro Functions for Use in APPC/VM,” on page 521.

- **DCLBFR (Declare Buffer)**

DCLBFR declares an interrupt buffer. (Both APPC/VM and IUCV interrupts are presented in the same buffers.)

DCLBFR should not be directly issued by a program in CMS; HNDIUCV uses DCLBFR to initialize the virtual machine's APPC/VM environment.

- **DESCRIBE**

DESCRIBE gives the following information:

- The next message pending on non-APPC paths
- The next message pending on an APPC path that is in Receive state
- A SENDREQ on an APPC path.

DESCRIBE should not be used in CMS because this function clears the pending-message external interrupt for the described message. This interrupt may not belong to the issuer of the DESCRIBE function; thus, other programs running in the same virtual machine can be affected because the message is lost and never reflected to the true target.

### • **IPOLL (Interrupt Poll)**

IPOLL determines if there are any replies or incoming messages pending. If IUCV finds any replies or incoming messages pending, information about them is stored in the buffer provided. The maximum number of interrupts that can be retrieved on a single request is the number of interrupt buffers which can fit on one page. INTERRUPT POLL can be used instead of DESCRIBE and TEST COMPLETION to avoid some of the processing overhead involved in large numbers of messages and replies.

IPOLL can be directly issued by a program in CMS. If it is not, APPC/VM completes the first message on the REPLY queue for the entire virtual machine, and that interrupt may not belong to the application that issued the IPOLL. Thus, other programs running in the same virtual machine can be affected because the message or reply is lost and never reflected to the true target.

### • **RTRVBFR (Retrieve Buffer)**

RTRVBFR releases an interrupt buffer. (Both APPC/VM and IUCV interrupts are presented in the same buffers.)

RTRVBFR should not be directly issued by a program in CMS; HNDIUCV and CMS abend processing use RTRVBFR to terminate a virtual machine's APPC/VM environment.

### • **SETMASK and SETCMASK**

SETMASK and SETCMASK disable and enable APPC and non-APPC interrupts.

These functions should not be used by a program in CMS because they disable certain APPC/VM external interrupts for the entire virtual machine. Thus, other programs running in the same virtual machine may be affected.

### • **TESTCMPL (Test Completion)**

TESTCMPL determines the next APPC or non-APPC function that has completed.

TESTCMPL can be directly issued by a program in CMS; however, the issuer must be careful that a message ID or path ID is specified in the IUCV parameter list. If it is not, APPC/VM completes the first message on the REPLY queue for the entire virtual machine, and that message may not belong to the application that issued the TESTCMPL.

### • **TESTMSG (Test Message)**

TESTMSG waits for the following:

- A message pending or message complete interrupt on non-APPC paths
- A message pending interrupt on an APPC path that is in Receive state
- A request-to-send interrupt on an APPC path
- A function complete interrupt on an APPC path.

TESTMSG should not be used by a program in CMS because it places the entire virtual machine in a wait state if no incoming messages or replies are pending. Thus, other programs running in the same virtual machine may be affected.

---

## Chapter 10. APPC Mapped with APPC/VM

The APPC/VM assembler interface implements the base set and various options sets of APPC (SNA LU 6.2) communication functions. This chapter details the relationship between APPC and APPC/VM, and then maps APPC/VM functions with the APPC functions provided with the SNA LU 6.2 protocol.

For more information on the LU 6.2 protocol, see these documents:

- *SNA Format and Protocol Reference Manual: Architectural Logic for LU Type 6.2*
- *SNA Transaction Programmer's Reference Manual for LU 6.2.*

---

### APPC Conversations

User programs and resource manager programs in z/VM must follow the rules of an APPC conversation. APPC/VM supports and enforces these rules, as described in the following sections.

**Note:** An APPC conversation is represented within a TSAF or CS collection as an APPC/VM path. SNA sessions have no representation in a TSAF or CS collection. VTAM allocates and ends the SNA session on which APPC/VM conversations are established.

### Establishing a Conversation

If your virtual machine manages a resource, and another virtual machine is trying to establish a path to the resource, you receive a connection pending interrupt. Check to be sure that the connection pending interrupt is for an APPC connection. Do not assume that the program trying to connect is on the local TSAF or CS collection, or that the program is a VM program.

The server virtual machine is responsible for invoking the transaction program (resource manager program) and verifying the contents of the FMH5. CP recognizes nothing smaller than the server virtual machine. CMS and GCS recognize nothing smaller than a program. In general, in the CMS and GCS environments, each inbound connection does not cause the resource manager to create another instance of the transaction program. Instead, the program is notified that another path is being established.

It is the program's responsibility to receive the Attach FMH5 (optionally) and save its relevant contents. In addition, the program must issue an IUCV ACCEPT before communicating on the APPC/VM path. ACCEPT is not part of the APPC architecture. If there is something wrong in the Attach FMH5 data (for example, the program does not support the synchronization level specified), then it is the program's responsibility to sever the connection with the appropriate sever code.

After the CONNECT/ACCEPT sequence has been successfully completed on both sides, the two programs can exchange data using the half-duplex protocol of an APPC conversation. APPC/VM fully supports the base set of APPC communication and enables programs to support basic and mapped conversations.

### APPC/VM Interrupts

APPC/VM uses external interrupts to signal certain events and can be categorized as follows:

- Those interrupts that let applications process other paths while waiting for input or a function to complete on other paths:
  - Message pending interrupts
  - Connection pending interrupts
  - Function complete interrupts
  - Connection complete interrupts.
- Those interrupts that asynchronously indicate your partner has issued a SENDREQ or a SEVER:
  - Request-to-send interrupts

- Sever interrupts.

This interrupt-oriented signalling of your partner's activity is unique to APPC/VM; it does not map to any APPC architected function. In situations where your APPC/VM conversation is carried on a VTAM link, interrupts describing your partner's issuing of SEVER or SENDREQ may not be delivered to you until you perform some other operation on the conversation. This is because VTAM provides no asynchronous means for delivering the SENDREQ or SEVER indication to APPC/VM VTAM Support (AVS), and therefore the notification cannot be passed along to your program.

APPC/VM supports some IUCV macro functions that do not correspond to any APPC function. A program that wants to avoid non-APPC functions should be enabled only for connection pending interrupts.

## APPC/VM Conversation States

APPC/VM defines several states that a program can be in during a conversation. Most of these are based on states defined by APPC. The following table lists the conversation states for APPC and the APPC/VM counterparts. (Note that several APPC/VM states do not map to an APPC state.)

| <i>Table 76. APPC Conversation States and Corresponding APPC/VM Implementation</i> |                                                                                                                           |
|------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>APPC State</b>                                                                  | <b>APPC/VM Implementation</b>                                                                                             |
| Backout Required                                                                   | Backout_Received<br>Backout_Required                                                                                      |
| Confirm<br>Confirm Send<br>Confirm Deallocate                                      | Confirm<br>Confirm<br>Confirm                                                                                             |
| Deallocate                                                                         | Sever                                                                                                                     |
| Defer Receive<br>Defer Deallocate                                                  | Defer_Receive<br>Defer_Sever                                                                                              |
| Receive                                                                            | Receive                                                                                                                   |
| Reset                                                                              | Reset                                                                                                                     |
| Send                                                                               | Send                                                                                                                      |
| Sync-Point                                                                         | Prepare_Received<br>or<br>Unsolicited_Request_Commit_Received<br>(if the sync-point control modifier is request send.)    |
| Sync-Point Send                                                                    | Prepare_Received<br>or<br>Unsolicited_Request_Commit_Received<br>(if the sync-point control modifier is request receive.) |
| Sync-Point Deallocate                                                              | Prepare_Received<br>or<br>Unsolicited_Request_Commit_Received<br>(if the sync-point control modifier is request sever.)   |
| N/A                                                                                | Committed_Received                                                                                                        |
| N/A                                                                                | Connect                                                                                                                   |

| Table 76. APPC Conversation States and Corresponding APPC/VM Implementation (continued) |                                   |
|-----------------------------------------------------------------------------------------|-----------------------------------|
| APPC State                                                                              | APPC/VM Implementation            |
| N/A                                                                                     | Solicited_Request_Commit_Received |

## APPC/VM Return Codes

CP reports errors that it finds in the IPRCODE or IPAUDIT field. The target application or communications servers report errors that they find in the IPCODE field on SEVER or SENDERR functions; this same condition may be reported in IPRCODE, IPAUDIT, or IPCODE depending on the following:

- Whether the path goes through a communications server (TSAF and AVS), and
- Where CP detected the error along the path.

CP does not report the error in both IPRCODE/IPAUDIT and IPCODE at the same time.

An application should sever if it gets an error in IPRCODE. The application can sever the path using the APPCVM SEVER function with a SEVER code X'0210' to indicate DEALLOCATE\_ABEND\_PROG.

The return code mapping tables in this chapter have entries for the return code (or condition code), and the corresponding IPRCODE and/or IPCODE. **APPC/VM return codes that do not correspond to defined APPC return codes are not discussed in this chapter.**

### Notes:

1. All APPC return codes are mapped to a return code and/or sever code in APPC/VM.
2. The LU 6.2 Architecture for SYNCPT conversations has secondary return codes (reason codes) for each of the following APPC return codes:
  - DEALLOCATE\_ABEND
  - DEALLOCATE\_ABEND\_PROG
  - DEALLOCATE\_ABEND\_SVC
  - DEALLOCATE\_ABEND\_TIMER
  - DEALLOCATE\_NORMAL
  - RESOURCE\_FAILURE\_NO\_RETRY
  - RESOURCE\_FAILURE\_RETRY

VM does not support these. An application should always initiate a roll-back process when it gets one of the above return codes on a SYNCLVL=SYNCPT conversation.

## APPC Verb Names Mapped to APPC/VM Macro Functions

APPC/VM supports the base set of APPC functions. The following table lists the base set of APPC verbs for basic conversations, and their APPC/VM counterparts:

Table 77. Base Set of APPC Verbs and APPC/VM Functions

| APPC Verb      | APPC/VM Implementation                      |
|----------------|---------------------------------------------|
| ALLOCATE       | CONNECT                                     |
| CONFIRM        | SENDCNF TYPE=NORMAL                         |
| CONFIRMED      | SENDCNFD                                    |
| DEALLOCATE     | SEVER or SENDCNF TYPE=SEVER                 |
| FLUSH          | SENDATA FLUSH=YES, RECEIVE=NO, BUFLN=0      |
| GET_ATTRIBUTES | No specific functions, but indirect support |

Table 77. Base Set of APPC Verbs and APPC/VM Functions (continued)

| APPC Verb                                 | APPC/VM Implementation |
|-------------------------------------------|------------------------|
| RECEIVE_AND_WAIT                          | RECEIVE                |
| REQUEST_TO_SEND                           | SENDREQ                |
| SEND_DATA                                 | SENDDATA RECEIVE=NO    |
| SEND_DATA<br>followed by RECEIVE_AND_WAIT | SENDDATA RECEIVE=YES   |
| SEND_ERROR                                | SENDERR                |

In addition, the APPC PREPARE\_TO\_RECEIVE verb (from the *Prepare to Receive* option set) is implemented in APPC/VM with the RECEIVE or SENDCNF TYPE=PREPRECV functions.

Here's how other types of APPC base set verbs map to APPC/VM:

- Mapped conversation verbs

APPC/VM lets programs support mapped conversations. You must specify TYPE=MAPPED on the APPCVM CONNECT to do this. For mapped conversations, the APPC/VM implementation is roughly the same as in the preceding table.

- Operator control verbs

Some operator control commands are provided for APPC/VM VTAM Support (AVS). The following table shows the APPC verbs that have equivalents for AVS. APPC operator control verbs not shown here do not have AVS equivalents.

Table 78. APPC Operator Control Verbs Mapped to AVS Commands

| APPC Verb                | AVS Equivalent   |
|--------------------------|------------------|
| CHANGE_SESSION_LIMIT     | AGW CNOS command |
| INITIALIZE_SESSION_LIMIT | AGW CNOS command |
| RESET_SESSION_LIMIT      | AGW CNOS command |

For more information on the AGW CNOS command, see [z/VM: Connectivity](#).

In addition, APPC/VM implements APPC type-independent conversation verbs as follows:

- You can use the GET\_TYPE function by providing a general-purpose application running on top of APPC/VM.
- The SYNCPT and BACKOUT verbs are implemented on VM for protected conversations through two interfaces:
  - In CMS you can use several callable services library routines to initiate a sync-point or roll back process. For more information on these routines, see [z/VM: CMS Callable Services Reference](#).
  - The APPC/VM assembler interface contains several macros that initiate a sync-point or roll back process.

## APPC ALLOCATE

The APPC ALLOCATE verb maps to the APPCVM CONNECT function.

**Note:** Do not make assumptions about the target of the APPCVM CONNECT when the CONNECT completes—your CONNECT may complete before the target program is even invoked.

**Parameters:** The following list maps APPC ALLOCATE parameters (in bold) to APPC/VM equivalents (in italics):

**LU\_NAME** - *locally known LU name in the connection parameter list extension*

In APPC/VM, locally known LU names are 16 bytes.

**MODE\_NAME** - *mode name in the connection parameter list extension*

In APPC/VM, mode names are 8 bytes.

**TPN** - *transaction program name in the connection parameter list extension*

**TYPE** - *TYPE= parameter on APPCVM CONNECT*

APPC/VM supports the APPC options:

- TYPE(BASIC\_CONVERSATION) as TYPE=BASIC
- TYPE(MAPPED\_CONVERSATION) as TYPE=MAPPED.

**RETURN\_CONTROL** - *RETURN= parameter on APPCVM CONNECT*

APPC/VM supports the APPC options:

- RETURN\_CONTROL(WHEN\_SESSION\_ALLOCATED) as RETURN=ALLOCD
- RETURN\_CONTROL(IMMEDIATE) as RETURN=IMMED.

APPC/VM does not support the APPC option

RETURN\_CONTROL(DELAYED\_ALLOCATION\_PERMITTED).

**SYNC\_LEVEL** - *SYNCLVL= parameter on APPCVM CONNECT*

APPC/VM supports the APPC options:

- SYNC\_LEVEL(NONE) as SYNCLVL=NONE
- SYNC\_LEVEL(CONFIRM) as SYNCLVL=CONFIRM
- SYNC\_LEVEL(SYNCP) as SYNCLVL=SYNCP.

**SECURITY** - *security fields in the connection parameter list extension*

APPC/VM supports the APPC options:

- SECURITY(NONE) as a X'01' value in the security type field of the connection parameter list extension.
- SECURITY(SAME) as a X'00' value in the security type field of the connection parameter list extension, and the user ID in the connection pending interrupt.
- SECURITY(PGM(USER\_ID PASSWORD)) as a X'02' value in the security type field of the connection parameter list extension, and the user ID and password in the security fields of this extension.

SECURITY(PGM(PROFILE)) is not supported.

**PIP** - *address of PIP data in the connection parameter list extension*

APPC/VM supports the PIP option set on the source and target program.

A source program specifies information about PIP data in the connection parameter list extension.

This consists of the address of the PIP data, length of the PIP data, and a flag to indicate whether the data is presented in a single buffer or multiple buffers.

The target program must make a special indication when receiving PIP data. It does this by specifying PIP=YES on the APPCVM RECEIVE.

**RESOURCE** - *IPPATHID in connect complete interrupt*

In APPC/VM, the path ID is a halfword number.

**RETURN\_CODE** - *IPRCODE and IPCODE*

The APPC RETURN\_CODE variable corresponds to the following in APPC/VM:

- IPRCODE in the APPCVM CONNECT output parameter list
- IPCODE in the APPCVM SEVER external interrupt.

The connecting program must look at the IPRCODE when it receives a CC=1 on CONNECT. Also, if your partner rejects the connection with SEVER (CC=2), then the connecting program must look at IPCODE to determine the allocation error.

| RETURN_CODE                      | IPRCODE                 | IPCODE         |
|----------------------------------|-------------------------|----------------|
| OK                               | 0                       | Not applicable |
| ALLOCATION_ERROR                 |                         |                |
| ALLOCATION_FAILURE_RETRY         | X'0B',X'0C',X'0D',X'0E' | X'0111'        |
| ALLOCATION_FAILURE_NO_RETRY      | X'0B'                   | X'0110'        |
| UNSUCCESSFUL                     | X'0F'                   | X'0112'        |
| SECURITY_NOT_VALID               | X'31'                   | X'0160'        |
| TRANS_PGM_NOT_RECOGNIZED         | X'0B'                   | X'0142'        |
| TRANS_PGM_NOT_AVAILABLE_RETRY    | X'0C',X'0D',X'0E'       | X'0141'        |
| TRANS_PGM_NOT_AVAILABLE_NO_RETRY | X'0F'                   | X'0140'        |
| SYNC_LEVEL_NOT_SUPPORTED_BY_LU   | X'89'                   | X'0131'        |
| PARAMETER_ERROR                  |                         |                |
| Invalid LU name                  | X'28'                   | X'0301'        |
| Invalid mode name                | X'29'                   | X'0302'        |

**State Changes:** For both APPC ALLOCATE and APPCVM CONNECT, you, the invoker, are in Send state when the function successfully completes.

**Abend Conditions:** The parameter check condition is as follows:

| Parameter Check Condition                                                                           | IPRCODE |
|-----------------------------------------------------------------------------------------------------|---------|
| The program is not allowed to specify MODE_NAME(SNASVCMG), or MODE_NAME(SNASVCMG) is not supported. | X'29'   |

## APPC CONFIRM

The APPC CONFIRM verb maps to the APPC/VM function, SENDCNF TYPE=NORMAL.

**Parameters:** The following list maps APPC CONFIRM parameters (in bold) to APPC/VM equivalents (in italics):

### RESOURCE - *PATHID* parameter of *APPCVM SENDCNF*

The resource ID returned in APPC/VM is a path ID. The path ID is a halfword number.

### REQUEST\_TO\_SEND\_RECEIVED - *SENDREQ* interrupt

APPC/VM indicates that the partner issued REQUEST\_TO\_SEND by reflecting a SENDREQ interrupt.

### RETURN\_CODE - *IPCODE*

The APPC RETURN\_CODE variable corresponds to the following in APPC/VM:

- IPCODE from APPCVM SENDERR or APPCVM SEVER.

If the SENDCNF completes with a SENDERR or SEVER, then the virtual machine that invoked SENDCNF should look at the IPCODE field to determine the error.

| RETURN_CODE      | IPCODE                                              |
|------------------|-----------------------------------------------------|
| OK               | X'0000'                                             |
| ALLOCATION_ERROR | Any allocation error code (X'0110' through X'0160') |

| RETURN_CODE               | IPCODE  |
|---------------------------|---------|
| DEALLOCATE_ABEND_PROG     | X'0210' |
| DEALLOCATE_ABEND_SVC      | X'0220' |
| DEALLOCATE_ABEND_TIMER    | X'0230' |
| PROG_ERROR_PURGING        | X'0430' |
| SVC_ERROR_PURGING         | X'0530' |
| RESOURCE_FAILURE_NO_RETRY | X'0610' |
| RESOURCE_FAILURE_RETRY    | X'0620' |

**State Changes:** No state changes occur.

**Abend Conditions:** The parameter check conditions follow:

| Parameter Check Condition      | IPRCODE |
|--------------------------------|---------|
| SYNC_LEVEL(NONE) was specified | X'25'   |
| Invalid resource ID            | X'01'   |

The state check conditions follow:

| State Check Condition                                            | IPRCODE                                 |
|------------------------------------------------------------------|-----------------------------------------|
| Conversation not in Send state                                   | X'20', X'22', X'23', X'24', X'44'-X'4C' |
| Conversation started but did not finish sending a logical record | X'2C'                                   |

## APPC CONFIRMED

The APPC CONFIRMED verb maps to the APPCVM SENDCNFD function.

**Parameters:** The following list maps the APPC CONFIRMED parameter (in bold) to the APPC/VM equivalent (in italics):

### **RESOURCE - PATHID** parameter on APPCVM SENDCNFD

In APPC/VM, the path ID is a halfword number.

**State Changes:** Your program can be in any of the following states:

- RECEIVE, if the SENDCNFD is in response to a SENDCNF TYPE=NORMAL.
- SEVER, if the SENDCNFD is in response to a SENDCNF TYPE=SEVER. Sever state is the APPC/VM equivalent of Deallocate state.
- SEND, if the SENDCNFD is in response to a SENDCNF TYPE=PREPRECV.
- SEND or RECEIVE, if the SENDCNFD is in response to the partner's backout.

**Abend Conditions:** The parameter check conditions follow:

| Parameter Check Condition | IPRCODE |
|---------------------------|---------|
| Invalid resource ID       | X'01'   |

The state check conditions follow:

| State Check Condition             | IPRCODE                                        |
|-----------------------------------|------------------------------------------------|
| Conversation not in Confirm state | X'20', X'21', X'22', X'24', X'44', X'4A'-X'4C' |

## APPC DEALLOCATE

The APPC DEALLOCATE verb maps to the APPC/VM functions SEVER and SENDCNF TYPE=SEVER.

**Parameters:** The following list maps APPC DEALLOCATE parameters (in bold) to APPC/VM equivalents (in italics):

### RESOURCE - *PATHID* parameter of *APPCVM SENDCNF* and *APPCVM SEVER*

In APPC/VM, the path ID is a halfword number.

### TYPE - *TYPE* and *CODE* parameters of *APPCVM SEVER*

#### TYPE(SYNC\_LEVEL)

Use the following APPC/VM functions:

- APPCVM SEVER TYPE=NORMAL, to do a DEALLOCATE TYPE(SYNC\_LEVEL) when SYNCLVL=NONE.
- APPCVM SENDCNF TYPE=SEVER, followed by APPCVM SEVER TYPE=NORMAL, to do a DEALLOCATE TYPE(CONFIRM) when SYNCLVL=CONFIRM.
- APPCVM SETMODFY TYPE=SEVER, followed by a function to initiate a sync-point, to do a DEALLOCATE TYPE(SYNC\_LEVEL) when SYNCLVL=SYNCPT.
- APPCVM SETMODFY TYPE=SEVER, followed by APPCVM CONFIRM to do a DEALLOCATE TYPE(SYNC\_LEVEL) when SYNCLVL=CONFIRM.

#### TYPE(FLUSH)

Use APPCVM SEVER TYPE=NORMAL.

#### TYPE(CONFIRM)

Use the APPCVM SENDCNF TYPE=SEVER, followed by APPCVM SEVER TYPE=NORMAL, to do a TYPE(CONFIRM).

#### TYPE(ABEND\_PROG)

Use APPCVM SEVER TYPE=ABEND with the appropriate sever code (CODE=X'210').

#### TYPE(ABEND\_SVC)

Use APPCVM SEVER TYPE=ABEND with the appropriate sever code (CODE=X'220').

#### TYPE(ABEND\_TIMER)

Use APPCVM SEVER TYPE=ABEND with the appropriate sever code (CODE=X'230').

#### TYPE(LOCAL)

Use APPCVM SEVER TYPE=NORMAL after receiving a sever indication from your partner.

### LOG\_DATA - *BUFFER* and *BUFLEN* parameters of *APPCVM SEVER*

The LOG\_DATA can be from 8 to 600 bytes in length. APPC/VM supports the APPC option:

- LOG\_DATA(NO) as BUFLLEN=0
- LOG\_DATA(YES) as BUFLLEN > 0.

### RETURN\_CODE - *IPRCODE* and *IPCODE*

For all types of DEALLOCATE except SYNC\_LEVEL(CONFIRM), the only possible return code is OK. For SYNC\_LEVEL(CONFIRM), the same mapping exists as for the return codes from CONFIRM. See the return code table under [“APPC CONFIRM”](#) on page 576 for details.

**State Changes:** After the Sever completes, your program is in Reset state.

**Abend Conditions:** The parameter check conditions follow:

| Parameter Check Condition | IPRCODE |
|---------------------------|---------|
| Invalid resource ID       | X'01'   |

The state check conditions follow:

| State Check Condition                                                                                             | IPRCODE                    |
|-------------------------------------------------------------------------------------------------------------------|----------------------------|
| Issued TYPE(FLUSH), TYPE(CONFIRM), or TYPE(SYNC_LEVEL) from the wrong state.                                      | X'20', X'22', X'23', X'24' |
| Issued TYPE(LOCAL) from the wrong state.                                                                          | X'20', X'21', X'22', X'23' |
| Issued TYPE(FLUSH) or TYPE(SYNC_LEVEL), and the conversation started but did not finish sending a logical record. | X'2C'                      |

## APPC FLUSH

The APPC FLUSH verb maps to APPCVM SENDDATA FLUSH=YES, RECEIVE=NO, BUFLLEN=0.

**Parameters:** The following list maps APPC FLUSH parameters (in bold) to APPC/VM equivalents (in italics):

**RESOURCE - *PATHID* parameter of APPCVM SENDDATA**

In APPC/VM, the path ID is a halfword number.

**State Changes:** Your program will be in Receive state if the SENDDATA FLUSH=YES is issued from Defer\_Receive state. Otherwise, no state change occurs.

**Abend Conditions:** The parameter check conditions follow:

| Parameter Check Condition | IPRCODE |
|---------------------------|---------|
| Invalid resource ID       | X'01'   |

The state check conditions follow:

| State Check Condition          | IPRCODE                                 |
|--------------------------------|-----------------------------------------|
| Conversation not in Send state | X'20', X'22', X'23', X'24', X'44'-X'4C' |

## APPC GET\_ATTRIBUTES

APPC/VM provides the function of the GET\_ATTRIBUTES verb, but does not provide a specific APPC/VM function.

The transaction program is responsible for obtaining the following:

- The PARTNER\_LU\_NAME from the VM area, after initially receiving the allocate data.
- The MODE\_NAME from the VM area, after initially receiving the allocate data.
- The SYNC\_LEVEL in the connection pending interrupt and/or Attach FMH5.
- The SECURITY\_USER\_ID from the connection pending interrupt and/or the Attach FMH5.

APPC/VM does not provide SECURITY\_PROFILE.

## APPC PREPARE\_TO\_RECEIVE

The APPC PREPARE\_TO\_RECEIVE verb maps to the APPC/VM function SENDCNF TYPE=PREPRECX.

**Parameters:** The following list maps APPC PREPARE\_TO\_RECEIVE parameters (in bold) to APPC/VM equivalents (in italics):

**RESOURCE - *PATHID* parameter on APPCVM SENDCNF**

In APPC/VM, the path ID is a halfword number.

**TYPE(FLUSH) - APPCVM RECEIVE with BUFLLEN=0 from Send state**

In APPC/VM, if you are in Send state and issue RECEIVE with a receive area of 0 length, this is equivalent to APPC PREPARE\_TO\_RECEIVE TYPE(FLUSH).

**LOCKS - no parameter**

APPC/VM does not support the *LOCKS* option set.

**RETURN\_CODE - IPCODE**

The APPC RETURN\_CODE variable corresponds to the following in APPC/VM:

- The IPCODE of APPCVM SENDERR or APPCVM SEVER TYPE=ABEND.

If the SENDCNF completes with a SENDERR or SEVER, then the virtual machine that invoked SENDCNF should look at the IPCODE field to determine the error.

The same mapping exists as for the return codes from CONFIRM. See the return code table under “APPC CONFIRM” on page 576 for details.

**State Changes:** After this function completes, your program is in Receive state.

**Abend Conditions:** The parameter check conditions follow:

| Parameter Check Condition | IPRCODE |
|---------------------------|---------|
| Invalid resource ID       | X'01'   |

The state check conditions follow:

| State Check Condition          | IPRCODE                                 |
|--------------------------------|-----------------------------------------|
| Conversation not in Send state | X'20', X'22', X'23', X'24', X'44'-X'4C' |

## APPC RECEIVE\_AND\_WAIT

The APPC RECEIVE\_AND\_WAIT verb maps to the APPC/VM function, RECEIVE.

**Parameters:** The following list maps APPC RECEIVE\_AND\_WAIT parameters (in bold) to APPC/VM equivalents (in italics):

**RESOURCE - PATHID parameter on APPCVM RECEIVE**

In APPC/VM, the path ID is a halfword number.

**FILL - no parameter**

APPC/VM supports FILL(BUFFER), but does not support FILL(LL). Support for FILL(LL) can be provided by a program.

**DATA - BUFFER parameter of APPCVM RECEIVE**

The APPC parameter, DATA(variable), and the APPC/VM parameter, BUFFER=, specifies the address of the buffer to place the data being received.

**LENGTH - BUFLen parameter of APPCVM RECEIVE**

The APPC parameter, LENGTH(variable), and the APPC/VM parameter, BUFLen=, define the RECEIVE area length.

When control is returned to the program at the completion of RECEIVE\_AND\_WAIT, the LENGTH variable contains the length of data received. For APPC/VM, the length variable, IPBFLN2F, contains one of the following:

- The amount of space left in the buffer
- A count of how much data is pending that did not fit into the buffer.

When you are in Send state and specify a 0 length, the Receive completes before the target responds. This maps to PREPARE\_TO\_RECEIVE TYPE (FLUSH). When you issue RECEIVE with a 0 length from Receive state, it completes immediately even if nothing is pending on the path. In APPC/VM, you can use RECEIVE and then wait for a message pending or sever interrupt on the same path to do the equivalent of an APPC RECEIVE\_AND\_WAIT with a 0 length.

**REQUEST\_TO\_SEND\_RECEIVED - SENDREQ interrupt**

APPC/VM indicates that the partner issued REQUEST\_TO\_SEND by reflecting a SENDREQ interrupt.

**WHAT\_RECEIVED - IPWHATRC in function complete interrupt**

You can receive data along with other indicators.

**WHAT\_RECEIVED(DATA)**

In APPC/VM, this indication is presented by either IPWHATRC=IPDATA, or IPWHATRC does not equal IPDATA with the length field (IPBFLN2F) less than IPBFLN1F when you issued RECEIVE.

**WHAT\_RECEIVED(DATA\_COMPLETE,DATA\_INCOMPLETE,LL\_TRUNCATED)**

Does not occur in APPC/VM, because APPC/VM does not support FILL(LL).

**WHAT\_RECEIVED(SEND)**

In APPC/VM, this indication is IPWHATRC=IPSEND.

**WHAT\_RECEIVED(CONFIRM)**

In APPC/VM, this indication is IPWHATRC=IPCNFRM.

**WHAT\_RECEIVED(CONFIRM\_SEND)**

In APPC/VM, this indication is IPWHATRC = IPSNDCNF.

**WHAT\_RECEIVED(CONFIRM\_DEALLOCATE)**

In APPC/VM, this function is IPWHATRC=IPCNFSEV.

**WHAT\_RECEIVED(TAKE\_SYNCPT)**

In APPC/VM, this indication can be either IPWHATRC = IPPREPAR or, IPWHATRC = IPREQCOM and IPWHATRC2=IPTPRECV.

**WHAT\_RECEIVED(TAKE\_SYNCPT\_SEND)**

In APPC/VM, this indication can be either IPWHATRC = IPPREPAR or, IPWHATRC = IPREQCOM and IPWHATRC2=IPTPSEND.

**WHAT\_RECEIVED(TAKE\_SYNCPT\_DEALLOCATE)**

In APPC/VM, this indication can be either IPWHATRC = IPPREPAR or, IPWHATRC = IPREQCOM and IPWHATRC2=IPTPSEVR.

**RETURN\_CODE - IPCODE in function complete interrupt**

The APPC RETURN\_CODE variable corresponds to the following in APPC/VM:

- The IPCODE of APPCVM SENDERR or APPCVM SEVER TYPE=ABEND
- The IPWHATRC field of the APPCVM RECEIVE output parameter list.

If the RECEIVE completes with a SENDERR or SEVER TYPE=ABEND, then the virtual machine that issued RECEIVE should look at the IPCODE field to determine the error. IPWHATRC could also contain IPSNORM to indicate DEALLOCATE\_NORMAL.

| RETURN_CODE            | IPCODE                                                 |
|------------------------|--------------------------------------------------------|
| OK                     | X'0000'                                                |
| ALLOCATION_ERROR       | Any allocation error code<br>(X'0110' through X'0160') |
| DEALLOCATE_ABEND_PROG  | X'0210'                                                |
| DEALLOCATE_ABEND_SVC   | X'0220'                                                |
| DEALLOCATE_ABEND_TIMER | X'0230'                                                |
| PROG_ERROR_NO_TRUNC    | X'0410'                                                |
| PROG_ERROR_TRUNC       | X'0420'                                                |
| PROG_ERROR_PURGING     | X'0430'                                                |
| SVC_ERROR_NO_TRUNC     | X'0510'                                                |
| SVC_ERROR_TRUNC        | X'0520'                                                |
| SVC_ERROR_PURGING      | X'0530'                                                |

| RETURN_CODE               | IPCODE  |
|---------------------------|---------|
| RESOURCE_FAILURE_NO_RETRY | X'0610' |
| RESOURCE_FAILURE_RETRY    | X'0620' |

**State Changes:** When RECEIVE completes, your program may be in any of the following states:

- Receive state, when WHAT\_RECEIVED is DATA
- Send state, when WHAT\_RECEIVED is SEND
- Confirm state, when WHAT\_RECEIVED is CONFIRM, CONFIRM\_SEND, or CONFIRM\_DEALLOCATE.
- Prepare\_Received state, when IPWHATRC=IPPREPAR
- Unsolicited\_Request\_Commit\_Received state, when IPWHATRC=IPREQCOM.

No state change occurs when the verb is issued in Receive state and WHAT\_RECEIVED is DATA.

**Abend Conditions:** The parameter check conditions follow:

| Parameter Check Condition | IPRCODE |
|---------------------------|---------|
| Invalid resource ID       | X'01'   |

The state check conditions follow:

| State Check Condition                                            | IPRCODE                          |
|------------------------------------------------------------------|----------------------------------|
| Conversation not in Send or Receive state                        | X'20', X'23', X'24', X'44'-X'4C' |
| Conversation started but did not finish sending a logical record | X'2C' (see note)                 |

**Note:** This condition could also be reported in IPAUDIT by the IPADITRN flag.

## APPC REQUEST\_TO\_SEND

The APPC REQUEST\_TO\_SEND verb maps to the APPC/VM function SENDREQ.

**Parameters:** The following maps the APPC REQUEST\_TO\_SEND parameter (in bold) to the APPC/VM equivalent (in italics):

### **RESOURCE** - *PATHID parameter of APPCVM SENDREQ*

In APPC/VM, the path ID is a halfword number.

**State Changes:** No state changes occur.

**Abend Conditions:** The parameter check conditions follow:

| Parameter Check Condition | IPRCODE |
|---------------------------|---------|
| Invalid resource ID       | X'01'   |

The state check conditions follow:

| State Check Condition                               | IPRCODE                                       |
|-----------------------------------------------------|-----------------------------------------------|
| Conversation not in Send, Receive, or Confirm state | X'20', X'24', X'44'-X'46', X'48', X'4A'-X'4C' |

## APPC SEND\_DATA

The APPC SEND\_DATA verb maps to the APPC/VM function SENDDATA RECEIVE=NO.

**Parameters:** The following list maps the APPC SEND\_DATA parameters (in bold) to the APPC/VM equivalents (in italics):

**RESOURCE - PATHID parameter of APPCVM SENDDATA**

In APPC/VM, the path ID is a halfword number.

**DATA - BUFFER parameter of APPCVM SENDDATA**

The APPC parameter, DATA(variable), and the APPC/VM parameter, BUFFER=, specify the address of the data to send.

**LENGTH - BUFLen parameter of APPCVM SENDDATA**

The APPC parameter LENGTH(variable) and the APPC/VM parameter BUFLen= specify the length of the data to send.

**REQUEST\_TO\_SEND\_RECEIVED - SENDREQ interrupt**

APPC/VM indicates that the partner issued REQUEST\_TO\_SEND by reflecting a SENDREQ interrupt.

**RETURN\_CODE - IPCODE in function complete interrupt**

The APPC RETURN\_CODE variable corresponds to the following in APPC/VM:

- The IPCODE of APPCVM SENDERR or APPCVM SEVER.

If the SENDDATA completes with a SENDERR or SEVER, the virtual machine that issued the SENDDATA should look at the IPCODE field to determine the error.

| RETURN_CODE               | IPCODE                                                 |
|---------------------------|--------------------------------------------------------|
| OK                        | X'0000'                                                |
| ALLOCATION_ERROR          | Any allocation error code<br>(X'0110' through X'0160') |
| DEALLOCATE_ABEND_PROG     | X'0210'                                                |
| DEALLOCATE_ABEND_SVC      | X'0220'                                                |
| DEALLOCATE_ABEND_TIMER    | X'0230'                                                |
| PROG_ERROR_PURGING        | X'0430'                                                |
| SVC_ERROR_PURGING         | X'0530'                                                |
| RESOURCE_FAILURE_NO_RETRY | X'0610'                                                |
| RESOURCE_FAILURE_RETRY    | X'0620'                                                |

**State Changes:** No state changes occur.

**Abend Conditions:** The parameter check conditions follow:

| Parameter Check Condition     | IPCODE           |
|-------------------------------|------------------|
| Invalid resource ID           | X'01'            |
| Invalid logical record length | X'2A' (see note) |

**Note:** This condition could also be reported in IPAUDIT by the IPADIINV flag.

The state check conditions follow:

| State Check Condition          | IPCODE                                      |
|--------------------------------|---------------------------------------------|
| Conversation not in Send state | X'20', X'22', X'23', X'24', X'44'-<br>X'4C' |

## APPC SEND\_ERROR

The APPC SEND\_ERROR verb maps to the APPC/VM function SENDERR.

**Parameters:** The following list maps the APPC SEND\_ERROR parameters (in bold) to the APPC/VM equivalents (in italics):

**RESOURCE - *PATHID* parameter of *APPCVM SENDERR***

In APPC/VM, the path ID is a halfword number.

**TYPE - *TYPE* parameter of *APPCVM SENDERR***

APPC/VM supports APPC options:

- TYPE(PROG) as TYPE=PROG
- TYPE(SVC) as TYPE=SVC.

**LOG\_DATA - *BUFFER* and *BUFLN* parameters of *APPCVM SENDERR***

The APPC LOG\_DATA variable corresponds to the APPC/VM BUFFER and BUFLN. The LOG\_DATA can be from 8 to 600 bytes in length. APPC/VM supports the APPC option:

- LOG\_DATA(NO) as BUFLN=0
- LOG\_DATA(YES) as BUFLN with a value > 0.

**REQUEST\_TO\_SEND\_RECEIVED - *SENDREQ* interrupt**

APPC/VM indicates that the partner issued REQUEST\_TO\_SEND by reflecting a SENDREQ interrupt.

**RETURN\_CODE - *IPCODE* in function complete interrupt**

The APPC RETURN\_CODE variable corresponds to the following in APPC/VM:

- The IPCODE of APPCVM SENDERR or APPCVM SEVER TYPE=ABEND
- The IPWHATRC field of the APPCVM SENDERR output parameter list.

If the SENDERR completes with an indication that the communication partner issued a SENDERR or SEVER, the virtual machine should look at the IPCODE field to determine the error.

If you issue SEND\_ERROR from Send state, the following return codes are possible. IPWHATRC may also contain IPSNORM to indicate DEALLOCATE\_NORMAL.

| RETURN_CODE               | IPCODE                                                 |
|---------------------------|--------------------------------------------------------|
| OK                        | X'0000'                                                |
| ALLOCATION_ERROR          | Any allocation error code<br>(X'0110' through X'0160') |
| DEALLOCATE_ABEND_PROG     | X'0210'                                                |
| DEALLOCATE_ABEND_SVC      | X'0220'                                                |
| DEALLOCATE_ABEND_TIMER    | X'0230'                                                |
| PROG_ERROR_PURGING        | X'0430'                                                |
| SVC_ERROR_PURGING         | X'0530'                                                |
| RESOURCE_FAILURE_NO_RETRY | X'0610'                                                |
| RESOURCE_FAILURE_RETRY    | X'0620'                                                |

If you issue SEND\_ERROR from Receive state, the following return codes are possible. IPWHATRC may also contain IPSNORM to indicate DEALLOCATE\_NORMAL.

| RETURN_CODE               | IPCODE  |
|---------------------------|---------|
| OK                        | X'0000' |
| RESOURCE_FAILURE_NO_RETRY | X'0610' |
| RESOURCE_FAILURE_RETRY    | X'0620' |

If you issue SEND\_ERROR from Confirm state, the following return codes are possible:

| RETURN_CODE               | IPCODE  |
|---------------------------|---------|
| OK                        | X'0000' |
| RESOURCE_FAILURE_NO_RETRY | X'0610' |
| RESOURCE_FAILURE_RETRY    | X'0620' |

**State Changes:** If you issue the SENDERR, you remain in or are put into Send state.

**Abend Conditions:** The parameter check conditions follow:

| Parameter Check Condition | IPRCODE       |
|---------------------------|---------------|
| LOG_DATA not supported    | Not supported |
| Invalid resource ID       | X'01'         |

The state check conditions follow:

| State Check Condition                               | IPRCODE                                           |
|-----------------------------------------------------|---------------------------------------------------|
| Conversation not in Send, Receive, or Confirm state | X'20', X'24', X'44'-X'46', X'48',<br>X'4A'- X'4C' |

---

## Part 4. CP System Services

This part contains the following chapters:

- [Chapter 11, “Access Verification System Service \(\\*RPI\),” on page 589](#)
- [Chapter 12, “Account System Service \(\\*ACCOUNT\),” on page 697](#)
- [Chapter 13, “Asynchronous CP Command Response System Service \(\\*ASYNCMD\),” on page 717](#)
- [Chapter 14, “DASD Block I/O System Service \(\\*BLOCKIO\),” on page 719](#)
- [Chapter 15, “Error Logging System Service \(\\*LOGREC\),” on page 727](#)
- [Chapter 16, “Identify System Service \(\\*IDENT\),” on page 729](#)
- [Chapter 17, “Message System Service \(\\*MSG\),” on page 737](#)
- [Chapter 18, “Message All System Service \(\\*MSGALL\),” on page 739](#)
- [Chapter 19, “SCLP System Service \(\\*SCLP\),” on page 741](#)
- [Chapter 20, “Signal System Service \(\\*SIGNAL\),” on page 745](#)
- [Chapter 21, “Spool System Service \(\\*SPL\),” on page 749](#)
- [Chapter 22, “Symptom System Service \(\\*SYMPTOM\),” on page 771](#)
- [Chapter 23, “VM Event System Service \(\\*VMEVENT\),” on page 773](#)

**Note:** For information on Monitor System Service (\*MONITOR), see [Appendix A, in \*z/VM: Performance\*](#).

---

## Chapter 11. Access Verification System Service (\*RPI)

The access verification system service (\*RPI) handles IUCV communications between the CP access control interface (ACI) and an external security manager (ESM) service virtual machine, such as the Resource Access Control Facility (RACF). The ACI is a group of CP modules that mediate between CP and the ESM to handle authorization checking. z/VM supplies stub modules that are replaced by the ESM when it is installed. Part of this ESM-supplied code becomes the \*RPI system service. Therefore, the \*RPI system service is available only if an ESM is installed and the interface to \*RPI is as defined by the ESM.

---

### Using the CP Access Control Interface

The CP *access control interface* (ACI) is a group of modules that mediate between CP and an *external security manager* (ESM). An ESM is a service virtual machine that runs outside the primary operating system to help maintain the latter's security and integrity. The RACF Security Server for z/VM is an example of an ESM.

The access control interface consists of the CP modules: HCPRPD, HCPRPF, HCPRPG, HCPRPI, HCPRPW, HCPRPP, and HCPRWA, and the ACIPARMS control block. These modules are supplied in CP as stub modules. When an ESM is installed, these modules can be replaced with ESM versions that do not exceed one page in size. These modules are installation-wide exits. HCPRPD, HCPRPI, HCPRPP, and HCPRPW comprise the portion of the ACI in which CP takes an active part. CP routes control to these modules and expects certain return conditions. HCPRPF and HCPRPG are provided solely for ESM use. HCPRWA and HCPRPW are nonexecutable modules which can be used as data areas.

HCPPWAPF is an entry point that can be called by the ESM to notify CP of the level of support provided for optional features, such as password phrases. HCPPWA is not part of the ACI and it is not intended to be modified by the ESM.

The CP module, HCPDAO, may be called by an ESM to query or to update the security bit settings for each command, DIAGNOSE, and security relevant system function. The *security bit settings* control the calls that CP makes to the ACI.

The following topics are discussed in this chapter:

## Overview

CP's SSI Configuration Manager defines a "security" service that calls entry points in the module HCPRPP to handle the following SSI related events: Worthiness checks; Enablement function; Join processing; State change notification; STABLE preparation; SSI level change. See [“HCPRPP Module” on page 604](#) for more details. CP and the ESM use a control block called ACIPARMS to communicate with each other about security-relevant events. An event may be a CP command, DIAGNOSE code, or system function.

Figure 76 on page 590 provides an overview of the CP access control interface and the suggested method for an ESM to use it. The general security steps are as follows:

1. The ESM replaces the CP stub modules HCPRPW, HCPRPI, HCPRPD, HCPRPF, HCPRPG, and HCPRWA with its own tailored versions.
2. When a command, DIAGNOSE, or security-relevant system function is issued, CP checks the ACI security bit settings for that event. If the ACI needs to be called, CP creates an ACIPARMS parameter list specifically for that request and then calls the ACI through either HCPRPI or HCPRPW, sending ACIPARMS as input.
3. The request is then passed to the ESM through IUCV.
4. The ESM performs the requested function, records its response in the appropriate ACIPARMS field (ACICODE), and returns the ACIPARMS control block to CP.
5. CP then carries out the ESM's security decision. The process continues at step [“2” on page 590](#) for the next event.

Figure 76. Overview of the CP Access Control Interface to an ESM

## HCPRPI Module

The HCPRPI module contains six entry points: HCPRPICN, HCPRPIIL, HCPRPISV, HCPRPIQS, HCPRPIRM, and HCPRPIRA.

### Entry Points HCPRPICN, HCPRPIIL, HCPRPISV, HCPRPIQS, and HCPRPIRM - IUCV Interface

The HCPRPICN, HCPRPIIL, HCPRPISV, HCPRPIQS, and HCPRPIRM entry points are defined to support an IUCV interface. These entry points comprise the skeleton for the \*RPI system service through which the Security Manager service virtual machine can communicate with the ACI modules. These entry points, along with their respective assigned functions, are defined to CP's IUCV processing as the interrupt handlers for the \*RPI system service:

#### Entry Point Function

##### HCPRPICN

IUCV Connect interrupt handler

##### HCPRPIIL

IUCV message pending interrupt handler

##### HCPRPISV

IUCV Sever interrupt handler

##### HCPRPIQS

IUCV Quiesce interrupt handler

##### HCPRPIRM

IUCV Resume interrupt handler

For example, if a virtual machine issues an IUCV connect to \*RPI, CP's IUCV processing routes control to HCPRPICN.

The ESM may replace these skeleton entry points with code to perform the IUCV services required to communicate with the ESM virtual machine. This ESM-supplied code becomes the \*RPI system service. In conjunction with this, the ESM virtual machine must contain the IUCV code needed to communicate with the \*RPI system service. The ESM virtual machine must use the same protocol for IUCV communications as the ESM-supplied interrupt handlers.

For information about IUCV, see [Part 2, “The Inter-User Communications Vehicle,” on page 295](#).

CP's stub version of the HCPRPICN entry point issues an IUCV sever for the path that the connect was on.

CP's stub versions of the HCPRPIIL, HCPRPISV, HCPRPIQS, and HCPRPIRM entry points issue a defer (ACIDEFR) return code in the ACICODE field of ACIPARMS, and return to CP. However, there is no CP handling of this return code, and the ESM replacement module does not need to reproduce it.

Interface specifications for the HCPRPICN, HCPRPIIL, HCPRPISV, HCPRPIQS, and HCPRPIRM entry points follow.

#### Input Registers:

##### R1

Address of the external interrupt.

The interrupt buffer is mapped by IPARML, and the contents differ depending on the type of interrupt.

##### R11

Address of the dispatched VMDBK

**Output:** None

**Attributes:** MP, dynamic, resident

**Linkage:** Call with a dynamic save area

**Register Usage:****R0**

Scratch

**R1**

Address of external interrupt

**R2**

Scratch

**R3**

Scratch

**R4**

Scratch

**R5**

Scratch

**R6**

Scratch

**R7**

Scratch

**R8**

Scratch

**R9**

Scratch

**R10**

Scratch

**R11**

Address of dispatched VMDBK

**R12**

Base register

**R13**

Address of save area

**R14**

Scratch

**R15**

Scratch

**General Notes:** Registers R11 and R13 should not be changed by the installation-supplied code.

CP's stub module expects register 1 to contain the address of ACIPARMS on input and output. However, the ESM's replacement module should expect R1 to contain the address of the external interrupt buffer on input; there are no output requirements.

**Entry Point H CPRPIRA - Request Services from the ESM**

The H CPRPIRA entry point is defined to support authorization requests (calls) from CP to the ESM. For a subset of commands and DIAGNOSE codes, CP calls this entry point to check whether the user is authorized *before* it performs the requested function. CP sends the address of ACIPARMS in Register 1. ACIPARMS contains information about the command or DIAGNOSE code that has been issued. The calls to this entry point and the format of ACIPARMS for each call are described in detail in [“CP Calls to the ACI” on page 637](#).

CP's stub module returns a code of ACIDEFR in the ACICODE field in ACIPARMS. This indicates to CP that the ESM has made no authorization check.

The ESM replacement module is expected to receive the input parameters in ACIPARMS, and to send the ESM's response back to the caller in the ACICODE field.

Figure 77 on page 593 lists the interface specifications for this entry point.

**Input Registers:**

**R1**

Address of ACIPARMS parameter list

**R11**

Address of the dispatched VMDBK

**Output:**

**R1**

Address of ACIPARMS parameter list

ACICODE field contains the return code

**Attributes:** MP, dynamic, resident

**Linkage:** Call with a dynamic save area

**Register Usage:**

**R0**

Scratch

**R1**

Address of ACIPARMS

**R2**

Scratch

**R3**

Scratch

**R4**

Scratch

**R5**

Scratch

**R6**

**R9**

Scratch

**R10**

Scratch

**R11**

Address of dispatched VMDBK

**R12**

Base register

**R13**

Address of save area

**R14**

Scratch

**R15**

Scratch

**General Notes:** Registers R11 and R13 should not be changed by the installation-supplied code.

*Figure 77. Interface Specifications for the HCPRPIRA Entry Point*

## Exit from HCPRPI

Return from all the executable entry points in HCPRPI is made to the calling module by the HCPEXIT macro, located in the HCPSI macro library.

The HCPEXIT macro is coded in HCPRPI as:

```
HCPEXIT EP=(HCPRPIRA,HCPRPICN,HCPRPIIL,HCPRPIQS,HCPRPIRM,HCPRPISV)
```

Each entry point branches to this instruction to exit.

## HCPRPW Module

The HCPRPW module contains two entry points, HCPRPWEF and HCPRPWPR.

### Entry Point HCPRPWEF - Logon Password Verification Routine

This entry point is defined to support calls from CP to the ESM for password checking for the following commands:

- LOGON
- AUTOLOG
- XAUTOLOG.

For LOGON, AUTOLOG, and XAUTOLOG, CP calls the HCPRPWEF entry point to check whether the user is authorized *before* it processes the command. CP sends the address of the ACIPARMS parameter list in Register 1. ACIPARMS contains information about the command that has been issued. The format of ACIPARMS for each command is described in [“CP Calls to the ACI” on page 637](#).

CP's stub module returns a code of ACIDEFR in the ACICODE field. This indicates to CP that the ESM has made no authorization check.

The ESM replacement module is expected to receive the input parameters in ACIPARMS, and to send the ESM's response back to the caller in the ACICODE field.

[Figure 78 on page 595](#) lists the interface specifications for this entry point.

**Input Registers:****R1**

Address of ACIPARMS parameter list

**R11**

Address of the dispatched VMDBK

**Output:****R1**

Address of ACIPARMS parameter list

ACICODE field contains the return code

**Attributes:** Non-MP, dynamic, resident

**Linkage:** Call with a dynamic save area

**Register Usage:****R0**

**R15**

Scratch

**General Notes:** Registers R11 and R13 should not be changed by the installation-supplied code.

*Figure 78. Interface Specifications for the HCPRPWEF Entry Point*

## Exit from HCPRPWEF

Return is made to the calling module by the HCPEXIT macro, located in the HCPPSI macro library. The HCPEXIT macro is coded in HCPRPWEF as:

```
HCPEXIT EP=(HCPRPWEF)      Return to Caller
```

## Entry Point HCPRPWPR - Logon Password Prompting Routine

This entry point prompts for password/phrase data and passes the entered data back in ACIPARMS. CP calls the HCPRPWPR entry point to prompt for and collect password/phrase data for later verification by entry point HCPRPWEF. CP sends the address of the ACIPARMS parameter list in Register 1.

CP's stub module returns a code of ACIDEFR in the ACICODE field. This indicates to CP that no ESM is installed.

The ESM replacement module is expected to receive the input parameters in ACIPARMS, and to send the response back to the caller in the ACICODE, ACIOPPLN and ACIOPP fields.

Interface specifications for the HCPRPWPR entry point follow.

### Input Registers:

#### R1

Address of ACIPARMS parameter list

### Output:

#### R1

Address of ACIPARMS parameter list

ACICODE field contains the return code

**X'08'** - the password/phrase string has been successfully collected

**X'10'** - a console error occurred

ACIOPPLN = length of entered data

ACIOPP = entered data

**Attributes:** Non-MP, dynamic, resident

**Linkage:** Call with a dynamic save area

### Register Usage:

#### R0

Scratch

#### R1

Address of ACIPARMS

#### R2

Scratch

#### R3

Scratch

#### R4

Scratch

#### R5

Scratch

#### R6

Scratch

#### R7

Scratch

|            |                             |
|------------|-----------------------------|
| <b>R8</b>  | Scratch                     |
| <b>R9</b>  | Scratch                     |
| <b>R10</b> | Scratch                     |
| <b>R11</b> | Address of dispatched VMDBK |
| <b>R12</b> | Base register               |
| <b>R13</b> | Address of save area        |
| <b>R14</b> | Scratch                     |
| <b>R15</b> | Scratch                     |

**General Notes:** Registers R11 and R13 should not be changed by the installation-supplied code.

## Exit from HCPRPWPR

Return is made to the calling module by the HCPEXIT macro, located in the HCPSI macro library. The HCPEXIT macro is coded in HCPRPWPR as:

```
HCPEXIT EP=(HCPRPWPR)      Return to Caller
```

## HCPRPD Module

The HCPRPD module contains one entry point, HCPRPDEP, which functions as the DIAGNOSE code X'A0' processor.

### Entry Point HCPRPDEP - DIAGNOSE Code X'A0' Processor

CP's stub version of HCPRPDEP contains a call to module HCPRPE (entry point HCPRPEEP), which handles subcodes X'00' and X'08' of DIAGNOSE code X'A0'. Subcode X'00' retrieves the ACI group name, ACIGROUP, for a given user ID from the user's directory. Subcode X'08' sets the condition code to indicate whether an ESM is installed. Subcode X'48' retrieves the ESM product information from HCPRWAPP and copies it into the buffer pointed to by the RX register. These subcodes are documented in [“DIAGNOSE Code X'A0' – Obtain ACI Information” on page 134](#). Upon return from HCPRPE, HCPRPD stores registers R0 and R15 in the caller's R0 and R15 registers, and returns to the caller.

For subcode X'00', the ESM's replacement module should duplicate the call to HCPRPE as it appears in the stub module so that this subcode continues to be supported in the same way.

For subcode X'08' the ESM should set the guest (virtual machine) condition code to 0 indicating that an ESM is installed. The condition code is set using the HCPCALL macro, located in the HCPGPI macro library. The call is coded as:

```
HCPCALL HCPGSVC0      Set guest condition code to zero
```

For subcode X'48', the ESM does not need to modify the stub code in HCPRPD and HCPRPE, but should update the ESM product information in the HCPRWAPP table. This table is mapped by the RWAESM DSECT in the ACIPARMS macro.

An ESM may also provide additional functions in this entry point by defining its own subcodes for DIAGNOSE code X'A0' and by handling those subcodes in HCPRPD. The subcodes should be specified in the Ry register. If the ESM is to contain calls to HCPDA0, it is suggested that these calls be implemented

as DIAGNOSE code X'A0' subcodes, and made from HCPRPD. See [“HCPDA0 Module for Updating ACI Security Bits”](#) on page 610 for more information.

The interface specifications for the HCPRPDEP entry point follow.

**Input Registers:**

**R5**

Address of the Rx register

**R6**

Address of the Ry register

**R11**

Address of the dispatched VMDBK

See DIAGNOSE code X'A0' for a description of Rx and Ry register specifications for subcodes X'00', X'08', and X'48'.

**Exit Values:**

**Subcode X'00':**

Normal:

**R15 =**

0 (Successful request)

**Rx =**

First doubleword is unchanged. Second doubleword contains the ACI group name.

**Ry =**

Unchanged

Guest condition code = 0

Error:

- If the input user ID is invalid:

R15 = 0

Virtual machine condition code = 1

- Otherwise:

R15 = 8 (Unsuccessful request)

R0 = X'04' Protection exception indicator

R0 = X'05' Addressing exception indicator

R0 = X'06' Specification exception indicator

Virtual machine condition code = 1

**Subcode X'08':**

**R15 =**

0 (Successful request)

**Rx =**

Unchanged

**Ry =**

Unchanged

Guest condition code is set to 0 = ESM is installed

Guest condition code is set to 1 = ESM is not installed

**Subcode X'48':**

**R15 =**

0 (Successful request)

**Rx =**

Points to area updated with ESM product information

**Ry =**  
Unchanged

Guest condition code is set to 0

**Invalid Subcode:**

**R15 =**  
8 (Unsuccessful request)

**R0 =**  
X'06' Specification exception indicator

**Note:** R15 in these cases refers to the caller's R15 as opposed to the guest's R15.

**Attributes:** Non-MP, dynamic

**Linkage:** Call with a dynamic save area

**Register Usage:**

**R0**  
Scratch

**R1**  
Scratch

**R2**  
Scratch

**R3**  
Scratch

**R4**  
Scratch

**R5**  
Address of Rx register

**R6**  
Address of Ry register

**R7**  
Scratch

**R8**  
Scratch

**R9**  
Scratch

**R10**  
Scratch

**R11**  
Address of dispatched VMDBK

**R12**  
Base register

**R13**  
Address of save area

**R14**  
Scratch

**R15**  
Scratch

**General Notes:** Registers R11 and R13 should not be changed by the installation-supplied code.

## Return Codes

When HCPRPD returns to its caller, the return code in Register 15 is handled as shown in [Table 79 on page 600](#).

Table 79. Supported HCPRPD Return Codes

| RC | Meaning                                                                                                                                    |
|----|--------------------------------------------------------------------------------------------------------------------------------------------|
| 0  | Processing was successful. Complete the guest instruction.                                                                                 |
| 4  | Processing failed due to a condition that would cause a guest program check. Simulate the guest program interruption passed in Register 0. |
| 8  | Nullify the guest instruction.                                                                                                             |
| 12 | Generate a machine check for a storage error, then nullify the instruction. The guest real address of failing storage is in Register 1.    |
| 16 | Generate a machine check for processing damage, then terminate the instruction.                                                            |
| 20 | Generate a machine check for storage error, then terminate the instruction. The guest real address of failing storage is in Register 1.    |
| 24 | Issue an error message or soft abend for a paging I/O error, then nullify the instruction. Register 1 has the message or abend number.     |

## Exit from HCPRPD

Return is made to the calling module by the HCPEXIT macro, located in the HCPSI macro library. The HCPEXIT macro is coded in HCPRPDEP as:

```
HCPEXIT EP=(HCPRPDEP)          Return to Caller
```

## HCPRPE Module for handling DIAGNOSE X'A0'

HCPRPE is a CP module that can be called by an ESM to handle certain DIAGNOSE code X'A0' subcodes and other functions. The following entry points are provided:

### Entry Point Function

#### HCPRPEEP

To handle DIAGNOSE code X'A0' subcodes X'00', X'08', and X'48'.

#### HCPRPEPX

To inform CP of the ESM's POSIX capabilities.

#### HCPRPESG

To inform CP of a change to a user's POSIX Supplementary GID list.

The suggested way for an ESM to call HCPRPE is through HCPRPD, the DIAGNOSE code X'A0' processor (see “HCPRPD Module” on [page 597](#)). After the appropriate input parameters are set up, the HCPRPE call can be coded as follows:

```
HCPCALL HCPRPExx
```

where xx are the last two letters of the entry point name.

## Entry Point HCPRPEEP - Handle DIAGNOSE Code X'A0' subcodes X'00', X'08', and X'48'

If no ESM is installed, HCPRPDEP will call HCPRPEEP to handle subcodes X'00', X'08', and X'48'. If an ESM is installed, it continues to call HCPRPEEP for subcodes X'00' and X'48', but it should handle subcode X'08' in HCPRPDEP. See “HCPRPD Module” on [page 597](#) for additional information.

## Entry Point HCPRPEPX - Notify CP of POSIX capabilities

If the ESM contains POSIX support, it should inform CP of this by calling HCPRPEPX; otherwise, CP will not attempt to acquire POSIX database information from the ESM or invoke the ESM to authorize the various POSIX functions. If HCPRPEPX is not invoked, the system will behave as if the ESM returned ACIDEFR on all POSIX-related requests:

- For AUTOLOG, XAUTOLOG and LOGON requests, the POSIX-related information will be obtained from the CP directory. See [“LOGON Command” on page 650](#) and [“AUTOLOG and XAUTOLOG Commands” on page 639](#) for more information about these fields and their use in these requests.
- For POSIX set IDs requests, the entire request is considered to have been deferred to CP. See [“POSIX Set ID Functions” on page 683](#) for more about this type of request.
- For POSIX group database queries, the entire request is considered to have been deferred to CP. See [“POSIX Group Database Query Function” on page 684](#) for more about this type of request.
- For POSIX user database queries, the entire request is considered to have been deferred to CP. See [“POSIX User Database Query Function” on page 686](#) for more about this type of request.
